Background: Fuchs' endothelial corneal dystrophy (FECD) is a hereditary disease of the corneal endothelium, which is characterized by the progressive and slow loss of corneal endothelial cells, thickening of Descemet's membrane and extracellular matrix deposition (*guttae*). Due to the progression and consequent loss of endothelial cells, the removal of fluids is affected, leading to stromal edema and in some cases, to blindness. Several genes are associated with Fuchs' dystrophy, including *COL8A2*, *SLC4A11* and *TCF4*. The main aims of this study were to evaluate the segregation pattern of mutations in the *COL8A2* and *SLC4A11* genes and analyze the familial association between the TGC trinucleotide repeat expansion in the *TCF4* gene in three families with FECD. **Methods:** We analyzed 39 individuals belonging to 3 families with FECD and 100 controls subjects. The *COL8A2* and *SLC4A11* genes were evaluated through Sanger sequencing. The TGC microsatellite in the *TCF4* gene was genotyped using the Short Tandem Repeat-Assay (STR-Assay) and analyzed by prediction programs *in silico*. **Results:** We found a deletion in the *SLC4A11* gene, rs113526162 (c.1172-19_1172-18delTC), co-segregating with the trait in one family, which was absent in controls subjects. *In silico* predictions allowed us to show that this mutation may induce changes in the mutant transcript. STR analysis demonstrated that the expanded allele of the *TGC* repeat also co-segregated with the trait in one family. The penetrance of the expansion in the study was 100%. **Conclusions:** These findings suggest that the deletion has an effect on regulatory splicing factors and might generate an abnormal or non-functional protein, affecting specific tissues in which this protein is expressed. Despite the fact that the expansion is present in only one family, we showed a strong relationship between the *TGC* expansion with FECD. However, further studies are necessary to understand the exact contribution to the disorder.

2544F

Exploring the characteristics of hearing loss and its etiology in a unique subset of families with hereditary deafness. *A. Pandya[1], M. Tekin[2], A.H. O'Brien[1], S.H. Blanton[2], K.S. Arnos[3].* 1) Pediatric Genetics and Metabolism, University of North Carolina, Chapel Hill, Chapel Hill, NC; 2) Dr. John T. Macdonald Foundation Department of Human Genetics, John P. Hussman Institute for Human Genomics, Miller School of Medicine, University of Miami, Miami, FL; 3) Department of Science, Technology, & Mathematics, Gallaudet University, Washington DC.

Hearing loss (HL) is one of the most common neurosensory defects affecting nearly 37 million individuals, with one in a thousand newborns identified with profound congenital HL. Despite marked genetic heterogeneity, studies in population isolates, inbred families and large cohorts have enabled mapping of at least 167 loci and identification of 99 genes for non-syndromic HL. The high frequency of assortative mating amongst the deaf and presence of a Deaf culture have resulted in a unique subgroup of families with deaf parents who have deaf or hearing offspring. This population offers an opportunity to explore the inheritance and clinical characteristics resulting from the presence of multiple rare deafness genes in a single individual due to the phenomenon of gametic phase disequilibrium. We have studied 375 deaf probands from 327 matings where both parents are deaf (DxD), ascertained through the North American repository of DNA from deaf individuals. One hundred ninety seven of these families were non complementary with only deaf offspring, and 79 were segregating with both deaf and hearing children. Screening for mutations in the *GJB2/GJB6* and *MT-RNR1* genes in all probands identified 185 probands to have bi-allelic pathogenic *GJB2* mutations. This represents 49.3% percent who have their HL explained by mutations in *GJB2,* which is significantly higher than the observation in the deaf population at large. Of these, the majority (68%) were homozygous for the common 35delG pathogenic sequence variant. Another 7.2% of the probands were identified with a *GJB6* deletion and a *GJB2* sequence variant as the etiology for their HL. Thirteen percent of the probands are heterozygous carriers for a single pathogenic *GJB2* variant as compared to the 3.5% carrier frequency in the general population. All probands have severe to profound HL. There remain 165 probands without an identified etiology for their hearing loss. We are screening these probands for mutations in known deafness genes, to be followed by analysis of the coding exome with the goal of identifying known and novel genes for HL. The unique structure of these families will allow identification of previously uncharacterized interactions and or modifiers of HL as was the case with *GJB2/GJB6* mutations.

Purpose: Small and co-workers (Ophthalmology, 2016) recently showed that mutations affecting the expression of *PRDM13* cause North Carolina macular dystrophy (NCMD, MCDR1). The purpose of this study was to investigate the PRDM locus in additional families with this phenotype **Methods:** 18 new families with the NCMD phenotype (a total of 46 affected individuals) were studied using a combination of Sanger sequencing of the DNase I hypersensitivity site upstream of *PRDM13* and a PCR-based assay for the detection of a previously described duplication of the PRDM13 gene. IRB approval was obtained and informed consent was obtained from all participants. **Results:** The original NCMD publication reported four different mutations (V1-V4) distributed among eleven different kindreds. To date, we have identified the disease-causing mutations in 10 new independent families the NMCD phenotype. Seven of these harbor the previously described V1 mutation (all from the USA) and Five families harbor the previously described V2 mutation (3 European, 1 USA). These two variants segregated perfectly in the 36 affected and 10 unaffected members of these 12 new NCMD families. No mutations have yet been identified in the other six families. We have an additional 7 families yet to be studied. **Conclusions:** We identified 12 new families with disease-causing mutations in the DNase I hypersensitivity site upstream of the *PRDM13* gene . Additional families with the NCMD phenotype continue to support that these mutations are causative of MCDR1 / NCMD. .

Massively parallel sequencing identified *KCNQ1* **compound heterozygous mutations caused Jervell and Lange-Nielsen syndrome or nonsymdromic hearing loss in three Chinese families.** *H. Yuan, C. Wang, Y. Lu, J. Cheng.* Medical Genetics Center, Southwest Hospital, Third Military Medical University, Chongqing 400038, China.

   Jervell and Lange-Nielsen syndrome (JLNS) involves congenital profound hearing loss associated with prolongation of the QTc interval in the electrocardiogram (ECG), and predisposes to lethal cardiac arrhythmia, especially under sympathic stimulation during periods of stress, exerciseor fright. As the main responsible gene for JLNS, mutations in *KCNQ1* are also cause of another dominant forms of disease, long QT syndrome type 1 (LQT1), characterized by long QTc without hearing loss. We investigated the underlying genetic defects for 10000+ subjects with congenital profound hearing loss by massively parallel sequencing (MPS). Compound heterozygous mutations of *KCNQ1* were identified in 4 subjects from 3 Chinese families. Besides the common manifestation of congenital profound hearing loss, detailed clinical evaluation presented variations of phenotype among the 4 patients: two siblings showed typical JLNS cardiac phenotype of long QTc greater than 500ms and recurrent syncopal episodes; one subject showed extra-cardiac-and-ear symptoms of iron-deficiency anemia and epilepsy; one case without QTc prolongation and no cardiac complains. Sanger sequencing confirmed the compound mutations of *KCNQ1* inherited from both parents carrying heterozygous mutation. Among the 6 disease-causing mutations, 5 mutations (c.683+5G>A, c.905C>T, c.965C>T, c.1484_1485delCT and c.1831G>A) were previously reported, while c.546C>A mutation was first identified in this study. Besides expanding the spectrum of *KCNQ1* mutations causing JLNS, our results also showed the diversity of JLNS phenotypes, and showed the importance of molecular genetic analysis in confirming the clinical diagnosis and making pre-symptom diagnosis possible.

2547F

Comparison of bioinformatic prediction with molecular analyses of *FOXC1* **mutations from patients with Axenfeld-Rieger syndrome.** *M. Seifi, T. Footz, S.A Taylor, M.A Walter.* Department of Medical Genetics, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, Alberta, Canada.

   Mutations in the gene forkhead box C1 (*FOXC1* [MIM 601090]) cause Axenfeld-Rieger syndrome (ARS [MIM 602482]), an autosomal dominant disorder characterized by malformations of the ocular anterior segment and non-ocular abnormalities. Here, we investigated the effect of four missense variants (p.H128R, p.C135Y, p.M161V and p.T368N) on the structure and function of *FOXC1*, and tested the predictive value of SIFT (sorting intolerant from tolerant) and PolyPhen (polymorphism phenotyping) for all known *FOXC1* missense variants. Our results show that the *FOXC1* p.C135Y variant significantly reduced DNA binding, transactivation, nuclear localization and expression levels of the recombinant protein, and has a shortened protein half-life. The p.M161V reduced transactivation capacity without changing other *FOXC1* functions. The p.H128R variant reduced DNA binding, transactivation, and nuclear localization. Molecular modeling of the FOXC1 forkhead domain predicted that p.H128R changes FOXC1's structure. In contrast, *FOXC1* p.T368N was indistinguishable from wild type *FOXC1* in all tests, consistent with being a rare, non-disease causing variant. The molecular investigations of these 4 and the 27 previously studied *FOXC1* missense mutations were compared to predictions from the SIFT and PolyPhen prediction tools. SIFT and PolyPhen correctly identified as pathogenic only the *FOXC1* mutations with significant functional defects. Our study demonstrates that the p.H128R, p.C135Y and p.M161V *FOXC1* missense variants cause ARS via different mechanisms. The variant p.T368N is likely a non-disease causing substitution. Importantly, our results support the use of SIFT and PolyPhen as reliable tools to predict the pathogenicity of *FOXC1* forkhead domain missense variants.

Pharmacogenetic variants in *TPMT* **alter cellular responses to cisplatin** *in vitro*. A.P. Bhavsar[1,2], E.P. Gunaretnam[2,3], Y. Li[2,3], B.C. Carleton[2,3], C.J.D. Ross[1,2]. 1) Faculty of Pharmaceutical Sciences, The University of British Columbia, Vancouver, British Columbia, Canada; 2) Child & Family Research Institute, BC Children's Hospital, Vancouver, British Columbia, Canada; 3) Department of Pediatrics, Faculty of Medicine, The University of British Columbia, Vancouver, British Columbia, Canada.

Background: Cisplatin is a highly-effective and widely-used chemotherapeutic agent that also has a high incidence of drug-induced ototoxicity, especially in children. Pharmacogenomic studies of drug absorption, distribution, metabolism and excretion genes identified low-activity variants in thiopurine methyltransferase (*TPMT*) as strong predictors of the development of cisplatin-induced ototoxicity. It has been suggested that low-activity TPMT variants may lead to elevated levels of its substrate *S*-adenosylmethionine, which has been shown to exacerbate cisplatin toxicity, however direct studies of cisplatin-*TPMT* interactions have not been reported. In this work we sought to establish this drug-gene interaction in an *in vitro* cell based system. Methods: Epitope-tagged *TPMT**3A, *3B and *3C mammalian expression clones were generated by site-directed mutagenesis from the *TPMT**1 wild type clone. Expression of TPMT variants was monitored by immunoblotting following transient transfection into HEK293T cultured cells. To examine how the TPMT*3A variant affected cellular cisplatin response, *TPMT* expression clones were transiently transfected into murine inner ear cell lines, HEI-OC1 or UB/OC-1, and cell viability was assessed using an MTT assay. In addition, the expression of a cisplatin-response gene was monitored by quantitative PCR (qPCR) following transient transfection of HeLa cells with *TPMT* expression clones. Where required, gene silencing was performed using specific siRNA reagents. Results: Quantification of TPMT variant levels in cell culture showed that TPMT*3A was present at >20-fold lower amounts than the wild type, in agreement with published reports. This correlated with a significantly increased susceptibility to cisplatin cytotoxicity as the cisplatin IC_{50} in both HEI-OC1 and UB/OC-1 cells decreased approximately 30% upon expression of *TPMT**3A compared to wild type *TPMT*. Similarly, a sensitive cisplatin-response biosensor showed significantly higher induction in the presence of TPMT*3A compared to wild type TPMT. Taken together, these data suggest that TPMT*3A significantly sensitizes cells to cisplatin response and toxicity. Conclusions: This study has identified cellular cisplatin responses that are affected by *TPMT* variant status. We demonstrated an *in vitro* interaction between cisplatin and *TPMT**3A that supports the previously reported pharmacogenetic association with cisplatin-induced ototoxicity.

2549T

Mutations in the *PCYT1A* **gene are responsible for isolated forms of early-onset retinitis pigmentosa.** S. Banfi[1,2], F. Testa[3], M. Filippelli[3], R. Brunetti-Pierri[3], G. Di Fruscio[3], V. Di Iorio[3], M. Pizzo[2], N. Brunetti-Pierri[4], F. Simonelli[3]. 1) TIGEM, Fondazione Telethon, Pozzuoli, Naples, Italy; 2) Department of Biochemistry, Biophysics and General Pathology, Second University of Naples, Naples, Italy; 3) 1Eye Clinic, Multidisciplinary Department of Medical, Surgical and Dental Sciences, Second University of Naples, Naples, Italy; 4) Department of Translational Medicine, Federico II University, Naples, Italy.

Background Mutations in *PTCY1A* have been recently linked to two different phenotypes: one characterized by spondylometaphyseal dysplasia and cone-rod dystrophy (SMD-CRD) and the other by congenital lipodystrophy, severe fatty liver disease, and reduced HDL cholesterol without any retinal or skeletal involvement. Isolated retinal involvement due to *PTCY1A* mutations has not been reported thus far. **Methods and Results** By next generation sequencing targeted to genes associated with inherited retinal diseases (IRD), we identified pathogenic mutations in the *PCYT1A* gene in three young patients with isolated retinal dystrophy from two different Italian families. Ophthalmological assessment (best corrected visual acuity, color vision testing, retinography, optical coherence tomography and standard electroretinogram) showed the presence of Early Onset Retinitis Pigmentosa (EORP). A thorough clinical evaluation of the patients, with whole skeleton X-ray, metabolic assessment and liver ultrasound failed to reveal signs of skeletal dysplasia, metabolic and hepatic alterations. **Conclusions** This is the first report showing that the *PCYT1A* gene can be responsible for isolated forms of EORP thus further expanding the phenotypic spectrum induced by mutations in this gene. .

2550F

***EYS* knockout in zebrafish leads to mislocalization of cone opsins and progressive retinal degeneration.** *M. Liu[1], Z. Lu[1], X. Hu[1], Z. Tang[1,2].* 1) College of Life Science and Technology, Huazhong University Science and Technology, Wuhan, Hubei, China; 2) Key Laboratory of Molecular Biophysics of Ministry of Education, Department of Genetics and Developmental Biology, College of Life Science and Technology, Huazhong University of Science and Technology, Wuhan, Hubei 430074, PR China.

Retinal degeneration (RD) is the leading cause of human vision loss. Based on different clinical symptoms, RD is divided into retinits pigmentosa (RP), cone rod dystrophy (CRD), cone dystrophy and macular degeneration. Eyes shut homolog (*EYS*) is the largest gene known to be expressed in the human eye, spanning more than 2Mb within the *RP25* locus. *EYS* mutations have been reported to cause both RP and CRD, but its physiological function in photoreceptors and how *EYS* mutations lead to progressive retinal degeneration is still unclear. To reveal the underlying roles of *EYS*, we generated an *EYS* mutant zebrafish line using TALEN technology. HE staining showed that the retina ONL in *EYS* mutant zebrafish became thinner from the 3rd month, and degenerated in an age dependent way. Furthermore, TEM results showed that the number of photoreceptors decreased at the 3rd month, and decreased more significantly at the 10th month. The red cone opsins and UV cone opsins appeared to be mislocalized on the 2nd month. The outer segment of blue cones, green cones and rods also showed progressive degeneration, but their opsin didn't show mislocalization. Taken together, we built a vertebrate *EYS* mutant model for the first time, and found that red cone opsins and UV cone opsins mislocalizeed in the photoreceptors, which may be one of the major causes of photoreceptor degeneration.

2551W

In-frame indels in inherited eye disease and how structural modelling can help estimate their relative pathogenicity. *P.I. Sergouniotis[1,2], S.J. Barton[3], S. Waller[3], R. Perveen[3], J.M. Ellingford[2,3], C. Campbell[3], G. Hall[3], R.L. Gillespie[2,3], S.S. Bhaskar[3], S.C. Ramsden[3], G.C. Black[2,3], S.C. Lovell[4].* 1) Manchester Royal Eye Hospital, Manchester, UK; 2) Centre for Ophthalmology & Vision Sciences, University of Manchester, Manchester, UK; 3) Centre for Genomic Medicine, University of Manchester, Manchester, UK; 4) Department of Computational & Evolutionary Biology, University of Manchester, Manchester, UK.

Purpose: Although small in-frame insertions/deletions (indels) are common, the molecular mechanisms and frequency by which they give rise to disease phenotypes remain largely unknown. The aim of this study is to provide insights into the role of in-frame indels (≤ 21 nucleotides) in two genetically heterogeneous eye disorders. **Methods**: 486 probands with retinal dystrophy and 181 probands with childhood cataracts underwent multigene panel testing in a clinical diagnostic laboratory. In-frame indels were collected and evaluated both clinically and *in silico*. Variants that could be modeled in the context of protein structure were identified and analysed using integrative structural modeling. **Results**: 55 small in-frame indels were detected; 17 of these changes were novel to this study and 18 variants were reported clinically. A reliable model of the corresponding protein sequence could be generated for 8 variants. Structural modeling indicated a diverse range of molecular mechanisms of disease including disruption of secondary and tertiary protein structure and alteration of protein-DNA binding sites. **Conclusions**: In retinal dystrophy or childhood cataract subjects, one small in-frame indel is clinically reported in every ~37 individuals tested. The clinical utility of computational tools evaluating these changes increases when the full complexity of the involved molecular mechanisms is embraced.

2552T

Expanding the RASopathies: Germline mutations in SYNGAP1. *K.A. Rauen, L. Bivina. Department of Pediatrics, MIND Institute, University of California Davis, Sacramento, CA.*

The RASopathies are a defined group of medical genetic syndromes caused by germline mutations in genes that encode components or regulators of the Ras/mitogen-activated protein kinase (MAPK) pathway. These disorders currently include neurofibromatosis type 1 (NF1), Noonan syndrome, Noonan syndrome with multiple lentigines, capillary malformation–arteriovenous malformation (CM-AVM) syndrome, Costello syndrome, cardio-facio-cutaneous syndrome and Legius syndrome. Because of the common underlying Ras/MAPK pathway dysregulation, the RASopathies exhibit numerous overlapping phenotypic features. The Ras/MAPK pathway plays an essential role in regulating the cell cycle and cellular growth, differentiation, apoptosis and senescence, all of which are critical to normal development. RasGAPs (GTPase-activating proteins) are negative regulators of the Ras/MAPK pathway. Haploinsufficiency in neurofibromin (encoded by the *NF1* gene) and p120 RasGAP (encoded by the *RASA1* gene) are both examples of RasGAPs and cause NF1 and CM-AVM syndromes, respectively. SYNGAP1 (synaptic Ras GTPase activating protein 1) is a more recently described RasGAP thought to be selectively expressed only in neurons. Germline mutations in the *SYNGAP1* gene have been described and associated with Autosomal Dominant Intellectual Disability Type 5, a non-syndromic intellectual disability that has not been thought of as part of the RASopathies. Here we present two individuals with pathogenic germline nonsense mutations in SYNGAP1 identified through exome sequencing and further expand upon the SYNGAP1 phenotype. We present this as a new RASopathy based on the identification of causative mutations in this new RasGAP gene with neuronal-restricted expression understanding that it has a unique neurologically-centered clinical phenotype which does overlap phenotypically with other RASopathies. .

2553F

Loss of the protein arginine methyltranserase PRMT7 causes severe intellectual disability, facial dysmorphism, microcephaly, short stature, brachydactyly and seizures. *D. Chitayat[1,2], K.D. Kernohan[3], A. McBride[3], Y. Xi[3], N. Martin[1], J. Schwartzentruber[4,5], D.A. Dyment[3,6], K.M. Boycott[3,6], S. Blaser[7]. 1) The Prenatal Diagnosis , Department of Obstetrics and Gynecology, Mount Sinai Hospital, Toronto, Ontario, Canada; 2) Division of Clinical and Metabolic Genetics, Department of Pediatrics, Hospital for Sick Children, University of Toronto, Toronto, Canada M5G 1X8; 3) Children's Hospital of Eastern Ontario Research Institute, University of Ottawa, Ottawa, Ontario, Canada K1H 8L1; 4) McGill University and Genome Quebec Innovation Centre, Montreal, Quebec, Canada H3A 0G1; 5) Department of Human Genetics, McGill University, Montreal, Quebec, Canada H3A 1B1 5Department of Genetics, Children's Hospital of Eastern Ontario, 401 Smyth Road, Ottawa, Ontario, Canada K1H 8L1; 6) Department of Genetics, Children's Hospital of Eastern Ontario, 401 Smyth Road, Ottawa, Ontario, Canada K1H 8L1; 7) Department of Diagnostic Imaging, Hospital for Sick Children, University of Toronto, Toronto, Canada M5G1X8.*

The human proteome is incredibly complex and highly regulated to enable proper cellular functioning. Post translational modifications (PTMs) play a vital role in proteome regulation; to date, more than 150 PTMs have been described. The most abundant modifications include phosphorylation, glycosylation, ubiquitination, nitrosylation, acetylation, bromination and methylation. Each PTM has potential to affect three dimensional protein structure, enzymatic activity, protein stability, protein-protein interactions and protein-nucleic acid interactions. One such modification is the covalent addition of a methyl group to arginine or lysine residues, which is used to regulate a substantial proportion of the proteome. Arginine and lysine methylation are catalyzed by protein arginine methyltransferase (PRMTs) and protein lysine methyltransferase proteins (PKMTs), respectively; each methyltransferase has a specific set of target substrates. We report a male with severe intellectual disability, facial dysmorphism, microcephaly, short stature, brachydactyly, cryptorchidism and seizures who was found to have a homozygous 25,309 bp deletion encompassing the transcription start site of *PRMT7*, which we confirmed is functionally a null allele. We show that the patient's cells have decreased levels of protein arginine methylation, and that affected proteins include the essential histones, H2B and H4. Finally, we demonstrate that patient cells have altered Wnt signaling, which may have contributed to the skeletal abnormalities. Our findings confirm the recent disease association of *PRMT7*, inform the phenotypic understanding of this disorder and provide insight into the molecular pathogenesis of this new condition.

2554W

Youngest surviving patient diagnosed with *MAGEL2* mutation (Schaaf-Yang syndrome, OMIM #615547). *V. Neerukonda[1], B. Marr[2], I. Cherrick[3], Z. Powis[4], W. Alcaraz[4], R.R. Lebel[1].* 1) Development, Behavior, and Medical Genetics, SUNY Upstate Medical University, Syracuse, NY; 2) Crouse Memorial Hospital, Neonatal Intensive Care Unit. Syracuse, NY; 3) Department of Pediatrics, SUNY Upstate Medical University, Syracuse, NY; 4) Ambry Genetics, Aliso Viejo, CA.

This male infant had congenital macrocephaly, delivered by Cesarean section at 38 weeks of gestation to a 21 year old G2P0010>1011 female whose pregnancy was complicated by third trimester maternal respiratory distress. Paternal age was 24. The neonatal period was notable for respiratory insufficiency requiring intubation, ventilator support, and an extended NICU stay. The genetics service was consulted on day three of life for multiple craniofacial dysmorphic features and Arthrogryposis Multiplex. Brain Magnetic Resonance Image (MRI), Echocardiogram, and karyotype were normal. Exam revealed macrocephaly, hypertelorism, down slanting palpebral fissures, micrognathia, webbed neck, micropenis, tapering digits, hypotonia, and Arthrogryposis Multiplex. He developed Diabetes Insipidus, Adrenal Insufficiency, Failure to thrive, and became tracheostomy and ventilator dependent. Brain MRI at fifteen months revealed a dysplastic corpus callosum, hypoplastic vermis, myelin dysplasia and global atrophy. The microarray was normal. Whole exome sequencing revealed a heterozygous *de novo* frame shift mutation c.3122delT 9 (p.V1041Afs*7) in the *MAGEL2* gene resulting in a truncated protein. *MAGEL2* is located inside the Prader Willi Syndrome (PWS) critical region of 15q11-13 along with four other genes (*MKRN2, NDN, NPAP1,* and *SNURF-SNRPN*) implicated in PWS phenotype. *MAGEL2* encodes the melanoma-antigen-subfamily-like-2 protein and is involved in cell cycle regulation, neuronal signal transduction and neurite growth, by preventing proteasome-mediated protein degradation. Many animal models note a high degree of homology in the coding region of *MAGEL2* between mice and humans. *MAGEL2* null mice develop a PWS phenotype. *MAGEL2* is expressed predominantly within the developing central nervous system parenchyma, especially in localized areas like the hypothalamus that are implicated in the PWS phenotype. We are aware of thirteen reported persons, nine of whom are alive, with a *MAGEL2* mutation (7 *de novo* mutations and 2 cases of gonadal mosaicism). The age range at diagnosis spans from *in utero* to early adulthood. We propose this is the youngest known patient to be both diagnosed and survive, after being investigated for a PWS like phenotype and neurologic deficits, most likely due to mutation in the *MAGEL2* gene. This patient confirms and extends the distinct phenotype of Schaaf-Yang syndrome (OMIM #615547).

2555T

Isolated hereditary congenital ptosis can be caused by defects of craniofacial development. *S.A. Di Gioia[1], W.M. Chan[1], B. Barry[1], A. Magli[2], T. de Berardinis[2], P. Pavone[3], E.C. Engle[1].* 1) Department of Neurology, F.M. Kirby Neurobiology Center, Boston Children's Hospital, Boston, MA; 2) Università degli Studi di Napoli, Dipartimento di Scienze Oftalmologiche, Naples, Italy; 3) Unit of Pediatrics, University Hospital OVE-Policlinico, Catania, Italy.

To uncover genetic causes of congenital ptosis, or drooping of the upper eyelid, we analyzed exome sequence of affected and selected unaffected members of 12 unrelated multiplex families segregating isolated hereditary congenital ptosis. Genome wide SNP data (Illumina OmniExpress array) was also generated for a subset of the families for both linkage and CNV analyses. Using these approaches, we identified three novel variants in three unrelated Italian families, none of which were annotated in the EXAC database. Remarkably, the variants were in three different genes, each of which had been previously identified as important for craniofacial development. Affected members of Pedigree UU, diagnosed with a mild form of unilateral ptosis, harbored a novel *FGFR2* variant, c.760C>T, p.H254Y. Mutations in *FGFR2* are typically associated with syndromic craniosynostosis. Affected members of Pedigree IQ, with variable expression of ptosis, harbored a novel missense variant, c.379G>A p.A127T, in the helix-loop-helix domain of *TWIST1*. *TWIST1* mutations are typically associated with Saethre-Chotzen syndrome, a second form of craniosynostosis. There were no signs or symptoms of craniosynostosis detected by the physicians who referred these families. Lastly, Pedigree TQ was diagnosed with severe congenital bilateral ptosis suggestive of blepharophimosis, ptosis and epicanthus inversus syndrome (BPES). CNV analysis revealed the presence of a heterozygous deletion on the short arm of chromosome 2 (chr2:45024863-43300029) that segregated with affection status, and that removed the entire *SIX2* gene. A deletion of *SIX2* with similar breakpoints was recently reported in a novel form of frontonasal dysplasia with clinical features similar to Pedigree TQ. Together, these data expand the phenotype of known craniosynostosis genes and confirm the *SIX2* phenotype. Moreover, they suggest that the presence of ptosis should alert clinicians to the possibility of variants in genes that may be more commonly associated with more severe forms of craniofacial developmental disorders.

Further delineation of Au-Kline Syndrome: A craniosynostosis and Kabuki-like syndrome due to loss of function mutations and deletions of *HNRNPK.* *P.Y. Au[1,2], C. Goedhart[1,2], M. Kerr[1,2], M. Ferguson[3], J. Breckpot[4], K. Devriendt[4], K.J. Wierenga[5], E.A. Fanning[5], U. Kini[6], H. Stewart[6], L. Lange[7], A. Pagnamenta[7], J. Taylor[7], D. Keays[8], D.K. Grange[9], S.L. Dugan[10], J.S. Parboosingh[1,2], A.D. Kline[3], A.M. Innes[1,2], Care for Rare Canada Consortium.* 1) Medical Genetics, University of Calgary, Cumming School of Medicine, Calgary, Alberta, Canada; 2) Alberta Children's Hospital Research Institute for Child and Maternal Health, University of Calgary, Alberta, Canada; 3) Harvey Institute for Human Genetics, Department of Pediatrics, Greater Baltimore Medical Center, Baltimore, Maryland; 4) Center for Human Genetics, KU Leuven, Leuven, Belgium; 5) Department of Pediatrics, Section of Genetics, University of Oklahoma Health Science Center, Oklahoma City, Oklahoma, USA; 6) Department of Clinical Genetics, Oxford University Hospitals NHS Foundation Trust, Oxford, UK; 7) National Institute for Health Research Biomedical Research Centre, Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK; 8) Research Institute of Molecular Pathology, Vienna, Austria; 9) Department of Pediatrics, Division of Genetics and Genomic Medicine, Washington University School of Medicine, St. Louis, Missouri, USA; 10) Division of Medical Genetics, Department of Pediatrics, University of Utah, Salt Lake City, Utah.

We recently reported 2 patients with intellectual disability and dysmorphic features with *de novo* loss of function mutations in *HNRNPK* (heterogeneous nuclear ribonucleoprotein K). With 2 additional previously reported deletion cases, this is now known as Au-Kline syndrome (AKS). Lange et al. [2016] reported a further case with a Kabuki-like presentation and nodular heteropia. Through international collaboration, 4 additional patients with *HNRNPK* mutations, and a patient with 9q21.32 microdeletion encompassing *HNRNPK,* have now been identified, resulting in a current total of 9 known patients with AKS. Frameshift and splice mutations have been found in 6 patients identified by WES, and deletion encompassing *HNRNPK* in 3 patients identified by aCGH. Loss of function intolerance of *HNRNPK* is supported by a high pLI score of 1.0 [ExAC et al. 2015]. AKS is characterized by striking dysmorphism including long facies, long ears, a deeply grooved tongue, connective tissue anomalies and aortic dilation, and intellectual disability. Further clinical delineation is now possible with this larger cohort. Features of AKS are shared not only with TGFβ pathway related disorders, but also with Kabuki syndrome (KS). The AKS facial gestalt includes long palpebral fissures, ptosis and shallow orbits, resembling KS. Additionally, >50% of AKS patients have craniosynostosis with at least one suture affected, typically the metopic and sagittal sutures. AKS should therefore also be considered in the differential for syndromic craniosynostosis. Of note, in previously reported KS cohorts ascertained prior to availability of molecular testing, both craniosynostosis and bifid/fissured tongue have been reported [Armstrong et al. 2005], suggesting that some Kabuki-like patients may have *HNRNPK* mutations. The prenatal presentation of AKS includes increased nuchal translucency and/or fetal hydrops. Although haploinsufficiency of *Hnrnpk* in mice is associated with susceptibility to hematopoietic neoplasm [Gallardo et al. 2015], no AKS patients have had malignancy. However, the eldest patient is only 18 years of age. AKS is likely not as rare as initially expected, with several individuals rapidly identified through clinical WES (or reanalysis of WES data) since the publication of our original patients. As the features of AKS are striking, this syndrome is clinically recognizable. Therefore, Sanger sequencing of *HNRNPK* in patients suspected to have an AKS phenotype is currently underway.

2557W

Phenotypic and mutational spectrum of patients with overgrowth, macrocephaly and Weaver-like features. *A.S.A. Cohen[1,2], Y. Shen[3], J. Denny[4], S.J.M. Jones[1,3,5], W.T. Gibson[1,2].* 1) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Child and Family Research Institute, Vancouver, BC, Canada; 3) Canada's Michael Smith Genome Sciences Centre, British Columbia Cancer Agency, Vancouver, BC, Canada; 4) Centre for Molecular Medicine and Therapeutics, Vancouver, BC, Canada; 5) Department of Molecular Biology and Biochemistry, Simon Fraser University, Burnaby, BC, Canada.

In late 2011, we and others discovered that constitutional mutations in *EZH2* cause Weaver syndrome (WS). WS is a rare overgrowth disorder characterized by tall stature, large head, advanced bone age, facial dysmorphism, intellectual disability and cancer susceptibility. Since then, we have collected samples on almost 70 patients with Weaver-like features from across the world. We have also collected detailed phenotypic information where available. We have tested these patients for mutations in *EZH2*, as well as *NSD1*, which when mutated causes a similar overgrowth disorder called Sotos syndrome. With this detailed phenotyping and targeted gene testing approach, we were able to reach a DNA-level diagnosis in close to 25% of our cohort. Furthermore, we were able to expand on the phenotypic spectrum of WS to include neuronal migration disorders. In addition, using whole-exome sequencing in a select subset of undiagnosed patients, we identified a rare *de novo* mutation in *EED* in one patient. Sanger sequencing was then carried out in the patients with the greatest phenotypic overlap, and a second patient was found to carry a different rare *de novo* mutation in *EED*. Interestingly, EED is the main partner of EZH2 within the Polycomb Repressive Complex 2, which maintains gene silencing. With two independent individuals having similar rare phenotypes associated with different *de novo* mutations in the coding sequence of the same (relatively small) gene, we believe the association to be causal and that we have identified a novel overgrowth gene. We will present an overview of this Weaver-like cohort, including frequencies of the main phenotypic traits observed and a list of all the mutations detected in *EZH2*, *NSD1* and *EED*.

2558T

Persistent thrombocytopenia, growth retardation and developmental delay in a three-year-old female: Possible Forsythe-Wakeling syndrome. *M. Hajianpour[1], M. Popescu[2].* 1) East Tennessee State University, Department of Pediatrics/ Medical Genetics, Quillen College of Medicine, Johnson City, TN; 2) East Tennessee State University, Department of Pediatrics, Hematology/ Oncology, St. Jude's Tricities Affiliate Clinic, Johnson City, TN.

Proband is a 3 y.o. female with persistent thrombocytopenia, developmental delay/ language deficit, growth retardation, mild body asymmetry, keratinized, purple, nodular skin rash on the face and exposed areas and dysmorphic features, such as narrow bifrontal diameter (mild), positional plagiocephaly (normal skull CT scan), frontal bossing, slightly posteriorly rotated left ear, low nasal bridge, bulbous nose, thin vermilions, micrognathia, pointed chin, hypoplastic nipples, and mild fifth fingers clinodactyly. She was born at 29 weeks of gestation by C-section delivery due to maternal pre-eclampsia/fetal distress/IUGR to a 20 y.o., G2, P1 mother. Her BW was 1050 g with a BL of 33 cm. Developmental milestones and speech were delayed. She developed thrombocytopenia at age 2 years. She had episodes of low bicarb with normal renal ultrasound. Chromosome analysis, microarray, breakage study, sister chromatid exchange, and molecular studies for Shwachman-Diamond anemia were negative. No ROH was detected on CMA. Two bone marrow biopsies showed normal histology. The Russell-Silver syndrome (RSS) was considered. But presence of thrombocytopenia and typical skin rash together with lack of cafe-au-lait spots do not support RSS. Growth retardation, dysmorphic features, typical skin rash, and thrombocytopenia were reported in a single Pakistani family (consanguineous marriage) with four affected siblings (Forsythe et al., 2009). They all had microcephaly (one with HC of 9%ile), postnatal growth retardation, and global developmental delay with language deficit and dysmorphic features, such as frontal bossing, sunken eyes, high nasal bridge, and large, prominent, low-set ears. Three siblings developed persistent thrombocytopenia and steroid- nonresponsive nephrotic syndrome (SUNS), resulting in death in two children. One child did not have nephrotic syndrome or thrombocytopenia by age 25 months. The oldest child with thrombocytopenia, developed SUNS at age 7 y, with a renal biopsy showing glomerulosclerosis, tubular atrophy and other abnormalities. None had photosensitivity, poor vision, or deafness, but two had keratinized, purple, nodular skin lesions. Fibroblasts showed intermediate recovery of RNA synthesis following UV irradiation. Dysmorphic features and fibroblasts findings were thought to be reminiscent of Cockayne syndrome. A 27-Mb interval of shared homozygosity on chromosome 1p33-p31.1 (rs2354462 to rs718883) in these patients may indicate a related gene locus.

2559F

Dubowitz syndrome: A literature review and prospective whole exome sequencing study confirm high clinical and genetic heterogeneity. *A. Innes[1,2], T. Hartley[3], B. McInnes[2], P.Y. Au[1,2], A.E. Chudley[4], C. Clericuzio[5], C.R. Greenberg[4], J.L. Lauzon[1], R.B. Lowry[1], J. Moilanen[6], M. Nowaczyk[7], L. Penney[8], S.L. Sawyer[9], K.M. Boycott[3,9], D.A. Dyment[3,9], Care4Rare Canada Consortium.* 1) Department of Medical Genetics, Cumming School of Medicine, University of Calgary, Calgary, Canada; 2) Alberta Children's Hospital Research Institute, Calgary, Canada; 3) Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada; 4) Departments of Pediatrics and Child Health and Biochemistry and Medical Genetics, University of Manitoba, Winnipeg, Canada; 5) Pediatric Genetics, University of New Mexico, Albuquerque, NM; 6) Department of Clinical Genetics, Oulu University Hospital, Medical Research Center and PEDEGO Research Unit, University of Oulu, Oulu, Finland; 7) Departments of Molecular Medicine & Pathology and Pediatrics, McMaster University, Hamilton, Canada; 8) Department of Pediatrics, Dalhousie University, Halifax, Canada; 9) Department of Genetics, CHEO, Ottawa, Canada.

The Dubowitz Syndrome (DS OMIM 222370) was first reported in 1965. Including a previous definitive review (Tsukahara and Opitz, 1996), nearly 200 cases have been reported in the literature. While typical clinical features include microcephaly, sparse hair, eczema and mild craniofacial and developmental anomalies, a wide variety of clinical features have been reported. Autosomal recessive inheritance has been postulated, and some patients appear predisposed to malignancy. Despite the apparent frequency of this condition, no common recurrent genetic cause has been identified. Recent small studies have suggested clinical and genetic heterogeneity may explain this paradox. To further explore this possibility we embarked on a detailed literature review of the 50 patients published from 1996 to present and performed whole exome sequencing on 10 trios with probands diagnosed by a clinical geneticist with DS. The literature review underscored both clinical and genetic heterogeneity. For 39 of the 50 patients, photographs were available and a wide variety of facial features and clinical problems were noted. Consanguinity and/or familial recurrence were noted in 8 and 6 families respectively. Strikingly while zero of 19 patients reported from 1996-2005 had an underlying genetic abnormality identified, 16/31 patients (52%) reported since 2006 had a presumed causal variant identified on genetic testing (nearly all via aCGH or WES). While there are almost no recurrent abnormalities; causes that will be discussed include biallelic mutations in *LIGIV* and *NSUN2*, as well as certain CNVs. *De novo* dominant mutations in several genes were also seen. Four patients developed a solid tumor and others had bone marrow failure, increased chromosome breakage was frequent in this group. These literature findings were reproduced in our WES cohort. Of 10 patients, four had different definitive mutations identified (biallelic *BRCA1* and *SCL35A1* mutations, de novo *ARID1B* mutation and *HDAC8* deletion) and in another a *de novo* variant in *CREBBP* is being studied further. For the other five patients no clear causal variants were identified, although novel candidate genes are currently being pursued via global matchmakers. Nevertheless no recurrent genes were seen across multiple patients. The implications of these findings for clinicians considering a clinical diagnosis of DS will be reviewed, including recommendations for further investigation, management and counselling.

2560W

Craniosynostosis in RASopathies. *N. Okamoto[1], K. Ueda[1], M. Yaoita[2], T. Niihori[2], Y. Aoki[2].* 1) Dept Medical Genetics, Osaka Med Ctr/Res Inst, Osaka, Japan; 2) Department of Medical Genetics, Tohoku University School of Medicine, Sendai, Japan.

   Noonan syndrome (NS), Costello syndrome, and cardio-facio-cutaneous (CFC) syndrome are characterized by a distinctive facial appearance, heart defects, ectodermal abnormalities and intellectual disability. These syndromes are caused by a dysregulation of the RAS/mitogen activated protein kinase (MAPK) signaling pathways, and are collectively called "RASopathy". Fibroblast grout factor receptors (FGFR) is interacted with the RAS/MAPK signaling pathways. FGFR proteins are receptor tyrosine kinase upstream of the RAS/MAPK signaling pathway. Genomic mutations in FGFR are the most common causes of inherited craniosynostosis (CS), Apert, Crouzon, Pheiffer and Muenke syndrome. These syndromes are caused by the dysregulated FGFR signaling cascade. Recently CS with *KRAS* mutations was reported. Approximately 10% of published cases with *KRAS* mutations have CS [Addissie et al., AJMG 2015]. The review suggested that individuals with NS associated with *KRAS* mutations have greater risk for CS. In addition, Noonan syndrome caused by *SHOC2* mutation has been reported to have severe CS [Takenouchi, et al., AJMG 2014]. These clinical findings support the idea that RAS/MAPK pathway might be associated with the development of cranium and have interaction with *FGF*. We present 9 patients with CS who had *KRAS, BRAF*, and *PTPN11* mutations. This is the first report of CS with *BRAF* and *PTPN11* mutations. We suggest that patients with CFC syndrome and NS should be followed carefully for cranial deformation. In RASopathy patients with cranial deformities or neurological symptoms due to suspected increased intracranial pressure or microcephaly, further assessment, including 3D-CT of the head, might be necessary to evaluate for possible CS. Proper treatment including surgical intervention is necessary. .

Williams-Beuren syndrome: Case report and three-year follow-up.
G. Rodríguez-González[1,2], A. Marín-Medina[1,2], S.A. Alonso-Barragán[1,2], A. Ramírez-Velasco[1,2], L. Gutiérrez[2], M.G. Domínguez-Quezada[1,2], I.P. Dávalos-Rodríguez[1,2]. 1) Doctorado en Genética Humana, IGH, CUCS, Universidad de Guadalajara; 2) CIBO, UMAE, HP, CMNO; IMSS.

   Williams-Beuren Syndrome (WBS) (MIM # 194050) is caused by a hemizygous deletion of 1.5 to 1.8 Mb in 7q11.23 The SWB is characterized by short stature, dysmorphic facial features, mental retardation, cardiovascular disorders, infantile hypercalcemia and sociable personality. It has a frequency of 1/10000 to 1/20000 births. Objective: To present a male patient whose clinical data led us the diagnosis of Williams-Beuren syndrome. Case report: Male patient, 4 years old, product of second pregnancy, full-term, obtained by caesarean section. Mother of 27 years, father of 32 years, at birth, non consanguineous. Sister of 7 years old, apparently healthy. After 15 days of extra uterine life he was hospitalized due to pneumonia, at one year old left orquidopexy was done. Delay of psychomotor skills development. At 15 months, cardiological evaluation reported right branch pulmonic stenosis and at two years old ophthalmologic evaluation reported convergent strabismus. At physical examination revealed a sociable personality, short stature, normocephalic skull, epicantus, upward slanting palpebral fissures, strabismus, flat nasal bridge, large mouth, thick lips and low set ears. In chest presence of systolic murmur in pulmonary focus grade II, remaining unchanged. Previous clinical data allowed the diagnosis of SWB. Cytogenetic analysis: 46, XY [16]. ish (7) (q11.23q11.23) (ELN -) [5] Conclusions: In this case the presence of short stature, characteristic facies, pulmonary stenosis and social behavior allowed the clinical diagnosis of WBS, Cytogenetic study reported 7q11.23 deletion. Early clinical diagnosis of SWB enables a multidisciplinary monitoring and early treatment of complications.

2562F

Molecular genetics of focal facial dermal dysplasias types 3 and 4. *B. Lee[1,2], I. Nazarenko[1], L. Edelmann[1], F. Morice-Picard[3], A.M. Slavotinek[4], R.J. Desnick[1]. 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 2) Department of Pediatrics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 3) Centre de Référence des Maladies Rares de la Peau, Service de Dermatologie et Dermatologie Pédiatrique. Hôpital Pellegrin-Enfants, Bordeaux, France; 4) Division of Genetics, Department of Pediatrics, University of California, San Francisco, San Francisco, CA, USA.*

The Focal Facial Dermal Dysplasias (FFDDs) are a group of rare developmental disorders which have been classified into four subtypes based on: 1) the location of the congenital "scar-like" facial lesions in the bitemporal (FFDD Types 1-3) or in the peri-auricular (FFDD Type 4) regions, 2) presence of additional facial abnormalities, and 3) pattern of inheritance. Although the genetic etiologies for FFDD Types 1 and 2 have not been delineated, we recently identified homozygous recessive mutations in *TWIST2*, a transcriptional factor involved in craniofacial mesenchymal development, and a 1.3 Mb copy number duplication or triplication at chromosome 1p36.22p36.21 causing FFDD Type 3, (Tukel et al. *Am. J. Hum. Genet.* 2010), and homoallelic recessive *CYP26C1* mutations underlying FFDD Type 4 (Slavotinek et al. *Hum. Mol. Genet.* 2014). Here, we report the clinical spectrum and causative mutations in 22 unrelated FFDD Type 3 patients and six unrelated FFDD Type 4 patients. Among the FFDD Type 3 patients, *TWIST2* mutations and the 1p36 copy number duplication or triplication were each identified in five FFDD Type 3 patients, respectively, (combined total of 10/22 or 46%). Among the five FFDD Type 4 patients, all were found to have *CYP26C1* mutations including three novel mutations, IVS5+1G>T, IVS5+2insT, p.Arg77Pro. Currently, efforts are underway to identify the causative genes underlying the remaining 12 FFDD Type 3 patients. The interaction of TWIST2 with other genes, especially located in the 1p36.22p36.21 region, was assessed by *in silico* analysis. Two genes, *DHRS3* and *CYP26A1,* were suggested as candidate genes that interacted with TWIST2. Therefore, the 4.2 Mb *TWIST2* regulatory region and the coding regions of *DHRS3* and in *CYP26A1* were sequenced, and several variants with unknown significance were identified, and their potential pathogenic effects are being investigated. In addition, whole genome and exome sequencing has been undertaken in a consanguineous family and are now being analyzed. In conclusion, the results of our study indicate that FFDDs are a group of disorders that are genetically heterogeneous and additional causative genetic defects will be identified in the future.

2563W

Assessment and management of feeding difficulities in patients with trisomy 13 syndrome. *E. Nishi[1,2], N. Fueki[3], Y. Gomi[3], C. Seki[3], M. Arakawa[1], K. Takano[1,2], Y. Fukushima[2], T. Kosho[1,2]. 1) Department of Medical Genetics, Nagano Children's Hospital, Azumino, Japan; 2) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 3) Department of Rehabilitation, Nagano Children's Hospital, Azumino, Japan.*

Trisomy 13 (T13) syndrome is a most common autosomal trisomy syndrome, characterized by multiple congenital anomalies, severe developmental delay, and a short life span with the 1-year survival rate as 5–10 % and the median survival time as 7 days according to a large-scale population-based study. Feeding difficulties in patients with T13 remain one of the challenges of their management. In one study, 53% of children with T13 had bottle or breast feeding during the first few weeks or months [Baty et al.,1994]. To evaluate the management of swallowing and feeding in patients with T13, we reviewed detailed clinical data of 4 patients with full T13 in the outpatient clinic specialized for patient with swallowing and feeding problems in Nagano Children's Hospital, from 2012 to 2016. Patients (3 boys, 1 girl), aged from 2 years old to 6 years old, were diagnosed with full T13. All had multiple congenital defects and medical complications including congenital heart defects, cleft lip or cleft palate, and holoprocencephaly. Three of them needed tracheostomy, and two required mechanical ventilation. They were discharged home at the age from two months to 1 year old. They all showed feeding difficulties, required for a nasal or oral gastric tube from infancy. Three needed gastrostomy, but the other accomplished bottle feeding and ceased to use tube feeding at age 7 month. Further evaluation through videofluoroscopic (VF) swallow studies revealed details of their feeding and swallowing problems, including abnormal oral sensation, uncoordinated tongue movement, dyscoordination between sucking and swallowing, inappropriate sizes and forms of the food, and presumed risk of aspiration. In conclusion, the current study, though the sample size is small, suggests a wide variation in oral feeding in patients with T13. Also, detailed and comprehensive evaluation including VF would contribute to safe oral feeding. The evidence is helpful for clinicians to offer the best information on management options to families of patients with T13.

2564T

Mutations in *LZTR1* can underlie rare cases of autosomal recessive Noonan syndrome. *J.J. van der Smagt, N.E. Verbeek, K.L.I. van Gassen.* clinical genetics, UMCU, Utrecht, Utrecht, Netherlands.

Noonan syndrome (NS) is a quite common autosomal dominant syndrome characterized by a recognizable constellation of dysmorphic features, heart defects and short stature. Activating mutations in many genes of the RAS-MAPK pathway have been demonstrated to be causative. In 2000 the existence of an autosomal recessive form of NS indistinguishable from classical autosomal dominant NS was suggested(1), but subsequently this has never been confirmed. In 2015 heterozygous LZTR1 mutations were shown to cause Noonan syndrome in a small autosomal dominant pedigrees (2). No role in the RAS-MAPK pathway had been known for LZTR1. Germline loss of function mutations in LZTR1 had been described in the disorder schwannomatosis (3). Two unrelated index patients with Noonan syndrome are described, that were mutation negative for known Noonan genes but were either homozygous for a missense variant or compound heterozygous for a splice mutation and a missense variant in LZTR1, on whole exome screening. In both cases carrier parents were normal on physical and cardiac evaluation. Both indexes had sibs with the same LZTR1 genotype who died either during pregnancy (fetal hydrops) or shortly after birth (AVSD+ hypertrophic cardiomyopathy +neural tube defect).So these sibs with an identical LZTR1 genotype had at least symptoms consistent with NS. In neither family schwannomatosis has occurred. Discussion: Albeit very rare autosomal recessive Noonan syndrome does occur an can be caused by homozygous or compound heterozygous LZTR1 mutations.The lztr1 protein excusively localizes to the Golgi apparatus (4), linking this subcellular structure to NS. The loss of function mutation in one of our cases suggests that LZTR1 may have a primarily inhibitory effect on RAS MAPK signaling, just like NF1. Interestingly loss of function mutations in both genes are also associated with nerve sheath tumors. Refs: 1.)Ineke vander Burgt and Han Brunner. Genetic Heterogeneity in Noonan syndrome.. Am J Med Genet 200;94:46-51 2.)GL Yamamoto, et al. Rare variants in SOS2 and LZTR1 are associated with Noonan syndrome. J Med Genet 2015;52:413–421. 3.)A Piotrowski, et al. Germline loss-of-function mutations in *LZTR1* predispose to an inherited disorder of multiple schwannomas. Nat Genet. 2014 February ; 46(2): 182–187. 4.)TG Nacak, et al. The BTB-kelch Protein LZTR-1 Is a Novel Golgi Protein That IsDegraded upon Induction of Apoptosis. Journal of biological chemistry 2006;281:5065-71.

ARCN1 **Mutations cause a novel craniofacial syndrome due to COPI-mediated transport defects.** *K. Izumi[1,2,3], M. Brett[4], E. Nishi[3], S. Drunat[5,6], E.S. Tan[7], K. Fujiki[2], S. Lebon[5], B. Cham[7], K. Masuda[2], M. Arakawa[3], A. Jacquinet[8], S.T. Chen[2], A. Verloes[5,6,9], Y. Katou[2], P. Gressens[5,9,10], R. Foo[11], S. Passemard[5,6,9], E.C. Tan[4,12], V. Ghouzzi[5,9], K. Shirahige[2].* 1) Division of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Research Center for Epigenetic Disease, Institute for Molecular and Cellular Biosciences, The University of Tokyo; 3) Division of Medical Genetics, Nagano Children's Hospital; 4) KK Research Centre, KK Women's and Children's Hospital; 5) INSERM UMR1141; 6) Département de Génétique, Hôpital Robert Debré; 7) Genetics Service, Department of Paediatrics, KK Women's and Children's Hospital; 8) Département de Génétique, CHU et Université de Liège; 9) Université Paris Diderot Paris 7, Hôpital Robert Debré; 10) Center for Developing Brain, King's College, St. Thomas' Campus; 11) Genome Institute of Singapore; 12) Paediatrics ACP, SingHealth Duke-NUS Medical School.

Cellular homeostasis is maintained by the highly organized cooperation of intracellular trafficking systems including COPI, COPII, and clathrin complexes. COPI is a coatomer protein complex responsible for intracellular protein transport between the endoplasmic reticulum (ER) and the Golgi apparatus. Using exome sequencing, we identified four individuals with heterozygous mutations in *ARCN1*, which encodes the coatomer subunit delta of COPI. All individuals with *ARCN1* mutations have a highly conserved clinical phenotype including facial dysmorphisms, severe micrognathia, rhizomelic shortening, short stature, joint laxity, microcephaly, and mild developmental delay. *ARCN1* mutant cell lines demonstrated an ER stress response, suggesting the involvement of ER stress response in the pathogenesis of the *ARCN1*-related syndrome. The clinical overlap between *ARCN1*-related syndrome and Stickler syndrome prompted us to evaluate the role of COPI-mediated transport in collagen transport, and defective intracellular collagen transport was demonstrated in cell lines with *ARCN1* dosage reduction. *ARCN1*–related syndrome represents a novel clinically recognizable syndrome. Our findings demonstrate the importance of COPI-mediated transport, which is a fundamental biological process, in human development.

2566W

Computer-assisted facial recognition of Angelman syndrome: A possible diagnostic aid. *L. Bird[1,2], L. Wolf[3].* 1) Dysmorphology Genetics, Rady Children's Hospital, San Diego, CA; 2) University of California San Diego; 3) Tel Aviv University, Tel Aviv, Israel.

Angelman syndrome (AS) is characterized by severe intellectual disability, seizures, limited speech and distinct behavioral profile. Absence of a functional copy of the paternally-imprinted *UBE3A* gene on chromosome 15 causes AS. 75% of AS is due to deletion of chromosome 15q11.2; the remainder is due to paternal uniparental disomy (UPD), imprinting defect (ID) or mutation of the maternally-inherited *UBE3A*. Subtle facial dysmorphism (midface recession, prognathism, broad mouth) can be appreciated in older AS individuals, but most AS children are generally non-dysmorphic. Automated facial recognition technology has the potential to assist in syndrome identification. Face2Gene (F2G) is a free tool that uses Facial Dysmorphology Novel Analysis (FDNA) technology to evaluate 2D facial photographs. We compared F2G's accuracy of AS recognition with that of clinical experts. The FDNA system was trained using frontal images from 60 individuals (mostly children) with molecularly diagnosed AS (46 with deletion, 9 with UPD or ID, 5 with *UBE3A* mutations). 20 experts were provided a compilation of frontal photographs of 25 children, some of whom had molecularly proven AS (n=10) and the rest having other syndromes (n=15), and were asked to designate which of the children had AS. (Experts did not know the actual number of AS images among the 25.) Frontal images of 117 additional unique molecularly-diagnosed AS patients were used to determine the accuracy of the FDNA technology and to determine which syndromes are most often erroneously identified. Clinical experts and F2G had comparable accuracy, sensitivity and specificity on the 25-image challenge set. Deletion (n=6) and non-deletion AS cases were equally recognized by experts and F2G. AccuracySensitivitySpecificityAccuracy FemalesAccuracy MalesAccuracy WhiteAccuracy non-WhiteExperts72%60%81%80%67%73%72%F2G76%50%*93%82%71%79%73%*sensitivity increased to 80% if AS appearing on the top 10 match list was considered a correct response F2G accuracy (AS #1 match on list) on the expanded set of images was 42/117 = 36%; if AS appeared in the top 5, 10 or 20 matches, sensitivity increased to 62%, 75% and 82%, respectively. The most common other condition on the top 10 match list was Pitt-Hopkins syndrome, which occurred in 33/117. These results show that automated facial recognition could assist clinicians in syndrome recognition. Sensitivity and specificity are likely to improve as the image collection increases.

The Rubinstein-Taybi syndrome (RTS) is a multiple congenital anomalies – intellectual deficiency syndrome characterized by growth retardation, microcephaly, characteristic facial features, and broad thumbs and first toes. RTS is genetically heterogeneous with mutations in the *CREBBP* or *EP300* genes encoding transcription cofactors involved in histone acetylation. RTS knock-out mouse studies showed an improvement of long-term memory using histone deacetyltransferase (HDAC) inhibitors. This suggests a therapeutic option for RTS. Among the identified HDAC inhibitors, sodium valproate has the marketing authorization for epilepsy and mood disorders and can go through the blood brain barrier. We conducted an exploratory phase 2 therapeutic trial («proof of concept »), with a primary endpoint to estimate the efficiency of sodium valproate after one year of treatment (30 mg/kg/d) on long term memory in RTS children. Secondary Outcomes included cognitive profiles, brain imaging, motor skills evaluation, and histone acetylation profile. It was a monocentric, double-blind, phase 2 trial, designed as a one-step Fleming with a control group, randomized 2:1 into two parallel groups. 41 RTS cases between ages 6 and 21 participated. Using subtests of neuropsychological battery test especially designed for memory evaluation (point location for CMS, and image recognition for RBMT), results were not significant between the treatment group and the placebo group for the primary outcome. However regarding motor skills for walking, it was noticed a slight decrease of cadence and an increase of the duration of the double step in the valproate group, showing an amelioration in the treatment group. Posturometry showed more oscillations in the placebo group during the task. This confirms the *CREBBP* and *EP300* roles in motor skill learning, and encourages to pursue therapeutic approaches with HDAC inhibitors in RTS.

Craniofacial phenotype segregates with Loeys-Dietz Syndrome mutation/type. *D.K. Liberton[1], R. Mishra[1], E. Akpa[1], H. Bolan[2], M. Rasooly[2], D. Cantave[3], P.A. Guerrerio[2], J.S. Lee[1].* 1) National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD; 2) National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD; 3) Clinical Center, National Institutes of Health, Bethesda, MD.

   Loeys-Dietz Syndrome (LDS) is an autosomal dominant connective tissue disorder with five known types based on their underlying genetic mutation. The main presentation includes arterial tortuosity and aneurysms but there are also craniofacial findings such as hypertelorism, cleft palate, and craniosynostosis. However, there is a large degree of craniofacial phenotypic variability in affected individuals. In this study, we examined patients with Type I (*TGFBR1* mutation) and Type II (*TGFBR2* mutation) who were evaluated at the Craniofacial Dental Clinic at the National Institutes of Health Clinical Center as part of an IRB approved protocol. All patients underwent a cone-beam computed tomography scan (Planmeca Promax 3D) and 3D surface image (3dMD) as well as a comprehensive craniofacial and oral exam. Clinically, both groups demonstrated midface hypoplasia, mandibular retrognathia, and low-set ears. There was variable expression of exophthalmia, hypertelorism, craniosynostosis, drooping nasal tip, cleft palate/bifid uvula/narrow palate and enamel defects. We performed cephalometric analysis on five patients from the two types and compared their craniofacial findings. Both types demonstrated significantly short cranial base, short upper facial height, shortened mandibular base, mandibular retrognathia, and increased gonial-jaw angle. The major morphological difference between the two types was in maxillary and mandibular development. Type I individuals were mildly deficient for measures of maxillary and mandibular growth while Type II individuals were more than two standard deviations below the norm for both measures, indicating significant and severe hypoplasia of the mid- and lower- face in this group. This work expands upon the known craniofacial phenotypes associated with LDS and suggests that there is significant phenotypic variability among and as well as within different mutations. TGFβ signaling is critical for mediating epithelial-mesenchyme interactions, including those important for mandibular, calvarial, and tooth morphogenesis (ref 2). Deep phenotyping and morphometric analysis improves our understanding of the diagnostic features of this disorder and supports the critical role of TGFβ in human craniofacial development. Future research will investigate the developmental mechanisms of these mutations and also examine the craniofacial phenotypes of Type III (SMAD3 mutation), Type IV (TGFB2 mutation), and Type V (TGFB3 mutation) LDS patients.

Severe oral aversion in three children with rasopathies. *S. Mizuno[1], E. Nishi[2], M. Inaba[1], Y. Muramatsu[1], Y. Aoki[3], C. Hayakawa[1].* 1) Dept Pediatrics, Central Hospital, Aichi Human Service Ctr Pediatrics, Kasugai, Aichi, Japan; 2) Department of Clinical Genetics, Nagano Childrens Hospital, Azumino, Nagano, Japan; 3) Department of Medical Genetics, Tohoku University School of Medicine.

   Cardio-facio-cutaneous (CFC) syndrome (MIM #115150) is a multiple congenital anomaly/mental retardation syndrome characterized by cardiac abnormalities, a distinctive facial appearance, cutaneous abnormalities, and mental retardation. Its phenotype overlaps with both Noonan syndrome and Costello syndrome. These three syndromes belong to a class of genetic syndromes caused by the mutation of genes associated with the RAS/MAPK pathway.CFC syndrome is genetically distinguished by the detection of BRAF, MEK1/2, and KRAS mutation. However the phenotype-genotype correlation of this syndrome has not been fully clarified.

2570T

Application of whole exome sequencing to reverse dysmorphology: Case report of one patient with pathogenic variant in *HDAC8.* *A.B.A. Perez[1], M.P. Migliavacca[1], N.L. Sobreira[2]. 1) Medical Genetics Center, UNIFESP, Sao Paulo, Brazil; 2) Johns Hopkins University - IGM.*

The application of New Generation Sequencing (NGS) for Mendelian Diseases is enabling the delineation of new syndromes that have less distinctive clinical features by a process that can be termed "reverse dysmorphology." Here, the classical practice of identification of the phenotype first and analysis of the genotype second is reversed. In this way, cases are first recognized by their genotype and subsequently the phenotypes of the individuals are compared to the features of the disease assigned to that genotype. The Cornelia de Lange syndrome (CDLS) is a multisystem malformation syndrome recognized primarily on the basis of characteristic facial dysmorphism, including low anterior hairline, arched eyebrows, synophrys, anteverted nares, maxillary prognathism, long philtrum, thin lips, and 'carp' mouth, in association with prenatal and postnatal growth retardation, mental retardation and, in many cases, upper limb anomalies. However, there is wide clinical variability in this disorder, with milder phenotypes that may be difficult to ascertain on the basis of physical features. Up to now there are five different types of CDLS and 19 genes related to them. **Purpose:** To describe a patient with multiple dysmorphisms and a previous clinical diagnosis of Ohdo Syndrome that underwent Whole Exome Sequencing (WES) with detection of a pathogenic variant in the *HDAC8* gene and further acknowledgment of characteristic features of CDLS type 5. **Methods:** A 6 years old female patient with IUGR, neonatal seizures, cardiac malformation, horse-shoe kidney, developmental delay, hypothyroidism and bilateral deafness had her exome sequenced in the Illumina ™ platform and analysis performed with access through the PhenoDb website. **Results:** A rare missense variant was found in exon 4 of *HDAC8* (c.C356T; p.T119M) with a SIFT score of 0 and a GERP score of 4.89. **Discussion:** This new approach permits the recognition of common clinical features that were initially too subtle or too variable (when seen in patients of different age, sex, and ethnicity) to enable a new syndrome to be identified solely on clinical grounds. This approach may be particularly valuable for the investigation of disorders with high locus heterogeneity, like CDLS.

2571F

A case report of Bardet-Biedl Syndrome. *I.M. Salazar-Dávalos[1], M.A. Aceves-Aceves[1], S.A. Alonso-Barragán[1,2,3], A. Valdez-Haro[2,3], C. Enriquez-Barajas[3], M.F. Romero-Moran[1], D. García-Cruz[1,2], N.O. Dávalos[1,2], I.P. Dávalos[1,2,3]. 1) CUCS, Instituto de Genética, Universidad de Guadalajara, Guadalajara, Jalisco, México; 2) Doctorado en Genética Humana, CUCS, Universidad de Guadalajara, México; 3) CIBO, HE, IMSS, México.*

INTRODUCTION Bardet-Biedl Syndrome (BBS) MIM #209900, is an autosomal recessive and genetically heterogeneous ciliophaty. BBS clinically characterized by retinitis pigmentosa, polydactily, central obesity, behavioral dysfunction, mental retardation, hypogonadism and kidney dysfunction. *(Beales et al., 1999).* Eight proteins implicated in the disorder assemble to form BBSome. OBJECTIVE Present a male patient with clinical diagnosis of BBS. CASE REPORT A male aged 24 years old, presented congenital postaxial polydactily on hands and feet and bilateral cryptorchidism. Bilateral orchidopexy was performed at 8 years old. At 10 years, he presented decreased visual acuity. Later, he presented behavioral dysfunction and hypogonadism. At 16 years old, high blood pressure was diagnosed. At present he studies at a special school. Physical examination: height 1.67 m, weight 123kg, BMI 44.1 kg/m2, central obesity, postaxial polydactyly on hands and feet and hypogonadism. Ophthalmological evaluation revealed compatible data with retinitis pigmentosa. Abdominal ultrasound reported hepatic steatosis and multilobulated kidneys. CONCLUSIONS The diagnosis of Bardet-Biedl syndrome is established with the presence of four major clinical criteria or three major criteria and two minor. *(Beales et al 1999).* The major clinical criteria in the patient: retinitis pigmentosa, obesity, polydactyly, learning difficulty, hypogonadism and kidney abnormalities, led us to consider the clinical diagnosis of BBS. An early diagnosis of BBS allows an interdisciplinary approach and a suitable treatment of complications.

2572W

Surgical procedures and anesthetic complications in 27 Brazilian patients with Mucopolysaccharidosis (MPS) types I, II and VI. *C.A. Kim, D.C. Soares, L.M. Albano, R.S. Honjo, D.R. Bertola, J.F. Franco.* Medical Genetics Unit, Hospital das Clínicas da Faculdade de Medicina da USP, Sao Paulo, Brazil.

Background: Mucopolysaccharidosis (MPS) are multisystemic disorders caused by lysosomal enzyme deficiencies. MPS patients are generally considered high risk for anesthesia care due to a difficult airway, cervical spine disease and an increased prevalence of cardiovascular manifestations. **Objective:** To assess the incidence of anesthetic complications in patients with MPS I, II, and VI. **Methods**: We have studied 27 MPS patients (13 MPS I; 8 MPS II; 6 MPS VI) diagnosed by enzymatic and urinary GAGs analysis. **Results**: First symptoms appeared at about 6mo to 8y (MPS IH – mean 7mo; MPS IHS – mean 2y; MPS IS – mean 6y10mo; MPS II – mean 3y6mo; MPS VI – mean 1y). The mean ages at diagnosis were: MPS IH –1y6mo; MPS IHS – 4y8mo; MPS IS – 13y7mo; MPS II and VI – 5y. There were five familial cases. The age of onset of ERT ranged from 1y2mo to 31y9mo. The duration of ERT ranged from 40wk-556wk (mean 259wk). Before ERT, the main clinical complications were high blood pressure (25%), hypoacusis (37%), and hydrocephalus (15%). After ERT these same findings worsened: 37%, 59%, and 22%, respectively. Among 27 patients, 22 (81%) were submitted to surgical procedures (mean of 2.9 surgeries/patient). The most common procedures were: herniorrhaphy (16/27), adenotonsillectomy (13/27) and median nerve decompression (3/27). In contrast, other non-routine procedures, such as cardiac valvuloplasty (1/27), spinal decompression (1/27), ventriculoperitoneal shunt (5/27) and orthopedic surgery for scoliosis correction (1/27) were needed. Five patients presented anesthetic complications (23%) and two of them deceased during the procedures due to orotracheal intubation. **Conclusions**: Because of the high anaesthetic risk, the benefits of a procedure in patients with MPS should always be balanced against the associated risks. Therefore, careful evaluation of anaesthetic risk factors should be made before the procedure, involving evaluation of airways and cardiorespiratory and cervical spine problems. In addition, information on the specific type of MPS, prior history of anaesthesia, presence of cervical instability and range of motion of the temporomandibular joint are important and may be pivotal to prevent complications during anaesthesia.

Somatic mosaicism for a lethal *TRPV4* mutation results in non-lethal metatropic dysplasia. *M.M. Weinstein[1], T. Kang[2], R.S. Lachman[3], M. Bamshad[4,5,6,7], D.A. Nickerson[4,5], D. Krakow[3,8,9,10], D.H. Cohn[1,3,9,10], University of Washington Center for Mendelian Genomics.* 1) Molecular, Cell, and Developmental Biology, University of California Los Angeles, Los Angeles, California; 2) Microbiology, Immunology, and Molecular Genetics, University of California Los Angeles, Los Angeles, California; 3) International Skeletal Dysplasia Registry, University of California Los Angeles, Los Angeles, California 90095, USA; 4) Department of Genome Sciences, University of Washington, Seattle, WA 98195, USA; 5) University of Washington Center for Mendelian Genomics, University of Washington, Seattle, Washington, USA, 98195; 6) Department of Pediatrics, University of Washington, Seattle, WA 98195; 7) Division of Genetic Medicine, Seattle Children's Hospital, Seattle, WA 98105, USA; 8) Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA 90095; 9) Orthopaedic Surgery, David Geffen School of Medicine at UCLA, Los Angeles, CA 90095; 10) Orthopaedic Hospital Research Center, David Geffen School of Medicine at UCLA, Los Angeles, CA 90095.

Somatic mosaicism for dominant mutations has previously been observed causing milder, and sometimes clinically undetectable, disease in patients. Dominant mutations in *TRPV4*, which encodes the Transient Receptor Potential Cation Channel Subfamily V Member 4 calcium channel, result in a series of musculoskeletal disorders that include a set of peripheral neuropathies and a broad phenotypic spectrum of skeletal dysplasias. The skeletal phenotypes range from brachyolmia, in which there is scoliosis with mild short stature, through perinatal lethal metatropic dysplasia. We describe a case with phenotypic findings consistent with metatropic dysplasia, but in whom no *TRPV4* mutation was detected by Sanger sequence analysis. Exome sequence analysis identified a known lethal metatropic dysplasia mutation, *TRPV4[L618P]*, which was observed in about 23% of reads covering the locus, a significantly lower frequency than would be expected for a heterozygous change. The affected individual was shown to be a somatic mosaic for the mutation, providing an explanation for the difficulty of observing the change by Sanger sequence analysis and for the milder than expected phenotype observed. The data identify a new genetic mechanism for metatropic dysplasia and illustrate the power of high-throughput sequencing to detect variants present in the mosaic state.

2574F

A double mutation including a novel mutation of *SLC9A9* **gene and mosaic mutation of** *PORCN* **gene in a male patient with multiple congenital anomalies, intellectual disability, and autism spectrum disorder.** *M. Minatogawa[1], C. Abe[1], T. Yokoi , Y. Enomoto , K. Ida , Y. Tsurusaki , N. Harada , T. Naruto[2], K. Kurosawa .* 1) Medical genetics, Kanagawa children medical center, Yokohama, Japan; 2) Biomedical sciences, Tokushima university graduate school, Tokushima, Japan.

   Background: There are some congenital anomalies and/or intellectual disabilities that are not enough to be explained by a single gene mutation. As a result of advances in clinical exome and genome sequencing technology, double or multiple causative genes mutation have recently been reported. We report on a male patient presented with congenital anomalies, intellectual disability, and autism spectrum disorder, who carries a novel mutation of *SLC9A9* responsible gene of the autism spectrum disorder and mosaic mutation of *PORCN* responsible gene of Goltz syndrome. Case report: We describe a 4-year-old boy with clinical features with multiple congenital anomalies including scalp aplasia, dermatrophia, hypoplastic nails, left central polydactyly, glaucoma, left blepharoptosis, and right cryptorchism, dyssomnia, failure to thrive, moderate intellectual disability, and autism spectrum disorder. Clinical whole exome sequencing for the diagnosis of mendelian disorders was performed. The case was found to be a de novo mosaic heterozygous nucleotide substitution for the nonsense mutation in exon 12: c.1077delC (p.Y359X) in *PORCN* gene, and a parental origin heterozygous nucleotide substitution for the nonsense mutation in exon 12: c.1462C>T (p.Q488X) in *SLC9A9* gene. Putting these mutations together, it permitted explanation for all of his clinical features. Conclusion: We often encounter patients with congenital anomalies and/or intellectual disabilities which do not enable us to explain by a single gene mutation. It is important to keep in mind that some of the patients carry multiple causative genes mutation when analyses are done. *COI:;None.*

2575W

PIK3C3 **as responsible gene for new neurocutaneous syndrome with learning disorder, epidermal nevus and cataract.** *A. Matsumoto[1], Y. Inaguma[2], M. Noda[2], D. Usui[4], M. Goto[1], E. F. Jimbo[1], H. Tanabe[2], A. Maeda[4], K. Kikkawa[3], M. Y. Momoi[1], H. Osaka[1], K. Nagata[2], T. Yamagata[1].* 1) Pediatrics, Jichi Medical University, Shimotsuke, Japan; 2) Department of Molecular Neurobiology, Institute for Developmental Research, Aichi Human Service Center, Kasugai, Japan; 3) Department of Pediatrics, Kochi Health Sciences Center, Kochi, Japan; 4) Department of Pediatrics, Hata Kenmin Hospital, Kochi, Japan.

   PIK3C3 encodes Class III phosphoinositide 3-kinase which regulates vesicular trafficking, autophagy and nutrient sensing. Classes of PI3Ks phosphorylate the different ring of phosphatidylinositol and have different functions. We detected the deletion of *PIK3C3* on the aCGH in the siblings with epidermal nevus, cataract and borderline intelligent quotient (IQ). (Patients and methods) ; The patient was a girl of 6 years of age. At six years and 2 months of age, the girl's full IQ, working memory index, verbal comprehension index, perceptual reasoning index, and processing speed index were 80, 69, 99, 87, 76, respectively, according to the Wechsler Intelligence Scale for Children-Fourth Edition (WISC-IV). WISC-IV's profile is borderline IQ and diagnosed as specific learning disorder. She showed hypotonia, cataract and retinitis pigmentosa. Many epidermal nevus was detected in her body. Her 8-month-old-brother showed the epidermal nevi since seven months of age. His development was not delayed, so far and his ophthalmological evaluation was normal. Their gDNA was extracted from lymphocytes after obtaining informed consent from their parents. Array CGH analysis was performed using Agilent Human genome CGH 180K. The expression level of PIK3C3 among family members was analyzed by western blot. *In utero* electroporation, PIK3C3 was suppressed using RNAi that was induced to the fetal brain on embryonic day 14.5 and the brain was analyzed after birth. (Results) A heterogenous 107Kb deletion at 18q12.3 (nt. 39554147-39661206) was detected in the patient, her brother and mother by array aCGH. Exon5 to 23 of PIK3C3 located in this deleted region. Mutation on PIK3C3 was not detected by direct sequence. In the western blot analysis, PIK3C3 expression levels were 0.61-fold in patient, 0.91-fold in father, 0.38-fold in mother, and 0.41-fold in brother, compared to the control samples. Suppression of PIK3C3 in the embryonal brain resulted the delayed migration of cortical neurons and axon extension to the contralateral hemisphere was delayed. (Conclusion) *PIK3CA*, the class I of PIKs, has been shown to be a causative gene for epidermal nevi. The de novo *PIK3C3* deletion was reported in the patient with ID and agenesis left cerebellum. PIK3C3 knockdown mice have been reported to develop congenital cataract and microphthalmia. Taken together, deletion of *PIK3C3* appears account for epidermal nevi, cataract and also the ID in the patients.

2576T

Phenotypic spectrum in females carrying mutations in *ZC4H2*. *K.J. Buckingham[1], J.X. Chong[1], C.T. Marvin[1], A.G. Shankar[1], A.E. Tattersall[1], R. Cornejo Jr.[1], K.M. Shively[1], J.M. Graham Jr.[2], D.L. Earl[1,3], I.A. Glass[1], D.A. Nickerson[4], M.J. Bamshad[1,3,4], University of Washington Center for Mendelian Genomics.* 1) Department of Pediatrics, University of Washington, Seattle, WA; 2) Department of Pediatrics, Cedars-Sinai Medical Center, Los Angeles, CA; 3) Division of Genetic Medicine, Seattle Children's Hospital, Seattle, WA; 4) Department of Genome Sciences, University of Washington, Seattle, WA.

Arthrogryposis is a heterogeneous group of disorders characterized by non-progressive congenital joint contractures of two or more different body areas and is often associated with reduced fetal movements. Arthrogryposis is a clinical feature of more than 500 rare conditions and can be caused by abnormalities of the central or peripheral nervous system, neuromuscular junction, or muscle. The distal arthrogryposes (DA) are a phenotypically and genetically heterogeneous subset of arthrogryposis conditions. Persons with DA typically have a normal neurological exam and no cognitive delay, however these characteristics can be difficult to discern early in life. Analysis of exome sequence data from a large cohort of families putatively diagnosed with DA identified mutations in *ZC4H2* in seven kindreds. Six out of the seven kindreds were simplex female cases, each with a different mutation – four of which were confirmed to be *de novo*. Clinical characteristics of these cases include camptodactyly, contractures of the ankles, hip dysplasia, scoliosis, cleft lip/palate, seizures, and intellectual disability. The seventh case was an affected male. Five (four nonsense, one frameshift) of the six mutations identified in the simplex female cases are predicted to result in loss of function (LOF), while the sixth female case and the only male case both had missense mutations, p.(Gln194Arg) and p.(Cys206Tyr), affecting residues in the highly conserved zinc-finger domain of ZC4H2. None of these mutations have been previously reported. Hemizygous mutations in *ZC4H2* cause Wieacker-Wolff syndrome (WWS), a severe X-linked recessive condition characterized by arthrogryposis, hypotonia, motor and developmental delay, and sometimes early death. Some carrier females are unaffected, while others are reportedly "mildly affected" with features including intellectual disability, camptodactyly, and ankle contractures. The females in our cohort with predicted LOF mutations appear to be comparatively more severely affected than previously described females in WWS families and simplex female cases. Most previously reported WWS families have missense variants suggesting that LOF variants may cause a more severe phenotype in WWS females. However, two females with heterozygous deletions spanning *ZC4H2* and "mild" phenotypes have been described, raising the possibility that nonsense/frameshifts mutations cause WWS via a different mechanism (e.g., dominant negative) than that of full gene deletions.

2577F

Expanding the phenotypic spectrum of a single mutation: The same nonsense mutation in *HOXD13* can alternately cause brachydactyly type E or synpolydactyly in different families. *C.T. Marvin[1], J.X. Chong[1], K.J. Buckingham[1], K.M. Shively[1], T.M. Harrell[1], A.G. Shankar[1], R. Cornejo Jr.[1], A.E. Tattersall[1], D.A. Nickerson[2], M.J. Bamshad[1,2,3], University of Washington Center for Mendelian Genomics.* 1) Dept. of Pediatrics, University of Washington, Seattle, WA, USA; 2) Dept. of Genome Sciences, University of Washington, Seattle, WA, USA; 3) Seattle Children's Hospital, Seattle, WA, USA.

Homeobox (HOX) genes are highly conserved and encode transcription factors that regulate the development of multiple organs and body areas. *HOXD13* regulates the skeletal development of the wrist, fingers, ankle, and toes, and mutations in *HOXD13* cause multiple distinct skeletal abnormalities of the digits. Putative loss of function mutations and expansions of the N-terminal polyalanine repeat cause synpolydactyly, while missense variants can cause synpolydactyly 1 as well as brachydactyly types D and E, syndactyly type V, and brachydactyly-oligodactyly. We studied a single affected male who presented with bilateral complex syndactyly of the third web space with an extra digit on each hand and no mobility of the proximal or distal interphalangeal joints on the left. Review of the family history found a pattern of finger and toe malformations including syndactyly and apparently isolated camptodactyly in the extended paternal family. Exome sequencing of the proband with subsequent Sanger validation and segregation studies revealed a paternally inherited heterozygous nonsense mutation in the homeodomain of *HOXD13* (c.820C>T, p.[R274*]). This variant is predicted to be damaging (CADD 28.8), highly conserved (GERP 4.05), and very rare (not present in ExAC, EVS, or 1000 Genomes). This same nucleotide change has been reported in a family which had isolated brachydactyly type E. Our finding of c.820C>T, p.[R274*] in a family with synpolydactyly suggests that this nonsense mutation has more variable effects on phenotype than previously suspected and that the phenotypic outcome of synpolydactyly versus brachydactyly, or a combination thereof, may be the product of modifier variants in *HOXD13* or other genes, epigenetic factors, or other environmental factors present during development.

2578W

Novel *RPL11* splicing variant associated with an atypical familial presentation of Diamond-Blackfan anemia-7. *C.M. Carlston[1], J.C. Palumbos[2], H. Bagley[3], C. Barbagelata[2], W.L. Wooderchak-Donahue[1], R. Mao[1], J.C. Carey[2].* 1) Pathology Dept, University of Utah/ ARUP, Salt Lake City, UT; 2) Pediatrics Dept, Division of Medical Genetics, University of Utah School of Medicine, Salt Lake City, UT; 3) Intermountain Healthcare, Salt Lake City, UT.

Diamond-Blackfan anemia (DBA) is a collection of clinically and genetically heterogeneous inherited red blood cell aplasia disorders with or without congenital anomalies. Mutations in genes encoding 16 ribosomal proteins, a ribosomal RNA, and the GATA1 transcription factor have all been associated with various forms of DBA. Diamond-Blackfan anemia-7 (DBA7) (OMIM #612562), caused by heterozygous mutations in the *ribosomal protein L11* (*RPL11*) gene, accounts for approximately 5% of DBA. DBA7 is usually characterized by severe anemia, often accompanied by malformations including thumb anomalies, short stature, heart defects, craniofacial anomalies, and urogenital defects. Variable expressivity and incomplete penetrance have been observed within families. A two-year-old boy presented with chronic mild anemia (requiring no treatment), proportionate short stature, bilateral underdevelopment of the thumbs (preaxial hypoplasia, altered thenar eminence, and one apparent triphalangeal thumb), fenestrated atrial septal defect at birth, and hypospadias. Hematological testing in the proband showed slightly decreased hematocrit and hemoglobin, normal fetal hemoglobin, and elevated adenosine deaminase activity. Family history included maternal relatives with thumb defects, but the mother's thumbs were normal. Whole exome sequencing analysis detected a maternally-inherited variant, c.396+3A>G, in the *RPL11* gene that is predicted to affect splicing. A family correlation study of the identified *RPL11* variant found that it segregated with thumb anomalies. RNA studies in this family suggest that the identified variant produces an alternative transcript that may be susceptible to nonsense-mediated decay. This report describes a non-classical familial presentation of DBA7 more associated with thumb anomalies than with severe anemia.

2579T

Functional characterization of a novel mutation in *EPHB4* that underlies familial lymphangiomatosis. *M.E. March, D. Li, R. Pellegrino, L. Tian, F. Mafra, J. Snyder, F. Wang, J. Garifallou, H. Hakonarson.* Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA.

Lymphangiomatosis is a rare condition characterized by proliferation of lymphatic vessels. The specific presentation of the condition, and its severity, are determined by the location of the hyperproliferating lymphatic tissue. With the exception of the central nervous system, which lacks lymphatic vessels, any part of the body can be affected. The molecular basis of lymphangiomatosis is largely not understood. Whole exome sequencing of a family of subjects with dominantly inherited lymphangiomatosis led to the identification of variant in *EPHB4* that is predicted to affect mRNA splicing. RT-PCR performed with RNA from EBV-transformed lymphoblastoid cell lines from family members confirmed the presence of an aberrantly spliced, yet in-frame, variant in an affected subject. The variant contains a small insertion of 12 base pairs, corresponding to an in-frame insertion of 4 amino acids in the protein sequence. In order to examine the functional consequences of this alteration of the EPHB4 protein, we have generated expression constructs representing the wild type and abnormally spliced variants of *EPHB4*, and expressed them exogenously in cell lines. Wild type and mutant proteins are expressed to similar levels following transfection, and stimulation of cells with pervanadate followed by Western blotting shows that both proteins can be phosphorylated on tyrosine residues. However, under normal culture conditions, despite similar expression levels, the wild type protein is much more heavily tyrosine phosphorylated than the mutant. This indicates that the small insertion in the protein sequence caused by altered mRNA splicing has significant impact on protein functionality. Experiments are currently underway to examine the impact of these biochemical changes on the behavior of cells expressing EPHB4 in adhesion and migration assays. Additionally, we continue to investigate the mechanism through which this mutation acts in a dominant manner.

  Microcephaly-capillary malformation syndrome (MICCAP [MIM 614261]) is characterized by severe progressive microcephaly, intractable epilepsy, profound developmental delay and multiple small capillary malformations on the skin. MICCAP is caused by biallelic mutations in the STAM-binding protein gene (*STAMBP* [MIM 606247]) in chromosome 2p13, which has a key role in cell surface receptor-mediated endocytosis and sorting. McDonell et al reported that patient cell lines showed reduced STAMBP expression, elevated apoptosis and insensitive activation of the RAS-MAPK and PI3K-AKT-mTOR pathways. Here we report the first mutation located in the SH3 binding motif of the *STAMBP* gene. The patient is a 2-year-old Japanese boy with no family history of nonconsanguineous parents. The boy was born by vaginal delivery in 37th gestational weeks without any perinatal abnormalities. At birth he had a weight of 2680 g (-0.8SD) and OFC 33.0 cm (0SD). He showed progressive microcephaly, hypertelorism, ptosis, downturned mouth, and multiple capillary malformations involving the trunk and extremities. At 2 years he was not able to hold up his head yet. When he had infections, his feeding became poor necessitating tube feeding. He developed seizures at 7 months. Seizures were refractory to multiple anti-epileptic medications. Head MRI showed symmetric atrophy of the cerebral cortex. Karyotype and genomic microarray were normal. We performed whole exome sequencing on the proband and his parents, and identified a homozygous mutation (c.707C>T; p.S236F) in the *STAMBP* gene. His parents had the mutation in a heterozygous fashion. To interrogate RAS-MAPK pathway function, we performed western blot analysis of patient derived lymphoblastoid cell lines (LCLs) using antibodies against phosphorylated S6 ribosomal protein (pS6) in starvation condition. Serum starvation of LCLs significantly reduced the expression of the pS6 protein not only in WT LCLs but also in patient derived LCLs, indicating that insensitive activation of PI3K-AKT-mTOR pathway was not observed in patient derived LCLs. STAMBP interacts with the SH3 domain of STAM to transduce downstream signals from the Jaks-STAM complex. Because the substitution of S236F found in our patient is located in the SH3 binding motif, the mutation is likely to be pathogenic. Our western blot result is inconsistent with that in the previous report, suggesting that other mechanisms may underlie the MICCAP phenotype.

Contractures, rhabdomyolysis, metabolic crisis and encephalopathy caused by bi-allelic mutations in *TANGO2.* *L. Fernandez[1], P. Zornio[1], A. Dries[1], D. Zastrow[1], J. Kohler[1], S. Schelley[2], G. Enns[2], K. Van Haren[3], A. Myers[2], C. Eng[4], M. Walkiewicz[4], Members of the UDN[5], E. Ashley[1,6], P. Fisher[1,3], J. Bernstein[1,2], M. Wheeler[1,6].* 1) Undiagnosed Diseases Network, Stanford School of Medicine, Palo Alto, CA, USA; 2) Division of Medical Genetics, Stanford School of Medicine, Palo Alto, CA, USA; 3) Division of Neurology, Stanford School of Medicine, Palo Alto, CA, USA; 4) Baylor Miraca Genetics Laboratories, Houston, TX, USA; 5) Undiagnosed Diseases Network, National Institutes of Health, Bethesda, MD, USA; 6) Division of Cardiovascular Medicine, Stanford School of Medicine, Palo Alto, CA, USA.

  Transport and Golgi organization (TANGO) proteins play an important role in cargo loading of newly synthesized secretory proteins in the endoplasmic reticulum (ER). TANGO2 is localized to the Golgi and cytoplasm. Bi-allelic mutations in *TANGO2* have been recently reported in individuals with rhabdomyolysis, metabolic crisis, encephalopathy, and cardiac arrhythmia. We report on a 4 year-old, Hispanic male with global developmental delay, contractures preventing ambulation, and an episode of acute decompensation with encephalopathy, hypoglycemia, lactic acidosis, and rhabdomyolysis. Comprehensive metabolic workup including fatty acid oxidation probe on fibroblasts, mitochondrial genome, and intracellular acylcarnitine profile did not reveal a diagnosis. Trio whole exome sequencing performed through the Undiagnosed Diseases Network identified pathogenic variants in the *TANGO2* gene: a heterozygous point mutation c.460G>A (p.G154R) and heterozygous exon 3-9 deletion. Parental sequencing confirmed compound heterozygosity. Compared to the clinical features of other subjects reported with bi-allelic *TANGO2* mutations, this individual does not present with seizures, cardiac arrhythmias, hypothyroidism, optic atrophy, microcephaly or macrocephaly, or hearing loss. Interestingly, our patient has macrocytic anemia and contractures in all limbs, findings not reported in previous cases and not explained by exome sequence reanalysis. Functional studies performed on fibroblasts and lymphoblastoid cell lines of individuals with biallelic *TANGO2* mutations have shown evidence of involvement of perturbed vesicular Golgi/ER transport and increased ER stress; other studies favor a functional defect in mitochondrial beta-oxidation of fatty acids as contributing to disease. Ongoing work to characterize iPS-cell derived lineages from our patient may elucidate the mechanisms by which *TANGO2* mutations impact cellular function in multiple tissues.

2582T

Balanced X-autosome translocation suggests association between AMMECR1 and growth, bone and heart alterations. *M. Moyses-Oliveira[1,2], R. Fish[3], F. Petit[4], G. Giannuzzi[2], V. Meloni[1], M. Soares[5], L. Kulikowski[6], A. Di Battista[1], T. Liehr[7], N. Kozyakova[7], G. Carvalheira[1], J. Andrieux[8], M. Neerman-Arbez[3], M. Melaragno[1], A. Reymond[2].* 1) Department of Morphology and Genetics, Universidade Federal de Sao Paulo, Sao Paulo, Sao Paulo, Brazil; 2) Center for Integrative Genomics, University of Lausanne, 1015 Lausanne, Switzerland; 3) Department of Genetic Medicine and Development, 1211 University of Geneva Medical School, Geneva, Switzerland; 4) Clinique de Génétique, CHU Lille - Hôpital Jeanne de Flandre, 59037 Lille, France; 5) Psychobiology Department, Universidade Federal de São Paulo, 04023-062 São Paulo, Brazil; 6) Department of Pathology, Laboratório de Citogenômica, LIM 03, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, 05403-000 São Paulo, SP, Brazil; 7) Institute of Human Genetics, Jena University Hospital, Friedrich Schiller University, D-07743 Jena, Germany; 8) Institut de Génétique Médicale, CHU Lille - Hôpital Jeanne de Flandre, 59037 Lille, France.

Female balanced X-autosome translocations are usually associated with absence of functional copies of the gene mapping at the breakpoint through disruption of the derivative-chromosome copy and inactivation of the normal X-chromosome. We report on a nine year-old girl with karyotype 46,X,t(X;9)(q23;q12)dn, disproportionate short stature (<1st centile), septal atrial defect, scoliosis, bone dysplasia, and normal cognition. Array-CGH and breakpoint sequencing confirmed the full complement of genetic material, whereas EdU incorporation method and HUMARA assay showed preferential inactivation of the normal X-chromosome. The autosomal breakpoint affects a heterochromatic region, while the X-chromosomal breakpoint was mapped between the *AMMECR1* and *RGAG1* genes. Whereas expression of the latter was unmodified, RT-qPCR showed absence of *AMMECR1* expression in blood and lymphoblastoid cells of the proband. The encoded protein contains evolutionary conserved nucleic acid-binding RAGNYA domains and localizes to the nucleus. *AMMECR1* is co-expressed with genes implicated in cell cycle and translation regulation, five of which were previously associated with growth and bone alteration syndromes. Concordantly, we also identified an individual with bone dysplasia and ventricular septal defect and duplication of the *AMMECR1*. Our knockdown of the zebrafish orthologous gene resulted in animals with phenotypes such as shorter tails, thinner bodies, kinked tail-ends, poorly defined somites, pericardial edema, tachycardia and hydrocephaly, features reminiscent of the proband's phenotype. Additionally, a phenotype similar to the *ammecr1* knockdown zebrafish was previously observed in zebrafish ribosomal protein knockdown and *top2a* mutant. The knockdown phenotype was partially rescued by co-injection of mRNA from the human ortholog. Our results suggest that *AMMECR1* is potentially involved in cell cycle control and linked to a new syndrome(s) with growth, bone and heart alterations.

2583F

Recurrent *ZIC1* frameshift mutation in siblings causes syndromic cerebral and cerebellar dysgenesis, tethered chord and scoliosis, without craniosynostosis. *G.M. Mancini[1], R. Schot[1], M. Wilke[1], C. Lincke[2], J. Hoogeboom[1], R. de Coo[3], F.W. Verheijen[1], M. van Slegtenhorst[1].* 1) Clinical Gen, Erasmus Med Ctr, Rotterdam, ZH, Netherlands; 2) Pediatrics, Erasmus Med Ctr, Rotterdam, ZH. Netherlands; 3) Child Neurology, Erasmus Med Ctr, Rotterdam, ZH, Netherlands.

The ZIC family of zinc finger proteins are transcriptional regulators , which govern essential steps of brain development. Deletion of contiguous genes *ZIC1* and *ZIC4* on chromosome 3q24 has been associated with Dandy-Walker malformation (DWM) and cerebellar vermis dysplasia with reduced penetrance in patients and double K.O. mice (Grinberg et al, Nat Genet 2004, 36(10):1053). Isolated *ZIC4* mutations have not been reported, but inherited missense and de novo truncating gain of function *ZIC1* mutations have been associated with coronal craniosynostosis and intellectual disability (Twigg et al, AJHG 2015, 97:378) in 5 families. During screening of patients with neurodevelopmental disorders and brain malformations , we found by exome sequencing a *de novo* heterozygous frameshift mutation in *ZIC1* (c.1214_1215ins10, p.Pro406fs) in two siblings, a boy and a girl of Caucasian ancestry, suggesting germ line mosaicism They share an identical phenotype of severe developmental delay, no speech and no independent deambulation, congenital microcephaly (- 3.5 SD) and strabismus. Similar features were noted consisting of deep set eyes and prominent lips, sharp brachycephalic skull without evidence of premature suture closure at X-rays and scoliosis. MRI of brain and spinal cord showed in both children sacral lipoma, spina bifida occulta, agenesis of the corpus callosum, hypoplastic pons and brain stem, wide IVth ventricle communicating with the cisterna magna, hypoplastic vermis and cerebellar hemispheres, without upward rotation of the vermis, and patchy white matter lesions diffusely present in the white matter. In the boy the vermis hypoplasia is associated with incomplete separation of cerebellar hemispheres, compatible with a partial rhombencephalosynapsis. Retrospective comparative review of the MRI from the patient with the p.Gln389* mutation of Twigg et al (AJHG 2015), confirmed major differences with the present patients. Testing of *ZIC1* transcripts in skin fibroblasts from our patients is ongoing. It has been suggested that modifying factors contribute to the phenotypic expression of the *ZIC1* mutations. We conclude that, besides the contiguous *ZIC1* and *ZIC4* deletion associated with DWM, the phenotypic spectrum of *ZIC1* mutations, be it loss- or gain-of-function, is much wider than appreciated until now and that it includes both DWM, distinctive CNS dysgenesis patterns and syndromic craniosynostosis.

2584W

The pathogenic germline variant p.Arg882His in the DNA methyltrans-ferase 3A (*DNMT3A*) gene is associated with Tatton-Brown-Rahman syndrome. *J. Heeley[1], N. Shur[2], K. Miller[2], L. Manwaring[4], K. Levine[3], G. Douglas[3], M. Shinawi[4].* 1) Mercy Kids Genetics, Mercy Hospital St. Louis, St Louis, MO; 2) Department of Pediatrics, Section of Genetics & Metabolism, Albany Medical Center, Albany, NY; 3) GeneDx, Gaithersburg, MD; 4) Department of Pediatrics, Division of Genetics and Genomic Medicine, Washington University School of Medicine, St. Louis, MO.

   Background: Somatic pathogenic variants in *DNMT3A* are found in 30% of acute myeloid leukemia cases and are typically present in the founding clones. Most pathogenic variants that cause AML do so via haploinsufficiency, but more than half of AML cases with *DNMT3A* variants are due to substitutions at amino acid R882. Variants at R882 have been shown to alter the catalytic domain resulting in a dominant negative effect. Recently, constitutional pathogenic variants in *DNMT3A* have been determined to cause an overgrowth syndrome with intellectual disability (Tatton-Brown-Rahman syndrome; TBRS). In this report we describe two patients with TBRS associated with novel *DNMT3A* germline variants. One of the patients has the R882H variant which is recurrently observed as a somatic variant in AML. **Methods:** Whole exome sequencing (WES) was performed at a diagnostic laboratory and revealed novel pathogenic variants in the *DNMT3A* gene in two patients. Their clinical findings were compared with previously reported cases. **Results:** Patient 1 is a 9-year-old male who presented with severe hypotonia, macrosomia, macrocephaly, dysmorphic features, and global developmental delay (formal IQ testing was ~50). WES revealed heterozygosity for a constitutional p.Arg882His pathogenic variant (c.2645G>A) from peripheral blood. Similar results were obtained from buccal swabs. Patient 2 is a 6-year-old female who presented with hypotonia, complex partial seizures, dysmorphic features, macrosomia and macrocephaly. Starting at age 2, patient exhibited regression with loss of motor and language milestones and was diagnosed with autism. Using WES, a heterozygous nonsense variant, W306X (c.918G>A), was identified. **Conclusion:** Both patients with pathogenic germline variants in *DNMT3A* had similar phenotypic features, which were consistent with previous reports of TBRS due to other *DNMT3A* variants. Although it was initially hypothesized that the p.Arg882His variant is limited to somatic tissues and cancer development, our data indicate that this variant can also cause TBRS. To our knowledge, this is the first reported patient with a constitutional variant at R882. Our patients have not shown evidence of leukemia or other malignancy to date. However, as there is a presumed risk for developing malignancies in patients with constitutional *DNMT3A* variants, optimal screening and surveillance protocols should be developed to monitor those patients.

2585T

Bi-allelic mutations in *PKD1L1* are associated with laterality defects in humans. *F. Vetrini[1,2], L.C.A. D'Alessandro[3,5], Z.C. Akdemir[1], A. Braxton[2], M. Azamian[1], M.K. Eldomery[1], K. Miller[5], C. Kois[6], V. Sack[6], N. Shur[6], A. Rijhsinghani[6], J. Chandarana[2], Y. Ding[4], S. Jhangiani[4], C.M. Eng[1,2], T. Harel[1], J.A. Rosenfeld[1], N. Hanchard[1,5], J.W. Belmont[1], J.R.L. Lupski[1,4,5], Y. Yang[1,2].* 1) Department of Molecular and Human Genetics, Houston, TX, USA; 2) Baylor Miraca Genetics Laboratories, Houston, TX, USA; 3) Division of Cardiology, Texas Children's Hospital, Houston, TX, USA; 4) Human Genome Center, Baylor College of Medicine, Houston, TX, USA; 5) Department of Pediatrics, Baylor College of Medicine, Houston, TX, USA; 6) Albany Medical Center, Albany, NY, USA.

   Disruption of the establishment of left-right (L-R) asymmetry leads to *situs* anomalies ranging from *situs inversus totalis* (SIT) to *situs ambiguus* (heterotaxy). The genetic causes of laterality defects in humans are highly heterogeneous. Using whole-exome sequencing (WES), we identified homozygous mutations in *PKD1L1* from three affected individuals in two unrelated families. *PKD1L1* encodes a polycystin-1-like protein and its loss of function is known to cause laterality defects in mouse and medaka fish models. Family 1 had one fetus and one deceased child with heterotaxy and complex congenital heart malformations. WES identified a homozygous splicing mutation c.6473+2_6473+3delTG, which disrupts the invariant splice donor site in intron 42, in both affected individuals. In the second family, a homozygous c.5072G>C (p.Cys1691Ser) missense mutation was detected in an individual with SIT and congenital heart disease. *In silico* analysis shows that the p.Cys1691Ser substitution affects a highly conserved cysteine residue and is predicted by molecular modeling to disrupt a disulfide bridge essential for the proper folding of the G protein–coupled receptor proteolytic site (GPS) motif. Damaging effects associated with the substitutions of this conserved cysteine residue in the GPS motif have also been reported in other genes, namely *GPR56, BAI3* and *PKD1* in human and *lat-1* in *C. elegans,* further supporting the likely pathogenicity of p.Cys1691Ser in *PKD1L1*. The identification of bi-allelic *PKD1L1* mutations recapitulates the previous findings regarding phenotypic consequences of the orthologous genes in mice and medaka fish and further expands our understanding of genetic contributions to laterality defects in humans   .

2586F

De novo missense variants in *PPP1CB* are associated with features overlapping with Noonan syndrome. *H.M. McLaughlin[1], L. Ma[2], Y. Bayram[3], M.T. Cho[1], A.M. Lewis[3], J.J. White[3], S.N. Jhangiani[3,4], J.R. Lupski[3,4,5,6], K. Mayberry[7], W. Mu[8], V. Weinstein[9], A. Krokosky[10], Y. Shao[3], R.E. Schnur[1], K. Retterer[1], S. Bale[1], I. Wentzensen[1], J. Bodurtha[8], C. Juusola[1]. 1) GeneDx, Gaithersburg, MD; 2) Department of Pediatrics, Columbia University Medical Center, New York, NY; 3) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 4) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 5) Texas Children's Hospital, Houston, TX; 6) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 7) Spectrum Health, Grand Rapids, MI; 8) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 9) Division of Genetics and Metabolism, Children's National Medical Center, Washington D.C; 10) Walter Reed National Military Medical Center, Bethesda, MD; 11) Department of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX; 12) Division of Genetics and Metabolism, Phoenix Children's Hospital, Phoenix, AZ; 13) Medical Genetics Section, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey.*

Protein phosphatase-1 (PP1) is a serine/threonine-specific protein phosphatase involved in the dephosphorylation of a variety of proteins. PP1 has been shown to interact with *SHOC2*, a gene that is mutated in a Noonan syndrome disorder. The PP1 catalytic subunit beta (*PPP1CB*) gene encodes a subunit of PP1 that is important for the regulation of many cellular processes including adipogenesis, cytoskeletal organization, regulation of synaptic plasticity pathways, and muscle contraction and its expression has been inversely correlated with arterial stiffness. A de novo frameshift mutation in *PPP1CB* was previously reported in a patient with severe intellectual disability, short stature, dysmorphic features, and lymphangioma. Using whole exome sequencing, we identified five *de novo PPP1CB* missense variants (p.Pro49Arg, p.Glu183Ala, p.Glu183Val, p.Asp252Tyr p.Glu274Lys) in seven unrelated individuals who share many clinical features with Noonan syndrome. Overlapping clinical features in these individuals include facial dysmorphism, macrocephaly, developmental delay, intellectual disabilities, congenital heart defects, skeletal and connective tissue abnormalities, and short stature. The dysmorphic features present in these individuals resemble those associated with Noonan syndrome and include prominent forehead, short, broad nose, hypertelorism with short palpebral fissures, and webbed neck. Congenital heart defects were present in the majority (5/7) of the individuals in our series and were comprised of aortic anomalies including dilatation and coarctation, hypoplastic arch, and peripheral pulmonic stenosis. Some individuals also exhibited connective tissue anomalies including joint hypermobility, doughy skin, bifid uvula, high arched palate, and pectus excavatum. All five affected amino acid residues are highly conserved among the PP1 subunit family, and all are predicted to disrupt PP1 subunit binding and impair dephosphorylation, likely leading to perturbation of downstream cellular processes. Our data suggest that *de novo* missense variants in *PPP1CB* are associated with a novel syndromic disorder which may be considered within the differential diagnosis for individuals with suspected Noonan syndrome and related disorders.

2587W

CHIME syndrome with *PIGL* mutation: Description of a Brazilian case with mild elevation of alkaline phosphatase. *R.S. Honjo[1], J.R.M. Ceroni[1], M.R. Passos-Bueno[2], G.L. Yamamoto[1,2], C.A. Kim[1], D.R. Bertola[1,2]. 1) Genetics Unit, Instituto da Criança, São Paulo, SP, Brazil; 2) Instituto de Biociências da Universidade de São Paulo, São Paulo, SP, Brazil.*

CHIME syndrome (MIM 280000) is an extremely rare autosomal recessive disorder characterized by **C**oloboma, congenital **H**eart defects, migratory **I**chthyosiform dermatosis, **M**ental retardation, and **E**ar anomalies/**E**pilepsy. It is a glycosylation disorder caused by mutations in *PIGL*, which encodes for an enzyme responsible for the de-N-acetylation of N-acetylglucosaminyl-phosphatidylinositol in the glycosylphosphatidylinositol (GPI) biosynthesis. We report on a 4-year-old male patient, the first and only child of non-consanguineous parents, with neonatal respiratory complications. He presented with neuromotor delay, including severe speech delay; seizures; macrosomia; dysmorphic facial features; bilateral retinal coloboma; dry/hyperpigmented cutaneous lesions in thorax and abdomen; large hands, with mild brachydactyly, finger pads and palmar hyperkeratosis. Complementary exams showed bilateral pyelectasis; ALP of 456U/L (normal: 150-380U/L). Lymphocyte and fibroblast G-banded karyotype, as well as SNP-array were normal. Whole-exome sequencing revealed the presence of compound heterozygous mutations in *PIGL*: a missense recurrent mutation and an intragenic deletion. The latter was confirmed by bridging PCR. The patient here presented showed typical clinical features of CHIME syndrome including mild elevation of ALP. In the six cases so far described, five of them presented a missense mutation in one allele, associated with a loss-of-function mutation in the other one, as our patient. In the few individuals in which ALP serum levels were measured, they showed mild elevation. Only one atypical case, with two frameshift different mutations, was reported recently showing high serum elevation of ALP. This finding suggests that higher compromise of the protein function may explain the difference in ALP serum levels. CHIME syndrome is one of the inherited disorders of the formation and function of GPI and part of the growing group of congenital disorders of glycosylation (CDG). Several other *PIG* genes are responsible for disorders that share in common intellectual disability, epilepsy, coarse facial features and multiple organ anomalies. This group of disorders is still poorly recognized, requiring description of further typical and atypical cases, in order to give better knowledge of the whole phenotypic spectrum of the *PIG* gene family disorders. (FAPESP/CNPQ).

2588T

Phenotypic variability in rare disease: Using *KAT6A* syndrome to explore rare disease variation in the context of genetic background. *V. Arboleda[1], S. Nelson[1,2].* 1) Department of Pathology and Laboratory Medicine, University of California, Los Angeles, Los Angeles, CA; 2) Department of Human Genetics, University of California, Los Angeles, Los Angeles, CA.

Understanding natural history of rare disorders can provide prognostic insight for families and provide a method by which researchers can identify patients who are eligible for clinical trials. There are few well-done natural history studies for rare disorders and with the advent of clinical Exome sequencing there has been a huge increase in the number of monogenic disorders with an identified gene, with few avenues for providing systematic descriptions of patient cohorts. We recently reported the first description of *de novo* nonsense mutations in *KAT6A* (a.k.a. MOZ, MYST3) that were identified by clinical exome sequencing in 4 independent families. *De novo* truncating mutations have now been identified in more than 40 additional patients around the world, 16 of which have been reported in the literature. Through the KAT6A Foundation, we have identified 2 of the oldest individuals in the KAT6A cohort, who are 31 and 28 years old. Using in-depth interviews with parents of individuals' diagnosed based on mutations in *KAT6A*, we are able to identify features of the syndrome that are often overlooked and present only in a subset of individuals. Our early assessments indicate that defects in neurodevelopmental pathways, gastrointestinal motility, and cardiac development, are the most commonly observed. However, rare patients also express severe manifestations of autoimmunity, and it is unclear whether the autoimmunity is related to *KAT6A* mutation directly or secondary other factors. Defining a syndrome based on the totality of phenotypes expressed by individuals with *KAT6A* mutations reveals the degree of phenotypic variance, even among individuals who have the exact same mutation. We hypothesize that each individual's genetic background modulates expression of KAT6A syndrome but can also independently increase susceptibility to other diseases that are unrelated to the KAT6A diagnosis. To address this, we have begun a systematic effort to collect functional genomic data from KAT6A families and tissue samples. This, coupled with the growing knowledge of the genetic heritability of common disease can be used to disentangle phenotypes caused primarily by the *KAT6A* mutation from those inherited in the patient's collective genetic background of the patient.

2589F

Recurrent *de novo* missense mtuations in *PPP1CB* cause a novel rasopathy closely resembling Noonan syndrome with loose anagen hair. *K.W. Gripp[1], K.A. Aldinger[2], J.T. Bennett[2], L. Background Germline mutations resulting in dysregulation of the RAS/MAPK pathway cause syndromic conditions collectively referred to as rasopathies. Rasopathies share phenotypic manifestations including short stature with macrocephaly, developmental delay, cardiac manifestations, skin hyperpigmentation and a malignancy predisposition. Noonan syndrome is a rasopathy caused by mutations in multiple genes encoding components of the RAS/MAPK pathway. Despite its variable phenotype, limited genotype-phenotype correlations exist. Noonan syndrome with loose anagen hair (NS-LAH) is characterized by distinctive hair anomalies, developmental differences and structural brain abnormalities and is caused by a single recurrent missense *SHOC2* mutation. SHOC2 forms a complex with protein phosphatase 1 (PP1). Protein phosphatases counterbalance kinases and control activation of signaling proteins, such as the mitogen activated protein kinases of the RAS/MAPK pathway. **Methods and Results** Using exome analysis, we identified nine unrelated patients with (de novo) missense mutations in PP1 catalytic subunit beta (*PPP1CB*), sharing a recognizable phenotype. These *PPP1CB* variants met the standardized ACMG criteria for pathogenicity. Four individuals had the recurrent *PPP1CB* c.146G>C, p.Pro49Arg mutation; three had *PPP1CB* c.548A>C, p.Glu183Ala; and one each had c.166G>C, p.Ala56Pro; or c.820G>A, p.Glu274Lys. Findings typical for rasopathies were present in all individuals: 5/9 had short stature; 6/9 had relative or absolute macrocephaly; 7/9 had feeding difficulties with long term feeding tube use in 3/9; 9/9 had delayed development. Facial features included hypertelorism in 6/9 and low-set or posteriorly angulated ears in 8/9. Eye abnormalities were seen in 7/9, hearing loss in 4/9. Notably slow growing, light colored or sparse hair suggestive of loose anagen hair was present in 6/9. Cardiac manifestations occurred in 5/9 (pulmonic or mitral valve anomaly, VSD, ASD or mild HCM). Short or webbed neck was present in 4/9 and pectus in 3/9. Brain imaging showed ventriculomegaly in 7/9 and cerebellar tonsillar ectopia or Chiari 1 malformation in 3/8. Hair microscopy showed dystrophic features like greenstick fractures and squared-off anagen bulbs. Functional studies are being performed. **Conclusions** Based on the phenotypic findings and PPP1CB's effect on the RAS/MAPK pathway through RAF dephosphorylation, this novel condition can be considered a rasopathy, most similar to NS-LAH.

2590W

De novo mutation in *RBM10* can cause non-lethal TRAP syndrome: Further delineation of an expanding phenotype. *R. Hamid, L. Fairbrother.* Dept Pediatrics, Div Med Gen, Vanderbilt Univ Sch Med, Nashville, TN.

Mutations within *RBM10* (OMIM*300080) cause TARP syndrome (OMIM#311900). TARP is an X-linked recessive disorder associated with **T**alipes equinovarus, **A**trial septal defect (ASD), Pierre **R**obin sequence (PRS) and **P**ersistence of the left superior vena cava (SVC) as well as other congenital anomalies and significant developmental delays. TARP was felt to be universally lethal in the neonatal period until a recent publication of a young boy with long term survival. (Gripp et al) We present a patient with a mild case of TARP syndrome. At the time of evaluation our patient was a 6y old with PRS, sensorineural hearing loss, bicuspid aortic valve, expressive speech delays (felt to speak at a 3y old level), and intellectual disability. Through WES, we identified a pathogenic mutation in *RBM10*, c.170_171delAT (NM_005676), p.Y57X confirming a diagnosis of TARP syndrome. In contrast to other individuals reported, our patient can walk, speak, and progress in the educational system. He did not have some of the cardinal features of TARP including the ASD, Talipes equinovarus, and Persistence of the Left SVC but did have overlap with previously reported individuals (PRS, atypical ears, and SNHL). In addition, compared to the previously reported life expectancy of children with TARP our patient demonstrates long-term survival is possible. Increased ordering of Whole Exome Sequencing (WES) has led to expanded knowledge of previously described Mendelian Disorders. In the past, only patients who had the cardinal features of a disease were typically tested for a particular disease but with advancements in WES, we are now discovering a spectrum of clinical manifestations for previously well described conditions. In this case WES yielded an unexpected result in our patient. Based on our patient's phenotype and that of those previously reported with TARP consideration of the RBM10 was not within our differential diagnosis. Importantly this case highlights the need to think outside of the box when considering differentials and the utility of WES in cases that do not fit the known phenotype of a described Mendelian condition.

A case of familial transmission of the newly described *DNMT3A*-Overgrowth Syndrome. *G. Lemire, J. Gauthier, J.-F. Soucy, M.-A. Delrue.* Département de pédiatrie, Service de génétique médicale, Centre Hospitalier Universitaire Ste-Justine, Université de Montréal, Montréal, Canada.

DNMT3A-Overgrowth Syndrome (also known as Tatton-Brown Rahman Syndrome) (MIM 615879) has recently been described in 13 individuals with *de novo* heterozygous mutations in *DNMT3A* gene. This autosomal dominant condition is characterized by overgrowth, dysmorphic facial features and moderate intellectual disability. Missense and truncating point mutations, a small in-frame deletion, as well as microdeletion 2p23 have been reported. Moreover, *DNMT3A* is commonly somatically mutated in acute myeloid leukemia. We herein report a family with an affected father and son. The proband is a 12 year-old boy with tall stature, macrocephaly, facial dysmorphism, and intellectual disability with severe language disorder. He also has mild scoliosis. His father is a 49 year-old man with tall stature, macrocephaly, learning difficulties, and minor facial dysmorphism. He had a right occipital osteoma removed at 20 years of age. A heterozygous splice site mutation NM_022552.4 (*DNMT3A*): c.2323-2A>T was found in both individuals by whole exome sequencing analysis. This mutation has not been previously reported and is believed to be pathogenic. Indeed, this substitution involves a highly conserved canonical splice site and is predicted to cause exon skipping. *DNMT3A* has been reported to regulate bone metabolism via osteoclast activity. We therefore suspect that it was involved in the pathogenesis of our patient's bone tumor. This is the first report of a familial transmission of *DNMT3A*-Overgrowth Syndrome, supporting the autosomal dominant inheritance. The proband's phenotype is more severe than his father's, which illustrates variable expressivity in the syndrome.

2592F

Semidominant inheritance in Frank-ter Haar syndrome. *F. Rossignol, P.M. Campeau.* Medical Genetics, CHU Sainte-Justine, Université de Montréal, Montréal, Québec, Canada.

 Introduction: Frank-ter Haar syndrome (FTHS, MIM 249420) is an autosomal recessive disease characterized by craniofacial, cardiac and skeletal anomalies, including brachycephaly, a prominent forehead, wide fontanels, macrocornea with or without glaucoma, bowing of the long bones and finger deformities. It is caused by homozygous mutations in the *SH3PXD2B* gene, encoding an adaptor protein involved in podosome formation and extracellular matrix degradation. Here, we report a patient with FTHS associated with reduced penetrance in the paternal side of the family.   **Case description:** A 4 month-old child presented with a large anterior fontanel, a prominent forehead, a wide nasal root, mandibular diastasis, supernumerary teeth, a high arched palate, sphenoidal anomalies, a bell-shaped thorax, and hypoplasia of the corpus callosum. Two mutations in *SH3PXD2B* (NM_001017995.2) were found, respectively c.967G>A (p.G323R, rs111492578) and c.2279G>A (p.R760H, not in dbSNP). Both mutations have a prevalence <0.01% in ExAC, and are predicted to be damaging in SIFT and possibly damaging in PolyPhen2.   On family history, the father presented congenital glaucoma without other signs of FTHS. His brother has a patent posterior fontanel in his adult years. Their mother, who was adopted, presented both glaucoma and a patent posterior fontanel. The patient's maternal family history is unremarkable. Segregation analysis in the family is ongoing.   **Discussion:** This is the first case of symptomatic carriers for Frank ter-Haar syndrome. It suggests that further investigations and surveillance in heterozygous carriers of mutations in *SH3PXD2B* might be warranted.

2593W

Optimized exome sequencing to characterize complex syndromic retinal dystrophy phenotypes. *I. Sanchez-Navarro[1,2,3], L. Tian[3], C. Villaverde[1,2], L. Rodrigues Jacy da Silva[1,4], R. Pellegrino[3], F. Mafra[3], O. Zurita[1,2], L. Vazquez[3], Y. Li[3], X. Chang[3], A. Almoguera[3], D. Li[3], J. Snyder[3], M. Corton[1,2], C. Ayuso[1,2], H. Hakonarson[3].* 1) Department of Genetics, Health Research Institute–Jimenez Diaz Foundation University Hospital (IIS-FJD-UAM) Madrid, Spain; 2) Center for Biomedical Network Research on Rare Diseases (CIBERER), ISCIII, Madrid, Spain; 3) Center for Applied Genomics, Abramson Research Center, Children's Hospital of Philadelphia; 4) Universidade de Mogi das Cruzes, São Paulo, Brazil.

 Statement of purpose: To deepen our understating of syndromic retinal dystrophies (SRD), using Clinical Exome Sequencing (CEX) and Whole-Exome Sequencing (WES). **Methods:** 32 SRD cases previously studied in FJD (Madrid) and 7 cases from CAG-CHOP (Philadelphia) biorepositories were selected for the study. These patients presented with systemic phenotypes with eye affectation (mainly retinal dystrophy) and symptoms such as neuronal alteration, renal or cardiac disease, and obesity, among other features. Some of them were clear ciliary syndromes (Bardet-Bield Syndrome, Joubert Syndrome, Alström Syndrome, Jeune Syndrome), other non-ciliary diseases (Stickler) with other cases presenting with less clearly defined systemic diseases.   Commercial clinical exomes (TruSightOne) were used to study the 32 cases from FJD. Libraries were prepared using TruSigthOne kits and sequenced on a NextSeq500 (v2 chemistry) at FJD Genetics Department in Madrid. FastQ files were used to generate VCF using CAG-ARC-CHOP pipeline. Negative cases from this Clinical Exome Study and 7 other SRD not previously characterized cases from The Children's Hospital of Philadelphia (CHOP) were WES-sequenced (Agilent's SureSelect v5 sequenced on HiSeq with v4 chemistry) at the CAG at CHOP. Sequencing data was analyzed in the search of SNVs and CNVs. **Summary of results**: In the first pass analyses, we were able to characterize 29% of the cohort by means of a gene panel approach. At the moment, with the CEX-based approach we have been able to find the cause of the disease in 4 out of 19 cases studied. These findings included the genes *COL2A1*, *IFT140*, *PEX6* and *CRB1*. The previously uncharacterized cases are currently being analyzed at CAG-CHOP. Based on CAG-CHOP previous experience we expect to characterize about 40% of the cases under study.

2594T

Genetic risk factors identified for severe renal disease in Bardet-Biedl syndrome in the largest reported patient cohort. *E. Forsythe[1], K. Sparks[2], S. Best[1], S. Borrows[3], B. Hoskins[2], A. Sabir[4], T.G. Barrett[5], D. Williams[6], S. Mohammed[7], D. Goldsmith[8], D.V. Milford[4], D. Bockenhauer[9], L. Foggensteiner[3], P.L. Beales[1,2].* 1) Genetics and Genomic Medicine Programme, UCL Institute of Child Health, London, United Kingdom; 2) Bardet-Biedl syndrome National Clinical Service, Great Ormond Street Hospital, London, United Kingdom; 3) Nephrology Department, Queen Elizabeth Hospital, Birmingham, United Kingdom; 4) Nephrology Department, Birmingham Children's hospital, Birmingham, United Kingdom; 5) Endocrinology department, Birmingham Children's hospital, Birmingham, United Kingdom; 6) Clinical Genetics Department, Queen Elizabeth Hospital, Birmingham, United Kingdom; 7) Clinical Genetics Department, Guy's Hospital, London, United Kingdom; 8) Nephrology Department, Guy's Hospital, London, United Kingdom; 9) Nephrology Department, Great Ormond Street Hospital, London, United Kingdom.

Introduction: The high risk of renal disease is a cause of great anxiety for patients with Bardet- Biedl syndrome due to the devastating effect on quality of life, morbidity and mortality. Other hallmark features associated with this pleiotropic autosomal recessive ciliopathy include rod-cone dystrophy, obesity, learning difficulties, polydactyly and hypogenitalism. Twenty one disease causing genes (*BBS1-21*) have been identified, and code for proteins that localise to the basal body and cilium. Molecular confirmation of Bardet-Biedl syndrome can be achieved in 80% of patients. The primary renal phenotype is highly variable and no renal genotype-phenotype correlation has previously been identified. Here we present evidence from the largest reported study to date correlating severe renal disease with genotype and mutation type. **Method**: Data from 350 patients attending the United Kingdom adult and paediatric Bardet-Biedl syndrome clinics were collected over a four year period (2010-14). Genotype, urinalysis, sonographic, biochemical and clinical data were analysed. **Results**: One hundred and ninety four adults and 156 paediatric patients attended the national clinics in Birmingham and London. Eight per cent of adults and 6% of children had end stage renal disease. Genotype and mutation type were statistically significant risk factors for severe renal disease (estimated glomerular filtration rate <45 ml/min/1.73m^2). Univariable logistical regression analysis indicated that genotypes *BBS2*, *BBS10* and *BBS12* were significantly more likely to be associated with severe renal disease than mutations in *BBS1* (p values: 0.02, 0.0004, 0.03 respectively). Compound truncating mutations and truncating/missense mutations were also statistically more likely to be associated with severe renal disease than compound missense mutations (p values= 0.0003, 0.02 respectively). Multivariable logistical regression analysis including known clinical renal risk factors (age, hypertension, diabetes, BMI) identified mutations in *BBS10* as an independent risk factor for severe renal disease (p=0.028). Only one patient homozygous for the common M390R mutation in *BBS1* developed end stage renal disease. **Conclusions**: This study describes the largest reported cohort of patients with renal disease in Bardet-Biedl syndrome. Here we identify for the first time valuable genetic risk factors which are directly applicable to prognosis, clinical risk stratification and genetic counselling. .

2595F

SDCCAG8 affects AIMP2 localization and alters its downstream target, p53. *K. Weihbrecht[1,2], C. Searby[1,2], W. Goar[1,2], V.C. Sheffield[1,2], S. Seo[2].* 1) Department of Pediatrics, Univ. of Iowa, Iowa City, IA; 2) Department of Ophthalmology, Univ. of Iowa, Iowa City, IA.

Bardet-Biedl Syndrome (BBS) is an autosomal recessive, pleiotropic disorder, with 21 genes currently identified as causative. One of these genes is serologically defined colon cancer antigen 8 (SDCCAG8 [MIM 613524]), a nephronophthisis-related ciliopathy gene (*NPHP10* or *BBS16*). Patients with mutations in this gene exhibit retinal and renal abnormalities, obesity, and learning disabilities. Currently, little is known about the molecular functions of SDCCAG8 and how loss of SDCCAG8 function leads to the observed phenotypes. Our previous work identified strong interactors of SDCCAG8, consisting mainly of components of the multi-aminoacyl tRNA synthetase complex (MSC). More specifically, 8 out of 9 aminoacyl tRNA synthetases (ARS) as well as aminoacyl-tRNA-synthetase-complex interacting multifunctional protein 2 (AIMP2) interact with SDCCAG8. We also determined that among the MSC components, SDCCAG8 directly interacts with AIMP2. AIMP2 has a known non-canonical role in the apoptotic pathway via p53 activation. In response to DNA damage, a subset of AIMP2 localizes to the nucleus and binds to and prevents the ubiquitination of p53. This leads to an upregulation of apoptosis in response to DNA damage. Recently, we developed two *SDCCAG8* knockout IMCD3 cell lines using CRISPR-mediated technology. Using these cell lines, we examined the effect of *SDCCAG8* loss on AIMP2 localization in these cells. Immunofluorescence microscopy and cell fractionation with immunoblotting show that loss of *SDCCAG8* leads to increased AIMP2 in the nucleus of cells. Additionally, we showed that overall p53 levels increased in knock-out cells. Further work focuses on how these changes affect downstream elements of p53 utilizing a luciferase reporter assay. Based on our early findings, we suspected that SDCCAG8 acts as a negative regulator of AIMP2 to the nucleus under normal cell conditions. However, recent findings show that SDCCAG8 is found at near equal levels in cytoplasmic and nuclear fractions, which suggests a possible role of SDCCAG8 as a chaperone or signal for AIMP2's nuclear localization. Loss of SDCCAG8 may cause a misregulation of normal localization, leading to the increased nuclear AIMP2. To determine the role of SDCCAG8 in this pathway, we will use cell fractionation followed by immunoprecipitation to determine if SDCCAG8 and AIMP2 are bound in the nucleus, which would suggest a role for SDCCAG8 as a chaperone of AIMP2.

Lipoid proteinosis: A clinical and molecular study in Egyptian patients.
H.H. Afifi[1], K.S. Amr[2], A.M.S. Tosson[3], T.A. Hassan[4], G.Y. El-Kamah[1]. 1) Clinical Genetics Department,Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 2) Medical Molecular Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 3) Pediatrics Department, Faculty of Medicine, Cairo University, Cairo, Egypt; 4) Otolaryngology Head and Neck Surgery Unit, Hearing and Speech Institute, Cairo, Egypt.

　Purpose: Lipoid proteinosis is an autosomal recessive disorder due to the loss of function of *ECM* gene. Clinical features include varying degrees of skin thickening, hoarseness of voice, beaded eyelid papules and less frequently neuropsychiatric abnormalities, and partial alopecia. **Objectives:** Clinical and molecular study of lipoid proteinosis in Egyptians. **Methods:** Clinical examination and molecular analysis of 9 individuals having lipoid proteinosis, and descending from 7 unrelated families, were performed. The families originated from different geographic governorates in Egypt. Extraction of DNA samples of the 9 patients and their parents from peripheral blood by standard methods was performed. Polymerase chain reaction (PCR) amplification of the *ECM1* gene was performed using eight pairs of primers spanning over the 10 exons and splice junctions **Summary and Results:** Patients exhibited a variety of clinical manifestations with skin affection and hoarseness of voice being the consistent feature in all of them. None of them had neuropsychiatric manifestations. We identified four novel homozygous insertion, small deletion, missense, and splice site mutations {c.10_11insC (exon 1), c.690_691delAG (exon 6), c.734G>A (exon 7), and c.1393G>T (intron 9/exon 10)}, as well as one previously published splice site mutation c.71G>C (exon1/intron 1). Parents were heterozygous for the mutation of their offspring. Novel mutations were not detected in 200 Egyptian controls. **Conclusions:** The novel mutation c.1393G>T (IVS10-1G>T) occurred in three unrelated Egyptian patients, which may suggest a founder effect of this allele in Egyptian patients. However, further studies are needed. Identification of pathogenic *EMC1* mutations is important for accurate diagnosis and proper genetic counseling.

2597T

N of 2: Assessing recurrent gene identifications with population and functional data. *S. Akle[1,2], C.A. Cassa[2,3].* 1) Organismic and Evolutionary Biology, Harvard University, Cambridge, MA. USA; 2) Brigham and Women's Hospital, Division of Genetics, Boston, MA, USA; 3) Harvard Medical School, Department of Medicine, Boston, MA, USA.

　The expanding use of clinical genomic sequencing promises not only to improve diagnostics, but also to drive the discovery of new disease genes. When a promising candidate variant is identified in a gene that is not already associated with disease, a second case with a variant in that gene, or an "N of 2", increases the chance of causality. Second case hits may come from collaborating labs or clinics, through the matchmaker exchange, or even from within large clinical sequencing programs (Lee 2014; Yang 2014). Such recurrent observations can help to identify new disease-gene associations.　Due to large clinical sequencing cohorts and the Matchmaker Exchange, these recurrent gene identifications are becoming more common. However, these associations may be due to chance alone. We have previously shown that there is a substantial chance that two individuals in a cohort carry variants in some genes (Akle 2015). Our tool (RD-Match, http://genetics.bwh.harvard.edu/rdmatch/) assesses the likelihood that two individuals simply happen to carry variants in the same gene that is unrelated to the phenotype. This probability can be estimated using data from the Exome Aggregation Consortium, a set of over 60,000 exomes from healthy individuals (Lek 2015).　Here, we extend this work to assess recurrent gene identifications from clinical exome cases. As an example, in a set of 2,000 clinical exome cases, 291 cases involved recurrent genes that were related to a diagnosis. Over 90% of those genes were not available on clinical genetic testing panels (NCBI 2012). In the set of solved exome cases, 91% of these novel genes would not have been conclusively associated with a disease given the recurrence rates, modes of inheritance and disease grouping. However, clinical labs make use of data from other cases, additional phenotypic data, and other resources to make assessments of causality.　Next, we integrate functional validation data into the assessment of N=2 cases. We specifically include three lines of evidence from *in vivo* assays: two assays of cell essentiality (Wang, 2015) and embryonic or early lethal mouse knockout data (JAX/MGI). We calculate a composite probability of association given the probabilities derived from these separately ascertained lines of evidence.　Recurrent observations can expedite the identification of new genes in rare disorders, but investigators must carefully integrate statistical evidence for association with other sources of evidence.

2598F

The identification of novel causative variants and likely non-pathogenic loss-of-function variants in consanguineous families. *P. Makrythanasis[1,2], M. Ansar[1], M.T. Sarwar[3], H. Shaikh[4], S.A. Antonarakis[1,2,16].* 1) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland; 3) Institute of Basic Medical Sciences (IBMS), Khyber Medical University, Peshawar, Pakistan; 4) Molecular Biology and Genetics Department, Medical Research Center, Liaquat University of Medical and Health Sciences, Jamshoro, Pakistan; 5) Department of Neurology, Oslo University Hospital, Oslo, Norway; 6) Department of Clinical Genetics, National Research Centre, Cairo, Egypt; 7) Institut Jerome Lejeune, Paris, France; 8) Pediatric Department, the University of Jordan, Amman, Jordan; 9) Department of Medical Genetics, University of Athens, Athens, Greece; 10) Department of Pathology, College of Medicine, University of Dohuk, Dohuk, Iraq; 11) Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco; 12) Genetics & IVF Department, the Farah Hospital, Amman, Jordan; 13) Department of Paediatrics, College of Medicine and Health Sciences, United Arab Emirates University, Al-Ain, United Arab Emirates; 14) Medical Genetics Unit, Saint Joseph University, Beirut, Lebanon; 15) Department of Medical Genetics, Oslo University Hospital and University of Oslo, Oslo, Norway; 16) iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

   Consanguinity and inbreeding increase the level of homozygosity through IBD alleles, thus increasing the frequency of autosomal recessive disorders. We have ascertained 155 consanguineous families with several phenotypes compatible with recessive heredity; mainly intellectual disability/developmental delay or visual impairment, originating from Arab countries and Pakistan. To identify the disease causing variants, we used a combination of homozygosity mapping and exome sequencing. At least five individuals per nuclear family were genotyped and in one individual per family exome sequencing was performed. We have identified pathogenic variants in already known genes in 38% of the families, while 21% of the families presented likely causative variants in candidate genes. In 41% families no causative or candidate variants in the coding regions covered by exome sequencing was identified. We have also looked for (likely) non-pathogenic homozygous loss-of-function variants in order to contribute to the improvement of the diagnostic algorithms and reduce the false positive calls for pathogenicity. We have identified 84 homozygous non-sense variants which did not segregate with the recessive phenotype and therefore are likely tolerated. We conclude that the discovery of novel pathogenic variants for recessive disorders and non-pathogenic homozygous loss of function mutation can be accelerated by analyzing large cohorts of consanguineous families, which in-turn will be beneficial for correct molecular diagnosis, and counselling of the affected families. An international, open-access database of these variants would facilitate the functional analysis of protein-coding genes, and the diagnostic capabilities of (near) Mendelian disorders. .

2599W

Dual genetic diagnosis as a valuable feature of whole exome sequencing. *A.M. Bertoli-Avella[1], O. Brandau[1], K. Kandaswamy[1], N. Nahavandi[1], D. Trujillano[1], P. Bauer[1], R. Abou Jamra[2], A. Rolfs[1,3].* 1) medical reporting, Centogene AG, Rostock, mecklenburg vorpommern, Germany; 2) Institute of Human Genetics, University of Leipzig Hospitals and Clinics, Leipzig, Germany; 3) Albrecht-Kossel-Institute, University of Rostock, Rostock, Germany.

   Abstract: Introduction: A significant proportion of patients who undergo extensive genetic testing remain undiagnosed. This is due to the fact that many approaches are focused on the identification of a single cause for the complete phenotypic picture of the patient. Such approaches might however miss the diagnosis in cases with multiple genetic disease phenotypes. This has serious consequences for the patients and their families, preventing the access to the right treatment or accurate counselling for pregnancies and prognosis. The advent of next-generation sequencing technologies has provided an opportunity to screen a patient's entire exome in order to establish genetic basis of diseases. This method for cases with unusual and blended clinical presentations is especially useful. Method: Whole exome sequencing (WES) was performed in 1555 index cases according to standardized settings. Data was generated and processed at CAP and CLIA certified laboratory, Centogene. In this cohort with a majority of childhood patients, we analysed the occurrence of clear dual or likely dual diagnoses. Results: We identified 35 families for whom whole exome sequencing provided a dual genetic diagnosis. These cases presented with a broader or atypical phenotype that could not be explained by a single variant. From these 35 families, pathogenic or likely pathogenic variants were reported for 8 families. For the remaining 27 a dual diagnosis seems a likely possibility due to the unexplained partial symptomatology and the identification of a pathogenic or likely pathogenic variant and at least one variant of uncertain significance with high pathogenicity scores in the corresponding gene. Some relevant examples were classic type of Ehlers-Danlos syndrome and X-linked Mental retardation type 102 (*COL5A2* and *DDX3X*), SESAME syndrome and Fanconi anemia, complementation group A (*KCNJ10* and *FANCA*) and Sanfilippo syndrome type B and ichthyosis vulgaris (*NAGLU* and *FLG*). Conclusion: Our result highlights the strength of an untargeted approach for the case of complex disease phenotypes. It clearly underlines the need for a complete standard procedure driven thorough exome analysis independent from an eventual observed diagnosis.   **Keyword**: whole exome sequencing; dual genetic diagnosis; molecular diagnosis.

2600T

Syndrome femur-fibula-ulna (FFU) report on additional findings as atypical presentation. *M. Garcia-Acero[1], J.C. Prieto[1,2].* 1) Instituto de Genetica Humana, Facultad de Medicina, Pontificia Universidad Javeriana, Bogotá, Colombia; 2) Hospital La Victoria SDS, Bogotá, Colombia.

Introduction: Skeletal dysplasias occur in about 1 case in 4000-5000 live births, with clinical and genetic variability. The classification has been difficult to focus primarily on clinical and radiological criteria associated with histological and genetic criteria, comprising those alterations of growth, number and bone structure. Femur-fibula-ulna (FFU) complex is a non-lethal congenital anomaly of unknown etiology, characterized by a highly variable combination of defects of the femur, fibula, and/or ulna, with striking asymmetry. Axial skeleton, internal organs and intellectual function are usually normal. **Case presentation:** We present a male patient, son of non-consanguineous parents, with clinical evidence of shortening of right forearm, bilateral clubfoot, bilateral dimpled knees, postaxial lower limb polydactyly and syndactyly toes 2-5 right foot, with radiographic findings of agenesis of ulna and fibula rights associated with fusion of sacral vertebrae. **Discussion:** Clinical and radiological findings of the patient are compatible with atypical presentation syndrome Femur-Fibula-Ulna (FFU) group three with vertebral involvement, corresponding to a rare form of skeletal dysplasia limb. The reason to gather in a single syndrome (FFU) is their tendency to occur together in the same patient much more frequently than expected based on opportunities combination of a single defect. They are usually sporadic, affecting males, unilateral, asymmetrical and committing mainly to the upper extremities and the right side. Familial recurrence is exceptional and explaining only by chance, without being observed parent-child transmission or relationship with the age of the same or consanguinity, nor by environmental factors, infectious, iatrogenic or radiation. It has not been explained by chromosome studies, or as deletion or duplication syndromes. **Conclusion:** The FFU syndrome consists of a series of asymmetrical malformations in the limbs characterized by highly variable combinations of congenital anomalies of femur, fibula, and/or ulna, which can occur with abnormal finger/foot on the side of the ulna/fibula. Depending on the involvement of malformed bones, FFU complex is classified into four groups: with an affected limb, with two, three and four. .

2601F

Identification of *MLL2* and *SATB2* in two patients with syndromic craniofacial anomalies. *H. Hain[1], D. Li[1], M. Harr[1,2], E. Zackai[2,3], H. Hakonarson[1,2,3].* 1) Center for Applied Genomics, Abramson Research Center, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 2) Division of Human Genetics, Department of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 3) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania, USA.

Whole exome sequencing (WES) offers a powerful diagnostic tool to rapidly and efficiently sequence all coding genes in individuals presenting for consideration of phenotypically and genetically heterogeneous disorders such as syndromic craniofacial anomalies. Here we present two patients with syndromic form of cleft palate who tested negative on targeted gene sequencing. WES analysis followed by Sanger sequencing identified *de novo* and novel mutations in *MLL2* and *SATB2* in two patients, respectively. The first patient has hypertelorism, micrognathia, cleft lip and palate, right ear hearing loss, aplasia cutis and more recent scalp alopecia with pili torti, which fit in Kabuki syndrome. The second patient for the SATB2-associated syndrome has cleft palate, speech delay, intellectual disability, mild pectus excavatum, midfacial flattening, and mild bilateral fifth finger clinodactyly. These case reports highlight the need for careful diagnosis of clinically heterogeneous syndromes, however delayed molecular diagnosis is not likely to have implication for patient health. The report also demonstrates that WES is an unbiased method and free of the constraint of having to develop a hypothesis, and an effective diagnostic tool in providing molecular diagnosis to patients with complex phenotype.

2602W

A novel mutation in the *VIPAS39* gene found in two families with atypical arthrogryposis, renal dysfuntion and cholestasis (ARC) syndrome. *T. Kaname[1], Y. Chinen[2], K. Yanagi[1], M. Iso[1], Y. Matsui[1], K. Hayashi[1], Y. Kuroki[1], T. Tohma[3], Y. Matsubara[4], IRUD-P consortium.* 1) Dept Gen Med, Natl Ctr Child Hlth Dev (NCCHD), Tokyo, Japan; 2) Dept Pedatr, Univ Ryukyu Grad Schl Med, Okinawa, Japan; 3) Wanpaku Clinic, Okinawa, Japan; 4) Research Institute, National Center for Child Health and Development (Japan), Tokyo, Japan.

Arthrogryposis, renal dysfunction and cholestasis (ARC) syndrome is a rare autosomal recessive multisystem disorder that has neurogenic arthrogryposis, renal tubular dysfunction and intrahepatic cholestasis. ARC syndrome can be caused by homozygous or compound heterozygous mutations in the *VPS33B* gene, whose product acts in intracellular trafficking. In several patients with ARC syndrome, mutations in the *VIPAS39* gene, whose product is a subset of VPS33B-positive vesicles involved in intracellular trafficking, were reported We present six patients in four families (two patients in two families and one patient in two family) with pathologically atypical ARC syndrome. All patients were born to non-consanguineous Japanese parents. The patients had dysmorphic features, bilateral clubfeet, arthrogryposis multiplex, aminoaciduria, ichthyosis and hyperbilirubinemia. The liver biopsies and pathological examination were performed in the patients. Although, multinucleation of hepatocytes and intra hepatocytic bile stasis in porta were observed in the liver of the patients, carcinoembryoinc antigen (CEA) staining revealed atypical spreading pattern compared with the pattern in ARC syndrome. Sanger sequencing of the *VPS33B* gene resulted no pathogenic mutations in all patients. Then, whole exome sequencing analysis was performed in the patients and their families. Of four families, two families (four patients) had the same homozygous mutation around exon 15 of the *VIPAS39* gene (c.913-1G to A.) The splicing mutation affected the *VIPAS39* expression in the patients, which might be a cause of the syndrome. The two families having the same mutation are unrelated but from the same main island of Okinawa, suggesting that there might be a founder effect in this area.

2603T

Chromatin remodelling disorders: The evolving phenotype of EP300 gene syndrome. *M.I. Van Allen[1,2], L. Armstrong[1,2], M. Steinrath[1], K. Meagher[1], T. Oh[1], The CAUSES study.* 1) Dept Med Gen, Univ British Columbia, Vancouver, British Columbia, Canada; 2) Children's and Family Research Centre, B.C. Children's Hospital, Vancouver, B.C.

Identification of new gene disorders via Whole Exome Sequencing (WES) has enhanced our understanding of molecular pathways and the impact of deletions and mutations in critical gene functioning during embryogenesis and postnatally. We present 4 new cases of individuals with EP300 gene alterations: (1) A 4 y/o boy with intellectual disability (ID), short stature (SS), prematurity, gut ischaemia, Tetralogy of Fallot, absent thymus and parathyroid glands, feeding dysfunction (FD), and distinctive facial features with normal thumbs/toes who has a novel *de novo* c.3734_3736delTTG(p.Val1245del) in frame deletion in EP300; (2, 3) A mother with ID and her 4 y/o son with ID, autism (ASD), SS, microcephaly, FD and both with facial dysmorphia and normal thumbs/toes who have the previously reported EP300 c.6915_6918 deletion (p.Asn2305LysFs); (4) A 12 y/o girl with ID, ASD, SS, hydrocephalus, arachnoid cyst requiring a shunt, Chiari 1 malformation, hearing loss, urachal cyst, echogenic kidneys, chronic constipation, and facial dysmorphia (with normal thumbs/toes) who has a *de novo* EP300 c.4505C>T(p.Pro1502Leu) change. The EP300 gene encodes p300 gene, a histone acetyltransferase that regulates transcription via chromatin remodelling and is important in the processes of cell proliferation and differentiation. The clinical features of EP300 gene syndrome are distinctive for multisystem involvement, malformations, and dysmorphic facial features. The clinical presentation overlaps with and is distinct from Rubenstein Taybi, Cornelia de Lange and Wiedemann-Steiner syndromes. All these syndromes have multiple malformations, postnatal growth concerns, neurological dysfunction, and deficits of essential physiological functions, along with microcephaly and mild to more severe ID. Facial features of our patients are phenotypically similar, changing with age, and distinct from other disorders of chromatin modelling, We consider EP300 gene syndrome to be a discreet disorder with a recognizable phenotype, and not a subtype of Rubenstein Taybi syndrome.

2604F

Debunking Occam's razor: Diagnosing multiple genetic diseases by whole exome sequencing. *T.B. Balci[1], T. Hartley[2], Y. Xi[2], X. Yang[3], C.L. Beaulieu[2], A.M. Smith[2], C. Armour[1], J. Richer[1], M. Tetrault[4], J. Schwartzentruber[4], E. Bareke[4], D.A. Dyment[1,2], A.N. Prasad[5], C.A. Rupar[5], C. Prasad[5], R. Mendoza-Londono[6], L. Dupuis[6], B.A. Fernandez[7], G. Horvath[8], J. Majewski[4], A.M. Innes[3], K.M. Boycott[1,2] FORGE and Care4Rare Canada Consortiums.* 1) Medical Genetics, Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 2) Children's Hospital of Eastern Ontario Research Institute, Ottawa, Ontario, Canada; 3) Department of Medical Genetics, Cumming School of Medicine, University of Calgary, Calgary, Alberta, Canada; 4) McGill University and Genome Quebec Innovation Centre, Montreal, Quebec, Canada; 5) Western University, London Health Sciences Centre, London, Ontario, Canada; 6) Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, Ontario, Canada; 7) Disciplines of Genetics and Medicine, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada; 8) Division of Biochemical Diseases, Department of Pediatrics, University of British Columbia and BC Children's Hospital, Vancouver, British Columbia, Canada.

   Purpose: Next generation sequencing has changed the landscape of rare disease diagnosis. Recent cohorts of patients who have undergone clinical whole exome sequencing (WES) have shown that while the identification of multiple genetic diagnoses in a single family is unanticipated, it is a reality. Here we outline the diagnostic odyssey of our cases with more than one genetic disease uncovered by WES and review published literature to reveal an overall rate for these events. Methods: We retrospectively analyzed the WES results for 773 families with undiagnosed rare diseases enrolled in the two national research programs in Canada, Finding of Rare Genetic Disease Genes and its successor, Enhanced Care for Rare Genetic Diseases. Reports of WES cohorts that mention cases with multiple diagnoses were reviewed for overall numbers. Results: In our series eight out of 216 solved families (3.6%) had two or more genetic diagnoses explaining their multiple findings. The overall rate of encountering multiple diagnoses among solved WES cases in recent reports, including ours was found to be 4.1% (1.4 - 14.3%). Conclusion: The rate of finding more than one genetic disease in patients with complex phenotypes is significant. These diagnoses of blended phenotypes would be almost impossible to reach without the relatively unbiased nature of WES (or related genome-wide sequencing tests). When initial results do not point to a single unifying cause and only explain part of a patient's findings, the medical geneticist should consider this rare occurrence in addition to, or perhaps even before, other possibilities, such as phenotypic variability.

2605W

Dominant, clustered mutations in desmoplakin (*DSP*) cause erythrokeratodermia-cardiomyopathy (EKC) syndrome, a novel cardio-cutaneous disorder, and impair desmosomal processing. *L.M. Boyden[1], C.Y. Kam[2], A. Hernandez-Martin[3], J. Zhou[1], B.G. Craiglow[1], L.M. Milstone[1], R. Sidbury[4], E.F. Mathes[5], S.M. Maguiness[6], D.A. Crumrine[5], M.L. Williams[5], R. Hu[1], K. Holland[7], A.S. Paller[2], R.P. Lifton[1], P.M. Elias[5], K.J. Green[2], K.A. Choate[1].* 1) Yale University, New Haven, CT; 2) Northwestern University, Chicago, IL; 3) Hospital Infantil del Nino Jesus, Madrid, Spain; 4) University of Washington, Seattle, WA; 5) University of California San Francisco, San Francisco, CA; 6) University of Minnesota, Minneapolis, MN; 7) Medical College of Wisconsin, Milwaukee, WI.

   Disorders of keratinization (DOK) feature marked genotypic and phenotypic heterogeneity. As most disease is cutaneous, the possibility of comorbidity is rarely investigated. In order to better understand the underlying pathobiology, we performed genetic and biochemical analyses of a DOK cohort. Via exome sequencing, we found that three subjects harbored *de novo* missense mutations within the gene encoding desmoplakin (*DSP*), clustered within a seven residue span of a single spectrin repeat. Subjects with these *DSP* mutations all exhibit a novel DOK, which we termed erythrokeratodermia-cardiomyopathy (EKC) syndrome, characterized by erythrokeratodermia and an initially-asymptomatic, progressive, and potentially fatal cardiomyopathy, a morbidity not previously associated with erythrokeratodermia. Desmoplakin is a primary component of desmosomes, the intercellular adhesion junctions most abundant in both epidermis and heart tissue. Affected skin shows aggregation of desmosomes, widening of intercellular spaces, and defects in lipid secretion. We demonstrate that *DSP* mutations in EKC syndrome subjects alter the epidermal localization of desmoplakin, other desmosomal proteins, and the gap junction protein connexin 43. We have since seen two additional probands, each found to have a *DSP* mutation in the same spectrin repeat, who also exhibit erythrokeratodermia and cardiomyopathy. Parental DNA from one of these subjects was not available; we have shown her *DSP* mutation is *de novo* via comparison of her chromosome 6 haplotypes to those of her siblings. Remarkably, her skin phenotype dramatically improved following immunosuppression necessitated by a heart transplant. While mutations in *DSP* are known to cause other disorders, our EKC subjects feature a unique, extreme whole-body erythorkeratodermia, with distinct molecular effects on desmosomal proteins and processing. The cardiac defects in EKC subjects, which were fatal in one, resulted in heart transplant in two, and were undiagnosed prior to our analysis in two, highlight the critical, potentially life-saving importance of this genetic discovery, which necessitates consideration of cardiac disease and genetic diagnosis in all patients presenting with erythrokeratodermia. These findings add a severe, previously undescribed syndrome to phenotypes caused by *DSP* mutation, and identify a specific region of the protein singularly critical to the pathobiology of EKC syndrome and to both epidermal and cardiac DSP function.

2606T

Alterations in the *NAA10* polyadenylation site in two families with X-linked anophthalmia. *J.J. Johnston[1], F.J. Stewart[2], H.M. Chapman[3], C.M. Chou[4], J.C. Sapp[1], A.A. Schäffer[5], S.K. Sen[1], A. Slavotinek[6], T.M. Glaser[3], G.C.M. Black[7,8], L.G. Biesecker[1].* 1) NHGRI, NIH, Bethesda MD; 2) NI Regional Genetics Service, Belfast, UK; 3) Department of Cell Biology and Human Anatomy, University of California, Davis School of Medicine, Davis, CA; 4) Departments of Human Genetics and Internal Medicine, University of Michigan Medical School, Ann Arbor, MI; 5) NCBI, NIH, Bethesda MD; 6) Department of Pediatrics, Division of Genetics, University of California, San Francisco, San Francisco, CA; 7) Centre for Genomic Medicine, Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, UK; 8) Centre for Ophthalmology & Vision Sciences, Institute of Human Development, University of Manchester, Manchester, UK.

Mutations in N-alpha-acetyltransferase 10 (*NAA10)* have been identified in several disease phenotypes including Ogden syndrome, Lenz microphthalmia and intellectual disability (ID), both with and without associated features. It is unclear how the alterations in *NAA10* lead to such widely variable phenotypes although substrate specific defects have been suggested. We evaluated a family with X-linked anophthalmia in which coding variants in *NAA10* were not identified. Re-examination of this pedigree based on linkage results and exome sequence analysis identified a non-coding alteration in the polyadenylation signal of *NAA10*. An additional family was identified with a similar phenotype and shown to have a different alteration in the polyadenylation signal. Neither variant was present in the ExAC database. RNA-seq and RT-PCR analysis of the RNA species present in family 1 suggest the use of a downstream polyadenylation signal and reduced overall mRNA levels. These two variants bring to 28 the total known variants in the polyadenylation site in humans associated with disease. The mutational spectrum of *NAA10* is distinct and peculiar. A splice variant has also been associated with syndromic microphthalmia. A missense mutation has been associated with Ogden syndrome. Three other missense variants have been associated with ID with or without LQTS. No loss of function mutations have been described and we presume these would be lethal in males. We propose a model whereby hypomorphic missense mutations with substrate specific effects lead to Ogden syndrome or ID, whereas RNA processing mutations that disrupt protein function cause syndromic microphthalmia. This represents a novel mechanism of disease as prior polyA site mutations, in other genes, have phenotypes similar to loss-of-function ORF mutations.

2607F

Recessive *NCOR2* mutations cause a new syndrome with intellectual disability, white matter anomalies, brachycephaly, and midface hypoplasia. *W. Li[1], B. de Vries[2], G. Mancini[3], A. Ryabets[7], H. Fu[4], T. Gardeitchik[2], A. van den Ouweland[3], M. van Slegtenhorst[3], A. Stegmann[6], X. Yang[5], M. Borchert[8], P. Campeau[4].* 1) Pathology and Laboratory Medicine, Children's Hospital Los Angeles, Los Angeles, CA, USA; 2) Department of Human Genetics, Radboud University Medical Center, Nijmegen, the Netherlands; 3) Department of Clinical Genetics, Erasmus University Medical Center, Rotterdam, The Netherlands; 4) Department of Pediatrics, CHU Sainte-Justine, University of Montreal, Montreal, QC, Canada; 5) Rosalind and Morris Goodman Cancer Research Center, Department of Biochemistry, McGill University and Department Medicine, McGill University of Health Center, Montreal, QC, Canada; 6) Department of Human Genetics, Maastricht University Hospital, Maastricht, The Netherlands; 7) Center for Endocrinology, Diabetes, and Metabolism Children's Hospital Los Angeles, Los Angeles, CA, USA; 8) Vision Center, Children's Hospital Los Angeles, Los Angeles, CA , USA.

Whole-exome sequencing of a pair of twins and two other individuals, from a total of three families, presenting with developmental delay or intellectual disability accompanied by brachycephaly, ventriculomegaly and midface hypoplasia identified bi-allelic mutations in *NCOR2*, a gene encoding the Silencing Mediator of Retinoic acid and Thyroid hormone receptor (SMRT). Features present in a majority of the patients were severe intellectual disability, speech impairment, hypotonia, epilepsy, ventriculomegaly, abnormal myelination, brachycephaly, midface hypoplasia, sparse hair, dysplastic ears, hearing loss, and feeding and respiratory difficulties. Allmutations identified were missense mutations affecting highly conserved residues in the C-terminal half of the protein, and were either not found or had very low minor allele frequencies in variant databases. SMRT is an essential component of the corepressor complex to which histone deacetylase 3 (HDAC3) is recruited for maximal histone deacetylase activity. HDAC3 can also be recruited to another homologous corepressor complex (NCoR), and binding to these complexes lead to a repression of certain nuclear receptors. Previous studies in mice showed *Ncor2* to be essential for forebrain development and neural stem cell maintenance, a finding correlating well with the severe neurological disease identified in the individuals described here. *In vitro* studies are currently underway to assess effects of the identified mutations on transcriptional corepressor functions of SMRT and the deacetylase activity of HDAC3. In conclusion, we define a new recessive condition with multisystem involvement caused by bi-allelic mutations in the SMRT corepressor encoding gene, *NCOR2*. .

2608W

Whole exome sequencing identifies genes converge on PI3K/mTOR and Ras/MAPK pathways as causes of heterogeneous complex lymphatic anomalies. *D. Li[1], T. Wenger[2], M. March[1], C. Seiler[3], L. Tian[1], C. Kao[1], R. Pandey[1], K. Nguyen[1], R. Chiavacci[1], P. Sleiman[1,4], M. Itkin[5], Y. Dori[5], H. Hakonarson[1,4,6].* 1) The Center for Applied Genomics, Abramson Research Center, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA; 2) Division of Craniofacial Medicine, Seattle Children's Hospital, Seattle, WA 98105, USA; 3) Zebrafish core, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA; 4) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA 19104, USA; 5) Center for Lymphatic Imaging and Interventions, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA; 6) Divisions of Genetics and Pulmonary Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA.

Complex lymphatic anomalies include several diagnoses with overlapping patterns of clinical symptoms and chylous effusions (pericardial, pleural, or peritoneal) can be present. To identify the underlying genetic basis, exome sequencing (ES) was performed in four families with either generalized lymphatic anomaly or lymphangiectasia diagnosis. In family-1, 6 affected individuals in multigenerational were revealed to have heterozygous *EPHB4* mutation (c.2334+1G>C), a gene previously implicated in a biological pathway related to venous and lymphatic cell fate determination. RNA-seq demonstrated that the *EPHB4* splice-altering mutation creates a cryptic splice donor that causes the retention of the intervening 12 bp of the intron. For family-2, ES revealed a homozygous variant, c.1393-7C>T, in *PIK3R6* in the proband with both parents being heterozygous. PIK3R6 is a regulatory subunit of PI3K complex. Zebrafish knockdown of either *EPHB4* or *PIK3R6* resulted in vessel misbranching and deformities in the lymphatic vessel development, indicative of possibly differentiation defects both in blood and lymphatic vessels and mimicking the presentations of the patients. Western blot analysis using zebrafish lysates, which contained vascular abnormality, confirmed that reduced EPHB4 signalling resulted in downstream mTORC1 overactivation. Strikingly, drugs that inhibit mTOR signalling were able to rescue this misbranching phenotype. In family 3 and 4, a recurrent *ARAF* mutation, c.640T>C:p.S214P, in the conserved phosphorylation site was identified, which putatively result in a ARAF gain of function because the phosphorylation of S214 is responsible for regulation of ARAF. ARAF activation in turn upregulates RFFL, leading to polyubiquitylation and destabilization of PRR5L, a component of mTORC2 and suppressor of PKC phosphorylation, to achieve persistent PKC activation and lead to cell pro-growth and pro-migration. We are currently recruiting ~10 unrelated patients to further validate our discovery and conducting follow-up functional assessments and the zebrafish model to elucidate the role these genes play in lymphatic development. The resulting functional data will be presented together with detailed phenotypic characterization of the additional families examined. In summary we report three novel genes that converge on PI3K/mTOR and Ras/MAPK pathways, presenting a potential avenue for therapeutic intervention for complex lymphatic anomalies.

2609T

Functional characterization of a point mutation in the *MAPK1* gene in a patient with undiagnosed disease. *N. Sosonkina[1], A. Takizawa[2], J.W. Prokop[1], T. Goto[3], M. Grzybowski[2], A. Geurts[2], M. Hirabayashi[3], J. Lazar[1], H.J. Jacob[1].* 1) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 2) Medical College of Wisconsin, Milwaukee, WI; 3) National Institute for Physiological Sciences, Okazaki, Aichi, Japan.

Patients with rare diseases often undergo an exhausting and expensive diagnostic odyssey. Advancements in DNA sequencing, whole exome (WE) and whole genome sequencing (WGS), have offered the revolutionary diagnostic tools to these patients leading to cures and therapies. However, a considerable number of found variants fall into category of variant of uncertain significance (VUS). To make a diagnosis more accurate, the pathophysiological role of a VUS needs to be explained. Here, we report the results of the characterization of a *de novo* variant c.404G>C (p.R135T) in the *MAPK1* gene found using WES in a female proband with the following major symptoms: microcephaly, intellectual disability, speech apraxia, ADHD, craniosynostosis, facial dysmorphic features, and cyclic vomiting syndrome. This *MAPK1* missense mutation was classified as a VUS. We first utilized our deep-Sequence-to-Structure-to-Function analysis tools and suggested that the variant may affect MAPK1 activation. We then sought for creating of what would be the first example of a transgenic rat with knocked-in point mutation to mimic patient variant and potentially patient phenotype. The substitution of C for the wild-type G at nt 398 of the rat *Mapk1* would mimic the patient mutation. We used different combinations of CRISPR/Cas9 system, and manipulated rat fertilized 1-cell embryos. As a result, we obtained one female founder. Another approach was to modify rat ES cells utilizing CRISPR/Cas9 system aiming at knocking-in the *MAPK1* variant. We established two heterozygous ES cell lines that will be used in subsequent experiments. In parallel, we have received skin biopsies from the patient and her parents and performed cell-based assays to investigate the function of the *MAPK1* variant. Interestingly, gene expression studies showed overrepresentation of mutant *MAPK1* allele. In conclusion, we have evaluated different approaches to functional characterization of a VUS found in a patient with rare disease.

2610F

Whole exome sequencing identifies a novel *TDRD7* mutation responsible for the comorbidity of congenital cataract and azoospermia in humans. *Y. Tan[1,2], P. Liang[3], S. Yuan[1], L. Meng[1], C. Sjaarda[3], G. Lu[2], G. Lin[1,2].* 1) Inst. Reproductive and Stem Cell Engineering, Xiangya School of Medicine, Central South University, Changsha, Hunan, China; 2) Reproductive and Genetic Hospital of CITIC-Xiangya, Changsha, China; 3) Department of Biological Sciences, Brock University, St. Catharines, Ontario, Canada.

Congenital cataract and azoospermia (both have multiple OMIM entries) in humans are two different diseases occurring in two different organs with very different symptoms and no similarity in known genetic etiology. Here we report the comorbidity of the two diseases in a consanguineous family, in which two brothers and one sister from the same marriage were all affected with congenital cataract, while the two brothers were also affected with infertility as unexplained azoospermia. Via whole exome sequencing of a single patient, we were able to narrow down the candidate causative mutation to a novel frame-shift insertion mutation (NM_014290:c.553_554insA, NP_055105:p.T110N) in the Tudor domain containing 7 (*TDRD7*) gene. The mutation is predicted to generate a severely truncated protein which lacks most of the functional domains in the TDRD7 protein. We verified the presence of this mutation by targeted genotyping and showed it as the only mutation following the expected Mendelian segregation pattern for an autosomal recessive allele in the 4-generation pedigree. Immuno-histological and western blot analyses demonstrated the absence of TDRD7 protein in the seminiferous tubules and skin fibroblasts of the male patients, respectively. Histological and FISH analyses of the testis biopsy samples demonstrated the presence of haploid spermatids but lack of mature sperms in the seminiferous tubules in the male patients. While mutations in *TDRD7* have been previously shown to be associated with congenital cataract in humans and to cause congenital cataract and abnormal spermatogenesis in *Tdrd7-/-* mice, our study represents the first report demonstrating a comorbidity of congenital cataract and azoospermia in humans. The link between these two diseases by TDRD7 suggests that despite involving different organs and cell types with very different cellular morphologies and functions, the developments of lens and sperm share a common biological process in post-transcription regulation, in which TDRD7 plays a critical role as a component of the RNA-granules known to function in RNA-processing. Our results warrant the addition of *TDRD7* to gene panels for genetic screening of cataract and male infertility.

2611W

Utilizing nonsense-mediated decay facilitates candidate disease gene characterization and discovery. *J.J. White[1], Z.C. Akdemir[1], S.N. Jhangiani[2], T. Gambin[3], E. Boerwinkle[2,4], R.A. Gibbs[1,2], C.M.B. Carvalho[1], J.R. Lupski[1,2,5,6], Baylor-Hopkins Center for Mendelian Genomics.* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030, USA; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX 77030, USA; 3) Institute of Computer Science, Warsaw University of Technology, Warsaw 00-665, Poland; 4) Human Genetics Center, University of Texas Health Science Center at Houston, TX 770530, USA; 5) Texas Children's Hospital, Houston, TX 77030, USA; 6) Department of Pediatrics, Baylor College of Medicine, Houston, Texas 77030, USA.

Nonsense-mediated decay (NMD) is an RNA surveillance pathway that results in degradation of mRNA transcripts bearing a premature termination codon (PTC). According to the most widely accepted model of NMD, mutant transcripts containing PTCs located in the last ~50-55bp of the penultimate exon and the entire last exon, can escape NMD resulting in translation of a mutant protein product. To bioinformatically select transcripts with variants that may escape from NMD and possibly underlie human disease via a dominant-negative or gain-of-function mechanism, we investigated our in-house cohort of ~5000 exomes consisting of a wide variety of Mendelian phenotypes. We developed an algorithm to computationally predict the location of stop codons in either the -1 or +1 frame for each transcript. We categorized PTCs into those capable of escaping from NMD (NMD-incompetent) and those likely subject to NMD (NMD-competent). By flagging the final NMD-competent PTC we identified the boundary between NMD-competent and NMD-incompetent regions for each transcript allowing us to rapidly predict whether or not frameshift variants can escape from NMD. To identify possible pathogenic NMD-incompetent variants among our disease cohort, we used a binomial test to compare the frequency and distribution of frameshift variants in the predicted NMD-competent and NMD-incompetent transcript regions with the ARIC database of ~11,000 exomes as a control dataset. To further prioritize candidate genes, we designed an NMD-incompetency score metric to rank each gene based on the enrichment of NMD-incompetent vs NMD-competent variants. Among the top ranking genes, we identified examples where protein truncating variants result in disease by a mechanism other than haploinsufficiency. These include *DVL1* (autosomal dominant Robinow syndrome MIM #616331), in which frameshift alleles cluster in the penultimate exon, are hypothesized to escape NMD and mediate pathogenicity via a gain-of-function and/or dominant-negative mechanism (PMID: 25817016). Collectively, we demonstrate that leveraging the knowledge of NMD and an NMD-incompetency score metric may be an effective and efficient tool for discovery of novel disease genes due to production of truncated or altered proteins. Furthermore, we suggest that gain-of-function and dominant-negative mutations are under-recognized in genomic analyses and likely contribute to a wide variety of human disease phenotypes.

2612T

Trio whole exome sequencing identifies *de novo* **pathogenic variants in** *FBN1* **and** *TRPS1* **in a patient with a suspected connective tissue disorder.** *D.B. Zastrow[1,2], L. Fernandez[1,2], J. Kohler[1,2], P. Zornio[1,2], A. Dries[1,2], D. Waggott[1,2], M. Manning[3,4], E. Farrelly[5], A. Hanson-Kahn[5,6], K. Miller[5], M. Walkiewicz[7], C. Eng[7], E.A. Ashley[1,2,6], P. Fisher[1,4,8], J.A. Bernstein[1,4,5], M. Wheeler[1,2], Members of the Undiagnosed Diseases Network.* 1) Stanford Center for Undiagnosed Diseases, Stanford University, Stanford, CA; 2) Division of Cardiovascular Medicine, Stanford University, Stanford, CA; 3) Department of Pathology, Stanford School of Medicine, Stanford, CA; 4) Department of Pediatrics, Stanford School of Medicine, Stanford, CA; 5) Lucille Packard Children's Hospital Stanford, Palo Alto, CA; 6) Department of Genetics, Stanford School of Medicine, Stanford, CA; 7) Baylor Miraca Genetics Laboratories, Houston, TX; 8) Department of Neurology, Stanford School of Medicine, Stanford, CA.

   A patient presented with a history of congenital diaphragmatic hernia, inguinal hernia, and recurrent umbilical hernia. She also had joint laxity, hypotonia, and dysmorphic facies. A unifying diagnosis was not identified based on clinical phenotype. As part of her evaluation in the Undiagnosed Diseases Network, trio whole exome sequencing (WES) was performed. After variant analysis and filtering, 89 de novo protein altering variants in 61 genes were found; 2 of these were consistent with the patient's clinical phenotype. We identified pathogenic stop gain variants in Fibrillin 1 (*FBN1* [MIM 134797]) and Zinc Finger Transcription Factor TRPS1 (*TRPS1* [MIM 604386]) resulting in 2 independent autosomal dominant conditions, each with de novo inheritance. A heterozygous known pathogenic variant c.4786C>T (p.R1596X, ClinVar ID 36082) in *FBN1* was detected. *FBN1* mutations are associated with Marfan syndrome (MFS [MIM 154700]) and a spectrum of similar phenotypes. A heterozygous c.1630C>T (p.R544X) pathogenic variant in *TRPS1* was also detected. *TRPS1* mutations are associated with Trichorhinophalangeal syndromes type I (TRPS1 [MIM 190350]) and type III (TRPS3 [MIM 190351]). Features of both MFS (aortic root enlargement (z=3.24), joint laxity and MFS Systemic Score=5) and TRPS1 (sparse hair, bulbous tip of the nose, long flat philtrum, thin upper vermilion border, protruding ears) are seen in the affected individual. MFS commonly presents with long bone overgrowth leading to increased height, which is in contrast to the short stature usually seen in TRPS1 due to premature closure of the growth plates. The height of our patient (97.0 cm: 31rst percentile by CDC; 17th percentile by WHO) may be a result of the differential effects of *FBN1* and *TRPS1* molecular mechanisms on bone formation. This discrepancy and young age of the proband made a clinical diagnosis difficult without genetic testing. Diagnostic criteria for MFS combine family history, medical history, physical exam, and molecular *FBN1* analysis. Our patient did not meet clinical criteria for MFS before WES. It was only after the de novo nonsense *FBN1* variant was found, and genotype-driven echocardiography revealed a mild aortic root enlargement that a diagnosis of MFS could be established. For isolated cases with a suspected genetic etiology, trio WES can allow for a more thorough interrogation of multiple genetic loci than single gene testing, and uncover etiologies responsible for blended phenotypes.

2613F

Expanded phenotypic spectrum of autosomal recessive EGFR-related disease due to a founder mutation in the Roma population: Report of a non-lethal case. *M. Szybowska[1], P. Kannu[2], E. Pope[3], G. Richards[4], I. Lara-Corrales[3], C. Li[1].* 1) Department of Genetics, McMaster Children's Hospital, Hamilton, Ontario, Canada; 2) Department of Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, Ontario, Canada; 3) Department of Dermatology, The Hospital for Sick Children, Toronto, Ontario, Canada; 4) GeneDx Inc, Gaithersburg, MD, USA.

   The epidermal growth factor receptor (EGFR) is known to be involved in modulating the growth and differentiation of multiple tissue types including the heart, brain, epithelium, and hair. It accomplishes this via direct ligand-mediated extracellular to nuclear transmembrane signalling as well as indirect neighbouring pathways. Somatic gain of function mutations affecting the EGF/EGFR pathway are a well-known cause of cancer. Since 2014, a constitutional homozygous loss of function mutation [c.1283G>A; p.G428D] in EGFR has been described in three cases of Roma descent presenting with lethal inflammatory skin and bowel disease [Campbell, et al, 2014, Ganatzsky et al, 2015]. We report a case of a 5 year old girl, ex-27 weeker, of Roma descent who presented at birth with electrolyte imbalance, complex congenital heart defect, cystic kidneys with nephrophthisis, ventriculomegaly with a small subependymal cyst, interstitial lung disease**,** and antenatal polyhydramnios. Physical exam was significant for severe short stature and craniofacial dysmorphism. Dermatological findings are characterized by very thin and translucent skin that broke down easily in the newborn period. The skin lesions evolved to become pustular rashes, prominent on scalp, face and extremities. Loose and wrinkly skin was noted at 4 months assessment, giving rise to progeroid appearance. She also had sparse scalp hair with abnormal texture. Whole exome sequencing revealed the same homozygous EGFR mutations [c.1283G>A; p.G428D] previously reported in the other cases. Despite her very complex medical history, her skin findings have improved overtime and the frequency of infections decreased. She requires regular management for chronic renal disease stage II-III, Fanconi like syndrome, failure to thrive, chronic gastritis with elevated liver enzymes and chronic diarrhea. Presently, she is verbal and ambulatory with mild global developmental delay. It is not clear whether this delay is intrinsic of this syndrome or a consequence of her early neonatal course. In summary, we present a nonlethal case with the same homozygous mutation previous noted to be associated with lethal skin and GI inflammation. This case contributes to our understanding of the natural history and prognosis of a new syndrome. It also highlights the utility of whole exome sequencing in the diagnosis of genodermatoses.

2614W

Non-penetrance in cerebro-costo-mandibular syndrome. *D. Lynch[1], A.M. Innes[1,2], R.E. Lamont[1,2], J.S. Parboosingh[1,2], F.P. Bernier[1,2].* 1) Medical Genetics, University of Calgary, Calgary, Alberta, Canada; 2) Alberta Children's Hospital Research Institute, Calgary, Alberta, Canada.

Cerebro-costo-mandibular syndrome (CCMS) is a rare disorder of skeletal development characterized by micrognathia, posterior rib gaps, and other variable features. We previously identified heterozygous mutations in an alternative exon of the spliceosomal gene *SNRPB* as the cause of CCMS, establishing that CCMS is a dominant disorder. This discovery allows us to offer diagnostic testing and improved genetic counseling to affected individuals and families. In our cohort of seventeen families, we observed both vertical transmission and *de novo* mutations. There were also four instances in three families where an unaffected mother had a heterozygous *SNRPB* mutation, indicating that CCMS is not fully penetrant. The identified mutations lead to deregulation of levels of the three SNRPB transcripts, and patients have a 32-42% reduction in total SNRPB RNA levels compared to controls. Analysis in one non-penetrant family shows that the unaffected mother does not have the reduction in SNRPB transcript levels that is typical in affected patients, which suggests a compensatory mechanism at the RNA level. Identifying the cause of this compensatory mechanism is important from a genetic counseling perspective, but also to elucidate the aetiology of CCMS and the mechanisms by which *SNRPB* is regulated. Sequence capture and massively parallel sequencing of *SNRPB* including coding, intronic, and flanking regions as well as a known *SNRPB* enhancer did not reveal any genetic differences between affected and unaffected family members sharing a *SNRPB* mutation. Preliminary qRT-PCR results in one family show that RNA levels of the *SNRPB* paralog *SNRPN* are increased by 45% in the unaffected mother, but remain unchanged in her affected child. While modifying factors remain unknown and could be genetic, environmental, or both, our preliminary analysis excludes variants in *SNRPB* and its known regulatory regions.

2615T

Genetic and functional comparison of identical germline and somatic *SETBP1* mutations. *R. Acuna-Hidalgo[1], P. Deriziotis[2], G.M. Findlay[3], C. Gilissen[1], M. Steehouwer[1], J.A. Veltman[1,4], S.E. Fisher[2], J. Shendure[3], A. Hoischen[1], B.W. van Bon[1], International Schinzel-Giedion syndrome collaboration.* 1) Department of Human Genetics, Radboud UMC, Nijmegen, Netherlands; 2) Department of Language and Genetics, Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands; 3) Department of Genome Sciences, University of Washington, Seattle, WA, United States; 4) Department of Clinical Genetics, University of Maastricht, Maastricht, Netherlands.

Schinzel-Giedion syndrome (SGS) is a rare developmental disorder characterized by multiple malformations, severe neurologic alterations and increased risk of malignancy. SGS is caused by *de novo* germline mutations clustering to a 12 bp hotspot in exon 4 of *SETBP1*. Mutations in this hotspot disrupt a degron (a signal for the regulation of protein degradation) and lead to the accumulation of SETBP1 protein. Identical *SETBP1* hotspot mutations have been observed recurrently as somatic events in leukemia. We collected clinical information of 47 SGS patients (including 26 novel cases) with germline *SETBP1* mutations. Comparing SETBP1 mutations in SGS and in leukemia shows that, despite sharing an overlap, the distribution of mutations within the hotspot differs between both conditions. Overexpression experiments confirm that mutations in the *SETBP1* hotspot destroy a degron and lead to increased SETBP1 protein, with different mutations having varying effects on SETBP1 stability and protein levels. Furthermore, we perform saturation genome editing (Findlay et al. Nature 2014) to analyze the effect of all theoretically possible mutations in the *SETBP1* hotspot and surrounding region. *In silico* modeling and functional studies substantiate that mutations seen more frequently in SGS are functionally weaker than those more prevalent in leukemia. Clinical data supports this finding; SGS patients with germline *SETBP1* mutations shown to be functionally stronger and more prevalent in leukemia show increased cell proliferation *in vitro*, increased incidence of malignancy and decreased survival. Our findings substantiate that, despite their overlap, somatic *SETBP1* mutations driving malignancy are more disruptive to the degron than germline *SETBP1* mutations causing SGS. Drawing on previous studies of somatic *SETBP1* mutations in leukemia, our results support a genotype-phenotype correlation in germline *SETBP1* mutations spanning a molecular, cellular and clinical phenotype.

2616F

Elucidation of *MRAS*-mediated Noonan syndrome with cardiac hypertrophy. *E.M. Higgins[1], J.M. Bos[1], H. Mason-Suares[2], K. Sol-Church[3], K.W. Gripp[3], R.A. Urrutia[1], M.J. Ackerman[1].* 1) Mayo Clinic, Rochester, MN; 2) Partners HealthCare, Boston, MA; 3) Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE.

Noonan syndrome (NS[MIM 163950]) is an autosomal dominant disorder with a characteristic clinical phenotype of facial dysmorphisms, short stature, and congenital heart defects. NS is a member of a family of developmental disorders termed "Rasopathies", caused mainly by gain-of-function mutations in genes encoding RAS-mitogen-activated protein kinase (MAPK) signaling pathway proteins. For our study, whole exome sequencing (WES) and trio-based genomic triangulation was performed on a 15-year old, female with a clinical diagnosis of NS and concomitant cardiac hypertrophy and her unaffected parents. Sequencing data was analyzed using Golden Helix VarSeq software. Filters were applied to identify rare (Sporadic: MAF<.00005 in ExAC, Recessive: MAF<.005 in ExAC), protein altering mutations that were either sporadic, de novo or inherited in a homozygous or compound heterozygous recessive manner. Candidate genes were ranked by ToppGene and Endeavour disease-network analysis candidate gene ranking algorithms based on association to the currently known NS causative genes. A single candidate gene that directly interacts with known NS-associated proteins was identified, and subsequently, a cohort of 110 phenotype-positive, genotype-negative NS patients was sequenced for this gene. Following analysis and filtering, WES identified a total of 176 candidate variants in 67 genes. A cumulative "rank list" based on the ranking software readouts identified *MRAS* (p.G23V, c.68G>T) as the most likely novel NS-susceptibility gene. *MRAS*-encoded RAS-related protein 3 (MRAS[MIM 608435]) interacts directly with the MAPK pathway via SHOC2 and PP1. p.G23V-MRAS localizes to a critical GTP-binding motif and is predicted to result in a gain-of-function by *in silico* prediction tools and by molecular dynamic simulation (MDS). Subsequent analysis of the phenotype-positive, genotype-negative NS cohort identified an additional rare, de novo p.T68I (c.203C>T) *MRAS* missense mutation in a female with NS, pulmonic valve stenosis and cardiac hypertrophy. Herein, with the discovery of two sporadic, de novo variants (p.G23V and p.T68I) identified by WES or direct DNA sequencing, we have established *MRAS* as the newest NS-susceptibility gene. MRAS plays a crucial role in the NS associated Ras/MAPK pathway and interacts directly with several previously identified NS associated proteins.

2617W

***AMMECR1*: A single point mutation causes developmental delay, midface hypoplasia, and elliptocytosis.** *E.G. Seaby[1], G. Andreoletti[1], J.M. Dewing[2], I. O'Kelly[2], K. Lachlan[3], R.D. Gilbert[4], S. Ennis[1].* 1) Human Genetics & Genomic Medicine, University of Southampton, Duthie Building (Mailpoint 808), Southampton General Hospital, Southampton, SO16 6YD, UK; 2) Centre for Human Development, Stem Cells and Regeneration HDH, University of Southampton, IDS Building, Southampton General Hospital, Southampton, SO16 6YD, UK; 3) Wessex Clinical Genetics Service, University Hospital Southampton NHS Foundation Trust, Princess Anne Hospital, Coxford Road, Southampton, UK; 4) Wessex Regional Paediatric Nephro-Urology Service, Southampton Children's Hospital, Southampton, UK and Faculty of Medicine, University of Southampton.

Deletions in the Xq22.3 – Xq23 region, inclusive of *COL4A5*, have been associated with a contiguous gene deletion syndrome characterised by Alport syndrome with intellectual disability (Mental retardation), Midface hypoplasia, and Elliptocytosis (AMME). The extra-renal biological and clinical significance of neighbouring genes to the Alport locus has been largely speculative. Whole exome sequencing was undertaken on maternal half siblings presenting with a phenotype of nephrocalcinosis, early speech and language delay and midface hypoplasia with submucous cleft palate and bifid uvula. In-house genomic analysis included extraction of all shared variants on the X chromosome in keeping with X-linked inheritance. Patient specific mutants were transfected into three cell lines and microscopically visualised to assess the nuclear expression pattern of the mutant protein. In the affected half-brothers, we identified a hemizygous novel nonsynonymous variant of unknown significance in *AMMECR1* (c.G530A; p.G177D), a gene residing in the AMME disease locus. Transfected cell lines with the p.G177D mutation showed aberrant nuclear localisation patterns when compared to the wildtype. Both brothers were then tested for elliptocytosis, which was present in the older sibling. Our study shows that a single missense mutation in *AMMECR1* causes a phenotype of elliptocytosis, midface hypoplasia and mild intellectual disability, previously reported as part of a contiguous gene deletion syndrome. Functional analysis confirms mutant-specific protein dysfunction. We conclude that *AMMECR1* is a critical gene in the pathogenesis of AMME, causing early speech and language delay, infantile hypotonia, midface hypoplasia, elliptocytosis, nephrocalcinosis, sensorineural hearing loss and submucous cleft palate.

2618T

A novel missense mutation in *PUF60* causes syndromic intellectual disability. *D.K. Bourque[1,2], K. Kernohan[3], T. Hartley[3], D. Pohl[1,2,3], K. Boycott[1,3], D. Dyment[1,3], Care4Rare Consortium.* 1) Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 2) University of Ottawa, Ottawa, Ontario, Canada; 3) Children's Hospital of Eastern Ontario Research Institute, Ottawa, Ontario, Canada.

Intellectual disability (ID) affects 1-3% of the general population and up to 50% of those affected have an underlying genetic cause. Next-generation sequencing offers an efficient means to identify the underlying molecular causes of syndromic ID. Our patient presented to Genetics at 17 years of age with a history of a complex, syndromic form of ID. On past history, she was born to a healthy woman, induced at 36 weeks gestational age after a pregnancy complicated by severe intrauterine growth restriction (IUGR). Her neonatal period was characterized by poor weight gain, hypotonia and congenital ptosis. In childhood, she experienced significant global developmental delay, as well as generalized tonic-clonic seizures, hypothyroidism, delayed puberty, scoliosis, and a fatty infiltration of the filum terminale. At last assessment, she continues to have short stature, microcephaly, and dysmorphic features (including bilateral ptosis, synophrys, flattened nasal bridge, and long philtrum). Comprehensive standard and targeted cytogenetic, molecular, biochemical, and metabolic workups over the course of her life did not reveal a cause for her disorder. She was enrolled in the Care4Rare Consortium and whole exome sequencing was performed on both her and her unaffected parents. She was found to have a de novo missense mutation in exon 6 of *PUF60* (c.G389A, p.Arg130His) on chromosome 8q24.3. This variant had never been seen in our local database, 1000 Genomes, EVS or ExAC. SIFT, PolyPhen-2, and CADD scores were all predicted to be deleterious. *PUF60* is a splicing factor involved in several nuclear processes, including transcriptional regulation. Haploinsufficiency of *PUF60* has been implicated in the phenotypic manifestations of the 8q24.3 deletion syndrome. An SNV in *PUF60* (c.C505T, p.His169Tyr) has been reported in one other individual, who had similar features to our patient (IUGR, postnatal growth retardation, microcephaly, global developmental delay, seizures, scoliosis, fatty filum terminale, and tethered cord); although, it was not associated with any endocrinologic abnormalities (Dauber *et al.* 2013). Functional analysis of that mutation revealed a loss of function effect on the PUF60 protein. Functional validation studies of our newly reported mutation are ongoing.

2619F

De novo **deleterious variants in *SON* are the cause of syndromic intellectual disability.** *M. Tokita[1,2], A. Braxton[1,2], Y. Shao[1,3], A. Lewis[1,3], M. Vincent[4], S. Küry[4], T. Besnard[4], B. Isidor[4,5], X. Latypova[4], S. Bézieau[4], P. Liu[1,2], C. Motter[6], C. Melver[6], N. Robin[7], E. Infante[8], M. McGuire[2,8], A. El-Gharbawy[8], R. Littlejohn[9], S. McLean[9], W. Bi[1,2], C. Bacino[1,3], S. Lalani[1,3], D. Scott[1,3,10], C. Eng[1,2,3], Y. Yang[1,2,11], C. Schaaf[1,3,11], M. Walkiewicz[1,2].* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Miraca Genetics Laboratories, Houston, TX; 3) Texas Children's Hospital, Houston, TX; 4) CHU de Nantes, Service de Génétique Médicale, Nantes, France; 5) INSERM, UMR-S 957, Nantes, France; 6) Genetic Center, Akron Children's Hospital, Akron, OH; 7) Department of Genetics, University of Alabama, Birmingham, AL; 8) University of Pittsburgh School of Medicine, Children's Hospital of Pittsburgh, Pittsburgh, PA; 9) Children's Hospital of San Antonio, San Antonio, TX; 10) Department of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX; 11) Jan and Dan Duncan Neurological Research Institute, Texas Children's Hospital, Houston, TX.

Through its role as a mediator of constitutive and alternative splicing, the SON protein influences diverse cellular processes including cell cycle progression, genomic integrity, and maintenance of stem cell pluripotency. In spite of the clear functional importance of SON, the phenotypic effects of deleterious variants in the *SON* gene have not been clearly established. In our WES cohort of over 6,000 individuals, we identified six patients with *de novo* truncating variants in *SON*. The detected variants included one nonsense variant in exon 3, three distinct frameshifting variants in exon 3, and one frameshifting variant in exon 4. We then identified an additional subject with two *de novo* missense variants in exon 3 in *cis* configuration. Further analysis revealed substantial phenotypic overlap among the seven patients with *SON* variants. All seven patients had developmental delay and/or moderate-severe intellectual disability. Three of the seven patients had a history of regression, three had a diagnosis of autism spectrum disorder, and four had documented EEG abnormalities. Of six patients evaluated, five had findings suggestive of cerebral volume loss on imaging. All seven patients had a history of severe feeding difficulties. Variable congenital malformations were also present in the cohort. Mildly dysmorphic features were apparent in all seven patients, the majority of whom had midface retrusion with deep set eyes, down-slanting palpebral fissures, and a smooth or short philtrum. To further explore the potential clinical relevance of *SON*, we reviewed published reports of individuals with copy number variants encompassing *SON*. An analysis of eight phenotypically characterized patients with deletions of *SON* less than 5 Mb in size revealed a severe phenotype that was highly consistent with the features observed in our cohort. Developmental delay, brain anomalies, poor feeding, and congenital malformations were all common among the microdeletion patients. Collectively, this data suggests that deleterious variants in *SON* are the cause of a severe multisystem disorder characterized by intellectual disability, congenital anomalies, and feeding difficulties. Furthermore, the phenotypic overlap between patients with sequence variants and those with microdeletions indicates haploinsufficiency may be the mechanism of disease causation, however, further work will be necessary to confirm this.

2620W

Missense mutations in the *PLK4* gene identified in a patient with autosomal recessive microcephaly and chorioretinopathy. *M. Tsutsumi[1], S. Yokoi[1,2], F. Miya[3,4], M. Miyata[5], M. Kato[6,13], N. Okamoto[7], T. Tsunoda[3,4], M. Yamasaki[8], Y. Kanemura[9,10], K. Kosaki[11], S. Saitoh[12], H. Kurahashi[1].* 1) Division of Molecular Genetics, ICMS, Fujita Health University, Toyoake, Japan; 2) Department of Pediatrics, Nagoya University Graduate School of Medicine, Nagoya, Japan; 3) Department of Medical Science Mathematics, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan; 4) Laboratory for Medical Science Mathematics, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; 5) Department of Pediatrics, Fujita Health University School of Medicine, Toyoake, Japan; 6) Department of Pediatrics, Yamagata University Faculty of Medicine, Yamagata, Japan; 7) Department of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan; 8) Department of Pediatric Neurosurgery, Takatsuki General Hospital, Osaka, Japan; 9) Division of Regenerative Medicine, Institute for Clinical Research, Osaka National Hospital, National Hospital Organization, Osaka, Japan; 10) Department of Neurosurgery, Osaka National Hospital, National Hospital Organization, Osaka, Japan; 11) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan; 12) Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 13) Department of Pediatrics, Showa University School of Medicine, Tokyo, Japan.

It has been well documented that mutations in genes encoding centrosomal proteins cause primary autosomal recessive microcephaly, although the association between centrosomal defects and the etiology of microcephaly syndromes is not fully understood. Recently, mutations in the *PLK4 (polo-like kinase 4)* gene, one of the key regulators of centriole duplication, identified in patients with microcephaly, growth failure and retinopathy has been reported. In this study, we performed whole exome sequencing analysis of an autosomal recessive microcephaly and chorioretinopathy (MCCRP2 [MIM616171]) patient and identified novel compound heterozygous mutations in the *PLK4* gene. One of these mutations, c.442A>G (p.(M148V)), resides in the kinase domain, and the other, c.2336G>A (p.(C779Y)), in the polo-box domain. Lymphoblastoid cell line derived from this patient showed that 25% of the mitotic cells had an aberrant spindle morphology, whereas >90% of the control mitotic cells were bipolar. Overexpression experiments of the mutant PLK4 proteins demonstrated that the p.C779Y had no effect on centriole amplification, suggesting a loss of function in centriole duplication. On the other hand, overexpression of the p.M148V proteins could amplify the centrioles and produce excess centrosomes to the same extent as wild-type PLK4. HeLa lysates transfected with the PLK4 expression plasmids were analyzed on a western blot. The altered mobility pattern of both mutant proteins further suggested alterations in post-translation modification, indicating that the p.M148V mutant is not functionally equivalent to wild-type PLK4. Our data lend support to the hypothesis that impaired centriole duplication caused by *PLK4* mutations may reduce mitosis efficiency, thereby inducing cell death or reduced cellular proliferation during early embryogenesis which is involved in the etiology of microcephaly disorder.

2621T

De novo *ACTB* and paternally inherited *COL13A1* missense mutations in a very atypical Baraitser-Winter syndrome case with familial history of joint hypermobility. *D.T. Uehara[1], S. Hayashi[1,2,3], K. Tanimoto[1], Y. Chinen[4], J. Inazawa[1,2,5].* 1) Department of Molecular Cytogenetics, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan; 2) Hard Tissue Genome Center, Tokyo Medical and Dental University, Tokyo, Japan; 3) Department of Neurobiology, Yale University School of Medicine, New Haven, CT, USA; 4) Department of Pediatrics, Faculty of Medicine, University of the Ryukyus, Nishihara, Japan; 5) Bioresource Research Center, Tokyo Medical and Dental University, Tokyo, Japan.

Among 645 Japanese subjects with intellectual disability (ID) and multiple congenital anomalies of unknown etiology screened by multiple microarray platforms, we detected a male patient with a total length of 40 Mb of runs of homozygosity (ROH) regions using SNP array. The proband is a familial case of joint hypermobility, where the father, an aunt and great grandfather from the paternal side were also affected. Additionally, he presented a few features resembling Aarskog-Scott syndrome (OMIM #305400) such as ID, short stature, brachydactyly, shawl scrotum, and hyperactivity. However, an investigation of *FGD1* had been previously performed, with negative results. In order to investigate recessive mutations harbored in the ROH regions, whole-exome sequencing (WES) was performed in the parent-child trio. Although no candidate gene lying in the ROH regions could be identified, two genes elsewhere with missense mutations emerged as the most plausible candidates: a *de novo ACTB* mutation (c.616C>T, R206W) and a paternally inherited *COL13A1* mutation (c.478G>A, G160S), both predicted as probably damaging according to *in-silico* tools. Gain-of-function missense mutations in *ACTB* have been associated with Baraitser-Winter syndrome (OMIM #243310), characterized by ID, hypertelorism, broad nose with large tip and prominent root, arched eyebrows, ptosis, iris or retinal coloboma, and pachygyria. The last three features are the most prominent and characteristic of Baraitser-Winter syndrome; however, none of them are present in our patient. *COL13A1* encodes the alpha chain of one of the nonfibrillar collagens and might be related to the joint hypermobility shown by the affected individuals from the paternal side, although it is unclear whether the mutation is segregating in the family. This case illustrates the various shifts in the diagnostic hypothesis before reaching a more accurate diagnosis after WES.

2622F

LRP4 mutations in bilateral renal agenesis with severe limb deficiencies. *A. Jacquinet[1,4], A. Lee[2], A. Swenerton[3], M.S. Patel[1], S. Langlois[1].* 1) Department of Medical Genetics, University of British Columbia, Vancouver, Canada; 2) Department of Pathology and Laboratory Medicine,University of British Columbia, Vancouver, Canada; 3) Provincial Medical Genetics Program, BC Children's & BC Women's Hospitals, Vancouver, Canada; 4) Department of Medical Genetics, University of Liège, Liège, Belgium.

   Introduction : Severe limb deficiencies have been reported in association with bilateral renal agenesis in several syndromes. Recently, truncating mutations in *LRP4* have been associated with a lethal autosomal recessive form of Cenani-Lenz syndrome (CLS). The objectives of our study was to delineate the phenotype of the third fetus, and through a search of syndromes, identify a group of disorders with overlapping phenotypes that may be allelic with CLS or due to mutations in the same pathway.   **Results :** A male fetus at 22 weeks' gestation was found to have bilateral renal agenesis by ultrasound. The pregnancy was interrupted and autopsy and skeletal survey revealed shortening of forearms and legs below the knees, radioulnar synostosis, foreshortened triangular shaped tibia and fibula, and oligosyndactyly with disorganized metacarpals, metatarsals and phalanges. Bilateral renal agenesis, absent ureters and small bladder were confirmed. Additional features included downslanting palpebral fissures, high-arched palate, small mouth, low-set and posteriorly rotated ears, nuchal oedema, pulmonary hypoplasia, hypospadias and absent olfactory nerves. An autosomal recessive disorder was suspected, given a prior obstetric history of termination at 18 weeks for unilateral limb anomalies and cleft lip. Based on the aforementioned renal and limb anomalies, the lethal form of CLS was considered. Sequencing of *LRP4* identified a paternally inherited variant (c.919+3G del) and a maternally inherited variant (c.4808T>A ;p.Ile1603Val). Both variants were rare in the general population and bioinformatically predicted to be damaging. We compared the phenotype with the two previously reported fetuses as well as with syndromes and disorders that may present prenatally with genitourinary anomalies plus acromesomelia of upper and lower limbs. We found significant overlap with a subset of cases of acro-renal-uterine-mandibular syndrome presenting with high-arched palate plus or minus micrognathia and microglossia, severe limb anomalies affecting the middle and distal segments, oligosyndactyly, renal agenesis, uterine anomalies and absence of olfactory nerves.   **Conclusion :** Based on the clinical features seen in three lethal cases of CLS, we propose that acro-renal-uterine-mandibular syndrome may be allelic with CLS or due to mutations in the molecular pathway involving *LRP4*.

2623W

Whole exome sequencing identifies moderate *GLMN* variants from sporadic Bean's syndrome. *L. Hu[1], J. Yin[1], K. Wu[1], Z.P. Qin[2], X.Y. Kong[1].* 1) Institute of Health Sciences, Shanghai, Shanghai, China; 2) Linyi Cancer Hospital, Linyi, Shandong.

   Bean's Syndrome or Blue Rubber Bleb Nevus Syndrome (BRBNS) mostly affects skin and gastrointestinal tract in early childhood. BRBNS is a rare venous malformation associated disorder, which has similar histological features to venous malformation (VM). Therefore, the two disorders might have similar underlying pathogenesis mechanism. Both familial and sporadic VM can be explained by mutations in *TEK*, the etiology of BRBNS is still undetermined so far. In addition, somatic mutations in *PIK3CA* have also been identified as causative factor in *TEK* mutation negative sporadic VMs. We applied whole exome sequencing to one sporadic VM and two sporadic BRBNSs with blood-derived samples as normal control. One of the BRBNSs was performed as parent-offspring-trio. After variant calling, we filtered the variant list against dbSNP138, 1000 Genome, ESP6500 for novel or rare variations and we only focused on protein-altering variations, such as missense, nonsense, frameshift and splicing site mutations. After that we identified one somatic *TEK* (c.2740C>T, p.L914F) from the sporadic VM affect, which has been proven to be causative. In addition, we identified one rare *GLMN* missense and one novel *GLMN* nonsense mutation from the unrelated BRBNS affects, respectively. However, incomplete penetrance was shown in one *GLMN* mutation carrier. Based on the whole exome sequencing, we found that the estimated cellularity of lesion tissues was about 0.3 and both VM and BRBNSs did not suffer from genomic instability. Because both *TEK* and *PIK3CA* positive VM affects have abnormal mTOR signaling, we supposed that abnormal mTOR might also invloved in *GLMN* mutation. In comparison to GLMN wide type, we found mTOR signaling activated much more in GLMN mutants transfected HUVECs and were sensitive to Rapamycin treatment. In addition, the symptoms of the other two independent BRBNSs were relieved, especially the gastrointestinal bleeding after Rapamycin treatment. Therefore, abnormal mTOR signaling could also be the underlying causative mechanism of BRBNSs.

2624T

SMAD2 mutations associated with DORV, other congenital heart anomalies, seizures, developmental delay and microform holoprosencephaly.
M. Shinawi[1], W.K. Chung[2], D. Pineda-Alvarez[3,6], G. Douglas[3], J.J. Murphy[4], J. Shimony[5], T.L. Toler[1]. 1) Dept Pediatric Gen, Box 8116, Washington Univ, St Louis, MO; 2) Dept of Pediatric & Medicine, Columbia University Medical Center, New York; 3) GeneDx, Gaithersburg, Maryland, USA; 4) Rush University Medical Center, Chicago, Illinois; 5) Dept Radiol, Washington Univ, St Louis, MO; 6) Now at Courtagen, Woburn, MA.

　　BACKGROUND: TGF-β signaling pathway is important for pattern formation and differentiation and is essential for the specification of primary body axes. Mutations in *SMAD2* have been reported in 2 patients from large cohorts of subjects with complex congenital heart disease (CHD) (DORV, dextrocardia with unbalanced complete atrioventricular canal and pulmonary stenosis), 2 patients with holoprosencephaly and more recently were associated with arterial aneurysms and dissections. **METHODS:** Whole exome sequencing (WES) was performed using Agilent Clinical Research Exome kit and Illumina HiSeq 2000 100 bp paired-end reads. Sanger sequencing was used to confirm positive exome findings. **RESULTS:** Patient 1 is a 2-year-old female who presented with a complex CHD (double outlet right ventricle (DORV), D-malposed great vessels, confluent branch pulmonary arteries, ASD, VSD, PDA, mitral and pulmonary atresia) and dysmorphic features. She later exhibited subglottal stenosis, laryngomalacia, staring spells with abnormal EEG, poor weight gain, short stature, and developmental delay. Brain MRI revealed a single central incisor and focused holoprosencephaly testing revealed a variant in *TGIF1* (c.320A>T, p.Gln107Leu) believed to be benign based on frequency in controls and previously reported functional analysis. WES identified a *SMAD2* mutation (c.475G>T, p.Glu159Ter) which was not found in the mother with the father not available for testing. Patient 2 is a 10-year-old female who also presented in first week of life with complex CHD (DORV with overriding aorta, VSD, ASD, PDA). She later exhibited developmental delay, learning disability, short stature and poor weight gain, seizures, some dysmorphic features, and mild-moderate conductive hearing loss. WES identified a *de novo* missense *SMAD2* mutation (c.935G>C, p.Cys312Ser). The mutations in our patients were not observed in 6500 individuals of European and African American ancestry in the NHLBI Exome Sequencing Project. **CONCLUSIONS:** Our data add to the accumulating evidence of the important role of SMAD2 in heart and brain malformations. We also describe the first patient, to our knowledge, with both complex CHD and holoprosencephaly associated with a *SMAD2* mutation, although the possible contribution of the *TGIF1* variant to holoprosencephaly cannot be excluded. Additional patients with *SMAD2* mutations are needed to better characterize the phenotypic and genotypic spectra of SMAD2-related disorders. .

2625F

Whole genome sequencing identifies compound heterozygous mutations in *RNU4ATAC* in a large family characterized by developmental, infectious and inflammatory disease.
Z. Deng[1], A. Almeida de Jesus[1], J. McElwee[2], R. Siegel[1], E. Hanson[1]. 1) NIAMS, National Institute of Health, Bethesda, MD; 2) Merck Research Laboratories, Boston, MA.

　　Introduction: Genome sequencing (WGS and WES) can identify monogenic disease mutations in patients with early onset symptoms suggestive of immune dysregulation. Here we report genetic findings from individuals with cognitive and skeletal defects, recurrent infection, and multisystem autoimmune disease arising in a single family. **Cases**: The three affected males were all born with intrauterine growth retardation to non-consanguineous parents. All have short stature, musculoskeletal abnormalities, developmental delays, dysmorphic features, polyendocrinopathy, combined immunodeficiency, and autoimmunity. Extensive clinical and cellular phenotyping coupled with targeted sequencing failed to yield a diagnosis. **Methods**: WGS was performed on the parents, 3 affected sons, 3 unaffected sons and 2 unaffected sisters. Variants were jointly called with the standard BWA-PICARD-GATK pipeline and the GenomeSTRiP CNV caller. A search for the likely causative mutation was performed using a combination of scripts that we developed and expert review. **Results**: High genome coverage was obtained for each sample (30X to 60X). Initial mutation searches were focused on rare protein coding changes consistent with X-linked, autosomal recessive or de novo inheritance models. No probable candidate mutations were identified. Analysis of CNV data and haplotype analysis of the X chromosome also was negative. Linkage analysis identified 4 regions in the genome with maximum LOD score achievable for the given pedigree. One of the candidate regions on chr2 harbors a non-coding RNA gene, *RNU4ATAC*, that plays an essential role in splicing minor introns found in about 800 human genes recently linked to Roifman Syndrome. The remarkable clinical similarities of our patients to Roifman Syndrome suggested *RNU4ATAC* as a likely candidate gene. We found two rare mutations in this gene that segregated with the disease: c.[13C>T] and c.[116A>C]. The first mutation has been reported as pathogenic in Roifman Syndrome. The second mutation is of unknown significance but it resides right next to a gene region critical to Sm protein-binding. It is also extremely rare (absent in public databases and more than 3700 internal WGS controls). **Conclusions**: Using WGS and mutation analysis, we have found the likely disease-causing mutations in patients with clinical features consistent with Roifman syndrome. Functional studies are currently underway to understand the effect of these mutations on immune cell function. .

2626W

Second-site mutations in a patient with KID syndrome cause reversion of the dominant mutation p.D50N in *GJB2* by inhibition of gap junction channels formation. *S. Gudmundsson[1], M. Wilbe[1], S. Ekvall[1], A. Ameur[1], N. Cahill[1], L.B. Alexandrov[2], M. Virtanen[3], M. Hellström Pigg[3], A. Vahlquist[3], H. Törmä[3], M-L. Bondeson[1].* 1) Department of Immunology, Genetics and Pathology, Uppsala University, Science for Life Laboratory, Uppsala, Sweden; 2) Theoretical Biology and Biophysics (T-6), Los Alamos National Laboratory, Los Alamos, NM; 3) Department of Medical Sciences, Dermatology, Uppsala University, Sweden.

Revertant mosaicism (RM) is a naturally occurring phenomenon where the pathogenic effect of a germline mutation is corrected by a second somatic event, giving rise to a mosaic appearance. RM has been observed in several inherited conditions, including inherited skin disorders. Here, we report on RM in a Keratitis-ichthyosis-deafness (KID) syndrome patient and further investigate the underlying molecular mechanisms. The patient was diagnosed with KID syndrome at the age of 3 based on characteristic skin lesions, hearing deficiency and keratitis. Investigation of *GJB2*, encoding the gap junction channel (GJC) protein connexin 26 (Cx26), revealed heterozygosity for the recurrent *de novo* germline mutation, c.148G>A, p.D50N.   Intrudingly, at age 20, the patient started to develop spots of healthy-looking skin that grew in size and number on the inside of her thighs, within her widespread erythrokeratodermic lesions. Like 15% of reported KID syndrome patients, she developed squamous cell carcinoma (SCC). Interestingly the SCC occurred at the same location as the RM. To further investigate the mechanism, Single Molecule Real-Time (SMRT) deep sequencing was performed on cDNA and gDNA from two biopsies from healthy-looking spots, generating over 10'000 sequence reads over the *GJB2* locus in all sample.   We identified five somatic nonsynonymous mutations in frequencies between 2.4-12.5%. Three mutations have previously been reported as pathogenic, causing hearing loss, and two are novel variants predicted as disease causing. All five mutations were independently present *in cis* with the p.D50N mutation, but absent in biopsies of lesional skin. No secondary mutations could be detected on the wild-type (wt) Cx26 allele. Functional studies of Cx26 in HeLa cells displayed co-expression of Cx26-D50N and wt Cx26 in GJC plaque. However, Cx26-D50N with second-site mutations displayed no formation of GJC plaque or co-expression with wt Cx26.   Conclusively, we show that the second-site mutations inhibit Cx26-D50N expression in GJCs, which results in expression of wt Cx26 alone and the reversion of the disease-mechanism, explaining reverted skin phenotype in our patient. To our knowledge, this is the first time RM is reported in a KID syndrome patient.

2627T

Re-evaluation of a "negative" clinical exome reveals a novel candidate for cleft palate and hypertelorism. *A. Gutierrez-Uzquiza[1], D. Li[1], E. Bhoj[1,2], M. Harr[2], E. Zackai[2,3], H. Hakonarson[1,2,3,4].* 1) Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA; 3) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA 19104, USA; 4) Divisions of Genetics and Pulmonary Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA.

Whole exome sequencing (WES) has proven to be a powerful tool for diagnosis in Mendelian disorders. A few large studies on the application of WES have reported a diagnostic yield of ≈25-28%, however the difference in yield in research setting has not been fully investigated. Here we present a family with an apparently autosomal dominant form of cleft palate who tested negative on clinical WES. However, when WES data was obtained from clinical lab and re-analyzed to exclude synonymous variants, variants with minor allele frequency (MAF) greater than 0.5%, and variants previously identified in controls by our in-house exome variant database, we identified a single nucleotide substitution, c.2708C>T:p.(S903F), in *PDGFRA* gene as the most likely candidate. The patient is a 4-month-old male with developmental delay, multiple congenital anomalies (cleft palate, posterior ear pits, tethered chord/meningocele with caudal appendage and left clubbed foot and hypertelorism) and family history is significant for mother born with cleft palate and posterior ear pits and a brother with congenital hyperinsulinism. *PDGFRA* (OMIM 173490), Platelet-derived Growth Factor Receptor alpha, plays a major role in palatogenesis, craniofacial and neural crest development. *Pdgfr[-/-]* mice have complete cleft palate (CP) that results from an extracellular matrix defect within the cranial neural crest-derived palatal mesenchyme. *PDGFRA* has been associated with isolated CP, however, our family clearly expands the phenotype to include syndromic CP. This report highlights the challenges in recognizing disease variants and that "negative" exome should be worth a second look.

2628F

De novo pathogenic variants in genes associated with autosomal recessive diseases. *J. Pappas[1,4], D. McKnight[2], M.R. Hegde[3], E. Moran[4], J. Borsuk[1], K. Daley[1], E. Reich[1].* 1) Dept Pediatrics, Clin Genetic Scvs, New York Univ, Sch Med, New York, NY; 2) GeneDx, Gaithersburg, MD; 3) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA; 4) Center for Children, NYU Hospital for Joint Diseases, New York, NY.

Whole exome and whole genome sequencing in families has demonstrated significant genetic disease burden due to de novo pathogenic variants (Veltman JA et al 2012; Ku CS et al 2012). De novo single nucleotide variants have been associated with sporadic occurrence of autosomal dominant and X-linked diseases (Ku CS et al 2013). There are very few cases of autosomal recessive disease due to de novo pathogenic variants in the medical literature (Kaur J et al 2016). We present two unrelated non-consanguineous families with a child affected by autosomal recessive disease due to an inherited maternal pathogenic variant and a de novo pathogenic variant likely on the paternal allele. Case 1 is a 3 year old female with congenital cataracts, developmental delays and progressive spasticity. Whole exome sequencing of case 1 and her parents revealed compound heterozygosity in the *RAB3GAP2* gene associated with Martsolf syndrome. The p.R385C pathogenic variant was maternally inherited and the p.Q429P was de novo likely on the paternal allele. The mother was of European non-Jewish ancestry and the father of Ashkenazi Jewish and Irish ancestry. The mother's age was 31 and the father's 34 at the delivery of case 1. Clinical evaluations concurred with the diagnosis of Martsolf syndrome. Case 2 is a 15 year old male, known to us since birth, with cataracts, glaucoma, retinal detachment, osteoporosis, multiple fractures, platyspondyly, chest deformity and developmental delays. Whole exome sequencing of case 2 and his parents revealed compound heterozygosity in the *XYLT2* gene associated with SpondyloOcular syndrome. The c.1584delC pathogenic variant was maternally inherited and the c.628+2T>C was de novo likely on the paternal allele. The mother was of northern European (non-Jewish) ancestry and the father of Ashkenazi Jewish ancestry. The mother's age was 30 and the father's 34 at the delivery of case 2. The clinical diagnosis of case 2 was SpondyloOcular syndrome. Both Martsolf syndrome and SpondyloOcular syndrome are rare conditions reported in a handful of cases due to homozygous pathogenic variants/consanguinity (Handley MT et al 2013, Taylan F et al 2016, Munns CF et al 2016). Our cases demonstrate that de novo pathogenic variants can be the mechanism of rare autosomal recessive disease in the offspring of non-consanguineous couples. The de novo pathogenic variant was likely on the paternal allele in both cases. Advanced paternal age was not observed in our cases.

Mandibulofacial dysostosis with alopecia: Report of an adult case with a novel EDNRA mutation. *P. Ahimaz, A. Iglesias.* Clinical Genetics, Columbia University Medical Center, New York, NY.

Endothelin receptor type A (EDNRA) is involved in the endothelin signaling pathway. Animal models have shown that EDNRA signaling plays a prominent role in mandibular neural crest cell specification. In 2015, Gordon et. al, reported four patients with *de novo* mutations in the EDNRA gene and consistent features of mandibular dysplasia, cleft palate, eyelid anomalies, hearing loss and alopecia. The term 'Mandibulofacial Dysostosis with Alopecia' (MFDA) was coined to describe this new syndrome. Here we report a 21 year old female of Bangladeshi descent with MFDA features and developmental delay. Upon examination, she was found to have tall stature, a receding hairline, sparse eyebrows, absent lower eyelashes, mild malar hypoplasia, square nasal tip, mandibular dysplasia, cleft palate, prominent ears and tapering fingers. Further testing showed that she also has bilateral hearing loss, hypoplastic kidney and acro-osteolysis. A SNP chromosomal microarray was obtained, which was normal. Subsequent whole exome sequencing analysis revealed a novel heterozygous missense p.S168L (c.503C>T) variant in coding exon 2 of the EDNRA gene. This nucleotide substitution is in a highly conserved region and is predicted to be pathogenic. Based on the clinical and molecular findings, our patient represents the fifth reported case of MFDA and the S168L variant is the third EDNRA alteration documented to cause this rare condition. In addition to the central MFDA features of mandibular dysplasia, general hypotrichosis, hearing loss and cleft palate, our patient also had atypical findings of renal malformation and acro-osteolysis, which have not been seen with this condition previously. The novelty of the S168L variant along with the clinical features seen in our patient demonstrate possible genotype-phenotype variability associated with this newly described disorder, which has not been well explored owing to its rare incidence. Further cases will help to elucidate the genotype-phenotype correlation and expand the phenotype.

Isolated optic nerve hypoplasia in 5 family trios: A clinical and exome study. *P. Bitoun[1,2], A. Boland-Auge[3], D. Bacq-Daian[3], E. Pipiras[4], B. Benzacken[4], A. Alexander[5], S. Kuzbari[6], V. Renault[3], J.F. Deleuze[3].* 1) Groupe Medical Jarente, Génétique Médicale, Paris, France; 2) SIDVA91, Juvisy s/orge 91; 3) Centre National de Génotypage CEA, Evry 91; 4) Laboratoire d'Embryo Cyto Génétique , APHP CHU Jean Verdier, Bondy 93; 5) GeneUS, Pearlgen, Austin TX, USA; 6) Banque d'ADN, Hôpital Robert Debré, Paris.

   Purpose: Optic nerve hypoplasia (ONH) is a rare congenital malformation with severe visual incapacity.Children are often only temporarily blind at birth and progress to severe visual impairment.ONH is often syndromic (septo-optic dysplasia / de Morsier syndrome) with MRI pituitary anomalies. Our purpose is to explore currently unknown genetic causes of isolated ONH. **Material and Methods:** 5 Probands (2 females/3 males) with normal MRI and parents were enrolled in genetic study after informed consent. Pediatric, dysmorphologic and ophthalmologic examinations and endocrine work up was performed. Patients had SNP array CGH and Exome Sequencing.Male patients were genotyped for HESX. DNA was extracted from lymphoblastoid cell lines or whole blood and with stringent quality control.DNA was sequenced at a mean of 30X in > 92% of samples using an Illumina platform; Bam file coherence and duplicate elimination used Sam Tools and Picard Tools, QC used house tools and Bedtools, variant call using GATK, annotation using sfnpEff and snpSift selecting variants with severe or moderate impact, variant Filters with de novo dominant hypothesis, absence in 1k, 65k genomes and Exac databases using Gene US from Pearlgen. **Results:** Patients had normal intelligence and distance VA around 20/200 , 3 had learning difficulties, one severe dyspraxia, and one had multiple endocrine deficiencies despite normal MRI and was treated micropenis and cortisol deficiency. 3 patients had sleeping disorders treated with melatonin. No HESX mutations were identified. A single 410,4 kb deletion of the 2p26.1 was identified on SNP array CGH. All parents were healthy and 3 fathers were unavailable. Candidate genes identified by NGS exome analysis needing further Sanger validation will be presented including analysis of 46 variants in 6 genes present in at least 2 families . **Discussion:** A 2p16.1 deletion was identified on array CGH. Whole Exome NGS analysis results in 5 family trios yielded 6 novel gene candidates for optic nerve hypoplasia.

2631F

Werner´s syndrome: First case report in Colombia. *A. Rincon Bolivar[1], J.C Prieto[1,2], J.A Rojas[1].* 1) Instituto de Genetica Humana, Universidad Javeriana, Bogota, Colombia, Bogota, Bogota, Colombia; 2) Hospital la Victoria SDS, Bogota, Colombia.

   Introduction: Werner´s syndrome is an autosomal recessive genetic disease, which is mainly characterized by scleroderma-like skin alterations, juvenile cataracts and signs of premature aging. Additionally these patients have other premature complications associated with age such as atherosclerosis, diabetes mellitus, hyperlipidemia, osteoporosis and high incidence of some types of cancer. **Case presentation:** We report a case of a 48-year-old male patient, who attends our medical genetics consult because he had noticed his voice weakening with a high pitched since about the age of 35 years, associated with premature graying and skin lesions. Patient has personal history of parental consanguinity and diabetes mellitus type 2 in treatment and family history of leukemia and melanoma. Physical examination on admission revealed the main findings of Werner´s syndrome, he appeared much older than his stated age, presents sclerotic skin lesions predominantly in the feet, "bird-like facial appearance", beak-shaped nose, high-pitched voice, gray hair, bilateral cataracts, short stature and hypogonadism. He has a brother also with characteristic clinical findings of the disease but with a more severe phenotype. WRN gene sequencing identifies the homozygous variant NM_00553.4: c.2581C> T (NP_000544.2: pGln861Ter), this generates a stop codon at position 861 and has been classified as pathogenic. This truncated protein affects the helicase domain making it unable to enter the cell nucleus. Werner protein plays a critical role in maintain the structure, integrity and repairing DNA. Patient monitoring continues without reporting other associated complications such as osteoporosis and cancer. **Discussion:** In conclusion this is the first reported case of Werner´s syndrome in the Colombian population, in whom clinical phenotype is similar to previously reported in other populations. We report this case because of the low frequency of this disease to avoid misdiagnosis and allow taking preventive measures in these patients to promptly identify complications associated with age, especially malignancies.

National Institute on Aging Cell Repository. *F. Rahimov, A. Green.* Coriell Institute for Medical Research, Camden, NJ.

The NIA Aging Cell Repository is a resource facilitating cellular and molecular research studies on the mechanisms of aging and the associated degenerative processes. The Repository was established in 1974 and the cells in this resource have been collected using strict diagnostic criteria and banked under the highest quality standards of cell culture. The collections of the Repository include highly-characterized, viable, and contaminant-free cell cultures for research on such diseases as Alzheimer disease, Progeria, Parkinsonism, Werner syndrome, and Cockayne syndrome as well as Gerontology Research Center samples from the Baltimore Longitudinal Study of Aging, the Longevity Collection including the Aged Sib Pair Collection, the Adolescent Study, Apparently Healthy Controls, Animal Models of Aging and both human and animal differentiated cell types. Cell lines and DNA may be used by academic and commercial entities. Biospecimens requested by academic/government/non-profit investigators are provided at no cost to the user. In addition, the Repository utilizes secure laboratory information management systems to monitor inventory and distribution of samples. The full catalog can be accessed at https://catalog.coriell.org/1/NIA.

2633T

Understanding the genetic basis of very early onset inflammatory bowel disease (vIBD). *J. You[1,2], N. Sobreira[2,3], D. Valle[2,3], A. Guerrerio[4].* 1) Predoctoral Training Program in Human Genetics, Johns Hopkins University School of Medicine, Baltimore, MD 21205, USA; 2) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD 21205, USA; 3) Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD 21205, USA; 4) Pediatric Gastroenterology and Nutrition, Johns Hopkins Children's Center, Baltimore, MD 21205, USA.

vIBD has an age of onset of < 6 years of age and a severe course. These features suggest a strong genetic contribution to the etiology of vIBD. As part of the Baylor Hopkins Mendelian Genomics Center, we are performing whole exome sequencing (WES) on 58 vIBD probands (38 probands are from multiplex families [4 likely autosomal dominant and 32 likely autosomal recessive] and 20 are isolated cases). Currently, we have completed WES on 27 probands and analyzed them by selecting rare (MAF <1%) functional variants (missense, nonsense, frameshift and splicing). We identified 5 heterozygous missense variants in genes associated with disorders already known to be associated with vIBD such as *NOD2* (3 probands), *PLCG2* (1 proband), *GUCY2C* (1 proband). One variant, *NOD2*-Q574X, is not present in ExAC, HGMD and ClinVar; another, *NOD*-R311W, has a MAF of 0.05% in ExAC, is classified as variant of uncertain significant in HGMD and not present in ClinVar; and a third, *NOD2*-E778K, has a MAF of 0.02% in ExAC and is not present in HGMD and ClinVar. The *PLCG2*- Y482H variant has a MAF of 0.3% in ExAC and is not present in HGMD and ClinVar. The *GUCY2C*-N689K variant has a MAF of 0.4% and is not present in HGMD and ClinVar. Segregation analyses of these variants in available family members showed imperfect segregation suggesting incomplete penetrance. Our analysis also identified a novel candidate gene, *ZNF275* (p.V12I), in one family. *ZNF275* is an X-linked gene previously associated with immunodeficiency by a GWAS. This variant was also present in the affected brother and unaffected mother and was not present in the unaffected father and sister. We also investigated genes that were mutated in two or more probands and identified *TDRKH* as a novel candidate gene. Two unrelated probands are compound heterozygous for, p.A359V and p.A359S in *TDRKH*. Both have a MAF of 0.5% in ExAC and neither are present in HGMD and ClinVar. We plan to perform additional analyses including a polygenic analysis, in which we investigate the same sets of genes mutated in two or more families; and a pathway analysis, searching for involvement of the same pathway in multiple affected families.

2634F

Whole genome sequencing reveals a novel *FOXP3* frame-shift mutation responsible for fetal demise in a large multigenerational pedigree of recurrent male intrauterine fetal death. *D.J. Tester[1], N.C. Ackerman[1], F.S. Cowchock[2], M.J. Ackerman[1].* 1) Cardiovascular Diseases, Mayo Clinic, Rochester, MN; 2) Center for Aging and Human Development, Duke University Medical School, Durham, NC.

Intrauterine fetal death (IUFD) or stillbirth occurs in approximately one out of every 160 pregnancies and accounts for 50% of all perinatal deaths. Post-mortem evaluation often fails to elucidate an underlying cause in many IUFD cases. Approximately 25% of IUFD have been attributed to genetic etiologies. Here, whole genome sequencing (WGS) was used to identify the underlying genetic cause for recurrent second trimester IUFD of males in a multigenerational pedigree. There were a total of 12 male cases of IUFD. Most deaths occurred at ≤ 20 weeks gestation. Hydrops fetalis was diagnosed at death in the most recent case. A fetal whole genome chromosome microarray analysis was normal. WGS was performed on DNA from 5 healthy obligatory carrier females and an unaffected male offspring of a carrier. Following variant filtering based on a recessive X-linked inheritance pattern, a rare FOXP3 frame-shift mutation (p.D303fs) that results in a premature truncation of the protein was discovered. Sanger sequencing confirmed the mutation in the affected fetus. The *FOXP3* gene encodes for a transcriptional regulator critical to the function of T-regulatory cells. FOXP3 mutations are associated with immune dysregulation, polyendocrinopathy, enteropathy, X linked (IPEX) syndrome which predominantly affects males and may present with a potentially life-threating complex autoimmune disorder in early childhood. Recent case reports have described FOXP3 mutations in three additional families with recurrent IUFD in males. Hydrops fetalis has been diagnosed in affected fetuses due to severe autoimmune hemolytic anemias. Here we demonstrate the utility of WGS-based pedigree analysis to identify the genetic cause for recurrent IUFD when chromosome studies, including microarray analysis, are normal. FOXP3 mutational analysis should be considered in cases of male IUFD. Further studies are needed to determine the prevalence of FOXP3 mutations in IUFD.

2635W

Multidisciplinary Mendelian gene discovery and clinical translation. *N.Y. Frank[1,2], N. Stitziel[1,3], S. Chopra[1], N. Carmichael[1], E. Hoffman[1], E. Krieg[1], J. Krier[1,2], S.R Sunyaev[1,2], R.L. Maas[1], D. Vuzman[1,2], Brigham Genomic Medicine.* 1) Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 2) Broad Institute of MIT in Harvard, Cambridge, MA; 3) Cardiovascular Division, Washington University School of Medicine, St. Louis, MO.

Despite major progress in defining the genetic basis of diverse Mendelian diseases, the molecular etiology of many cases remains unknown. Brigham Genomic Medicine (BGM) is an ongoing collaboration between clinical geneticists, computational biologists, and basic researchers aimed at identification of novel genes responsible for distinct familial disease phenotypes encountered in clinical practice. BGM has developed a unique genomic analysis pipeline which won the international 2012 CLARITY Challenge and has now been successfully used to solve undiagnosed cases, even when prior WES/WGS analyses have been unrevealing. Here we present three novel clinical cases where WGS followed by experimental validation led to successful genetic diagnosis with important implications for patient care. In one case, a family was referred to the BGM for a multigenerational history of aortic aneurysms and dissections. WGS in two first cousins with aortic dissection revealed a missense mutation in the lysyl oxidase (LOX) gene. In a second case, WGS revealed mutation in the WISP3 gene in a 34 year old male with precocious polyarthritis previously mis-attributed to rheumatoid arthritis. Lastly, in a third illustrative case, a missense mutation in the gene encoding complement component 3 (C3) was identified in a family with a novel hereditary syndrome of paroxysmal digital ischemia. In all three cases, these disease gene discoveries not only informed family members about genetic risk, but also led to the development of patient-specific guidelines for clinical management. These cases illustrate how genetic resolution even in long-standing individual cases of previously undiagnosed disease can have unexpected beneficial consequences.

2636T

Case vignettes of clinical and genetic disease discovery at the Stanford Center for Undiagnosed Diseases. *P. Zornio[1,2], J. Kohler[1,2], A. Dries[1,2], D. Waggott[1,2], L. Fernandez[1], E. Ashley[1,2,5], P. Fisher[1,3], J. Bernstein[1,4], M. Wheeler[1,2], Members of the UDN.* 1) Stanford Center for Undiagnosed Diseases, Stanford University, Stanford, CA; 2) Division of Cardiovascular Medicine, Stanford University, Stanford, California; 3) Department of Neurology, Stanford University, Stanford, California; 4) Department of Pediatrics, Stanford University, Stanford, California; 5) Department of Genetics, Stanford University, Stanford, California.

The Stanford Center for Undiagnosed Diseases (SCUD) is designed for patients with rare and undiagnosed diseases when standard clinical options have been exhausted. In collaboration with the National Institutes of Health, the Undiagnosed Diseases Network is comprised of 7 Clinical Sites (including the Stanford Center for Undiagnosed Diseases), 2 Sequencing Cores, one Model Organism Core, one Metabolomics Core, one Central Biorepository, and one network-wide Coordinating Center. The objectives are to 1) Provide answers to patients with mysterious conditions that have long eluded diagnosis, and 2) Advance medical knowledge about rare and common diseases. Since our launch in September, 2015, the SCUD has over two dozen active cases, with approximately 1/3 of patients receiving a clinical and/or molecular diagnosis. Here we present several vignettes of our first cases to demonstrate the novel approaches to diagnosis, in particular relating to novel genetic disease discovery.

2637F

CRISPR/Cas9 as a therapeutic tool for the germline correction of the BBS1 M390R mutation. *M. Cring, C. Searby, C. Carter, V. Sheffield.* University of Iowa, Iowa City, IA.

Bardet-Biedl Syndrome (BBS [MIM 209900]) is a pleiotropic disorder that results in a variety of phenotypes in humans and animal models including blindness, male infertility, polydactyly, intellectual disability, hydrocephalus, and obesity. BBS is a model ciliopathy, which affects approximately 1 in 1000 people worldwide. No current efficient treatments for ciliopathies exist, illustrating a critical need for the development of new therapeutic strategies. The most common cause of BBS is the M390R mutation in the *BBS1* gene (BBS1 [MIM 209901.0001]), which is implicated in approximately 25% of all molecularly diagnosed BBS cases. BBS1 is an essential component of the BBsome that is required for basal body and ciliary function. The BBS1 M390R mutation leads to the classic aforementioned phenotypes of BBS, including the lack of flagellar formation in spermatogenesis. Immunocytochemical analyses have shown that sperm cells in a mouse model of M390R are completely devoid of flagella. Our objective is to implement gene editing techniques using CRISPR/Cas9 to rescue flagellar formation in spermatocytes *in vitro* and *in vivo* in the *Bbs1*$^{M390R/M390R}$ mouse model. We have produced several CRISPR/Cas9 constructs in saCas9 and spCas9 plasmids targeting near the M390R locus in the mouse *Bbs1* gene, including an allele specific gRNA. Using cell free cleavage assays, we have identified several constructs that efficiently cleave near the M390R codon. On going work is aimed at rescuing flagellar formation *in vitro* by culturing primary testicular cells from *Bbs*$^{M390R/M390R}$ mice. These cells are electroporated with CRISPR/Cas9 constructs and single-stranded oligonucleotide homologous donor templates (ssODNs). The cells will be tested for functional rescue of flagellar formation by immunocytochemistry. On going work is also aimed at functional rescue of *Bbs1*$^{M390R/M390R}$ *in vivo* by injection and electroporation of *Bbs*$^{M390R/M390R}$ mouse testes with the CRISPR/Cas9 constructs and ssODNs. Functional *in vivo* rescue will be determined by successful impregnation of female mice, as well as by histology. By correcting the germline *in vivo*, all downstream progeny should be corrected. This study will provide data on the efficacy of *in vivo* germline correction.

2638W

Penetrance in the EHR record of 76 DiscovEHR Cohort participants with two recurrent pathogenic variants. *K. Manickam[1], D. Hartzel[1], N. Abdul-Hsun[2], F. Dewey[2], D. Lindbuchler[1], M. Barr[1], A. Lazzeri[1], M. Hallquist[1], A. Buchanan[1], W.A. Faucett[1], M. Murray[1]. 1) Precision Health Center, Geisinger Medical System, Forty Fort, PA; 2) Regeneron Genetics Center, Tarrytown, NY.*

Participants in the Geisinger Regeneron DiscovEHR cohort will only receive incidental or secondary genomic findings that are classified by stringent criteria as pathogenic/likely pathogenic (P/LP). Early return of results efforts have focused on two disorders: Familial Hypercholesterolemia (FH; *LDLR, APOB, PCSK9*) and Hereditary Breast and Ovarian Cancer (HBOC; *BRCA1, BRCA2)*. The identification of a P/LP variant is not sufficient to establish a condition diagnosis. We examined de-identified EHR records for evidence of penetrance in carriers of two specific P/LP variants in 76 unrelated participants with either: *BRCA2* 5722_5723delCT and *APOB* c.10580G>A. In total, there were 24 carriers of the *BRCA2* variant and 52 carriers of the *APOB* variant. We used established criteria for diagnosis of these disorders, which are based on signs, symptoms, and family history. In FH, three established diagnostic criteria are used to determine pre-test risk. All three criteria use cholesterol level and family history to assess risk (some use additional phenotypic information). For HBOC risk, criteria use personal history of cancer and family history to determine prior probability of a variant. Among the *APOB* variant carriers, 79% had hypercholesterolemia and this together with the sequence variant met minimal criteria set for FH diagnosis. This was a significantly higher percentage meeting FH diagnosis compared to other *APOB* variant carriers (43%, n=53) in the same cohort. Among the *BRCA2* variant carriers, 13% of females had a personal history of cancer consistent with the diagnosis. Overall the current age of BRCA2 is 59 and 37.5% were male. In analysis of available family history, 10 were seen for a clinical visit and a full pedigree was taken as the gold standard. In this group, only 40% had a family history that would indicate high risk for HBOC. All 76 patients with these variants will be re-contacted and offered in person visits for targeted phenotyping. We anticipate that the penetrance ascertainment will be increased through this clinical engagement effort. EHR based phenotypes in the DiscovEHR cohort for these recurrent P/LP variants in 2 genes on the ACMG 56 list are noted to have reduced penetrance. The return of results efforts in this cohort will allow for a calculation of penetrance in the pre-return EHR record as compared to penetrance in the post-return record.

2639T

***In silico* models for genotype/phenotype correlations of *F9* gene mutations causing severe Hemophilia B.** *L. Meléndez-Aranda[1,2], A.R. Jaloma-Cruz[2], M.M. Romero-Prado[1]. 1) Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Jalisco, México; 2) Centro de Investigación Biomédica de Occidente, Guadalajara, Jalisco, México.*

Introduction and Objective: *In silico* modeling of the amino acid substitutions found in Hemophilia B may identify the structural and functional effects on the mature FIX protein. In this work we apply informatics tools to describe the genotype/phenotype possible correlations of selected *F9* gene mutations at exons 2 and 3 causing severe hemophilia B and their effect on the structure and function of the propeptide and Gla domains of FIX protein. **Materials and methods**: Severe phenotype-associated mutations at exons 2 and 3 of *F9* gene were selected from the current Haemophilia B Mutation Database (http://www.factorix.org/). The PolyPhen program was used to perform multiple sequence alignments using the structural information of FIX protein (Polymorphism Phenotyping, http://genetics.bwh.harvard.edu/pph2/). The theoretical three-dimensional (3D) structure analysis of *F9* missense mutations was performed with the Swiss Model Workspace platform (http: //swissmodel.expasy.org/workspace/). **Results:** The PolyPhen program showed that amino acids in positions V30 and R46 (propeptide) as well as G58 and Y84 (Gla domain) are all highly conserved and have a probability of deleterious effect higher than 0.998 if replaced. The Swiss program revealed that the selected mutations in exon 3 affect the hydrogen bonding network of the Gla domain; in turn, this impairs the orientation of side chains of amino acids and their normal conformational structure (omega loop between amino acids at 3 to 11 positions) for binding to calcium, which is critical for interaction with phospholipids in platelet membranes. The limitations of the 3D structural analysis by crystallography (Swiss Model Workspace) prevented us to assess the effect of amino acid substitutions at the propeptide, which nevertheless has a strong impact on the structure and function of the mature FIX. **Conclusions**: Selected mutations in the propeptide and Gla domains affect highly conserved amino acids and have a significant functional effect on the carboxylation of glutamic acid residues via disruption of the interaction of mature FIX with platelets. The inclusion of the FIX propeptide in the established informatics models would have a strong impact on the structure and function of the FIX protein analysis.

The Israeli national genetic carrier screening program: Experience and outcome, CF and SMA as examples. *A. Singer[1], I. Grotto[2], P. Stafler[3], C. Vinkler[4].* 1) Department of Community Genetics,, Public Health Services, Ministry of Health, Tel Aviv, Israel; 2) Public Health Services, Ministry of Health, Jerusalem, Israel; 3) Cystic Fibrosis Center, Schneider Children's Medical Center of Israel, Petach Tikva, Israel; 4) Inst Medical Genetic Wolfson Medical Center, Holon, Israel.

The Israeli population is combined of various ethnic groups which are quite conserved. These groups are Jewish (Ashkenazi and non-Ashkenazi) and arabs (Muslem, Christian and Druze). High frequency of genetic diseases is unique to the Israeli population as a result of its religious isolated small communities, and high rate of consanguinity. Founder mutations are known to be present in these communities and were identified over the years (e.g. Tay Sachs). With the possibility to perform a molecular diagnosis of many genetic diseases, many disorders became candidates for screening. The Israeli Society of Medical Geneticists (ISMG) made recommendations to expand the carrier screening program and include all of the severe genetic diseases in which the carrier frequency has 1:60. These recommendations were accepted by the Israeli MOH and today 18 tests are offered free of charge to the general population. The program offers carrier screening for cystic fibrosis, fragile X, and spinal muscular atrophy for the general population and additional tests for severe diseases with high carrier frequency to specific ethnic groups according to the frequency of founder mutation in each group. Methods: Tests are offered by the primary physician as part of preconception recommendations. Pretest information are given by trained professionals. Carriers are referred to genetic counseling for discussion of pre-gestational and prenatal tests options. Fetal diagnostic tests (PGD, CVS/Amnio.) are included in the Israeli national health basket. Results: More than 400,000 tests were done during 2013-2014 for the above 18 traits. Of these 117,291 were CF carrier screening tests. The CF registry proves the impact of this program showing a marked reduction in CF birth rates from 14.5:100,000 live birth to 6:100,000 live birth during the last 20y with a shift towards milder mutations. It should also be mentioned that prenatal diagnosis allows later early intervention improving survival and quality of life of CF patients. Epidemiological data regarding the impact of this program on SMA will be presented.

Clinical exome reduces the gap between diagnostic and research. *B. Cogné, S. Schmitt, P. Boisseau, S. Küry, X. Latypova, W. Deb, T. Besnard, E. Séché, M. Nizon, M. Vincent, S. Mercier, B. Isidor, S. Bézieau.* Medical genetics unit, CHU Nantes, France.

Background: Whole exome sequencing (WES) has been proved to be an efficient tool in the diagnosis of monogenic diseases. The high diagnostic yield of WES justifies its clinical implementation in defined indications, thereby shortening the diagnostic odyssey. Furthermore, during the diagnostic test, the access to non-OMIM genes offers the possibility to enhance the identification of new disease-causing genes, especially for nonspecific phenotypes. **Method**: We selected 55 patients affected with heterogeneous genetic pathologies without any obvious disease-causing gene or previous unsuccessful targeted genes analyses; WES was performed in the proband only. Data were analyzed following the GATK's best practices and variants were prioritized using an in-house phenotype-guided analysis, using Human Phenotype Ontology terms. A first analysis was focused on rare indels, nonsynonymous SNV and canonical splice sites (+/-2bp) identified in clinically relevant genes (with HPO match); if negative, the analysis was extended to rare synonymous and intronic variants in OMIM and non-OMIM genes. CNVs were analyzed using CANOES and custom scripts were developed to annotate and filter CNVs, linking them to rare indels and SNVs identified in WES, in order to easily detect recessive conditions involving one CNV. **Results**: A diagnosis could be reached in 38% of patients (21/55), including nine autosomal recessive, seven autosomal dominant, three X-linked recessive and two X-linked dominant disorders. The CNV pipeline allowed the detection of a deletion of two exons in COQ2, which, together with a frameshift variant, was responsible for coenzyme Q10 deficiency. For "negative" exomes, we focused on variants absent from databases and predicted as deleterious (CADD phred score > 20), which highlighted three candidates variants in non-OMIM genes: one appeared *de novo* after segregation analyses and the two others had matches in GeneMatcher with patients presenting with a similar phenotype. **Discussion**: Our diagnostic yield is in the range of those already published in WES studies. For negative WES, we expect some of them to be resolved with the identification of new disease-causing genes. It is thus important to implement a local database that can be easily interrogated. Furthermore, the identification of new disease-causing genes could greatly benefit from the data sharing of candidate variants identified during the diagnostic procedure, reducing the gap between diagnosis and research.

2642T

A splicing mutation in *VPS4B* causes Dentin Dysplasia I. *F. Xiong[1], Q. Yang[1], D. Cheng[2], Da. Cheng[1], C. Liu[1], Y. Liu[1,3], Q. Yu[1], J. Xiong[1], J. Liu[2], K. Li[2], L. Zhao[4], Y. Ye[1], L. Hu[1], Z. Tian[5], X. Shang[1], L. Zhang[5], X. Wei[1], W. Zhou[1], D. Li[6], W. Zhang[4], X. Xu[1,7].* 1) Department of Medical Genetics, Southern Medical University, Guangzhou, Guangdong, China; 2) School of Stomatology, Zhengzhou University, Zhengzhou, China; 3) Department of Prenatal Diagnosis Center, Maternal and Child Health Hospital, Dongguan, China; 4) Department of Cell Biology, School of Basic Medical Sciences, Southern Medical University, Guangzhou, China; 5) Department of Stomatology, Nanfang Hospital, Southern Medical University, Guangzhou, China; 6) Department of Forensic Science, School of Basic Medical Sciences, Southern Medical University, Guangzhou, China; 7) Correspondence author.

Dentin dysplasia I (DDI) is a genetically heterogeneous autosomal-dominant disorder characterized by rootless teeth with abnormal pulpal morphology, the etiology of which presents as genetically heterogeneous.In this study,using a cohort of a large Chinese family with 10 DDI patients, we mapped to a 9.63 Mb candidate region for DDI on chromosome 18q21.2-q21.33. We then identified a mutation IVS7+46C>G which resulted in a novel donor splice site in intron 7 of the *VPS4B* gene with co-segregation of all 10 affected individuals in this family. The aberrant transcripts encompassing a new insert of 45-bp in size were detected in gingival cells from affected individuals. Protein structure prediction showed that a 15-amino acid insertion altered the ATP-binding cassette of VPS4B. The mutation resulted in significantly reduced expression of mRNA and protein and altered subcellular localization of VPS4B, indicating a loss of function of VPS4B. Using human gingival fibroblasts, the *VPS4B* gene was found to act as an upstream transducer linked to Wnt/beta-catenin signaling and regulating odontogenesis. Furthermore, knock-down of *vps4b* in zebrafish recapitulated the reduction of tooth size and absence of teeth similar to the tooth phenotype exhibited in DDI index cases, and the zebrafish mutant phenotype could be partially rescued by wild-type human *VPS4B* mRNA. We also observed that *vps4b* depletion in the zebrafish negatively regulates the expression of some major genes involved in odontogenesis. The study identifies *VPS4B* as a disease-causing gene for DDI, which is one of the important contributors to tooth formation through the Wnt/beta-catenin signaling pathway.

2643F

***GNPTAB* gene mutations in the Lithuanian mucolipidosis II and II/III patients.** *L. Ambrozaityte[1,2], B. Burnyte[1,2], L. Cimbalistiene[1,2], B. Tumiene[1,2], A. Utkus[1,2], I. Kavaliauskiene[1,2], T. Rancelis[1,2], V. Kucinskas[1,2].* 1) Dept. of Human & Medical Genetics, Faculty of Medicine, Vilnius University, Santariskiu 2, LT-08661 Vilnius, Lithuania; 2) Center for Medical Genetics, Vilnius University Hospital Santariskiu Klinikos, Santariskiu 2, LT-08661 Vilnius, Lithuania.

Mucolipidosis (ML) II and ML IIIα/β are allelic autosomal recessive metabolic disorders due to mutations in the *GNPTAB*, leading to a deficiency of the enzyme N-acetylglucosamine-1-phosphotransferase, which causes the lysosomal enzymes to accumulate in plasma. Lysosomal storage results in a global impairment of many lysosome dependent pathways (e.g. autophagy and endocytosis), leading to cellular dysfunction and death. ML II and IIIα/β patients have a complex phenotype, characterized by failure to thrive, developmental delays and manifests as thickened skin, coarse facial features, hypertrophic gingiva, thoracic deformity, kyphosis, clubfeet, and restricted joint movement. The sequence of the *GNPTAB* gene (NM_024312.4) has been identified by Sanger sequencing for six unrelated Lithuanian patients. Sequence variant c.1123C>T (p.Arg375Ter) (CM096593) has been detected to all of them; in a homozygous state in one case (ML II) or compound heterozygous state with the other detected mutations as c.1196C>T (p.Ser399Phe) (CM062765) or 2715+2T>G (p.?) (CS100356) (ML II/III). Data from the population analysis of 98 self-reported healthy unrelated individuals (equal male and female) from the Lithuanian population was used to identify mutations carrier frequencies. Whole exome sequencing has been performed on Applied Biosystems 5500 SOLiD™ system according to the optimized manufacturer's protocols, obtaining average coverage of 20x. In total 16 different variants have been detected in the Lithuanian population samples of the *GNPTAB*, five – exonic. The identified mutations of the Lithuanian ML II and II/III families have not been detected in the population samples. The genotype phenotype analysis of our patients correlate with the published data on ML II and II/III. Early knowledge of the *GNPTAB* genotype should favour gathering clinical information more prospectively and may influence the development of successful therapies.

2644W

Airway response to CFTR-directed therapeutics for cystic fibrosis is modulated by *SLC26A9*. G. He[1], T. Gonska[2,3,4], K. Keenan[4], W. Ip[4], P.Y. Böelle[5,6], F. Lin[1], N. Panjwani[1], J. Recent developments in cystic fibrosis (CF) therapeutics has included the strategic targeting of different *CFTR* mutation types with potentiator and corrector drugs. While such targeted approaches hold tremendous promise, there is variability in patient response. *SLC26A9* has been shown to be a modifier of early intestinal and pancreatic CF disease phenotypes. Recognizing that SLC26A9 is itself a solute transporter and is expressed and interacts with CFTR at the cell surface in lung-derived culture models, we sought to better understand its relationship to lung disease severity and to airway therapeutic response in CF. SLC26A9 association with lung disease severity was assessed in individuals from the Canadian and French CF Gene Modifier Consortia. Rs7512462 was found to influence lung function measures when at least one gating deficient CF-causing allele, G551D, was present, but not in individuals homozygous for the common F508del CF-causing allele, p=0.04. In addition, Canadian patients with at least one G551D allele showed differential lung function response to potentiator therapy dependent on their SLC26A9 rs7512462 genotype, p=0.0006. A relationship between SLC26A9 and 'gating deficient' CF-causing alleles in lung function severity and in potentiator therapeutic response, is consistent with SLC26A9 – CFTR interaction at the cell surface. As corrector therapeutics to improve CFTR delivery for 'processing-deficient' alleles are just becoming available, we investigated corrector drug-treated primary bronchiole cells of individuals possessing F508del alleles. Differences in forskolin-activated current responses (CFTR function with corrector treatment versus no treatment) were dependent on SLC26A9 rs7512462 genotype, p=0.02, implying knowledge of rs7512462 genotype may predict patient responses and facilitate improved management of patient care. Our findings suggest that variation in SLC26A9 is associated with airway disease severity provided residual CFTR is present, or can be prompted, to the surface of airway cells. Further, the full realization of personalized medicine in CF should incorporate genetic information beyond CFTR disease gene alleles, including *SLC26A9* variation.

Uitterlinden[1]. 1) Internal Medicine, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; 2) Clinical Genetics, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; 3) Dermatology, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; 4) Pathology, Erasmus MC, Rotterdam, Zuid-Holland, Netherlands; 5) Department of Cell and Developmental Biology, University College London, London, United Kingdom; 6) Department of Human Evolution, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany.

Woolly hair syndrome, as defined in the literature, encompasses phenotypes presenting with an abnormal variant of tightly curled and twisted scalp hair and diffuse to progressive hair loss. Woolly hair grows slowly, is brittle and stops growing after a few inches. The woolly hair occurs with or without mild to severe skin anomalies and in some cases cardiomyopathy. Autosomal dominant as well as autosomal recessive forms exist. We present a small Dutch family with two children affected with woolly hair syndrome and mild skin anomalies showing a recessive pattern of inheritance. Homozygosity mapping using Affymetrix SNP 6.0 arrays identified a number of homozygous areas in the DNA of the affected children, with one large 7.6 Mb region on chromosome 1. Subsequent whole exome sequencing (NimbleGen SeqCap EZ V2) was performed on an Illumina HiSeq2000 sequencer. Data analysis identified a novel causative gene for the phenotype in these patients. Sanger sequencing verified carrier status of a splice mutation in the parents and a homozygous mutation in the patients. RT-PCR experiments showed aberrant splicing. Immuno-histochemical studies on skin tissue are ongoing to learn more about the functionality of the involved protein.

2646F

Dominant and recessive disease trait inheritance associated with variation at a single locus: Lessons learned from next-generation sequencing. *J. Posey[1], T. Harel[1], J.A. Rosenfeld[1], Z.H.C. Akdemir[1], M.K. Eldomery[1], P. Liu[1,2], M. Walkiewicz[1,2], F. Xia[1,2], D. Muzny[2,3], C.M. Eng[1,2], C.A. Shaw[1,2], E. Boerwinkle[1,3,4], R.A. Gibbs[1,2,3], S.E. Plon[1,3,5,6,7,8], Y. Yang[1,2], J.R. Lupski[1,3,5,6].* 1) Human & Molec Genetics, Baylor College Med, Houston, TX; 2) Baylor Miraca Genetics Laboratories, Houston, TX; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 4) Human Genetics Center, The University of Texas Health Science Center, Houston, TX; 5) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 6) Department of Pediatrics, Texas Children's Hospital, Houston, TX; 7) Texas Children's Cancer Center, Houston, TX; 8) Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX.

The approach to Mendelian genetics often assumes a consistent relationship between mode of inheritance for a given disease and its associated gene. Despite this, several genes have been identified for which both monoallelic and biallelic variants lead to disease. The resulting phenotypes can be distinct (e.g. *BRCA2*) or share substantial overlap (e.g. *COL7A1*) despite differences in severity or phenotypic spectrum. Independent of disease mechanism, genotype-phenotype correlations may be associated with localization to specific protein domains (e.g. *NALCN, EGR2*), type or severity of variants (e.g. *APC*), and escape or trigger of nonsense-mediated decay (e.g. *HBB, RHO*). We hypothesize that molecular diagnoses may be overlooked when identified variants do not observe the expected mode of inheritance. We have identified several cases of dominant and recessive inheritance at a single locus, involving known and novel genes (e.g. *EMC1*). To investigate this systematically, we analyzed the first 345 cases referred to a diagnostic laboratory for trio whole exome sequencing (WES) to identify cases for which a heterozygous *de novo* variant was identified in a known disease gene described as causing a disease trait with autosomal recessive inheritance. This analysis revealed 7 cases (2.0%) with *de novo* variants in known autosomal disease genes associated with disease phenotypes that overlap with the reported phenotype; no second variant or deletion was identified in the exome data. Six cases involved missense variants (*PNPLA6, PIP5K1C, AGRN, SEC24D, ZBTB24, RBBP8*) and 1 involved a splice site variant at the -4 position (*UQCRB*). For 2 of these cases with *de novo* variants in genes associated with Boucher-Neuhauser syndrome (*PNPLA6*, MIM #215470) and Lethal congenital contractural syndrome 3 (*PIP5K1C*, MIM #611369), the variant was a novel missense variant that occurred in a conserved region of the protein; *in silico* bioinformatic analyses suggested a potentially damaging effect on protein function, possibly resulting in either an antimorphic or neomorphic allele. Although at present one cannot rule out a second regulatory variant undetected by WES, a single variant may be sufficient to cause a phenotype at some loci associated with recessive traits. Further investigation of both dominant and recessive disease alleles at a single locus will provide insights into disease mechanisms and genotype-phenotype correlations; moreover it may enhance molecular diagnostic rates.

2647W

Persistence of positive renal and cardiac effects of migalastat in patients with Fabry disease with amenable mutations following 30 months of treatment in the ATTRACT study. *D.G. Bichet[1], D.P. Germain[2], R. Giugliani[3], D. Hughes[4], R. Schiffmann[5], W. Wilcox[6], J. Castelli[7], E.S. Cantor[7], J. Kirk[7], N. Skuban[7], J. Barth[7].* 1) Hôpital du Sacré Coeur, University of Montreal, Montreal, Quebec, Canada; 2) Division of Medical Genetics, University of Versailles–St. Quentin en Yvelines (UVSQ), Montigny, France; 3) HCPA/UFRGS Porto Alegre, Porto Alegre, Brazil; 4) Royal Free Hospital, University College London, London, UK; 5) Baylor Research Institute, Dallas, TX, USA; 6) Department of Human Genetics, Emory University, Atlanta, GA, USA; 7) Amicus Therapeutics, Cranbury, NJ, USA.

Fabry disease is an X-linked disorder of lysosomal α-galactosidase A (α-Gal A) deficiency that causes substrate accumulation and clinical sequelae. Migalastat is an oral pharmacological chaperone that stabilizes amenable mutant forms of α-Gal A in patients with Fabry disease, increasing lysosomal activity. The ATTRACT study (NCT00925301) comprised an 18-month open-label randomized comparison of enzyme replacement therapy (ERT)-experienced patients switching to migalastat HCl 150 mg every other day (n=36) or remaining on ERT (n=21), and a 12-month open-label-extension (OLE) with migalastat. Thirty-one male and female patients with amenable mutations in the migalastat group completed the 18-month randomized period and entered the 12-month OLE. Forty-nine patients with amenable mutations received ≥1 dose of migalastat during the combined 30-month study periods. In patients receiving migalastat for 30 months, the mean (95% confidence interval [CI]) annualized rates of change (mL/min/1.73 m^2) from baseline in eGFR$_{CKD-EPI}$ and mGFR$_{iohexol}$ were −1.7 (−2.7, −0.8) and −2.7 (−4.8, −0.6), respectively. These annualized rates of change in eGFR$_{CKD-EPI}$ and mGFR$_{iohexol}$ are comparable to those previously reported in patients receiving ERT for 18 months: −1.0 (−3.6, 1.6) and −3.2 (−7.8, 1.3), respectively. In patients receiving migalastat for 30 months, the mean (95% CI) change from baseline in left ventricular mass index (LVMi, g/m^2) for all patients and for those with baseline left ventricular hypertrophy (LVH) were −3.8 (−8.9, 1.3) and −10.0 (−16.6, −3.3), respectively. For patients receiving ERT, previously reported 18-month changes in LVMi were −2.0 (−11.0, 7.0) for all patients and 4.5 (−20.9, 29.9) for patients with baseline LVH. LVMi reduction from baseline to month 30 in patients treated with migalastat with baseline LVH was statistically significant. The results indicate that in patients switched from ERT, the renal and cardiac effects of migalastat observed after 18 months persist over 30 months, making migalastat a promising first-in-class oral chaperone treatment for male and female patients with amenable mutations.

2648T

Efficacy of migalastat in a cohort of male patients with the classical form of Fabry disease in the phase 3 FACETS study. *D.P. Germain[1], R. Giugliani[2], D.G. Bichet[3], W. Wilcox[4], D. Hughes[5], H.M. Amartino[6], R. Schiffmann[7], C. Viereck[8], M. Yao[8], N. Skuban[8], J. Castelli[8], J. Barth[8].* 1) Division of Medical Genetics, University of Versailles–St. Quentin en Yvelines (UVSQ), Montigny, France; 2) HCPA/UFRGS Porto Alegre, Porto Alegre, Brazil; 3) Hôpital du Sacré-Coeur, University of Montreal, Montreal, Quebec, Canada; 4) Department of Human Genetics, Emory University, Atlanta, GA, USA; 5) Royal Free Hospital, University College London, London, UK; 6) Hospital Universitario Austral, Buenos Aires, Argentina; 7) Baylor Research Institute, Dallas, TX, USA; 8) Amicus Therapeutics, Cranbury, NJ, USA.

Fabry disease is an X-linked lysosomal storage disorder caused by *GLA* mutations, resulting in deficient lysosomal α-galactosidase A (α-Gal A) activity. Males with the "classical" Fabry disease phenotype generally have an earlier onset of disease and more severe symptoms. Migalastat is an oral pharmacological chaperone that stabilizes mutant α-Gal A to facilitate normal trafficking to lysosomes. Subgroup analyses were undertaken to explore the benefit of migalastat in this cohort of male patients from a 24-month phase 3 study (enzyme replacement therapy-naïve; FACETS). Male patients with classical phenotype were defined as having multiorgan system involvement (based on medical history and baseline assessments) and peripheral blood mononuclear α-Gal A activity <3% (n=14; mean ± standard deviation 42.4 ± 14 years). Changes from baseline (CFB) were calculated for estimated glomerular filtration rate using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula (eGFR$_{CKD-EPI}$), left ventricular mass index (LVMi), plasma globotriaosylsphingosine (lyso-Gb$_3$), and diarrhea symptoms based on the Gastrointestinal Symptoms Rating Scale (GSRS-D; scored on a 7-point Likert-type scale [1=absence of burden to 7=severe discomfort]). For male patients with classical phenotype, the annualized CFB (mean [95% confidence interval]; baseline [n=14]: 87.8 ± 33.6 mL/min/1.73 m^2) to month 24 (n=11) for eGFR$_{CKD-EPI}$ was −0.3 (−2.8, 2.3). For LVMi, the CFB (baseline [n=13]: 114.2 ± 28.5 g/m^2; baseline left ventricular hypertrophy was present in 7/13 patients) to month 24 (n=8) was −12.6 (−25.0, −0.2). For plasma lyso-Gb$_3$, the CFB (baseline [n=7]: 99.8 ± 35.3 nmol/L) to month 12 (n=7) was −36.8 (−69.9, −3.7). For GSRS-D, the CFB (baseline [n=14]: 2.5 ± 1.66) to month 24 (n=10) was −0.9 (−2.1, 0.4). These results demonstrate the clinical benefit of migalastat in male patients with amenable mutations and the classical phenotype of Fabry disease in terms of renal function, LVMi, plasma lyso-Gb$_3$, and diarrhea symptoms. These results are consistent with those seen in the broader study population.

2649F

Podocyte globotriaosylceramide (GL-3) content in male adult patients with Fabry disease is reduced following 6 months of treatment with migalastat. *B. Najafian[1], A. Sokolovskiy[1], J. Barth[2], J. Castelli[2], H. Williams[2], M. Mauer[3].* 1) University of Washington, Seattle, WA, USA; 2) Amicus Therapeutics, Cranbury, NJ, USA; 3) University of Minnesota, Minneapolis, MN, USA.

Fabry disease is an X-linked lysosomal storage disorder caused by *GLA* mutations, resulting in deficient α-galactosidase A activity and accumulation of glycosphingolipids, including globotriaosylceramide (GL-3) and plasma globotriaosylsphingosine (lyso-Gb$_3$). Kidney podocyte injury in Fabry nephropathy is associated with intracellular GL-3 burden, as demonstrated by correlations between proteinuria and volume fraction of podocyte cytoplasm filled with GL-3 and podocyte foot process width, both of which increase with age in young Fabry disease patients. Treatment with the oral pharmacological chaperone migalastat (150 mg QOD) reduces peritubular capillary GL-3 in patients with Fabry disease. This study aimed to establish whether migalastat also reduces podocyte GL-3 in these patients, using a novel approach to estimate the total volume of GL-3 inclusions/podocyte (V[Inc/PC]). Kidney biopsy samples from ERT-naïve male patients with Fabry disease with *GLA* mutations amenable to migalastat (N=8), taken at baseline and again after 6 months of migalastat treatment, were studied by masked unbiased electron microscopy stereology. The mean ± SD V(Inc/PC) of all patients decreased from 2568 ± 1408 μm^3 at baseline to 1282 ± 792 μm^3 after 6 months of migalastat (*P*=0.0182). There was a correlated reduction in mean podocyte volume from 6680 ± 2835 μm^3 at baseline to 3525 ± 2084 μm^3 (*P*=0.004) after 6 months of migalastat (*r*=0.98, *P*=0.00003). These findings indicate that the podocyte cytoplasmic shrinkage was proportional to GL-3 loss; thus, the volume fraction of podocyte cytoplasm attributable to GL-3 did not change significantly. The magnitude of podocyte GL-3 volume reduction following migalastat correlated with improvement of foot process width (*r*=0.82, *P*=0.02), indicative of reduced podocyte injury. Mean plasma lyso-Gb$_3$ also decreased from 118 ± 48 nM at baseline to 75 ± 42 nM after 6 months of migalastat (*P*=0.0004). This decrease correlated with % reduction in GL-3 volume/podocyte (*r*=0.79, *P*=0.02). There was a trend between decrease in GL-3 volume/podocyte and proteinuria (*r*=0.69, *P*=0.06) following treatment with migalastat for 6 months, but no association was found with glomerular filtration rate. In this study, migalastat treatment was associated with a loss of GL-3 inclusions in podocytes in patients with Fabry disease. The sensitive quantitative methods used herein can assess treatment efficacy for this important cell type over a relatively short period of time.

Migalastat improves gastrointestinal symptoms in patients with Fabry disease: Results from a double-blind, placebo-controlled phase 3 trial (FACETS). *R. Schiffmann[1], D.G. Bichet[2], D. Hughes[3], R. Giugliani[4], W. Wilcox[5], S.P. Shankar[5], D.P. Germain[6], C. Viereck[7], J. Castelli[7], M. Yao[7], N. Skuban[7], J. Barth[7].* 1) Baylor Research Institute, Dallas, TX, USA; 2) Hôpital du Sacré-Coeur, University of Montreal, Montreal, Quebec, Canada; 3) Royal Free Hospital, University College London, London, UK; 4) HCPA/UFRGS Porto Alegre, Porto Alegre, Brazil; 5) Department of Human Genetics, Emory University, Atlanta, GA, USA; 6) Division of Medical Genetics, University of Versailles–St. Quentin en Yvelines (UVSQ), Montigny, France; 7) Amicus Therapeutics, Cranbury, NJ, USA.

Gastrointestinal (GI) symptoms are a prominent manifestation of Fabry disease, with profound and often debilitating negative effects on patients. Migalastat is a first-in-class, oral pharmacological chaperone for patients with Fabry disease with amenable *GLA* mutations. FACETS was a 24-month trial with a 6-month double-blind, placebo-controlled (DBPC) stage, conducted in male and female patients with Fabry disease who were naïve to enzyme replacement therapy. The Gastrointestinal Symptoms Rating Scale (GSRS) was used to assess patient-reported GI symptoms in patients with amenable mutations (n=50). Patients received migalastat HCl 150 mg every other day or placebo. GI symptoms improved with migalastat in 3 of 5 domains (diarrhea, reflux, indigestion) assessed by GSRS. During the DBPC stage, a statistically significant decrease in diarrhea symptoms from baseline to 6 months was seen with migalastat compared with placebo (P=0.03). Based on the minimally clinically important difference for diarrhea, an improvement from baseline of ≥0.4 units was noted: 69% of patients on migalastat had a clinically relevant change vs. 11% of patients on placebo (P=0.012). In patients with symptoms at baseline, a statistically significant improvement in reflux was seen at 6 months compared with baseline (P=0.047). During the open-label extension (months 6-24), a statistically significant improvement from baseline was also observed for indigestion (P<0.05), and there was a trend toward improvement in constipation. Treatment with migalastat led to statistically significant, clinically relevant improvements in GI symptoms assessed by GSRS in patients with Fabry disease with amenable *GLA* mutations.

2651T

***ASAH1* gene mutations cause acid ceramidase deficiency, which has a broad phenotypic spectrum including two distinct diseases: Farber disease and spinal muscular atrophy with progressive myoclonic epilepsy (SMA-PME).** *E.H. Schuchman[1], A. Solyom[2], X. He[1], C. Simonaro[1].* 1) Genetics and Genomic Sciences, Icahn School of Medicine at Mt. Sinai, New York, USA; 2) Plexcera Therapeutics LLC, New York, USA.

Mutations in the *ASAH1* gene lead to acid ceramidase deficiency, accumulation of the lipid ceramide, and a broad phenotypic spectrum, culminating in two recognized diseases: Farber disease and Spinal Muscular Atrophy with Progressive Myoclonic Epilepsy (SMA-PME). The prevalence of both diseases is currently unknown and awareness of them is limited due to their rarity; both are likely underdiagnosed. All known phenotypes are associated with autosomal recessive inheritance. Farber disease represents a broad clinical spectrum presenting from infancy through late childhood, associated with the pro-inflammatory and pro-apoptotic characteristics of ceramide. Information from a growing cohort of over 30 living Farber patients reinforces the validity of the characteristic symptoms: early-onset polyarticular arthritis, subcutaneous nodules and dysphonia. However, it also reveals that there are patients who present with only one or two of these symptoms, and that the spectrum of disease includes remarkably attenuated forms with relatively little associated disability. Slowly progressive disease may only be diagnosed in adulthood. Cases of Farber patients diagnosed at over 40 years of age have recently been published, and indicate that peripheral osteolysis can also be caused by *ASAH1* mutations. Less in currently known about the natural history of spinal muscular atrophy with progressive myoclonic epilepsy (SMA-PME), although it is also proving to be a disease with a heterogeneous presentation. The broad spectrum of phenotypes associated with *ASAH1* mutations indicate that it should be considered for inclusion in targeted diagnostic panels for motor neuron disease, therapy resistant epilepsy, therapy resistant arthritis or contractures, and peripheral osteolysis. There is no specific therapy currently available for Farber disease or SMA-PME. Haematopoietic stem cell transplantation in Farber has shown variable results and carries a severe burden for the patients. Acid ceramidase enzyme therapy is currently under development.

Nine-year follow-up in a patient receiving migalastat pharmacological chaperone therapy for Fabry disease. *C. Swift[1], R. Schiffmann[1], J. Barth[2], N. Skuban[2], J. Castelli[2].* 1) Baylor Research Institute, Dallas, TX, USA; 2) Amicus Therapeutics, Cranbury, NJ, USA.

Fabry disease is a rare X-linked lysosomal storage disorder associated with altered autonomic function and neuropathic pain. This report will describe the long-term effects of oral migalastat on Fabry disease-associated pain in a patient with an amenable *GLA* mutation. In 2005, a 37-year-old male patient presented with an 8-year history of severe acroparesthesia in his hands and feet and a sensation of stiffness, predominantly in the lower extremities, that markedly affected his quality of life. He was treated with multiple pain medications, including daily oxycodone, tizanidine, and baclofen, and over-the-counter analgesics. The patient was diagnosed with Fabry disease following a kidney biopsy showing typical lysosomal inclusions in podocytes. His white blood cell (WBC) α-galactosidase A (α-Gal A) activity was markedly decreased to 13.4-25% of normal due to an A143T mutation. The patient began receiving migalastat (various doses) shortly after diagnosis and continued for 4.5 years (phase 2 study), followed by migalastat 150 mg every other day for an additional 4.5 years (phase 3 study). No drug-related adverse events were observed. α-Gal A activity increased 5-fold in WBCs and 30-fold in skin. Cardiac and renal function, as well as urine globotriaosylceramide levels, remained stable on migalastat treatment. Paresthesias and sensation of stiffness progressively improved, and the patient was able to decrease and then discontinue all of his pain medications by the 8th year of treatment with migalastat. Long-term migalastat treatment in this patient with Fabry disease was associated with increased α-Gal A activity in WBCs and skin and reversed symptoms of small-fiber neuropathy over the course of treatment. In this patient case, long-term treatment with migalastat ameliorated Fabry disease-associated pain, resulting in discontinuation of daily pain medications and enabling the patient to resume normal activities of daily living that were not possible prior to treatment.

A phenotype data sharing format for diagnosis and discovery. *C. Mungall[1], J. Jacobsen[2], J. Balhoff[3], J. Nguyen-Xuan[1], K. Shefchek[4], D. Keith[4], H. Hochheiser[5], S. Lewis[1], S. Köhler[6], P. Robinson[6], J. McMurry[4], T. Groza[7], D. Smedley[2], Monarch Initiative.* 1) Lawrence Berkeley National Laboratory, Berkeley, CA, USA; 2) Sanger Institute, Hinxton, UK; 3) RTI International, Durham, NC, USA; 4) Oregon Health and Sciences University, Portland, OR, USA; 5) University of Pittsburgh, Pittsburgh, PA, USA; 6) Charité – Universitätsmedizin Berlin, Germany; 7) Garvan Institute of Medical Research, Sydney, Australia.

While great strides have been made in exchange formats for genomic sequence and variation data (e.g. Variant Call Format; VCF), the same is not true for phenotypic features. Similarly, bioinformatics tools have rich models for genomic or phylogenetic data types, but lack a uniform phenotype representation. This is due in part to the diversity of phenotypic descriptions, from clinical observations, through QTLs, and newer high-throughput phenotype measurements. Further, phenotypic features are represented in different formats in a diversity of places: publications, databases, health records, registries, clinical trials, and even social media. In these contexts, biocuration has been pivotal to obtaining a computable representation, but is still deeply challenged by the lack of standardization, accessibility, persistence, and computability. As a result, it is extremely difficult to exchange, aggregate, and operate over phenotypic data in the same way that we do sequence data. To address this problem, we have designed an exchange format standard for flexible, extensible, and expressive representation of a broad range of phenotypes in humans or any other species. The Phenotype eXchange Format (PXF) (www.phenopackets.org) works hand-in-hand with phenotype ontologies such as the Human Phenotype Ontology, but allows for representation of other fields such as quantitative measurements, environments and exposures, together with a means of capturing the complete evidence that goes into an association. The goal is to enable PHI-free open exchange of phenotypic data suitable for computational creation by registries and clinics and outside paywalls for journals during publication of genotype-phenotype studies. This will allow consumption of these phenotypic data for computational use by clinical labs for defining gene panels, for diagnostic pipelines, for rare disease patient matchmaking, and for deposition and aggregation in public knowledge bases such as the Monarch Initiative. Open exchange of phenotypic data will allow innovation of algorithms and sharing of our greater understanding of the correlations between genotype, environmental factors, and phenotypic outcomes in more holistic and translational manner.

2654T

A high throughput TaqMan CFTR mutation genotyping workflow. *T. Harts-horne, J. Lang, E. Swartzman, P. Brzoska, L. Tracy.* Genetic Analysis, Thermo Fisher Scientific, South San Francisco, CA.

Cystic fibrosis (CF) is an autosomal recessive disease and is the most common genetic disease of Caucasians, affecting 1 in 3000 newborns and having a carrier frequency of 1 in 25. It a progressive incurable disease that is caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene, which impacts mucin production in lungs and other organs. To aid identifying individuals that carry CFTR mutations, we have developed of a high throughput, low cost CFTR genotyping workflow. TaqMan™ SNP Genotyping Assays were developed to nearly 200 CF-causing mutations that were selected from the CFTR1 and CFTR2 databases based on population frequency and predicted functional activity. The mutations occur primarily in coding and regulatory regions and include single nucleotide base substitutions, triallelic mutations, clustered mutations, small insertion deletions, large deletions, and repetitive sequences. The varied nature of the mutations presented challenges to assay development using a single chemistry and platform; these were overcome using nonstandard assay design strategies and analysis methods. CFTR assays were tested on both 384-well and OpenArray™ (3072-well nanofluidic plate) plates run on a real-time PCR system, using Coriell cell line gDNA samples carrying CFTR mutations for a subset of the mutations, and using synthetic DNA controls for all three genotypes per variant to demonstrate robust allelic discrimination. CFTR assays were also tested with DNA isolated from blood and buccal cell samples, and assay accuracy and concordance studies were performed. We will present our complete sample-to-data analysis workflow for high throughput CFTR mutation detection, and cover the development of 200 qualified TaqMan SNP genotyping assays to key CFTR mutations. Data will be presented for nonstandard assays and data analysis methods used to genotype difficult targets including homopolymer mutations and large deletions. Availability of these CFTR assays will enable tailored studies wherein: (1) targets are selected based on CFTR mutation occurrence in populations of interest; (2) small or large numbers of samples can be run on customizable OpenArray panels of 60, 120 or 180 assays, or on TaqMan Array 384-well plates; and (3) highly accurate and reproducible CFTR genotypes can be acquired from blood and buccal cell samples.

2655F

Embodying the ACMG/AMP standards and guidelines for the interpretation of sequence variants in process and code; considerations and the path forward. *E.A. Worthey[1,2], J. Anderson[1], G. Beard[1,2], C. Birch[1,2], D. Brown[1,2], L. Handley[1], J. Harris[1], J. Kelly[1], S. Newberry[1], M. Schroeder[1,2], F. Shater-Ferdosian[1], A. Uno-Antonison[1], A. Weborg[1], C. White[1], B. Wilk[1], D.P. Bick[1,2], Other members of the HudsonAlpha Clinical Sequencing Lab.* 1) Software Development and Informatics, HudsonAlpha Institute, Huntsville, AL; 2) Clinical Services Laboratory, HudsonAlpha Institute, Huntsville, AL.

The advent of genomic sequencing has altered how molecular changes are identified and is transforming medicine. It has uncovered causal molecular changes that would not otherwise have been found and has increased diagnostic success rates in patients with rare genetic disease. Our ability to accurately predict the impact of molecular changes has dramatically improved over the last decade, but much work still remains to interpret the impact on structure and function of molecular changes even within coding regions. Over the last two years there has been increased focus on the topic of consistency in variant classification methods and practices both amongst individual directors within and between Molecular Diagnostic labs. Studies seeking to evaluate consistency and discrepancy in interpretation have identified significant discord; exceeding 30% in some cases. Such findings have prompted formation of cross institutional collaborations aimed at producing definitive and follow-able guidelines for variant interpretation. One goal of such collaborations is identification of the reasons underpinning disparate calls so that as a community we can minimize their occurrence. In 2015 working groups from ACMG and AMP jointly produced final guidelines for interpretation of variants. One intent was to identify factors that should be prioritized in order to maximize classification accuracy. Another goal was to provide a comprehensive evidence-based approach to variant classifications. These guidelines have subsequently been adopted by many labs and embodied in various clinical analysis processes and interpretation software platforms. In many cases, such as ours, these guidelines have superseded or led to alteration or refinement of existing prioritization and classification schemas. The analysis presented here takes an in depth look at concordance and differences between the prior in house schema and the classifications rendered through encoding of these guidelines. Specifics examples will be shown that highlight areas where the updated guidelines need further refinement. We have learnt a lot from *in silico* embodiment of these guidelines; examples of datasets that can be ingested in order to support translation of ACMG evidence codes will also be highlighted. Finally we examine how close we are to being able to embody these guidelines in code to produce accurate suggested clinical interpretations without the need for significant director alteration during interpretation.

Using mouse genomic and phenotypic data to predict human genetic disease genes. *J.T. Eppig, S.M. Bello, J.A. Kadin, J.E. Richardson, C.L. Smith, MGI Staff.* The Jackson Laboratory, Bar Harbor, ME.

   Our ability to sequence exomes and genomes provides extraordinary opportunity to identify the genetic causes of hereditary human diseases. However, the large number of genetic variants uncovered from a patient provides serious challenges in identifying the causal gene or genes. The laboratory mouse, as the most studied of mammalian model systems, provides unique insights into the dissection of genetic mechanisms of human disease. Comparative phenotyping and directed gene mutation can aid in identification of candidate gene mutations and development of mouse models that recapitulate specific human genetic mutations.   The Human-Mouse Disease Connection is a translational tool (www.diseasemodel.org) designed for exploring and comparing human and mouse phenotypes and their associations with known human diseases, and to provide rapid access to mouse model resources and supporting references. Searches can be initiated based on human or mouse data using one or more parameters, including genes, genomic locations, or phenotypes or disease terms. Results are displayed initially as a visual color-coded grid comparing phenotypes and diseases associated with human and mouse orthologs; or users can choose to view data in tabular format based on genes or on diseases that correspond to the search parameters. New features provide for flexibility for targeted searching (e.g. UBE3A AND Angelman Syndrome) or broad searching (e.g. Hermansky-Pudlak Syndrome OR Storage Pool Platelet Disease). The ability to visually compare the breadth of human/mouse phenotype similarity provides new evidence for underlying genetic models, highlights potential human candidate genes for disease based on mouse phenotypes, and identifies mouse genes that can be engineered to develop new human disease models.   Supported by NIH grant HG000330.

Assessing the clinical utility of whole blood transcriptome analysis for rare, undiagnosed disorders. *Z. Zappala[1,2], L. Fresard[2], K.D. Kernohan[4], K.S. Smith[2], E.A. Ashley[1,3], J.D. Merker[2], K.M. Boycott[4], S.B. Montgomery[1,2].* 1) Department of Genetics, School of Medicine, Stanford University, Stanford, CA; 2) Department of Pathology, Stanford University, School of Medicine, Stanford, CA; 3) Department of Cardiovascular Medicine, School of Medicine, Stanford University, Stanford, CA; 4) Children's Hospital of Eastern Ontario, Ontario, Canada.

   Clinical exome and genome sequencing is increasingly being used to identify genetic variation underlying disease in patients suffering from rare, undiagnosed genetic disorders. Exome sequencing provides a cost effective way to identify pathogenic variation in protein-coding regions of the genome, while genome sequencing enables the discovery of variation that is either poorly covered or not well captured by exome sequencing (e.g. non-coding variation and structural variation). Both approaches rely on our ability to recognize pathogenic variation – either as rare, predicted loss-of-function/gain-of-function mutations or as large structural/copy number variation. As a result, the molecular diagnostic yield of clinical sequencing strategies is generally reported to be between 25-40%, leaving the majority of patients undiagnosed. We hypothesized that transcriptome analysis of undiagnosed patients would provide functional evidence for pathogenic variation and improve the molecular diagnostic success rate for a diverse set of rare disorders. To test this hypothesis, we performed whole blood transcriptome analysis on patients suffering from heritable cardiovascular disease, heritable cancer predisposition, and other unexplained pediatric disorders with a suspected genetic etiology. By comparing these patients' transcriptomes with a large set of healthy controls from the Depression, Genes, and Networks cohort (n = 909), we identify rare regulatory phenotypes including extreme gene expression, allele-specific expression, and novel splicing patterns. We then highlight aberrant regulatory phenotypes that affect known disease genes or are involved in processes associated with each patient's individual disease etiology and validate the phenotype with quantitative PCR. By integrating transcriptome analysis with genome and exome sequencing data, we identify rare variation associated with these regulatory events that are compelling for clinical diagnosis. Finally, we assess the utility of whole blood transcriptome analysis and compare it to other tissues that can be easily collected in order to understand the limitations of transcriptome analysis in clinical settings where disease presentation is diverse and biopsy of the most relevant disease tissue can be prohibitively invasive. Ultimately, we demonstrate how these integrated genomics analyses can improve the diagnostic yield for the majority of patients with unexplained genetic disorders.

2658F

Initiative on Rare and Undiagnosed Diseases in Pediatrics (IRUD-P) in Japan. *Y. Matsubara[1], K. Hata[1], T. Kaname[1], K. Kosaki[2], IRUD-P Consortium[3].* 1) Research Institute, National Center for Child Health and Development (Japan), Tokyo, Japan; 2) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan; 3) IRUD-P, Japan.

The Initiative on Rare and Undiagnosed Diseases (IRUD) is a national consortium designed to help patients and their families suffering from rare and undiagnosed disease conditions in Japan. The project started in July 2015. It is funded by the Japan Agency for Medical Research and Development (AMED). The aims of the project are to make diagnosis on patients with rare and undiagnosed diseases, to construct their genome database with clinical information, and to make banking system of precious specimens. The pediatric version of IRUD (IRUD-P) is coordinated by dual centers, the National Center for Child Health and Development (NCCHD) and Keio University, while the adult version of IRUD is led by the National Center for Neurology and Psychiatrics (NCNP). The IRUD-P assigned 17 regional core clinical centers which evaluate clinical symptoms of patients who are referred from local hospitals and clinics and perform first-line laboratory examinations. The obtained data are carefully examined by experts specialized in rare diseases and selected patients are enrolled into IRUD-P. The IRUD-P mainly accepts patients with undiagnosed diseases, but also provides genomic or genetic analysis for rare diseases in which genetic tests are not readily available in Japan. The consortium has four analytical centers for NGS: Tohoku University, NCCHD, Keio University and Yokohama City University. From July 2015 to April 2016, approximately 700 patients, who passed the first screening in the core clinical centers, were consulted to the IRUD-P centers. Specimens accompanied with medical information (n=2,300) were collected from patients and their families, mainly in trios, and sent to the centers. So far we have analyzed 350 patients and genetically confirmed diagnosis in 102 patients. Four patients were found to have new diseases or mutations in novel genes. For the remaining undiagnosed patients, the IRUD-P consortium is developing data sharing network system based on a phenomizer program. The DNA and blood cell specimens have been stored at the National Center Banking Network in Japan. The IRUD-P aims to promote genomic medicine in Japan and to build international collaboration and data-sharing on rare and undiagnosed diseases.

2659W

The Finnish national collection of balanced translocations and inversions facilitates gene mapping. *T. Varilo[1,3], T. Luukkonen[2,3], M. Pöyhönen[4], R. Salonen[5], K.O.J. Simola[6], K. Aittomäki[4], A. Palotie[1,2,7], J.D. Terwilliger[8,9], J. Ignatius[10].* 1) Dept Molecular Medicine, NPHI, Helsinki, Finland; 2) FIMM Institute for Molecular Medicine Finland, Helsinki, Finland; 3) National Institute for Health and Welfare, Helsinki, Finland; 4) Dept. of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland; 5) Dept. of Medical Genetics, Norio-centre, Rinnekoti Foundation, Helsinki, Finland; 6) Dept. of Pediatrics, Tampere University Hospital, Tampere, Finland; 7) Broad Institute of Harvard and MIT, Cambridge, MA, United States; 8) Columbia Genome Center, Columbia University, New York, NY, United States; 9) New York State Psychiatric Institute, New York, NY, United States; 10) Dept. of Clinical Genetics, Turku University Central Hospital, Turku, Finland.

We have gathered a nationwide collection of all carriers of reciprocal balanced translocations and inversions from every Medical Genetics Department and Clinical Genetics Laboratory in Finland. Our database contains medical records of carriers and their relatives carrying the same rearrangement identical by descent as well as other relatives for comparison. To date, we have systematically assembled 3016 carriers and their relatives, and gathered samples (n=124; DNA, RNA and cells from each). We are in process of collecting more biological samples, and linking our data to the comprehensive national disease registers. Additionally, we collaborate with the International Breakpoint Mapping Consortium (Tommerup N et al. 2015 Cancer Genetics). We utilize this valuable collection as a gene mapping tool. We have searched distinct diseases or traits segregating with a given chromosomal break in the families, and identified their precise molecular location on DNA level. We focus on families, which appear to have a striking correlation of a balanced translocation or an inversion and an abnormal phenotype. In individuals from each of these families, we have performed standard cytogenetic analyses, copy number analyses (genotyping and aCGH), genome-wide paired-end sequencing, and capillary sequencing with an objective to identify specific breakpoints for each translocation and rule out other causative genetic factors. In our first gene-mapping pilot, we identified a potential positional candidate gene for intracranial and aortic aneurysm (Luukkonen T et al. 2012 JMG). We have two other manuscripts in preparation. The first is a familial translocation t(1;12)(q43;q21.1), which truncates a *CHRM3* GENCODE isoform in a family suffering from strokes. The other one is a familial translocation t(2;18), which is associated with dyspraxia. Our results demonstrate the feasibility of genome-wide paired-end sequencing for the characterization of balanced rearrangements and identification of candidate genes in patients with potentially disease-associated chromosome rearrangements. This unique registry will be of benefit to both researchers and clinicians by facilitating diagnostic purposes, genetic counseling, and subsequent follow-up.

MyGene2: Radically open data sharing to accelerate the pace of gene discovery. *J.X. Chong[1], J.H. Yu[1], Q. Yi[2], E. Zhang[3], D.A. Nickerson[2], T. Groza[3], M.J. Bamshad[1,2,4], University of Washington Center for Mendelian Genomics.* 1) Department of Pediatrics, University of Washington, Seattle, WA, USA; 2) Department of Genome Sciences, University of Washington, Seattle, WA, USA; 3) 1.Phenomics Group, Garvan Institute of Medical Research, Sydney, Australia; 4) 1.Division of Genetic Medicine, Seattle Children's Hospital, Seattle, WA, USA.

Most rare diseases are Mendelian conditions (MC), which means that mutation(s) in a single gene can cause disease. Despite the increasing pace of gene discovery and utilization of exome/whole genome sequencing (ES/WGS) in clinical settings, ~70% of families who undergo clinical ES/WGS remain without a diagnosis—and therefore are unable to benefit from advances in precision medicine. In some of these families, one or more candidate genes are identified but it is unclear which, if any, are "causal," while in others, there is no efficient way to meaningfully prioritize among the tens to hundreds of genes with segregating variants. Some families in this situation have turned to social media in an attempt to "match" with other families with the same condition or test results. However, this process is highly inefficient, and most families do not have the means or technical expertise to do matching effectively.   To lower barriers to public sharing of health and genetic data with the goal of facilitating case-matching, gene discovery, and genotype-phenotype relationship studies, we developed a website, MyGene2 (http://www.mygene2.org). MyGene2 enables families with MC to publicly share health and genetic information (e.g. VCFs and BAMs) and allows clinicians and researchers to publicly share de-identified gene data on behalf of their patients and/or research participants. Users can search MyGene2 for genes of interest and browse health and candidate gene data contributed by all families who have created profiles. Users who contribute data themselves can network with other users and are notified automatically of matches. Tools to enable phenotype matching, real-time public reporting and crowd-sourced evaluation of putative novel gene discoveries, and direct queries by families of their own sequence data are in development. MyGene2 provides a unique opportunity for radically open data sharing with the goal of accelerating the pace of gene discovery for rare diseases. Its use can empower families to directly engage with clinicians and researchers and explore their own data for "answers," and widespread adoption could transform gene discovery efforts by reducing the timeline to publication from months or years post-discovery to days. We are confident that open sharing of health information linked to candidate genes will not only accelerate the pace of gene discovery and translation into diagnostics and clinical care, it will democratize the process of gene discovery.

2661F

Association between the angiotensinogen (*AGT*) gene M235T polymorphism, the methylenetetrahydrofolate reductase (*MTHFR*) gene C677T polymorphism and preeclampsia in Vietnam. *T. Minh[1], T. Cao Ngoc[2], N. Nguyen Viet[1], H. Nguyen Vu Quoc[2], T. Le Mai Hoang[1], U. Le Thanh Nha[1].* 1) Department of Medical Genetics, Hue University of Medicine and Pharmacy; 2) Department of Obstetrics and Gynecology, Hue University of Medicine and Pharmacy.

Background: The AGT M235T and MTHFR C677T polymorphisms has been considered to associated with preeclampsia (PE), but the results from previous studies were conflicting. The aim of this study was to: (1) determine the frequencies of M235T genotypes of AGT gene and the frequencies of C677T genotypes of MTHFR gene in normotensive and preeclamptic pregnant women, and (2) survey the association between these polymorphisms and PE. **Patients and methods:** 68 preeclamptic pregnant women and 272 normotensive pregnant women were determined M235T genotypes of AGT gene by allele – specific PCR technique, were determined C677T genotypes of MTHFR gene by PCR-RFLP with DNA samples extracted from whole blood. **Results:** The frequencies of 235MM, 235MT and 235TT genotypes in normotensive pregnant women were 1.8%; 15.8% and 82.4%, respectively. These frequencies in preeclamptic pregnant women were 1.5%; 14.7% and 83.8%, respectively. The frequencies of 677CC, 677CT and 677TT genotypes in normotensive pregnant women were 83.1%; 15.1% and 1.8%, respectively. These frequencies in preeclamptic pregnant women were 67.6%; 30.9% and 1.5%, respectively. There was no association between the M235T polymorphism and PE. There was the association between the MTHFR C677T polymorphism and PE (p = 0.0074). **Conclusion:** There was no association between M235T polymorphism and PE, but there was the association between the MTHFR C677T polymorphism and PE.

Menchaca, Guadalajara, Jalisco.

Introduction. Ataxia telangiectasia (AT) is a chromosomal instability syndrome caused by mutations in the *ATM* gene. Is a low incidence disease 1/40,000; characterized clinically by ataxia associated with a progressive neurological damage, immunodeficiency, telangiectasias, predisposition to cancer, and susceptibility to damage by ionizing radiation (IR) mediated by overproduction of oxidant radicals. Oxidative stress is the imbalance to favor a pro-oxidant state with consequent damage to biomolecules in the body. The antioxidant and antigenotoxic effect of curcumin and alpha lipoic acid (ALA) have not been evaluated in AT cells patients, therefore it is interesting to evaluate its effect since there is no treatment for these patients. Previously AT lymphoblastoid lines treated with ALA finding significant levels reduction of proteins involved in cell cycle that are elevated due to oxidative stress but without making techniques such as lipid peroxidation, besides unevaluated DNA damage. **Objective.** To evaluate the effect of ALA and curcumin to reduce oxidative damage caused by IR in lymphocytes from patients with AT measuring the concentration of lipid peroxidation and DNA fragmentation by comet assay. **Material and methods**. We used peripheral blood lymphocytes from 4 patients with AT as a study model. Lymphocytes microcultures during 72 h were exposed to curcumin 25 µmol and / or ALA 80 µmol and subsequently exposed to 1 Gy IR. After harvesting, lipid peroxidation test and comet assay were performed. **Results.** Irradiated lymphocytes showed no significant differences compared with control cells, curcumin showed a higher damage value compared to control and did not decrease the damage caused by radiation, even it associated with increased damage, while ALA had a smaller value and decreased the damage caused by radiation, as well as the ability to decrease the concentration of lipids peroxidation. **Conclusions**. Curcumin had a genotoxic effect, and pro-oxidant, whereas ALA had an antioxidant and antigenotoxic effect on lymphocytes from patients with AT *in vitro*.

Exome sequencing identifies *ATAD5* as a novel predisposition gene for familial uveal melanoma. *M.H. Abdel-Rahman[1,2], R. Pilarski[2], D. Hedges[2], G. Boru[1], K.M. Sample[1], K. Sadek[1], J.B. Massengill[1], D. Kinnamon[2], P. White[3], B. Kelly[3], S. Yoon[4,5], K. Myung[4,5], F.H. Davidorf[1], C.M. Cebulla[1].* 1) Ophthalmology, The Ohio State University, Columbus, OH; 2) Division of Human Genetics, Department of Internal Medicine and Comprehensive Cancer Center, Columbus, Ohio; 3) Biomedical Genomics Core, Nationwide Children Hospital, Columbus, Ohio; 4) Genome Instability Section, Genetics and Molecular Biology Branch, National Human Genome Research Institute, NIH, Bethesda, Maryland; 5) Center for Genomic Integrity, Institute for Basic Science, Korea.

Objectives: About 12% of uveal melanoma (UM) patients have features suggestive of hereditary cancer predisposition. Germline mutation in *BAP1* explains only a small subset of these patients, suggesting the existence of other candidate genes. Methods: Whole exome sequencing (WES) was carried out on a proband and his mother, both with UM. Tumor tissue on the proband was also sequenced. Validation of the mutation was carried out by direct sequencing. Functional studies of candidate genes and downstream signals were assessed in lymphoblastoid cell lines generated from the proband's peripheral blood leukocytes and from his tumor tissue. Direct sequencing of the coding region of *ATAD5* was carried out on an additional 26 unrelated UM patients. Results: Using WES, germline private deleterious variants were identified in 13 genes in common between the proband and his mother. Four of these (*ATAD5*, *DIDO1*, *PIK3C2B* and *MMS19*) have been previously associated with cancer. No evidence of biallelic inactivation of any of the four genes was observed in the UM tumor tissue from the proband. In view of association of haploinsufficiency in mammalian *Atad5* with genomic instability and tumorigenesis we further focused on this gene. The mutation in *ATAD5* (c. 3517G>A, p. Glu1173Lys) was in the functional ATPase domain of the protein. A decrease in the protein expression of the *ATAD5*, though not significant, was observed in the peripheral blood leukocytes of the proband compared to the controls. Accumulation of PCNA, an established downstream target of ATAD5, was observed in the proband's leukocytes suggesting failure of its unloading. Low level microsatellite instability was observed in the proband's tumor. A high frequency of somatic mutations was observed in the proband's UM compared to the average of the reported mutations in UM. Variants of uncertain significance in *ATAD5* were observed in several UM patients by direct sequencing. Conclusions: Our results suggest that the germline mutation in *ATAD5* is the main driver of UM, and possibly other cancers, in this family. Together with a recent study suggesting a role for germline *ATAD5* mutations in development of ovarian cancer, our results support *ATAD5* as a rare hereditary cancer predisposition gene for UM and other tumors in humans. .

Personal and family history in patients with high penetrance germline findings through paired tumor/normal sequencing. *J. Everett[1,3], K. Hanson[1], V.M. Raymond[1], M. Jacobs[1], E.M. Stoffel[1], J. Innis[1,2], D. Robinson[3], Y. Wu[3], P. Vats[3], R. Lonigro[3], C. Kumar[3], R. Mody[4], A. Chinnaiyan[3,5].* 1) Dept of Internal Medicine, University of Michigan, Ann Arbor, MI; 2) Dept of Human Genetics, University of Michigan, Ann Arbor, MI; 3) Center for Translational Pathology, University of Michigan, Ann Arbor, MI; 4) Dept of Pediatrics, University of Michigan, Ann Arbor, MI; 5) Dept of Pathology, University of Michigan, Ann Arbor, MI.

   Introduction: The Michigan Oncology Sequencing Project (MI-Oncoseq) uses exome sequencing of tumor-normal pairs to identify therapeutic targets. Pathogenic and likely pathogenic (P/LP) germline variants in high or moderate penetrance cancer genes are disclosed. Increased use of tumor sequencing has raised concerns about unanticipated germline findings. We examined correlation between personal history (PHx), family history (FHx) of cancer, and P/LP variants in high penetrance genes. **Methods:** Adults with refractory tumors and pediatric patients with any cancer are study eligible. Genetic counselor-collected, cancer focused pedigrees were reviewed for patients with P/LP variants in high penetrance cancer genes to determine if genetic testing or clinical criteria were met for the gene/syndrome identified. **Results:** Between August 2011 and March 2016, 691 patients completed sequencing. 27 patients (3.9%) had a P/LP germline variant associated with an autosomal dominant high penetrance syndrome (*AIP, APC, BRCA1, BRCA2, DICER1, FH, MLH1, MSH2, PDGFRB, PTPN11, RB1, RET, SBDS, SMARCA4, SOS1, TP53*). 10/27 (37%) had FHx meeting testing criteria, and in 7 of these 10 cases the variant was known from prior testing. An additional 11/27 (40.7%) had PHx of cancer or other findings associated with the gene identified. 6/27 (22%) did not meet clinical or testing criteria. Reasons for not meeting criteria included syndromes with non-cancer findings not queried at pedigree collection (3) and mosaicism (1). Two patients had true unanticipated P/LP variants: *APC* in a patient with hepatocellular carcinoma, and *RET* in a patient with no PHx/FHx of related cancers. **Conclusion:** Among patients having tumor-normal sequencing, 3.9% had a P/LP germline variant in a gene associated with a high penetrance cancer risk syndrome. 77% of these findings were clinically consistent with PHx/FHx. True unanticipated findings in high penetrance cancer genes were rare in our cohort (2/691; 0.2%) suggesting that concerns about unanticipated findings are unwarranted when PHx/FHx is collected and considered.

***BRCA* testing in Ovarian tumors initiated by a PAthologist (OPA): A pre-screen for germline testing and therapy choice.** *I.E. Fakkert[1], A.R. Mensenkamp[1], E.M. Leter[2], J.A. de Hullu[3], R.W. Willems[4], G.W. Woldringh[1], M. Simons[4], M. Jongmans[1,5], H. Bulten[4], M.J.L. Ligtenberg[1,4], N. Hoogerbrugge[1].* 1) Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands; 2) Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, The Netherlands; 3) Department of Obstetrics and Gynecology, Radboud university medical center, Nijmegen, The Netherlands; 4) Department of Pathology, Radboud university medical center, Nijmegen, The Netherlands; 5) Department of Medical Genetics, University Medical Center Utrecht, Utrecht, the Netherlands.

   Background: Dutch guidelines advise germline DNA *BRCA1* and *BRCA2* testing to all women with ovarian cancer (OC). Approximately 20% of all OC patients have a *BRCA* mutation in their tumor DNA, of which 75% are germline and 25% somatic mutations. Both may benefit from PARP inhibitor therapy. A tumor DNA *BRCA* test for all patients with newly diagnosed OC initiated by a PAthologist (OPA) may serve as a pre-screen for germline DNA *BRCA* testing and as a predictive test for response to PARP inhibitor therapy. **Methods:** Pathologists from multiple laboratories were invited to submit formalin fixed, paraffin embedded (FFPE) samples of all newly diagnosed epithelial OCs for tumor DNA *BRCA* testing. *BRCA* testing was performed using a combined approach of single molecule molecular inversion probe (smMIP)-based targeted next generation sequencing (NGS) and *BRCA1* Multiplex Ligation-dependent Probe Amplification (MLPA) for the detection of gross deletions and duplications in DNA from these samples. Turnaround time for tumor DNA *BRCA* testing was calculated from dates of request to test result. Test results were shared with patients by the gynecologic oncologist, who referred patients with a positive tumor DNA *BRCA* test for germline testing. **Results:** From October 2015 to April 2016 54 tumor DNA *BRCA* tests were requested for 51 women. *BRCA* testing was not feasible in five of the provided tumor samples, because of low tumor cell percentage (N = 2) or low DNA quantity or quality (N = 3). For three of these *BRCA* testing was performed on a different sample. In women with complete tumor DNA *BRCA* testing, median age at OC diagnosis was 63 (range 29-86). *BRCA* mutations were detected in 11 tumors (22%; 6 *BRCA1* and 5 *BRCA2*), of which eight were high-grade serous cancers, one low-grade serous, one endometrioid and one undifferentiated. Median age of women with tumor DNA *BRCA* mutations was 58 (47-85). Median turnaround time was 14 days (7-29). Germline testing was performed in four women and revealed two germline *BRCA1* mutations. **Conclusion:** Tumor DNA *BRCA* testing initiated by the pathologist was feasible in most tumors and turnaround times were short. Knowledge on tumor *BRCA* mutation status can be used to select patients for germline testing and to aid therapy choices shortly after OC diagnosis. **Future plans:** Uptake of tumor DNA *BRCA* testing will be evaluated with data from a national pathology registration database. Patients and physicians experiences will be evaluated by questionnaires.

2666T

Expanded phenotype in multiple endocrine neoplasia type 1 in *MEN1* **mutation carriers.** *J.M. Gass, K.J. Harris, P.S. Atwal.* Center for Individualized Medicine, Department of Clinical Genomics, Mayo Clinic , Jacksonville , FL.

   Introduction: Multiple endocrine neoplasia type 1 (MEN1) is a hereditary cancer associated with many different endocrine as well as non-endocrine tumors, caused by mutations in the *MEN1* gene. Clinical diagnosis is established in an individual with at least 2 MEN1-associated tumors or an individual with one MEN1-associated tumor and a first degree relative with a clinical diagnosis of MEN1. Primary hyperparathyroidism affects the majority of MEN1 individuals by age 50 years. Additionally, *MEN1* mutations trigger familial isolated hyperparathyroidism. We describe a 76-year-old female who presented to our Genetics Clinic with a family history of primary hyperparathyroidism and the identification of a pathogenic *MEN1* variant. **Methods:** Molecular testing for the known *MEN1* mutation c.1A>G as well as biochemical testing, MRI of the brain and abdomen were all performed using standard methods. **Results:** Molecular testing revealed our patient possessed the MEN1 pathogenic variant previously identified in her two offspring. This particular variant was also reported in a family with isolated hyperparathyroidism. Physical exam revealed red facial papules and onset in her seventies, involving her cheeks, nose and upper lip. Formerly, she was diagnosed with rosacea by a Dermatologist and noted no improvement with treatment. Clinically, these lesions appear to be facial angiofibromas. Glucagon was mildly elevated and pancreatic polypeptide was nearly seven times the upper limit of the normal range. Brain MRI was normal. However, an MRI of her abdomen revealed a 1.5 cm lesion at the tail of the pancreas with normal adrenal glands. The patient underwent spleen sparing distal pancreatectomy and subsequent pathology was consistent with a well differentiated pancreatic neuroendocrine tumor. **Conclusion:** Age-related penetrance and variable expressivity are well documented in families with MEN1. It is thought that nearly all individuals with MEN1 manifest disease by age 40. We present a case of late-onset MEN1 in the absence of the most common feature, primary hyperparathyroidism, but with the presence of a PNET and cutaneous findings. This family expands the phenotype associated with the c.1A>G variant and highlights the importance of providing comprehensive assessment of *MEN1* mutation carriers in families that at first blush may appear to have isolated hyperparathyroidism. .

Whole exome sequencing identifies *TSC1/TSC2* **biallelic loss as the primary and sufficient driver event for renal angiomyolipoma development.** *K. Giannikou[1], I.A. Malinowska[1], T.J. Pugh[2], R. Yan[1], Y.Y Tseng[2], C. Oh[2], J. Kim[2], M.E. Tyburczy[1], Y. Chekaluk[1], Y. Liu[1], N. Alesi[1], G. Finlay[3], C.L. Wu[4], S. Signoretti[1], A. Sivachenko[2], M. Meyerson[2], G. Getz[2], J. Boehm[2], E. Henske[1], D.J. Kwiatkowski[1], * equal contribution.* 1) Division of Pulmonary and Critical Care Medicine and of Genetics, Brigham and Women's Hospital, Harvard Medical School, 20 Shattuck Street, Boston MA 02115, USA; 2) Broad Institute of Harvard and MIT, Cambridge, MA 02142, USA; 3) Tufts New England Medical Center, Boston, MA 02111, USA; 4) Massachusetts General Hospital, Boston, MA 02114, USA.

   Renal angiomyolipoma is a kidney tumor of mesenchymal cells in the perivascular epithelioid (PEComa) family that is common in both Tuberous Sclerosis Complex (TSC) and Lymphangioleiomyomatosis (LAM). Multiple, bilateral angiomyolipomas in TSC can contribute to renal dysfunction and large angiomyolipomas can lead to life-threatening hemorrhage. Angiomyolipomas are known to have bi-allelic inactivating mutations in *TSC2* and less commonly in *TSC1*. The frequency and contribution of other somatic genetic events is unknown so far. We performed whole exome analysis in 32 resected tumors (n=30 angiomyolipoma, n=2 LAM) from 15 subjects, including three with TSC. Two germline and 23 somatic inactivating mutations in *TSC2* were identified in 30 of 32 samples (94%), as well as one germline *TSC1* mutation, most of them novel. Twenty of 32 (62%) samples showed copy neutral LOH (CN-LOH) mostly in *TSC2* and less commonly in *TSC1. A*t least 8 different LOH regions were defined by SNP analysis. Nine of 32 (28%) samples had small second hit mutations in *TSC2*. Whole exome sequencing in comparison to normal tissue identified 78 somatic non-synonymous coding region variants in 23 tumors, mainly missense and non-recurrent, all confirmed by other methods. Overall, there was a median of 4 somatic mutations per sample (range 0-12). Singleton missense mutations were identified in three known cancer associated genes *(BAP1, ARHGAP35* and *SPEN)*; their functional significance in angiomyolipoma development is uncertain. Comparison of 16 angiomyolipoma specimens from a TSC subject showed distinct genetic aberrations, indicating that most of the tumors arose independently. However, three of tumors had identical somatic mutations and CN-LOH suggesting that they derived from a common precursor cell followed by dispersion with acquisition of additional unique somatic mutations. Finally, analysis of an abdominal LAM tumor and LAM cell clusters isolated from pleural chylous fluid of a sporadic LAM subject revealed four identical somatic mutations and CN-LOH, indicative of a common clonal origin. In conclusion, our results indicate that *TSC2* and less commonly *TSC1* mutations are the primary and essential genetic driver events in renal angiomyolipoma/LAM development, and suggest that other somatic mutations are rare passenger events and likely do not contribute to tumor development. Angiomyolipomas appear to have one of the lowest somatic mutation rates ever reported for human tumors.

2668W

Unique features of GREM1 induced hereditary mixed polyposis syndrome in four Ashkenazi families. *Y. Goldberg[1], M. Schechter[2], T. Adar[2], E. Goldin[2], R. Beeri[3], E. Levy-lahad[3], N. Sharon[4], H. Baris[4], E. Half[5], I. Lerer[6], T. Peretz[1], S. Liebrerman[3].* 1) Sharett institute of Oncology, Hebrew University-Hadassah Medical Center,, Jerusalem , Israel; 2) Gastoenterology institute, Shaare Zedek Medical Center, Jerusalem, Israel; 3) Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel; 4) Gastoenterology institute, Rambam Medical Center, Jerusalem, Israel; 5) Genetic institute, Rambam Medical Center, Jerusalem, Israel; 6) Department of Human Genetics and Metabolic Diseases, Hebrew University-Hadassah Medical Center, Jerusalem, Israel.

A 40 kb duplication upstream of the *GREM1* gene has been identified as causing Hereditary Mixed Polyposis Syndrome (HPMS) in isolated Ashkenazi Jewish families, conferring a greatly increased risk of colon polyps and ultimately colon cancer. The paucity of confirmed carrier families leaves many clinical questions in diagnosing and managing HMPS unresolved. We present a collection of four non related families with HPMS who were referred to high risk clinics. The probands have undergone extensive work-up, found to carry the 40kb duplication and did not carry any other pathogenic variant in genes causing polyposis syndromes. The phenotype was extremely variable and unexpected; One of the carriers had Desmoid tumor at age of 48 and metastatic duodenal adenocarcinoma at age 67; A small tubular-adenoma was detected in a 13 year old girl; Another family fulfilled the Amsterdam criteria for Lynch syndrome. The number, pathology and age of onset of the colonic polyps in other carriers were also very variable. To estimate the incidence of HMPS, we looked for other carriers in a wider cohort of 184 Ashkenazi Jews who had colorectal cancer (142) or colonic polyps (42) and identified only one (1/184 = 0.5%) carrier. These data illustrate the phenotypic variability, and the overlap between HMPS and other colorectal and polyposis syndromes. It should help shape the diagnostic criteria, clinical guidelines and recommendations for these families who are at higher risk for gastro-intestinal cancer.

2669T

Whole exome and genome sequencing to identify familial multiple myeloma risk genes. *S. Lipkin[1], V. Joseph[2], C. Snyder[3], C. Vachon[8], N. Camp[5], J. McKay[9], R. Niesvizsky[1], S. Chen-Kiang[1], J. Garber[7], M. Daly[4], H. Yu[1], X. Wei[1], H. Lynch[3], R. Klein[6], C. Dumontet[9], K. Offit[2].* 1) Dept Medicine, Weill Cornell, New York, NY; 2) Memorial Sloan-Kettering Cancer Center, New York, New York; 3) Hereditary Cancer Institute, Creighton University; 4) Broad Institute, Cambridge, MA; 5) Huntsman Cancer Institute, University of Utah; 6) Department of Genetics, Mount Sinai School of Medicine; 7) Dana Farber Cancer Institute, Boston, Massachusetts; 8) Mayo Clinic, Rochester, Minnesota; 9) IARC, Lyon, France.

Important strides in our understanding of the genetic basis of cancer susceptibility over the past three decades have impacted the management of both adult and pediatric malignancies. The incorporation of cancer genetic testing into oncology signifies one of the first applications of precision medicine, since it allowed tailored cancer screening, prevention, and in some cases, therapeutic measures. More recent discoveries of mutations of *TP53, RUNX1, CEBPA, GATA2, KLHDC8B,* and *NPAT* have characterized novel syndromes of hereditary predisposition to hematological malignancies. As part of a program to understand the constitutional risk factors associated with inherited risk for many types of hematological malignancies, we have performed whole exome and genome sequencing on probands with familial and early onset Multiple Myeloma. Here we will describe mutation burden analyses, specific candidates and mechanistic validation of novel risk loci previously not associated with familial predisposition to Multiple Myeloma.

2670F

Genomic analysis of inherited breast cancer among Palestinian women.
S. Lolas-Hamameh[1,2,3], L. Kamal[1], D. Dweik[1], M. Salahat[1], P. Renbaum[3], T. Walsh[4], M.K. Lee[4], S. Gulsuner[4], S. Casadei[4], M.C. King[4], E. Levy-Lahad[2,3], M. Kanaan[1]. 1) Hereditary Research Lab, Bethlehem University, Bethlehem, Palestinian Territory; 2) Faculty of Medicine, Department of Human Genetics, Hebrew University of Jerusalem, Jerusalem, Israel; 3) Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem 91031, Israel; 4) Departments of Medicine and Genome Sciences, University of Washington, Seattle, Washington, 98195, USA.

Breast cancer incidence in Palestinian women has historically been low, but is rapidly increasing with increased education and later initiation of child bearing. Perhaps because of its historically low incidence, breast cancer in Palestinian women is strikingly familial. We studied inherited breast cancer predisposition in Palestinian women in a hospital-based cohort of 854 breast cancer patients. The cohort was divided into a mutation discovery series (N=391) of 224 women with positive family history and 167 women diagnosed by age 40 years, and general patient series (N=463). The discovery series was tested by the BROCA panel for 28 known and candidate breast and ovarian cancer genes. Considering only unambiguously damaging mutations (i.e. truncations, complete deletions, splice mutations leading to a mutant message, and experimentally validated loss-of-function missenses), in the discovery cohort we identified 38 different mutations, 17 not previously reported, in 47/391 cases (12.0%). Of the 47 patients with mutations, 47% (22) carried mutations in *BRCA1* or *BRCA2*, 12.8 % (6) in *TP53*, 10.6% (5) in *ATM*, 8.5% (4) in *CHEK2*, and the remaining 22.3% (10) in *BARD1*, *BRIP1*, *CDH1*, *ATR, MRE11A*, *PALB2* or *XRCC2*. One patient was a *BARD1/CHEK2* double heterozygote. The general patient series and 100 Palestinian controls were tested using allele-specific assays for 36 of these mutations, revealing 13/463 (2.8%) carriers among the patients and none among the controls. Overall, 14 mutations, in 6 genes, were recurrent in 37 unrelated patients. All recurrent mutations examined (BRCA2, CHEK2, TP53) occurred on a shared haplotype. Family history was the strongest predictor of harboring a mutation. Carrier frequency was 26% (18/70) among patients with family history and young diagnosis, 11% (17/154) among patients with family history only, and 7.2% (12/167) among patients with young onset only (P = 0.0003). *BRCA1* and *BRCA2* carriers were significantly more likely than carriers of mutations in other genes to have triple negative tumors (P = 0.04). This is the first large study to evaluate the genetics of inherited breast cancer in the Palestinian population. The mutational spectrum is highly heterogeneous, including 12 different genes with 38 different mutations, 45% of them novel. Furthermore, most familial cases did not harbor mutations in any BROCA gene, so these families can serve as a future resource for gene discovery. (Supported by the Breast Cancer Research Foundation).

2671W

Germline mutation burden in hereditary cancer predisposing genes: Pan-cancer analysis of the 51,289 individuals from the DiscovEHR study.
R.P. Metpally, S. Krishnamurthy, D. Smelser, S. Kip, D. Carey, H. Williams, Geisinger-Regeneron DiscovEHR Collaboration. Geisinger Clinic, Danville , PA.

Cancer is a complex disease with familial and environmental influences. Alterations in certain genes have been attributed to cancer risk and are providing molecular insights into tumor biology as may serve as putative drug targets. In this study, we describe the prevalence and spectrum of germline variants among cancer predisposing genes and highlight correlations between germline genotypes with tumor types. **Methods:** Using Geisinger-Regeneron DiscovEHR cohort, we sequenced the whole exomes of 51,289 study participants. Individuals were divided into those with (9,911) and without a cancer diagnosis. We analyzed the DNA sequences of 126 hereditary cancer genes of each individual. Pathogenicity of rare missense variants was predicted through weighted ensemble scoring using various damage prediction tools. **Results:** The top 5 malignancies in our population included skin (3069 individuals), prostate (1561), breast (1396), lung (639) and colon (626) cancer. Cancer susceptibility variants (26%) including Clinvar pathogenic (7.8% of individuals), novel missense pathogenic (9.5%) and nonsense (6.5%) were found in our cancer cohort. Genes with susceptibility variants in at least 40 individuals from our cohort are shown in Table 1. Top variants were distributed among several tumor types including skin, prostate, breast, colon, bladder, lung, thyroid, uterine, lymphoma and leukemia. **Conclusions:** Cancer predisposing germline mutations were found in a substantial number of DiscovEHR participants with cancers. Knowledge of these mutations and integration with somatic information will help to predict cancer susceptibility, and thus be beneficial in counseling patients, cascade screening of their families and directing more personalized and disease-specific care, all of which are important steps towards precision medicine.

PTEN hamartoma tumour syndrome: Two Colombian cases with Cowden Syndrome and Bannayan-Riley-Ruvalcaba Syndrome. *A. Nova[1], J.C Prieto[1,2], J.A Rojas[1].* 1) Bogota D.C, Instituto de Genetica Humana, Pontificia Universidad Javeriana, Bogota, Colombia, Bogota, Bogota, Colombia; 2) Hospital La Victoria SDS, Bogota, Colombia.

PTEN hamartoma tumour syndrome (PHTS) is the term adopted to describe Cowden syndrome (CS), Lhermitte–Duclos disease (LD), Bannayan-Riley-Ruvalcaba syndrome (BRRS), Proteus syndrome (PS), and Proteus-like syndrome. Recently, it also has been identified in a fraction of patients with autism spectrum disorder (ASD) who also display macrocephaly with and without additional developmental phenotypes characteristic of PHTS. For this reason currently this term describes a spectrum of disorders that have been linked to germline mutations in *PTEN* (phosphatase, tensin homologue, deleted on chromosome 10) that encodes a tumor suppressor protein, which mediates cell-cycle arrest and apoptosis. The prevalence of detectable PTEN germline mutations in these syndromes is 80% for CS patients, 83% for LD patients, 60% for BRRS patients, 50% for PLS patients, and 20% for PS patients. CS is a multiple hamartoma syndrome with a high risk of benign and malignant tumors of the thyroid, breast, endometrium and other organs. BRRS is a congenital disorder characterized by macrocephaly, intestinal polyposis, lipomas, and genital lentiginosis. While most cases are inherited in a family for generations, following an autosomal dominant pattern, at least 10% and perhaps as many as 44% of cases are due to a new (*de novo*) mutation. PHTS confers increased risks for specific malignancies, most notably breast, thyroid, renal, and endometrial cancers. Benign tumors that affect a variety of tissues are common and can range from subtle skin papules, requiring no treatment, to devastating vascular anomalies. Because the diagnosis of PHTS is difficult to establish by the variable and often subtle external manifestations, many individuals remain undiagnosed, so the true prevalence is unknown. Here we present two Colombians cases, affected by CS and BRRS syndrome respectively, both are carriers of a mutation in PTEN protein, aimed at avoid misdiagnosis and allow taking preventive measures in these patients to promptly identify malignancies and complications.

Physical activity is inversely associated with colorectal cancer risk in Lynch syndrome. *M. Pande[1], A.K. Win[2], K. Basen-Engquist[1], S.S. Hardikar[3,4], Y.N. You[1], M.A. Jenkins[2], S.K. Peterson[1], P.M. Lynch[1].* 1) The University of Texas MD Anderson Cancer Center, Houston TX, USA; 2) Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia; 3) Department of Epidemiology, University of Washington, Seattle WA, USA; 4) Division of Public Health Sciences, Fred Hutchison Cancer Research Center, Seattle WA, USA.

Background: The beneficial effect of physical activity on colorectal cancer (CRC) risk is well established, however little is known about the influence of physical activity on risk of CRC for those with a genetic predisposition to CRC such as carriers of germline DNA mismatch repair (MMR) gene mutations (Lynch syndrome). **Methods**: We analyzed data from 1865 MMR mutation carriers recruited into the Colon Cancer Family Registry from the USA, Canada and Australia between 1998 and 2012. Self-reported physical activity was summarized over the person's adult life starting at age 20 years, in metabolic equivalent hours per week (MET-h/week). Exposure was assessed prior to the outcome event (CRC) or censoring (diagnosis of a polyp or non-CRC cancer or questionnaire completion) whichever came earliest. Physical activity was categorized as <3.5, ≥3.5-<8.75, ≥8.75-<17.5, ≥17.5-<35, ≥35 MET-h/week (3.5 = 1 hour; 8.75 = 2.5 hours; 17.5 = 5 hours; 35 = 10 hours of brisk walking). A weighted Cox proportional hazards regression was used to estimate the association between physical activity and CRC, while adjusting for relevant confounders. **Results**: There were 691 CRC events over an observation of 80,625 person-years. Compared with the lowest level of physical activity (<3.5 MET h-week), higher levels of physical activity were associated with a decreased risk for CRC (Table 1), however, the association was not linear. The inverse association was maintained after adjusting for potential confounders, although estimates were attenuated. **Conclusion**: Physical activity was inversely associated with the risk of CRC in Lynch syndrome and may warrant counseling of these high-risk individuals to follow national physical activity guidelines.

Mutational profiles of cancer-relevant genes in Lynch syndrome tumor-igenesis. *N. Porkka[1], S. Valo[1,2], T.T. Nieminen[1], S. Eldfors[3], P. Peltomäki[1].* 1) Department of Medical and Clinical genetics, University of Helsinki, Helsinki, Finland; 2) Department of Biosciences, University of Helsinki, Helsinki, Finland; 3) Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland.

Predisposition to Lynch syndrome (LS) is caused by germline mutations in mismatch repair (MMR) genes, notably *MLH1*, *MSH2*, *MSH6*, and *PMS2*. It is the most common form of hereditary colorectal cancer (CRC) accounting 3 – 5% of all CRCs. Defects in MMR gene function cause accumulation of replication errors in the genome. This study was designed to profile different tumors from MMR gene mutation carriers for somatic alterations, starting from colorectal adenomas and carcinomas. The tumors originated from a nation-wide registry of LS families. Frequency of the CpG island methylator phenotype (CIMP) was analyzed using the methylation-specific multiplex ligation-dependent probe amplification test, which detects the methylation status of eight CIMP marker genes simultaneously. Next-generation sequencing of tumor and matching normal samples was conducted using the Nimblegen Comprehensive Cancer Panel, which covers the coding regions of 578 known cancer related genes. Somatic mutations (missense, nonsense, frameshift, in-frame coding indels and splice site mutations) with VarScan somatic p-value < 0.01 were recorded and categorized based on the allele frequency (< 25% vs. ≥ 25%) and type of mutation (truncating vs. non-truncating). CIMP occurred in 18% of (high-dysplasia) adenomas and 50% of CRCs. All adenomas and CRCs were MMR-deficient by MMR protein expression and microsatellite instability analysis. A great majority of the 578 cancer-associated genes showed somatic mutations in all tumor groups. The average frequency of somatic mutations per tumor was higher in adenomas compared to carcinomas, 1514 (range 73 – 4123) vs. 1103 (range 116 – 2379). Focusing on four known CRC driver genes *APC, BRAF, KRAS,* and *TP53*, the somatic mutation frequencies of each were higher in adenomas than carcinomas (although not statistically significant probably due to limited sample series). With adenomas and carcinomas combined, the average frequency of somatic mutations per tumor was 1245, which was significantly (P = 0.007) higher than that in Lynch syndrome breast carcinomas (671). Analysis of additional types of LS tumors and sporadic counterparts is in progress. The genes examined for somatic mutations represent multiple pathways relevant for cancer initiation and progression. The patterns of somatic alterations we found suggest that several molecular mechanisms, genetic and epigenetic, contribute to the high mutation frequencies characteristic of LS tumors.

Exome sequencing and analyses in a familial breast cancer cohort to identify novel cancer predisposition variation. *K. Praveen[1], W. Chang[2], M.B. Terry[3], J.H. Chung[1], S. Mukherjee[1], J. Staples[1], V. Arunachalam[1], S. Balasubramanian[1], Q. Huang[4], J. Penn[1], J. Reid[1], J.D. Overton[1], Y. Shen[4], F.E. Dewey[1], C. Gonzaga-Jauregui[1], W.K. Chung[2].* 1) Regeneron Genetics Center, Regeneron Pharmaceuticals, Tarrytown, NY; 2) Departments of Pediatrics and Medicine, Columbia University Medical College, New York, New York; 3) Department of Epidemiology, School of Public Health, Columbia University, New York, New York; 4) 4Departments of Systems Biology and Biomedical Informatics, Columbia University Medical College, New York, New York.

   Introduction: Familial breast cancer (FBC) accounts for ~30% of all breast cancer in the population. Germline variants in the predisposition genes that have been identified to date, such as *BRCA1, BRCA2, CHEK2* etc., collectively account for ~35% of FBC. Hence, a majority of familial cases have an unknown genetic cause and may have variants in novel cancer predisposition genes. **Methods:** We performed whole exome sequencing (WES) on a cohort of 1,331 individuals with a family history of breast cancer. The cohort was composed of 737 Ashkenazi Jewish, 550 Dominican individuals and 44 individuals of unknown ancestry. A total of 562 FBC patients and 669 unaffected relatives belonging to 491 families were sequenced. We analyzed all probands for pathogenic and loss-of-function variants in known breast cancer predisposition genes, and conducted family based analyses when multiple family members (≥3 affected individuals) were available for segregation of variants. We also performed case-control single variant association analysis on the cohort using mixed linear models. These results were then used for pathway-based analyses to look for enrichment of variants in pathways in breast cancer patients. **Results:** A screen for variants in known breast cancer predisposition genes identified known and likely pathogenic variants in 12 of 29 genes tested (31 variants). These variants likely increase breast cancer predisposition in 35 families. Amongst the prioritized candidates from the family based analysis, we identified genes involved in DNA repair, apoptosis and cell division, and innate immunity. There were no significant single variants from association analysis after multiple testing correction. However, pathway analysis revealed an enrichment of variants in metabolic and signaling pathways, such as Notch signaling and PI3K/AKT/mTOR pathways. **Conclusions:** Our family based analysis of FBC revealed novel candidate genes for FBC predisposition that function in pathways important in cancer susceptibility. We did not observe a meaningful overlap of candidate genes between families suggesting that there is considerable genetic heterogeneity in predisposition to FBC in patients who do not harbor causative variants in one of the major known predisposition genes. However, we noted a significant enrichment of variants in pathway based analysis suggesting that while FBC patients in our cohort carry variants in different genes, these genes may function in similar biological processes.

2676F

Frequency of pathogenic germline mutations in *EZH2* in 776 children with neuroblastoma. *D.R. Stewart[1], J.P. Evans[2], T. Pugh[3], R. Patidar[4], Y. Song[4], K. Conkrite[2], K.A. Cole[2], N. Menghani[2], L. Farra[2], S. Sindiri[4], X. Wen[4], S. Zhang[4], G. Lopez[2], J. Guidry Auvil[5], D.S. Gerhard[5], S.J. Chanock[1], J.M. Maris[2], J. Khan[4], J. Wei[4], S.J. Diskin[2], Cancer Genomics Research Laboratory.* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; 2) Children's Hospital of Philadelphia, Philadelphia, PA; 3) Princess Margaret Cancer Centre, Toronto, Canada; 4) Center for Cancer Research, National Cancer Institute, Bethesda, MD; 5) Office of Cancer Genomics, National Cancer Institute, Bethesda, MD.

   BACKGROUND. Genetic susceptibility to neuroblastoma (NB) is complex, and the contribution of rare germline mutations beyond *ALK* and *PHOX2B* is unknown. Here, we report on our efforts to identify rare, deleterious germline variants that play a role in the initiation of sporadic NB. We initially focused our analysis on known cancer-predisposition genes and genes underlying syndromes associated with NB. **METHODS.** We conducted Complete Genomics whole-genome sequencing (106 high-risk tumor-germline) and Illumina exome sequencing (222 high-risk tumor-germline; 52 overlapping, 54 non-overlapping with whole-genome). 500-genes were sequenced by custom-capture in an independent validation cohort of 500 NB patients (germline-only) and compared with 1001 cancer-free controls sequenced/analyzed by the same platform/pipeline. Rare variants were annotated using the database for non-synonymous functional predictions (dbNSFP). Indels were called by bam2MPG and Platypus in the 222 exome cohort and in 1000 Genomes (1000G). We queried 1000G, Exome Sequencing Project (ESP) and Exome Aggregation Consortium (ExAC) for pathogenic variation. **RESULTS.** In 776 children with NB, there were 4 pathogenic (P) or likely pathogenic (LP) germline *EZH2* variants not observed in 1000G, ESP or ExAC: 1) c.G598A; p.D200N (missense, splice-site) in a male, now deceased, with unfavorable histology, 2) c.1732_1735del; p.T578fs in a male, now deceased, with ganglioneuroblastoma (GNB) and unfavorable histology, 3) c.-1_2delCAT; p.Met1del in a male with GNB and unfavorable histology but still alive and, 4) c.1184delG; p.Gly395fs in a male with NB and favorable histology, still alive. The latter tumor also harbored a somatic 5.9 kb 3-exon deletion in *EZH2*. No truncating *EZH2* variants are reported in ExAC. There were no truncating *EZH2* or HG-MD-reported variants in the 1001 cancer-free controls (P < 0.05). **DISCUSSION.** Germline mutations in *EZH2*, a member of the polycomb repressive complex 2, are associated with Weaver syndrome (WS), an autosomal dominant overgrowth disorder. Case reports of children with WS and/or *EZH2* mutations include leukemia (ALL/AML) and NB. We found 4 germline P/LP *EZH2* variants in 4/776 children with NB (0.5%), including one whose tumor also harbored a somatic multi-exon deletion in *EZH2*. **CONCLUSION.** We establish the frequency of pathogenic germline *EZH2* mutations in sporadic NB. Risk of malignancy in children with pathogenic germline *EZH2* mutations merits further investigation.

Pancreatic cancer as an inclusion factor for genetic testing of breast and colorectal cancer susceptibility genes. *B.A. Thompson[1,2], E.L. Young[1], M.A. Firpo[1,3], S.J. Mulvihill[1,3], T. Werner[1,4], R. Bell[1], K.R. Smith[5], J. Berger[5], A. Fraser[5], L. Neumeyer[6], D.E. Goldgar[7], W.K. Kohlmann[1], S.V. Tavtigian[1,8].* 1) Huntsman Cancer Institute, Salt Lake City, UT; 2) Centre for Epidemiology and Biostatistics, School of Population and Global Health, University of Melbourne, Melbourne, Australia; 3) Department of Surgery, University of Utah School of Medicine, Salt Lake City, UT; 4) Division of Oncology, Department of Medicine, University of Utah, Salt Lake City, UT; 5) Population Sciences, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; 6) Department of Surgery and Arizona Cancer Center, University of Arizona, Tucson, AZ; 7) Department of Dermatology, University of Utah School of Medicine, Salt Lake City, UT; 8) Department of Oncological Sciences, University of Utah, Salt Lake City, UT.

   Genes associated with hereditary breast and ovarian cancer (HBOC) and colorectal cancer (CRC) susceptibility are known to play a role in pancreatic cancer susceptibility. Pancreatic cancer is still lacking adequate measures for prevention or early stage tumor detection. Germline genetic testing will be most beneficial for at-risk relatives of pancreatic cancer cases with pathogenic variants in established HBOC and CRC genes, but it is unclear what proportion of pancreatic cancer cases harbor pathogenic variants in those genes.In an initial experiment, a set of 66 pancreatic cancer cases diagnosed at the Huntsman Cancer Hospital (HCH), SLC, UT, unselected for age of onset or family history, were sequenced using a custom 34 gene panel including known HBOC and CRC genes. The proportion of cases with a pathogenic gene variant was estimated probabilistically. Cases with an established pathogenic variant were assigned weight=1.0. Cases with a Variant of Uncertain Significance (VUS) in *BRCA1/2* [MIM 113705, 600185] or a mismatch repair gene [MIM 276300] were assigned a weight equal to the VUSs probability of pathogenicity from curated publicly available databases. Carriers of VUS from other genes were assigned a weight from Align-GVGD, CADD, Polyphen-2, and MAPP scores. We found that 8.5% of these cases carried a pathogenic variant.To refine the carrier frequency estimate for unselected pancreatic cancer cases, a meta-analysis was conducted using the initial set, a second set from the HCH (n=95), the Cancer Genome Atlas (TCGA) cohort (n=154), and a published dataset from a similar screen of unselected patients (n=96). These were compared to the non-TCGA Exome Aggregation Consortium (ExAC) dataset, using Standardized Incidence Ratios (SIR).Overall, 11.9% of unselected pancreatic cancer cases carried a variant (including weighted VUS) in known HBOC and CRC susceptibility genes, that would alter the screening recommendations for at-risk relatives. High-risk genes contributed 5.4% (SIR 5.37, p<0.001), and moderate-risk breast cancer genes contributed 5.0% (SIR 2.51, p<0.001).We conclude that the frequency of mutation carriers among unselected pancreatic cancer cases is high enough to rationalize applying genetic panel tests that include both HBOC and CRC susceptibility genes to all newly diagnosed pancreatic cancer cases. This could further benefit at-risk relatives with cascade testing of healthy relatives for increased HBOC and CRC surveillance measures.

Effects of Western-style diet and genetic predisposition on the colon proteome. *S. Valo[1,2], D. Dermadi[2,3,4], S. Ollila[5], R. Soliymani[6], M. Pussila[2], L. Sarantaus[2], J. Linden[7], M. Baumann[6], M. Nyström[2].* 1) Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland; 2) Department of Biosciences, Genetics, University of Helsinki, Helsinki, Finland; 3) Laboratory of Immunology and Vascular Biology, Department of Pathology, Stanford University School of Medicine, Stanford, California, USA; 4) The Center for Molecular Biology and Medicine, Veterans Affairs Palo Alto Health Care System, Palo Alto, California, USA; 5) Research Program Unit, Faculty of Medicine, University of Helsinki, Helsinki, Finland; 6) Meilahti Clinical Proteomics Core Facility, Department of Biochemistry and Developmental Biology, Medicum, University of Helsinki, Helsinki, Finland; 7) Department of Basic Veterinary Sciences, University of Helsinki, Helsinki, Finland.

   Lifestyle and diet have a major effect on the development of colorectal cancer (CRC). Dietary habits of Western populations in particular are recognized as a risk factor for CRC. However, the mechanisms that mediate the effects of Western-style diet (WD) on colorectal tumor development are largely unknown. CRC develops via multiple steps which involve genetic changes, such as mutations in growth-regulatory genes, and epigenetic alterations, such as CpG island hypermethylation. These changes accumulate over time in the normal colonic epithelial cells due to aging and many environmental factors such as diet. Lynch syndrome (LS) is one of the most common inherited cancer susceptibility syndromes. It is caused by inherited defects of the DNA mismatch repair genes (MMR), which together with other genetic and epigenetic changes are known to accelerate tumorigenesis. Interestingly, the disease phenotype such as age of onset and tumor spectrum vary considerably between individuals that carry the same germline mutation, which suggests contribution of environmental effects. A long-term feeding experiment with mouse models for LS and sporadic CRC was conducted to characterize tumor-promoting changes in normal colonic mucosa caused by WD and/or genetic predisposition. Changes in the proteome of histologically normal colonic mucosa were monitored at different time points of feeding experiment (5 weeks, 12, 18 and 21 months) with two high-throughput proteomic methods (2D DIGE and LC-MS) followed by analysis of affected pathways. Overall, 27 out of 38 colonic tumors were detected in mice fed with WD. Data from the proteomic analysis indicated that the proteome was more consistently changed by diet and aging than by genotype. Proteomic study coupled with histological analysis of colon crypts indicated increased proliferation in the colon mucosa of mice fed with WD, which may promote colorectal tumorigenesis. Moreover, analysis of pathways indicated decreased apoptotic processes, disrupted lipid metabolism and increased oxidative stress in the normal-appearing tissue in association with WD consumption. In summary, the results offer new insights into the initiating molecular mechanisms through which Western-style diet contributes to colorectal carcinogenesis.

Skytte[11], K. Snape[12], E. Woodward[6], M. Tischkowitz[1], E. Maher[1].* 1) Department of Medical Genetics, University of Cambridge, UK; 2) Department of Clinical Genetics, Chapel Allerton Hospital, Leeds, UK; 3) Department of Clinical Genetics, Great Ormond Street Hospital, London, UK; 4) Department of Clinical Genetics, University Hospitals Leicester, UK; 5) Department of Clinical Genetics, Royal Devon and Exeter Hospital, Exeter, UK; 6) Manchester Centre for Genomic Medicine, UK; 7) Department of Clinical Genetics, Liverpool Women's Hospital, Liverpool, UK; 8) Institute of Genetic Medicine, Newcastle, UK; 9) Department of Clinical Genetics, Birmingham Women's Hospital, UK; 10) Department of Clinical Genetics, Guys Hospital, London, UK; 11) Department of Clinical Genetics, Aarhus University Hospital, Denmark; 12) Department of Clinical Genetics, St Georges Hospital, London, UK.

Expansion in the number of inherited neoplasia genes (INGs) and capability to sequence those genes simultaneously and has provided extensive opportunities to diagnose neoplastia susceptibility syndromes. Referrals for assessment by cancer genetics services have historically been guided by suspicion of a specific syndrome/gene but a more agnostic approach, based on broad indicators of susceptibility, is likely to be beneficial in light of those advances. One such indicator is the occurrence of multiple primary tumours (MPT) in the same individual (particularly if they occur at younger ages) but a previous analysis of individuals with MPT referred to a large UK cancer genetic service showed that only around a quarter were identified as harbouring a relevant pathogenic variant in an ING[1]. In cases where a constitutional genetic cause is present, possible reasons for non-detection include an atypical phenotype leading to the relevant ING not being tested, more than one deleterious variant in the same individual, mosaicism, structural variants affecting INGs and involvement and novel INGs. In order to address these possibilities, we have established an undiagnosed MPT patient series (currently n≈550) and are applying NGS technologies to blood DNA samples. Central techniques include the Illumina TruSight cancer panel to ensure high sequencing depth (>100X) of 94 known INGs and whole exome/genome sequencing. We have achieved a molecular diagnosis in at least 10% of cases from panel sequencing. Review of these cases revealed that the diagnosis had often not been made previously because of atypical or under-recognised tumour associations with the relevant ING. Unusual combinations of multiple primary tumour phenotypes may also result from *multilocus inherited neoplastic alleles syndrome* (MINAS)[2] and we have established a genotype/phenotype database (http://databases.lovd.nl/shared/diseases/04296) to aid clinical management and prognostification in such cases. Investigations of the role of mosaicism for known INGs, CNVs/structural variants and novel INGs in the cases that are currently undiagnosed are ongoing.   1.Eur. J. Hum. Genet. 2015 23, 581-587 2.JAMA Oncol. 2016 2(3), 373-9.

Familial medullary thyroid cancer (MTC) and its precursor, C cell hyperplasia (CCH), is associated with germline *RET* mutations causing multiple endocrine neoplasia type 2. However, some rare families with apparent MTC/CCH predisposition do not have a detectable *RET* mutation. To identify novel MTC/CCH predisposition genes we undertook exome resequencing studies in a family with apparent predisposition to MTC/CCH and no identifiable *RET* mutation. We identified a novel *ESR2* frameshift mutation, c.948delT, which segregated with histological diagnosis following thyroid surgery in family members and demonstrated loss of *ESR2* encoded ERβ expression in the MTC tumour. ERα and ERβ form heterodimers binding DNA at specific estrogen response elements (ERE) to regulate gene transcription. ERβ represses ERα mediated activation of the ERE and the *RET* promoter contains three ERE. *In vitro*, we showed that *ESR2* c.948delT results in unopposed ERα mediated increased cellular proliferation, activation of the ERE and increased RET expression. *In vivo*, immunostaining of CCH and MTC using an anti-RET antibody demonstrated increased RET expression. Together these findings identify germline *ESR2* mutation as a novel cause of familial MTC/CCH and provide important insights into a novel mechanism causing increased RET expression in tumourigenesis.

2681T

Germline hemizygous deletion of *CDKN2A-CDKN2B* **locus in a patient presenting with Li-Fraumeni syndrome.** *S. Chan[1], W.K. Lim[1,4], S. Michalski[2], J.Q. Lim[1], D. Ishak[1], M. Met-Domestici[1], C. Ng[1], K. Vikstrom[2], E. Epslin[2], J. Fulbright[2], M.K. Ang[1], J. Wee[1], K. Sittapalam[3], M. Farid[1], S. Lincoln[2], K. Itahana[4], S. Abdullah[5], B.T. Teh[1,4], J. Ngeow[1,4].* 1) National Cancer Centre Singapore, Singapore, Singapore; 2) Invitae, San Francisco, California, U.S.A. 94107; 3) Singapore General Hospital SIngapore; 4) Duke NUS Medical School, Singapore; 5) RIPAS Hospital, Bandar Seri Begawan, Brunei Darussalam.

Li-Fraumeni syndrome (LFS) is a rare cancer predisposition syndrome usually associated with *TP53* germline alterations. Its genetic basis in *TP53* wild-type pedigrees is less understood. Using whole genome sequencing (WGS), we identified a germline hemizygous deletion ablating *CDKN2A-CDKN2B* in a *TP53* wild-type patient presenting with high grade sarcoma, laryngeal squamous cell carcinoma and a family history suggestive of LFS. Quantitative reverse transcription PCR (RT-qPCR) analysis confirmed that basal gene expression of *p14[ARF]* and *p16[INK4A]* was 50% lower than in healthy controls (*p*<0.001 and *p*<0.01 respectively). Immunohistochemical analysis of both MPNST and laryngeal SCC tumors were clearly null for p14[ARF] and p16[INK4A] consistent with the genomic loss observed by WGS . Patient-derived LCLs demonstrated reduced basal gene and protein expression of the *CDKN2A*-encoded tumor suppressors p14[ARF] and p16[INK4A] with concomitant decrease in p21 and faster cell proliferation, implying potential deregulation of p53-mediated cell cycle control. Review of 13 additional patients with pathogenic *CDKN2A* variants suggested associations of germline *CDKN2A* mutations with an expanded spectrum of non-melanoma familial cancers. To our knowledge, this is the first report of a germline gross deletion of the *CDKN2A-CDKN2B* locus in an LFS family. These findings highlight the potential contribution of germline *CDKN2A* deletions to cancer predisposition and the importance of interrogating the full extent of *CDKN2A* locus in clinical testing gene panels.

2682F

Exome sequencing reveals germline gain-of-function *EGFR* **mutation in an adult with Lhermitte-Duclos Disease.** *S. Colby[1,2], L. Yehia[1,3], F. Niazi[1], J. Chen[1], J.L. Mester[1], C. Eng[1,4,5,6].* 1) Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH; 2) Case Western Reserve University School of Medicine, Cleveland, OH; 3) Department of Pathology, Case Western Reserve University School of Medicine, Cleveland, OH; 4) Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH; 5) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH; 6) Germline High Risk Focus Group, CASE Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH.

Lhermitte-Duclos disease (LDD) is a rare hamartomatous lesion of the cerebellar cortex that is pathognomonic for Cowden syndrome (CS), a multisystem autosomal-dominant disorder characterized by elevated risk for benign and malignant neoplasms. Presently, the only known etiology for LDD is germline phosphatase and tensin homolog (*PTEN*) mutation, however there is a subset of LDD patients who are negative for germline alterations in all genes known to be associated with CS (*PTEN*, *SDHB-D*, *PIK3CA/AKT1*, *KLLN*). Therefore, despite the rarity of this disease entity (estimated at 1 in 1,000,000), LDD provides a valuable patient population for discovery of other CS-relevant predisposition genes, which, like *PTEN*, have far-reaching somatic implications in common sporadic neoplasias. Whole-exome sequencing and variant prioritization of eight unrelated LDD probands who are wildtype for the known CS susceptibility genes revealed a pathogenic missense heterozygous epidermal growth factor receptor (*EGFR*) variant (c.977G>T [p.Cys326Phe]) in one proband. This variant disrupts a disulfide bridge in the extracellular domain of the receptor. We show the *EGFR* p.Cys326Phe variant is an activating gain-of-function mutation resulting in increased EGFR autophosphorylation, consistent with enhanced receptor activation. We demonstrate increased downstream phosphorylation of ERK1/2 and AKT, consistent with pathway activation mimicking loss-of-function of PTEN. Our findings suggest that activating mutations in *EGFR* contribute to the pathogenesis of *PTEN* wildtype LDD. Finding the underlying molecular etiology of identical phenotypes facilitates more accurate risk assessment, specific medical management and correct choice of targeted therapy, or in the future, targeted prevention.

2683W

Results of a universal tumor screening program for Lynch syndrome: Do *PMS2* mutations account for more cases than previously estimated? *J.E. Hunter[1], K.R. Muessig[1], J.M. Zepp[1], K.A. Arnold[1], K.M. Bergen[1], J. Cook[1], J.V. Davis[1], A.F. Rope[1], L.S. Acheson[2], S.K. Peterson[3], S. Syngal[4], G.L. Weisner[5], J.A. Reiss[1], K.A.B. Goddard[1].* 1) Center for Health Research, Kaiser Permanente Northwest, Portland, OR; 2) Departments of Family Medicine and Community Health, Reproductive Biology, and Oncology, Case Western Reserve University, Cleveland, OH; 3) Department of Behavioral Science, University of Texas MD Anderson Cancer Center, Houston, TX; 4) Dana-Farber Cancer Institute, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 5) Vanderbilt Hereditary Cancer Program, Department of Medicine, Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN.

Lynch syndrome (LS) is associated with an increased risk of several cancers, including colorectal (CRC) and endometrial cancers (EC). LS is due to mutations in DNA mismatch repair genes with 90% of cases attributed to pathogenic mutations in *MLH1* and *MSH2*, 7-10% in *MSH6*, <5% in *PMS2*, and 1-3% in *EPCAM*. Until recently, most patients with LS were identified by selective screening of patients who met high-risk criteria based on personal and family history of cancer and early age at onset. However, not all patients with LS meet high-risk criteria for selective screening and not all patients who meet high-risk criteria get screened. To increase the identification of patients with LS, universal tumor screening (UTS) programs that screen all newly diagnosed cases of CRC or EC for LS, regardless of high-risk criteria, are being increasingly implemented. We report on a study of UTS implementation at Kaiser Permanente Northwest among newly diagnosed cases of CRC. Individuals not included in the UTS program were those who declined screening, had a prior diagnosis of LS or another hereditary cancer syndrome, or had already initiated screening for LS with the genetics department prior to contact. Of the 191 patients who consented to the UTS program, tumor tissue was screened with microsatellite instability (MSI) testing. Patients with a high MSI result, indicative of LS, were offered follow-up testing, including immunohistochemistry, *MLH1* hypermethylation, *BRAF* mutation, and, when appropriate, germline genetic testing. A diagnosis of LS was confirmed for 6 unrelated patients (1 *MLH1*, 1 *MSH2*, 1 *MSH6*, and 3 *PMS2*). The high proportion of *PMS2* mutations identified via UTS (50%) was unexpected because *PMS2* had been previously estimated to account for a low proportion of LS cases. Given that *PMS2* mutations are associated with lower penetrance and later age at onset compared to mutations in other LS-associated genes, patients with *PMS2* mutations may be less likely to be identified by selective screening because they do not meet the high-risk criteria and may be more likely to be identified by UTS programs. Literature review of previously published UTS programs indicated that *PMS2* mutation testing was often not performed or the sequencing was limited. Thus including *PMS2* germline testing in UTS programs is likely to increase the diagnosis of patients with *PMS2* mutations, which could lead to this gene accounting for a higher proportion of LS cases than previously estimated.

2684T

Evaluation of BRCA1 related DNA repair genes in breast and ovarian carcinogenesis. *L. Maresca[1], R. Scarpitta[1], L. Spugnesi[1], S. Lodovici[2], M. Vitiello[2], L. Poliseno[2], A. Galli[2], M.A. Caligo[1].* 1) Section of Medical Genetics, University of Pisa, Pisa, Italy; 2) Institute of Clinical Physiology, CNR, Pisa, Italy.

Breast cancer is the most frequently occurring neoplasia in women. 5-10% of all breast and ovarian cancers can be explained by mutations in *BRCA* genes. *BRCA1* is a tumor suppressor gene encoding a nuclear phosphoprotein involved in many cellular processes. *BRCA1* is a highly polimorfic gene. Some of these mutations lead to the production of a truncated non functional protein. In addition, many missense mutations, called VUS (variants of unknown significance), have been identified. These variants have no known pathological significance. BRCA1 interacts with several proteins involved in DNA repair including MSH2, MSH6, MRE11A, RAD50, RAD51. The aim of this study is to determine which, among BRCA1 partner genes involved in DNA repair, may contribute to breast and ovarian carcinogenesis. Previous experiments performed by our research group, suggested that *MSH2*, *MSH6*, *MRE11A*, *RAD50* and *RAD51* may have a role in genomic instability induced by BRCA1 in *S. Cerevisiae*. We also performed a *MSH2* mutational analysis in selected breast and ovarian tumors from *BRCA1* VUS carriers and we identified probably pathogenic mutations in 36% of cases. On the basis of these results, the purpose of this work is to assess the mutational status of *MSH6*, *MRE11A, RAD50* and *RAD51* genes in breast and/or ovarian tumor tissues. Our hypothesis is that mutations in these genes may contribute to BRCA1 mediated carcinogenesis. We selected 34 FFPE tumors from patients affected by HBOC: 14 *BRCA1* VUS carriers, 8 *BRCA1* mutated and 12 *BRCA1*wt. Mutational analysis was performed by NGS targeted resequencing approach on PGM Ion Torrent. Sequencing data were analyzed by Ion Reporter software with high stringency somatic analysis setting. We identified 46 variants: 20 unique and 26 present in more than one patient. Among them, we selected 17 interesting and rare variants. All of them were confirmed and assessed in lymphocytic DNA. In conclusion we identified 8 somatic missense mutations probably pathogenic according to the prediction tools interrogated. 4 variants were on *MSH6* gene, 2 on *MRE11A*, 1 on *RAD50* and 1 on *RAD51*. Interestingly, *MSH6* was found altered in 20% of tumors analyzed and affected by predicted pathogenic mutations in 11% of samples. Moreover, in order to validate yeast results we will perform a GFP-dependent homology directed repair assay in MCF7 cell line knock out for MSH2 gene. This gene will be inactivated by CRISPR Cas9 system.

2685F

Germline compound heterozygous poly-glutamine deletion in *KIAA2018/usf3* **gene causes a pro-migration cellular phenotype in heritable and sporadic epithelial thyroid carcinoma.** *Y. Ni[1,4,5], S. Seballos[1], B. Fletcher[1], T. Romigh[1], L. Yehia[1], J. Mester[1,2], L. Senter[6,8], M. Saji[7,8], M.D. Ringel[7,8], T. LaFramboise[1,4,9], C. Eng[1,2,3,4,9].* 1) Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH; 2) Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH; 3) Stanley Shalom Zielony Nursing Institute, Cleveland Clinic, Cleveland, OH; 4) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH; 5) Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH; 6) Division of Human Genetics, Ohio State University School of Medicine, Columbus, OH; 7) Division of Endocrinology, Diabetes and Metabolism, Department of Internal Medicine, The Ohio State University School of Medicine, Columbus, OH; 8) Thyroid Center Unit, Comprehensive Cancer Center, The Ohio State University, Columbus, OH; 9) Germline High Risk Focus Group, CASE Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH.

   Cowden syndrome (CS, [MIM 158350]) is an autosomal dominant disorder that predisposes to breast, thyroid, and other epithelial cancers. Differentiated thyroid carcinoma (DTC), as one of the major component cancers of CS, is the fastest rising incident cancer in the USA, and the most familial of all solid tumors. To identify novel candidate genes of CS and potentially DTC, we analyzed a multi-generation CS-like family with papillary thyroid cancer (PTC), applying a combined linkage-based and whole-genome sequencing strategy and identified an in-frame germline compound heterozygous deletion, *del1Q/3Q* in *KIAA2018/USF3*. Among 49 unrelated CS/CS-like patients, 22% were found to have *KIAA2018del1Q/3Q*. Of 497 TCGA PTC patients, 138 (27%) were found to carry germline *KIAA201del1Q/3Q*, with somatically decreased tumor *KIAA2018* expression. We demonstrate an increased migration phenotype along with enhanced epithelial-to-mesenchymal transition (EMT) signature after *KIAA2018* knockdown or *KIAA2018del1Q/3Q* overexpression, which sensitizes cells to endoplasmic reticulum (ER) stress. Loss of *KIAA2018* function induced cell necrosis-like features and impaired respiratory capacity while providing a glutamine-dependent cell survival advantage, strongly suggests a metabolic survival and migration-favoring microenvironment for carcinogenesis. We identify a novel role for *KIAA2018/USF3* in thyroid tumorigenesis. Importantly, the results that glutamine-dependent survival and sensitivity to ER stress in KIAA2018-deficient cells provide avenues for therapeutic and adjunct preventive interventions for both sporadic cancer as well as cancer predisposition syndromes with similar mechanisms.

2686W

Identification of germline pathogenic alleles in 143 cancer predisposing genes in Mexican patients with hereditary breast cancer by massive parallel sequencing. *R. Quezada Urban[1], C.E. Díaz Velásquez[1], R. Gitler[2], M.P. Rojo Castillo[2], M. Sirota Toporek[2], A. Figueroa Morales[2], O. Moreno García[2], F. Mainero Ratchelous[3], L. Sabrina De Hoyos Arév[3], I. Delgado Enciso[4], V.H. Garzón Barrientos[5], G. Torres Mejía[7], L.I. Terrazas Valdés[1], F. Vaca Paniagua[1,6].* 1) Laboratorio Nacional en Salud: Diagnóstico Molecular y Efecto Ambiental en Enfermedades Crónico-Degenerativas, Facultad de Estudios Superiores Iztacala, UNAM, México; 2) Fundación Alma, México; 3) Instituto Mexicano del Seguro Social, México; 4) Instituto Estatal de Cancerología de Colima, México; 5) Hospital General de Chilpancingo, Guerrero, México; 6) Instituto Nacional de Cancerología, México; 7) Instituto Nacional de Salud Pública, Cuernavaca, México.

   The neoplastic disease with the highest incidence and mortality worldwide is breast cancer and almost 10% of that incidence is due to inherited pathogenic variants in predisposing genes such as *BRCA1* and *BRCA2*, but they only account for nearly 50% of the cases of hereditary breast cancer and ovarian cancer syndrome (HBOC). The range of inherited breast cancer susceptibility that is not caused by these genes has not been explored in Mexicans. Therefore, it is of great importance to identify new inherited pathogenic variants that allow a detailed analysis of the molecular epidemiology of HBOC in this population. In this work we aim to analyze exonic regions and splice sites on 143 genes of 137 patients with suspected HBOC through massive parallel sequencing, to identify new variants associated with this syndrome. We selected Mexican female patients with cancer that had family cancer history. Inclusion criteria followed the guidelines of the National Comprehensive Cancer Network for Genetic/Familial High-Risk Assessment of Breast and Ovarian Cancer. Data from international databases of normal populations and cancer patients, as well as annotation information and technical parameters were used to define pathogenic variants. In these patients the genes with the highest frequency of pathogenic alleles (stopgain/loss, frameshift indels) were *BRCA2* (26.09%, 6/137), *BRCA1* (13.04%, 3/137), *FANCC* (8.7%), *MSR1* (8.7%), *FANCL* (4.35%), *SDHB* (4.35%) and *TSC2* (4.35%). New or rare missense variants with unknown clinical significance (VUS), but defined as pathogenic in ClinVar or by algorithms assessing evolutionary conservation and deleterious structural changes at protein level, were found in single patients in the genes *AIP, ANTXR1, APC, ATR, CD96, ERCC3, ERCC6, FANCA, FANCB, FANCE, LIG4, LYST, MSH6, MSR1, MTAP, PDE11A, PDGFRA, PMS2, POLE, PTCH1, RAD50, RHBDF2, RUNX1* and *WRN*. These patients did not have pathogenic alleles, suggesting a potential contribution of these VUS to disease susceptibility. This work contributes to identify new susceptibility alleles that can predispose to HBOC in the Mexican population. Further studies need to be conducted to define the clinical impact of the VUS identified here, which together with international efforts will better define genetic susceptibility to breast cancer.

2687T

Familial clustering of haematological malignances: Harbingers of wider germline cancer susceptibility. *H.S. Scott[1,2,3,4,5], A.L. Brown[1,2], D. Hiwase[6], A.W. Schreiber[5], J.H. Feng[5], M. Babic[1], N. Poplawski[7], G. Suthers[7], M. Fine[7], L. Rawlings[1], S. Branford[1,2,3,4], S. Fuller[8], I. Lewis[6], R.J. D'Andrea[2,6], C.N. Hahn[1,2,4].* 1) Department of Genetics & Molecular Pathology, Centre for Cancer Biology, SA Pathology, Adelaide, SA, Australia; 2) School of Pharmacy and Medical Sciences, Division of Health Sciences, University of South Australia, Adelaide, South Australia, Australia; 3) School of Molecular and Biological Sciences, University of Adelaide, Adelaide, South Australia, Australia; 4) School of Medicine, University of Adelaide, Adelaide, South Australia, Australia; 5) ACRF Cancer Genomics Facility, Centre for Cancer Biology, SA Pathology, Adelaide, South Australia, Australia; 6) Department of Haematology, Centre for Cancer Biology, SA Pathology, Adelaide, South Australia, Australia; 7) SA Clinical Genetics Service, Directorate of Genetics and Molecular Pathology, SA Pathology, Adelaide, South Australia, Australia; 8) Department of Medicine,Sydney Medical School Nepean, The University of Sydney, Sydney, NSW, Australia.

This year germline predisposits to haematological malignancy (HM) makes their debut in the WHO classification of leukaemias. It's been a long time coming, well over 100 years since the first phenotypic recognition of familial HM in 1861, and nearly 17 years since the first genetic evidence; the discovery that *RUNX1* causes thrombocytopenia predisposing to MDS/AML (Song et al 1999). Today, there are at least 12 known FHM predisposition genes. Our systematic collection of over 120 (and growing) HM families has led us to identify germline mutations in *GATA2, RUNX1, CEBPA* and *DDX41*, with approximately 50% of familial MDS/AML now attributable to known FHM genes. Phenotypic heterogeneity exists between families with different mutations in the same gene; *GATA2* mutations predispose to a range of myeloid malignancies as well as lymphoedema and immunodeficiency, and *de novo* germline *GATA2* mutations are an under-recognised but frequent event in paediatric MDS. Our *RUNX1* mutated families show phenotypic heterogeneity within families, and our data indicate that germline variants in additional genetic modifiers may influence phenotype and penetrance. We find that rare germline variants in FHM and HM genes are also enriched in sporadic HM cohorts suggesting a significant contribution to predisposition and possibly treatment response. The majority of our unsolved families have lymphoid malignancies, most commonly non-Hodgkin lymphoma and chronic lymphocytic leukaemia. Our finding of familial lymphoma associated *DDX41* mutations led us to identify segregating mutations in a number of *DDX/DHX* genes, including the Warsaw Breakage Syndrome gene, *DDX11*, implicated in dysregulated DNA damage response (DDR), in several families. Genetic alteration of DDR pathways in families that have a history of lymphoma, and also solid tumours (pan-cancer) included damaging mutations in a range of BRCA/FANC genes such as *PALB2,* which predisposes strongly to both lymphoma and breast cancer in one family. Collectively, these mutations may have a large impact on our understanding of germline cancer predisposition, a finding supported by recent genetic population studies on sporadic cohorts, and opening the door for the application of rational therapies as evidenced by the BRCA/PARP inhibitor paradigm. However, as each individual gene mutation is rare, international collaborative studies will be essential for accurate measurements of risk and prognostication to assist individuals in the clinic.

2688F

Novel germline *TP53* **mutations in the Swedish constitutional** *TP53* **cohort.** *E. Tham, S. Bajalica Lagercrantz, P. Kharaziha, C. Larsson.* Karolinska Institutet, Stockholm, Stockholm, Sweden.

Individuals with a constitutional *TP53* mutation have a high risk of cancer in childhood and/or early adulthood, but show a large phenotypic variation. In some families, pediatric tumors are more frequent while in others only breast cancer is seen. The underlying cause for this variation is unknown. However, this question is of utmost importance for which surveillance should be offered to mutation carriers. It is therefore a large need for further molecular characterization of the genomic landscape with regard to both the TP53-mutations, as well as of genetic modulating factors, in order to understand the genotype-phenotype correlation.   In the Swedish cohort of 32 families, we found 25 different mutations in the *TP53* gene. Nine have not been reported previously as germline mutations according to the HGMD or IARC databases. Five of these have not even been reported as somatic mutations in the IARC or cosmic databases and are thus truly novel. We have generated cDNA expression constructs for all nine novel germline *TP53* mutants. All constructs have been sequenced to confirm inserted mutations. Transfection in p53 null H1299 cells have demonstrated a wide range of activities among the constructs in terms of induction of apoptosis in response to 12 G irradiation, as well as variable impact on the cell cycle regulation.   We showed that all novel mutation were express stably in cell lines and decrease spontaneous apoptosis and have a poorer response to therapy which indicate that affected individual has higher risk of tumorigenesis and less response to radio therapy.

2689W

Lynch syndrome family with co-occurrence of germline pathogenic splice site mutations of *MSH2* and *MSH6*. *I. Vogelaar[1], Y. Hu[1], F. Wang[1,2], M. Fairbank[3], R. Rapkins[4], J. Balcom[5], A. Leininger[6], M. Hitchins[1].* 1) Department of Medicine (Oncology), Stanford Cancer Institute, Stanford University, Stanford, CA 94305, USA; 2) School of Public Health, Harbin Medical University, Harbin, People's Republic of China; 3) Lynch Syndrome Australia; 4) Lowy Cancer Research Centre, University of New South Wales, Sydney, Australia; 5) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, USA; 6) Minnesota Oncology, Woodbury, MN, USA.

Lynch syndrome (LS) is caused by an autosomal dominant heterozygous germline (epi-)mutation of one of the DNA mismatch repair (MMR) genes (*MLH1, MSH2, MSH6* or *PMS2*). Disease penetrance, tumor spectrum, and mean age of onset vary depending on the gene mutated. Germline *MLH1 or MSH2* mutation carriers have especially high risks of developing colorectal cancer (CRC) and endometrial cancer (EC). *MSH2* mutation carriers also have a high risk of urinary tract cancer. Germline *MSH6* and *PMS2* mutation carriers have a substantially lower risk for CRC and age at diagnosis is approximately 10 years later compared to *MLH1* and *MSH2* mutation carriers. In *MSH6* mutation carriers, the risk for EC is comparable to *MLH1* and *MSH2* mutation carriers. Recently, a new classification system for LS was proposed based on the MMR gene mutated (e.g. *MLH1*-Lynch syndrome), with tailored clinical surveillance recommendations. We describe the first family with co-occurrence of two pathogenic germline MMR mutations, one in *MSH2* (c.2006G>T) and the other in *MSH6* (c.3936_4001+8dup). *MSH2* and *MSH6* are neighboring genes located on chr2p21. Pedigree analysis showed the two mutations segregated independently, indicating they are located on separate chr2p21 alleles; some family members carried both mutations, others carried one or the other, whilst others were negative for both. Functionally, RNA analyses showed both are splice mutations that result in out-of-frame exon skipping, ultimately resulting in protein truncation. The *MSH2* mutation leads to skipping of exon 13 and the *MSH6* mutation results in skipping of exon 9. The identification of two pathogenic mutations in one family has serious implications in terms of cancer risk stratification and genetic counselling. Firstly, the risk of cancer will vary between family members according to their mutation status, given that cancer risks vary by MMR gene mutated and number of MMR genes affected. Secondly, since both alleles are affected, double-mutation carriers are predicted to have a 100% risk of transmitting either one of the mutations to their offspring, whereas single-mutation carriers have a 50% risk of transmission. This family illustrates the need for caution when limiting genetic screening to site-specific mutation testing in families with LS (and other high-risk cancer syndromes). The possibility of a second cancer-predisposing mutation should be considered when the known familial mutation is not found in cancer-affected family members.

2690T

Germline heterozygous *SEC23B* variants in Cowden syndrome and apparently sporadic thyroid cancer: ER stress resistance and survival of the fittest. *L. Yehia[1,2], F. Niazi[1], Y. Ni[1], J. Ngeow[1,3], M. Sankunny[1], Z. Liu[1], W. Wei[1], J.L. Mester[1], R. Keri[4], B. Zhang[1], C. Eng[1,5,6,7].* 1) Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH; 2) Department of Pathology, Case Western Reserve University School of Medicine, Cleveland, OH; 3) Division of Medical Oncology, National Cancer Centre, Singapore; 4) Department of Pharmacology, Case Western Reserve University School of Medicine, Cleveland, OH; 5) Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH; 6) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH; 7) Germline High Risk Focus Group, CASE Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH.

Cancer-predisposing genes associated with inherited cancer syndromes help explain mechanisms of sporadic carcinogenesis and often inform normal development. Cowden syndrome (CS) is an autosomal-dominant disorder characterized by high lifetime risks of epithelial cancers, such that ~50% of affected individuals are wildtype for known cancer-predisposing genes. Using whole-exome and Sanger sequencing of a multi-generation CS family wildtype for all known CS-associated genes and affected by thyroid and other cancers, we identified a pathogenic missense heterozygous *SEC23B* variant (c.1781T>G [p.Val594Gly]) that segregates with the phenotype. We also found germline heterozygous *SEC23B* variants in 3/96 (3%) unrelated mutation-negative CS probands with thyroid cancer and in The Cancer Genome Atlas (TCGA) apparently sporadic thyroid, breast, and endometrial cancers. We note that the TCGA thyroid cancer dataset is enriched with unique germline deleterious *SEC23B* variants associated with a significantly younger age of onset. *SEC23B* encodes Sec23 homolog B, a component of coat protein complex II (COPII), which transports proteins from the endoplasmic reticulum (ER) to the Golgi apparatus. Interestingly, germline homozygous or compound-heterozygous *SEC23B* mutations cause an unrelated disorder, congenital dyserythropoietic anemia type II, and SEC23B-deficient mice suffer from secretory organ degeneration due to ER-stress-associated apoptosis. By characterizing the p.Val594Gly variant in a non-malignant thyroid cell line, we show that it is a functional alteration that results in ER-stress-mediated survival, cell-colony formation, and overgrowth - reflecting major hallmarks of cancer. We subsequently show via RNA-seq of untreated and Tunicamycin-treated (for ER stress induction) *SEC23B*-Wildtype and *SEC23B*-p.Val594Gly thyroid cells that SEC23B affects gene expression of ribosomal proteins and multiple mitochondrial respiratory chain enzymes. We also show that SEC23B exists in the nucleus in addition to its known presence in ER-Golgi, and localizes within nucleoli of mutant cells. Our findings suggest a non-classic role for SEC23B, whereby germline heterozygous variants associate with cancer-predisposition potentially mediated by ER stress "addiction.".

2691F

Rare germline variants in *PALB2* and *BRCA2* in familial and sporadic chordoma. *R. Yang[1], Y. Xiao[1], B. Zhu[1], H. Bennett[1], M. Rotunno[1], N. Liebsch[2], K. Jones[3], A. Vogt[3], L. Burdette[3], B. Zhu[3], B. Hicks[3], S.J. Chanock[1], M. Yeager[3], M.A. Tucker[1], M.J. Kelley[4], D.M. Parry[1], A.M. Goldstein[1].* 1) Division of Cancer Epidemiology & Genetics, NCI/NIH, Bethesda, MD; 2) Massachusetts General Hospital, Boston, MA; 3) Cancer Genomics Research Laboratory, Leidos Biomedical Research, Frederick National Laboratory for Cancer Research, Frederick, MD; 4) Duke University, Durham, NC.

Chordoma is a rare bone cancer that is believed to originate from notochordal remnants. It is typically sporadic, but occasionally occurs in a familial setting, usually in an autosomal dominant pattern. We previously identified germline *T* duplication as a major susceptibility mechanism in several chordoma families. However, genetic causes in the majority of sporadic cases and some chordoma families remain unknown. The goal of this study was to identify additional susceptibility genes in *T* duplication-negative families (five families with 19 cases) and sporadic cases (N=137) using whole-exome sequencing. We focused on rare exonic variants that were present in ≤0.1% in the 1000 Genomes Project (1,092 subjects), ESP (6,500 subjects), 500 healthy in-house population-based controls of European ancestry, and £ 1 family from our in-house database of >900 cancer-prone control families (excluding chordoma families and sporadic chordoma cases). We identified a missense non-synonymous (NS) variant in *PALB2* (c.1042C>A, p.Gln348Lys) that was present in two chordoma cases, one obligate gene carrier, and one case with juvenile pilocytic astrocytoma in one chordoma family. This variant was reported in 0.00023 and 0.00015 of individuals of European ancestry in ESP and The Exome Aggregation Consortium (ExAC), respectively. Five additional rare NS variants in *PALB2* were identified, each in a single sporadic case. *PALB2* is a binding partner of *BRCA2* and functions as a tumor suppressor gene. One of the top biological processes involving *BRCA2* is chordate embryonic development whose specific outcome is the progression of the embryo over time, from zygote formation through a stage including a notochord and neural tube until birth or egg hatching. Interestingly, we also identified 11 rare variants in *BRCA2* in 10 sporadic cases. Among these variants, one was a stopgain, one was a frameshift, and the others were NS missense variants. Two of these variants were classified as DM (disease-causing mutation) and one variant was classified as uncertain DM in the Human Gene Mutation Database for breast cancer and/or ovarian cancer. Results from the burden test showed that chordoma cases had a significantly higher number of rare exonic variants in *PALB2* (*P*=0.028) and *BRCA2* (*P*=0.025) compared to 500 population controls. We plan to validate all promising genes/variants using targeted sequencing and design experimental assays to evaluate the functional relevance of these variants.

2692W

***De novo* status and family history of cancer in individuals with germline likely/pathogenic *PTEN* variants.** *J. Mester, S. Keilman, R. Klein, E. Butler, V. Zvereff, S. Warren, K. Hruska.* GeneDx, Gaithersburg, MD.

PTEN Hamartoma Tumor syndrome (PHTS) describes individuals with germline mutation of the *PTEN* tumor suppressor gene (MIM +601728), with a frequency of *de novo* mutation estimated at almost 50%. While a clinical tool exists to estimate *a priori PTEN* mutation risk based on personal history, family history is not included. Thus we reviewed family history and testing data from individuals with pathogenic or likely pathogenic *PTEN* variants to understand whether family history may serve as a predictor of *PTEN* mutation status. Since 2000 our clinical laboratory has identified approximately 375 individuals with pathogenic or likely pathogenic *PTEN* variants through single-gene, panel-based, array, whole exome (WES), or targeted variant analysis. For the current study, patients were excluded if personal/family history or permission for research inclusion were not provided. Among 65 eligible probands, age at testing was not significantly higher for the 39 females (34 yrs) than the 26 males (28 yrs, p=0.19). Among 18 probands, familial testing revealed the variant to be inherited from a parent in 7, assumed *de novo* (parentage unconfirmed) in 8, and proven *de novo* in 3 (parentage confirmed by WES), leading to a *de novo* frequency of 61% (11/18). Age at testing was no different for those whose variant was inherited vs. *de novo* (p=0.29). Twenty-eight of 65 probands (43%) reported no first- or second-degree relatives with a PHTS-spectrum tumor, including 4 of the 7 whose variants were inherited. Nevertheless, all four were pediatric cases, placing relatives at an age below that for which tumor presentation may occur. Among relatives with cancer, median ages at diagnosis for thyroid (32yrs), endometrial (40yrs), and breast cancer (48yrs) were lower than seen in the general population per SEER data (50, 62, and 61 yrs respectively), although numbers affected were too low to derive meaningful statistical comparisons. These data imply that family history of early-onset thyroid, endometrial, or breast cancer may be a helpful predictor of *PTEN* mutation status; however, lack of cancer family history should not dissuade consideration of a PHTS diagnosis given the high likelihood of *de novo* mutation, or in pediatric cases where family members may not be old enough for tumors to occur.

2693T

Can we predict which pediatric solid tumor and brain tumor patients carry germline cancer susceptibility mutations? Results from the BASIC3 study. *S.E. Plon[1,2,3,4], S. Scollon[1,4], K. Bergstrom[1,4], T. Wang[5], R.A. Raesz-Martinez[1,4], U. Ramamurthy[1,6], D.M. Muzny[3], A. Roy[7,8], S.G. Hilsenbeck[5], Y. Yang[2,9], C.M. Eng[2,9], R.A. Gibbs[2,3], D.W. Parsons[1,2,3,4].* 1) Dept of Pediatrics, Baylor College of Medicine, Houston, TX; 2) Dept of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 4) Texas Children's Cancer Center, Texas Children's Hospital, Houston, TX; 5) Dan L Duncan Cancer Center, Baylor College of Medicine, Houston, TX; 6) Institute for Clinical and Translational Research, Baylor College of Medicine, Houston, TX; 7) Department of Pathology, Baylor College of Medicine, Houston, TX; 8) Department of Pathology, Texas Children's Hospital; 9) Baylor Miraca Genetics Laboratories, Houston, TX.

   Background: Recent studies have suggested that approximately 10% of pediatric cancer patients carry cancer susceptibility mutations. We determined whether demographic features, family history or tumor type are predictive of diagnostic findings from whole exome sequencing (WES). **Methods:** The BASIC3 study includes clinical germline and tumor WES in an ethnically diverse (49% Hispanic) cohort of sequentially diagnosed children with CNS and non-CNS solid tumors. At subject entry, a cancer genetics professional specifies whether genetic tests would be recommended based on cancer type, age and family history. These data were compared with the results of clinical germline WES. The associations between diagnostic findings and other factors were analyzed using Fisher's exact tests and between variants of uncertain significance (VUS) and other factors by Wilcoxon rank-sum tests or Kruskal-Wallis tests. **Results:** Among 255 enrolled patients (median age 6.5 years; range 0.1-17.9) there were 90 patients with CNS and 165 with non-CNS tumors. Diagnostic pathogenic or likely pathogenic cancer susceptibility variants in 19 genes were found in 25 (9.8%) patients (24 heterozygous dominant variants and 1 homozygous recessive variant). No gene was reported in more than 3 patients (3 each for *VHL* and *TP53*). Pathogenic variants were identified in genes previously associated with both adult and pediatric cancers. There was no significant association of a diagnostic finding with age, gender, race, ethnicity, or CNS versus non-CNS location. For the more common (>9 subjects each) pediatric tumor types e.g. Wilms tumor, there was no significant association between tumor type and diagnostic result. Only the "other" category including rare tumors, e.g. pheochromocytoma, had a significantly higher diagnostic rate (8/24; 33%; p=0.0007). There was a median of 3 VUS in cancer genes per subject (range 0-10) with no significant differences other than African American race (median 4; p=0.0004). In only 13 of 25 cases (52%) did the genetics professional recommend testing at study entry for the gene reported as a diagnostic finding. **Conclusions:** Diagnostic cancer susceptibility mutations were reported in 10% of unselected children with CNS and non-CNS solid tumors. Current clinical practice using age, tumor type and family history for genetic testing decisions is likely to miss a substantial number of patients and families that warrant increased cancer surveillance. Supported by 1U01HG006485.

The *PTEN* Gene ClinGen Expert Panel: A model for creating a framework for gene specific criteria using ACMG/AMP guidelines. *C. Eng[1,8], J. Mester[2], L. Milko[3], R. Ghosh[4], T. Pesaran[5], H. Costa[6], R. Karam[5], R. Huether[5], J. Ngeow[7], E. Sorokin[6], J. Barnholtz-Sloan[8], K. Hruska[2], L. Zhang[9], K. Lachlan[10], M. Hegde[11].* 1) Genomic Med Inst, Cleveland Clinic, Cleveland, OH; 2) GeneDx Laboratories, Gaithersburg, MD; 3) University of North Carolina, Durham, NC; 4) Baylor College of Medicine, Houston, TX; 5) Ambry Genetics, Aliso Viejo, CA; 6) Stanford University School of Medicine, Stanford, CA; 7) National Cancer Centre Singapore, Singapore; 8) Case Comprehensive Cancer Center, Cleveland, OH; 9) Memorial Sloan Kettering Cancer Center, New York, NY; 10) Princess Anne Hospital, Southampton, UK; 11) Emory Genetics Laboratory, Atlanta, GA.

   ClinVar is a publicly available resource of genetic variants along with evidence supporting each assertion submitted by clinical and research laboratories. Different groups using their own approaches and available evidence for variant interpretation often results in conflicting assertions. To help ClinVar users understand the level of evidence behind each assertion, ClinGen developed a hierarchical 4-star rating system where more stars indicate a greater level of review, with ClinGen-designated Expert Panels at 3 stars. For some genes an expert group already existed; for others, ClinGen is facilitating their development. PTEN, associated with Cowden, Bannayan-Riley-Ruvalcaba, and other syndromes caused by germline PTEN mutation, is the first gene in the Hereditary Cancer domain for which an expert panel has been developed within the ClinGen framework. The group's first meeting in Dec 2014 included ClinGen staff as well as experts in PTEN clinical care and research. The group was tasked with creating an expert panel drawn from both research and diagnostic groups and developing gene-specific criteria for PTEN based on the 2015 ACMG/AMP Variant Interpretation Guidelines, which will be submitted as part of the group's formal ClinVar Expert Panel application. To develop the criteria for PTEN, working groups were assembled around the following evidence types: population frequency, splicing, computational/predictive, functional, phenotype, and segregation/de novo data. The group decided to first define benign criteria, then pathogenic, and will then curate a test set of variants. Here we present proposed PTEN-specific benign criteria the group has decided upon to date. Stand-alone: allele frequency $\geq$ 1%. Strong: allele frequency 0.1-1%, homozygous (hmz) observation in 1 unaffected individual with hmz status confirmed, 2 without confirmation. Supporting: 1 observation in trans with a pathogenic variant or 3 observations in cis/phase unknown with different pathogenic variants, 2 hmz observations without clinical data. The computational/predictive working group was challenged by the paucity of known benign PTEN missense variants, and was unable to validate use of *in silico* predictors for this purpose. A formal evaluation of criteria for pathogenic variants is in progress. We hope this outline of our process and challenges for creating gene-specific criteria will be helpful to other expert panels as they develop and establish their variant interpretation guidelines.

A multiscale survey of inflammatory diseases and prostate oncophe-notypes. *K. Shameer[1,2], K.K. Yadav[3], L. Li[1,2], S.S. Yadav[3], J. O'Connor[3], J. Li[3], B.S. Glicksberg[1,2], K.W. Johnson[1,2], M.A. Badgeley[1,2], C. Elaiho[1,2], B. Read-head[1,2], B.A. Kidd[1,2], A. Kasarskis[2], A.K. Tewari[3], J.T. Dudley[1,2,4].* 1) Institute of Next Generation Health, Mount Sinai Health System, New York, NY, USA; 2) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 3) Department of Urology, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 4) Department of Health Evidence and Policy, Icahn School of Medicine at Mount Sinai, New York, NY, USA.

Prostate cancer (PCa) is the most common cancer detected in men (181,000 annual cases), and nearly 26,000 American men die each year due to PCa and related complications. Reports have shown that PCa is more aggressive when its comorbid with inflammatory diseases. However, the correlations and risks attributed to inflammatory diseases of the abdominal cavity and onco-phenotypes are not known. To investigate how inflammatory pathways and PCa genes induce aggressive oncophenotypes in the setting of PCa, we have compiled a multiscale survey that includes data from surgical observations, inflammatory phenotypes, clinical registries, biomarkers and mouse models. We applied an integrative informatics approach with experimental validation to understand the associations between inflammatory diseases (e.g., Crohn's disease, ulcerative colitis, collagenous colitis, indeterminate colitis, ischemic colitis, diverticulitis, hernia, etc.) and PCa. We found distinct patterns of shared molecular features---gene sets, pathways, and networks---and comorbidities across inflammatory disease and PCa. For example, we found that diverticuli-tis tend to increase inflammation in the abdominal cavity and could potentially lead to aggressive prostate oncophenotypes. To test abdominal inflammation and PCa correlation, we induced inflammation in a mouse model of hiatus hernia, which resulted in an increase in the expression of the combined markers of inflammation and PCa (*TGFB, TNFA, IL6,* and *IL2*). Evaluation of pathology stage, Gleason scores and physical attributes of previous inflamma-tion observed during robotic prostatectomy surgery also reveals trend towards aggressive tumor characteristics with an increase in inflammation. Gene-set overlap analyses showed that several inflammatory disease and prostate can-cer genes share genetic modules. Collectively, our findings provide the first set of computational, experimental and clinical evidence to recommend clinicians to evaluate the impact of inflammatory disease induced oncophenotypes in patients with PCa. Given that 1.3 million patients undergo prostate-specific antigen (PSA)-triggered invasive trans-rectal biopsy, the present findings in combination with PSA could facilitate the identification patient subset with aggressive cancer. Stratifying patients at risk for prostate cancer who are un-dergoing surgical interventions of abdominal cavity for inflammation diseases could also evaluate other non-surgical or therapeutic strategies.

Impact of SNP-SNP interactions on neurocognitive outcomes in survivors of hematopoietic cell transplantation (HCT) for hematologic malignancies. *N. Sharafeldin[1], A. Bosworth[2], S.K. Patel[2], Y. Chen[2], P. Singh[1], X. Wang[1,3], J. Richman[1], E. Morse[2], M. Mather[2], C. Sun[2], L. Francisco[1], S.J. Forman[2], L. Wong[2], S. Bhatia[1].* 1) University of Alabama at Birmingham, Birmingham, AL; 2) City of Hope, Duarte, CA; 3) University of Wisconsin-Mil-waukee, Milwaukee, WI.

Impaired cognition – an increasingly recognized concern after hematopoietic cell transplantation (HCT) – has significant potential to impact societal reinte-gration. Variability in patients' risk of cognitive impairment post-HCT suggests the need to explore genetic susceptibility. Cognitive function, however, is a complex phenotype which emphasizes the importance of considering non-ad-ditive genetic variance effects on its heritability. Here we present results from a prospective longitudinal study of 277 hematologic cancer survivors (58.5% males; 68.6% non-Hispanic whites) up to 3 years post-HCT. Patients' cognitive function was assessed using a 2-hour battery of standardized neurocognitive tests pre-HCT, 6 months, 1, 2, and 3 years post-HCT. The primary outcome was the Global Deficit Score (GDS), a widely accepted indicator of cognitive impairment, which was computed at each time point. Germline DNA was obtained pre-HCT and used to genotype 56 candidate genes related to the blood-brain barrier, telomere homeostasis, neural repair, neurotransmission, and DNA repair. We used logic regression with cross-validation to identify SNP-SNP interactions by searching for Boolean combinations (AND, OR, and NOT) of SNPs within each gene. Associations of these interaction terms with post-HCT cognitive impairment were estimated using generalized estimating equation models, adjusted for age, sex, race/ethnicity, cognitive reserve, and pre-HCT GDS. We found statistically significant associations of SNPs within 5 genes after accounting for multiple testing (Bonferroni $p \leq 8.9 \times 10^{-4}$): telomere homeostasis *TEP1* (odds ratio (OR) =5.85, 95%CI: 2.50, 13.69, p-val-ue=4.7×10^{-5}) and *TERF2* (OR=4.90, 95%CI: 2.05, 11.72, p-value=3.5×10^{-4}); and DNA repair *DCLRE1C* (OR=5.07, 95%CI: 2.28, 11.24, p-value=6.7×10^{-5}), *PMS2* (OR=4.17, 95%CI: 1.96, 8.87, p-value=2.1×10^{-4}), and *EXO1* (OR=4.59, 95%CI: 1.98, 10.65, p-value=3.8×10^{-4}). Using mechanism-specific cutoff p-values identified 2 additional genes: blood-brain barrier transporter gene (total 2 genes with p cutoff=0.025): *ABCB1* (OR=3.77, 95%CI: 1.62, 8.78, p-value=0.002) and DNA repair gene (total 40 genes with p cutoff=1.25×10^{-3}): *MRE11A* (OR=4.89,95%CI: 1.89, 12.66, p-value=1.1×10^{-3}).This study is the first to show an association between genetic variants that could be pathoge-netically involved with cognitive impairment. These findings, when replicated, could help identify vulnerable populations that could benefit from remediation.

Defining the genetic architecture of lung cancer etiology. *C.I. Amos[1], R. Hung[2], Y. Han[1], Y. Bossé[3], X. Xiao[1], Y. Li[1], J.K. Field[4], H. Bickebõller[5], X. Zong[2], D.C. Christiani[6], P. Brennan[7], M.T. Landi[8], J.D. McKay[7] OncoArray Lung Cancer Consortium.* 1) Biomedical Data Science, Dartmouth, Lebanon, NH, USA; 2) Lunenfeld-Tanenbaum Research Institute of Mt. Sinai Hospital, Toronto, Canada; 3) Department of Molecular Medicine, Laval University, Québec, Canada; 4) University of Liverpool, United Kingdom; 5) University Medical Centre Göttingen, Göttingen, Germany; 6) Harvard School of Public Health, Boston, MA, USA; 7) International Agency for Res. on Cancer, Lyon, France; 8) Division of Cancer Epidemiology & Genetics, National Cancer Institute, Bethesda, MD, USA.

Lung cancer is considered an archetypical environmentally induced disease because of the high risk from exposure to tobacco smoke. However, family studies clearly identified strong familial aggregation. Family studies and genome wide association studies have identified selected variants influencing lung cancer risk but have been underpowered to provide a more comprehensive assessment of genetic architecture. Here, we present the largest genome-wide scan of lung cancer susceptibility, in European-descent populations, comprising data derived from 29,863 patients and 55,586 controls. Analyses were adjusted for age, sex and the first three principal components for overall lung cancer and stratified by histology (adenocarcinoma, squamous carcinoma, and small cell carcinoma) and ever or never smoking. We found 24 loci influencing lung cancer risk for loci with minor allele frequencies of 0.5% or higher, of which 14 had not previously reached genome-wide significance levels. Effect sizes ranged from 0.37 for the functional variants rs17879961 in *CHEK2* to 2.12 for[LMT([1] rs11571833 in *BRCA2*, indicating the role of selected uncommon variant in strongly influencing lung cancer risk. Among the novel variants identified, 6 influenced overall lung cancer risk, 6 were specific to adenocarcinoma and 1 each influenced never and ever smokers respectively. Aside from previously described variants in the *CHRNA5* and *CYP2A6* regions that influence cigarette consumption, all other loci showed significant heterogeneity among histologies. Array based analysis found little shared heritability between adenocarcinoma and squamous carcinoma,. Evaluation of eQTL results derived from normal lung tissue identified consistent cis-acting effects of the variant rs77468143 influencing expression of *SECISBP2L*, rs6920364 influencing the extracellular ribonuclease *RNASET2*, and rs146729428 in the *EPHX2,* involved in inflammation. Several loci that influenced adenocarcinoma alone are involved in telomere maintenance or cell cycle, while several of the squamous cancer-specific loci are involved in DNA recombination and repair. These results indicate striking variation among histological subtypes of lung cancer. Further studies are ongoing to identify the impact that smoking has on lung cancer risk for these loci. These analyses provide a comprehensive assessment of genetic effects on lung cancer risk and will elucidate how these genetic variants interact with smoking behavior.

Sustained expression of the oestrogen receptor alpha (ESR1) drives two-thirds of breast cancer (BrCa) and defines the ESR1-positive subtype. This transcription factor engages enhancers upon oestrogen stimulation setting an oncogenic expression program in BrCa cells. Somatic copy number alterations involving *ESR1* occur in approximately 1% of ESR1-positive BrCa, implying that other mechanisms underlie the persistent expression of *ESR1*. We report the significant enrichment of somatic mutations within the set of regulatory elements (SRE) converging on *ESR1* in 7% of ESR1-positive BrCa. These mutations regulate *ESR1* expression by modulating transcription factor binding to the DNA. The SRE includes a recurrently mutated enhancer whose activity is also affected by the functional inherited single nucleotide variant (SNV) rs9383590 accounting for the risk associated with the rs2046210, rs3734805 and rs9383938 BrCa risk-loci. Overall, our work highlights the importance of considering the combinatorial activity of regulatory elements as a single unit to delineate the impact of genetic alterations on single genes in cancer.

Non-Hodgkin lymphoma (NHL) is comprised of multiple subtypes with distinct morphologic and clinical features. Genome-wide association studies (GWAS) have identified multiple loci for specific subtypes, but the scope of pleiotropy among subtypes has not been investigated. We utilized the analytical approach, Association analysis based on SubSETs (ASSET), to evaluate pleiotropy among four common NHL subtypes. ASSET is a statistical method for pleiotropy that explores all possible combinations of subsets, choosing the subset with the maximal test statistic and then evaluating its significance with adjustment for multiple testing. Data from eight GWAS, including 3,100 chronic lymphocytic leukemia (CLL) cases, 2,847 follicular lymphoma (FL) cases, 3,857 diffuse large B-cell lymphoma (DLBCL) cases, 825 marginal zone lymphoma (MZL) cases, and 9,504 controls of European ancestry, were utilized in the analysis. A total of 17 loci (defined as +/- 500kb from the most significant SNP) reached genome-wide significance ($P < 5 \times 10^{-8}$), most of which were driven almost exclusively by one subtype and had been previously reported. Two or more subtypes contributed to seven of the loci, and all four subtypes contributed to risk at two loci, 3p24.1 (*EOMES*) and 6p21.32 (HLA Class II region), suggesting some shared heritability near genes involved in adaptive immunity. Four potential novel loci from the ASSET analysis were taken forward for replication in 4,468 NHL cases and 2,185 controls of European ancestry. One locus, identified from the subset of 3 out of 4 subtypes (CLL, FL, and MZL), reached genome-wide significance in a joint meta-analysis of the discovery and replication sample sets (10q23.33, $P = 3.27 \times 10^{-9}$). Interestingly, this SNP resides in a transcription binding site for *IRF4*, a gene harboring variants associated with risk of CLL, and near *HHEX*, a gene involved in hematopoietic differentiation. Further related pleiotropy and pathway analyses are ongoing; however, results to date suggest that the genetic architecture of common NHL subtypes is largely distinctive, with only very modest pleiotropy.

2700F

Spectrum of somatic mutations in a patient population of Cyprus with unilateral vestibular schwannoma (VS). *R. Birkenhager, M.S. Stadler, A. Neuhold, S. Arndt, A. Aschendorff, R. Laszig.* Department of Otorhinolaryngology and Head and Neck Surgery, University Medical Center Freiburg, Killianstrasse 5, D-79106 Freiburg, Germany.

A vestibular schwannoma (VS) (acoustic neuroma) is a benign tumors originated from Schwann cells (SC) of the vestibular nerve and located in the cerebellopontine angle or the inner auditory canal. The tumor results from an over proliferation of SC; these cells wrap themselves around nerve fibres, often causing gradual hearing loss, tinnitus and dizziness. It can also affect with the facial nerve causing paralysis by compression. Early detection of the tumor is sometimes difficult, because the symptoms may be subtle and may not appear in the beginning. There are two types of VS: Bilateral and unilateral. Unilateral VS account for approximately 8 % of all cranial tumors. The exact cause of unilateral VS is unknown, most occur spontaneously. Until now there is only one single gene known for bilateral VS, that leads to neurofibromatosis type 2 (NF2). Our study group consists of 14 patients of Cyprus; all of them are clinically well characterized. Genetically a mutation analysis of the NF2 gene [MIM 607379] was performed at the genomic and tumor level; by PCR based individual exon and intron transitions sequencing of the corresponding gene. Additionally a haplotyping of the corresponding chromosomal region 22q12.2 was performed to identify LOH (loss of heterozygosity) areas, which may indicate genomic and / or somatic deletions. So far we identified 8 different missense/nonsense and splice mutations in NF2 gene, on somatic level exclusively in tumor cells, which all lead to a loss of function of the gene product Merlin and the appearance of VS, Mutations in the genomic level were excluded. In 5/14 samples genomic regions were identified on chromosome 22q12.2 with suspected LOH areas. In one case, a novel heterozygous mutation [c.1231C> T, p.Arg411Cys] was detected in the NF2 gene, which has a functional relevance and leads to loss of function of the corresponding gene Merlin. In addition to somatic changes and mutations there are possible indications of a genomic predisposition for unilateral vestibular schwannoma.

2701W

Novel regulators of ESR1 activity. *T.M. Campbell, B.A.J. Ponder, K.B. Meyer.* Cancer Research UK Cambridge Institute, Cambridge, United Kingdom.

Studying transcription factor (TF) interactions and gene regulatory networks in breast cancer, we have recently identified two distinct and opposing clusters of TFs associated with enhanced breast cancer risk, defining estrogen receptor-positive and estrogen receptor-negative breast cancer, respectively. These two clusters of TFs both regulate genes linked to risk loci identified by genome-wide association studies (GWAS), suggesting commonality of mechanisms. The relative activity of these two groups of TFs has a dramatic effect on patient outcomes and is likely to influence the phenotypic plasticity observed in breast cancer.[1] Here, we examine the molecular mechanisms underlying the opposing functions of the two networks. We identified novel TFs that interact with the estrogen receptor (ESR1) using Rapid Immunoprecipitation Mass Spectrometry of Endogenous Proteins (RIME), co-immunoprecipitation and microscopy experiments. The effect of identified TFs on ESR1 transcriptional activity was analysed using qRT-PCR, proteome/transcriptome analysis and luciferase reporter assay experiments. We demonstrate for the first time that two novel TFs associated with estrogen receptor-negative disease progression interact with the ESR1-FOXA1 TF complex and are able to influence the transactivational potential of ESR1. Moreover, signalling through FGFR2, a known risk factor in breast cancer development, appears to augment this interaction and further repress ESR1 target gene expression. This finding is consistent with our novel observation that risk SNPs in the *FGFR2* gene lead to a decrease in FGFR2 expression and activity, and is associated with greater estrogen responsiveness.[2] In conclusion, we show that members of two opposing clusters of risk TFs, associated with estrogen receptor-positive and -negative breast cancer, respectively, physically interact. Two TFs associated with estrogen receptor-negative disease associate with the ESR1-FOXA1 TF complex in order to repress ESR1 activity and drive cells towards a less estrogen-dependent cancer phenotype. [1]Castro *et al.* (2016) *Nature Genetics* 48: 12-21 [2]Campbell *et al.* (2016) *Carcinogenesis* PMID: 27236187.

2702T

Association of +331G/A polymorphism of the progesterone receptor (*PgR*) gene with susceptibility to breast cancer patients from Mexican population. *D.I. Carrillo-Moreno[1,5], L.E. Figuera[2], G.M. Zúñiga[3], A.M. Puebla[4], M.P. Gallegos-Arreola[5].* 1) Universidad de Guadalajara, Guadalajara, Jalisco,. México; 2) División de Genética, Centro de Investigación Biomédica de Occidente (CIBO), Instituto Mexicano del Seguro Social (IMSS);; 3) 3Laboratorio de Inmunofarmacología, Centro Universitario de Ciencias Exactas e Ingenierías (CUCEI), Universidad de Guadalajara (U de G); 4) Laboratorio de Mutagénesis , CIBO, IMSS; 5) Laboratorio de Genética Molecular, División de Genética, CIBO, IMSS. Guadalajara, Jalisco. México.

The polymorphism *+331G/A* of the progesterone receptor (*PgR*) gene, has been associated with susceptibility to breast cancer (BC) in different populations. The PgR is a sex steroid hormone receptor that binds progesterone and play to important role in the normal breast development. The *+331G/A* (rs10895068) promoter polymorphism are associated with cancer risk possibly by altering the expression of progesterone receptor B isoform. This study determined the association of *+331G/A* polymorphism with susceptibility of BC patients from Mexican population DNA of 162 BC patients and 64 healthy controls from general population was extracted. The *+331G/A* polymorphism was determined by polymerase chain reaction (PCR). The PCR fragments were digested with NlaIV restriction enzyme; the products were separated on a 6% polyacrylamide gel. The genotype frequencies of *+331G/A* polymorphism were 92% and 91% of *G/G*; 7.4% and 9% of *G/A*; and 0.6% and 0% of *A/A* from patients and controls respectively. The comparative analysis of association none shown associated with susceptibility to BC patients [odds ratio OR 0.78 Confidence intervals CI95% 0.26-2.3), p=0.77]. Conclusion: Our results indicate that the *+331G/A* polymorphism of *PgR* non shown association with to susceptibility to BC patients from Mexican population.

Rare disruptive mutations and their contribution to the heritable risk of colorectal cancer. *D. Chubb[1], P. Broderick[1], S.E. Dobbins[1], M. Frampton[1], B. Kinnersley[1], S. Penegar[1], A. Price[1], Y.P. Ma[1,5], A.L Sherborne[1], C. Palles[2], M.N. Timofeeva[3], D.T Bishop[4], M. Dunlop[3], I.P Tomplinson[2], R.S Houlston[1].* 1) Molecular and Population Genetics, The Institute of Cancer Research, London, UK; 2) Molecular and Population Genetics Laboratory,Wellcome Trust Centre for Human Genetics, University of Oxford, UK; 3) Centre for Population Health Sciences, University of Edinburgh, Scotland, UK; 4) Section of Epidemiology and Biostatistics, Leeds Institute of Cancer and Pathology, University of Leeds, St James's University Hospital, Leeds, UK; 5) Canada's Michael Smith Genome Sciences Centre, BC Cancer Agency, Vancouver, British Columbia, Canada,.

Colorectal cancer (CRC) displays a complex pattern of inheritance. It is postulated that much of the missing heritability of CRC is enshrined in high-impact rare alleles, which are mechanistically and clinically important. In this study, we assay the impact of rare germline mutations on CRC, analysing high-coverage exome sequencing data on 1,006 early-onset familial CRC cases and 1,609 healthy controls, with additional sequencing and array data on up to 5,552 cases and 6,792 controls. We identify highly penetrant rare mutations in 16% of familial CRC. Although the majority of these reside in known genes, we identify POT1, POLE2 and MRE11 as candidate CRC genes. We did not identify any coding low-frequency alleles (1–5%) with moderate effect. Our study clarifies the genetic architecture of CRC and probably discounts the existence of further major high-penetrance susceptibility genes, which individually account for >1% of the familial risk. Our results inform future study design and provide a resource for contextualizing the impact of new CRC genes.

2704W

Cancer risks are elevated among relatives of *MRE11A, RAD50* and *NBN* mutation carriers but similar to mutation-negative families in a laboratory-based cohort. *N.M. Chun[1], D. Qian[2], S. Li[2], V. Speare[2], H. LaDuca[2], H.M. Lu[2], A.W. Kurian[1,3].* 1) Medicine, Stanford University, Stanford, CA; 2) Ambry Genetics; 3) Health Research and Policy, Stanford University, Stanford, CA.

BACKGROUND: Genes for which cancer risks are not well characterized are included on clinical next-generation sequencing-based multi-gene panel tests (MGPT), including *MRE11A*, *RAD50*, and *NBN* (MRN). The protein products of these genes form the MRN complex and play an integral role in meiotic recombination and telomere maintenance. We aimed to further characterize cancer risks of MRN mutation carriers (MRN+) through family history analysis. METHODS: MRN+ were identified through hereditary cancer MGPT at a commercial laboratory. Complete family cancer histories were obtained from ordering clinicians as approved in an IRB reviewed protocol (n=180). Standardized Incidence Ratios (SIRs) relative to population incidences of breast, ovarian and other cancers were calculated for relatives of MRN+. A comparison cohort consisted of 180 families with a proband negative for MRN mutations (MRN–). RESULTS: Among 6277 relatives of MRN+, SIRs were greater than two times the population risk for breast, ovarian, pancreatic, gastric cancer and melanoma when MRN complex genes were combined (Table 1). However, similar risks were also observed for relatives of MRN– compared to the general population (Table 1). SIRs for ovarian, gastric and pancreatic cancers trended higher for relatives of MRN+ compared to MRN–, but were not statistically significant. CONCLUSIONS: Relatives of MRN+ have substantially elevated cancer risks compared to the general population; however, these risks are similarly increased among relatives of MRN–, likely reflecting an ascertainment bias in this laboratory cohort. As such, we are unable to determine whether the increased risks in relatives of MRN+ are attributable to the MRN mutation or other factors increasing familial risk. Future studies should investigate cancer risks among relatives of unselected MRN+.

Table 1. SIRs in relatives by mutation carrier status of index proband*

	MRE11A+	RAD50+	NBN+	MRN+	MRN-
Cancer	SIR (95% CI)	SIR (95% CI)	SIR (95% CI)	SIR (95% CI)	SIR (95% CI)

A genetic contribution to prostate cancer incidence in men of African ancestry. *D.V. Conti, C.A. Haiman on behalf of the African Ancestry Prostate Cancer and ELLIPSE GAME-ON Consortia.* Preventive Medicine, Univ Southern California, Los Angeles, CA.

The greater incidence of prostate cancer observed in men of African ancestry remains one of the most important unanswered health disparities globally. Reasons for this disparity by race/ethnicity are unknown, but likely include a multitude of factors, including social aspects such as access to health care, exposures to environmental and lifestyle factors and host/biological factors including inherited susceptibility. There is very strong evidence to suggest genetic differences in the allelic architecture of prostate cancer across populations. Admixture, genome-wide association (GWAS) and fine-mapping studies have identified multiple regions of the genome that harbor genetic risk alleles that are only identified in men of African ancestry, which may account, in part, for the greater disease incidence in this population. In an attempt to quantify the underlying genetic contribution to the greater incidence of prostate cancer in men of African ancestry, we combined genetic association results from all existing large-scale GWAS of prostate cancer globally in men of African ancestry totaling 10,155 cases and 10,857 controls. A total of 19.5 million genotyped and imputed SNPs, as well as insertion/deletion variants ≥1% frequency were tested for association with prostate cancer risk. Outside of the known susceptibility regions, markers at chromosomes 13q34 and 22q12, were associated with prostate cancer risk at a genome-significant level. At these susceptibility regions, the risk-associated alleles were found only in men of African ancestry. At 13q, the most associated marker (2.2% frequency in controls), was associated with an OR of 1.56 ($p=4.9 \times 10^{-12}$). This marker is located within a cluster of associated alleles 5' of the gene *IRS2* (insulin receptor S -2) and 3' of a long non-coding RNA (LINC00676). At 22q, the most notable signal was a missense variant in the *CHEK2* gene (1.5% frequency in controls; OR=1.61, $p=1.33 \times 10^{-9}$). These findings provide further support for population-specific alleles in contributing to the greater incidence of prostate cancer in men of African ancestry.

Somatic and germline mutational heterogeneity in high hyperdiploid acute lymphoblastic leukemia. *A.J. de Smith[1], K.M. Walsh[2], I. Smirnov[2], E. Sanders[1], H.M. Hansen[2], C. Metayer[3], J.L. Wiemels[1,2].* 1) Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States of America; 2) Division of Neuroepidemiology, Department of Neurological Surgery, University of California San Francisco, San Francisco, CA, United States of America; 3) School of Public Health, University of California Berkeley, Berkeley, California, United States of America.

High hyperdiploid acute lymphoblastic leukemia (HD-ALL), characterized by a non-random pattern of chromosomal gains (51-67 chromosomes), is one of the most common childhood cancers. Cure rates are high, yet significant treatment-related morbidity and mortality warrant more investigations into the etiology and molecularly-targeted therapies of this disease. Deep-sequencing of 538 cancer-related genes was performed using the UCSF500 Cancer Gene Panel in 57 HD-ALL tumors from California Childhood Leukemia Study patients. To enrich for discovery of novel driver genes, patients were selected without overt *KRAS* and *NRAS* hotspot mutations or common ALL deletions. A Combined Annotation Dependent Depletion (CADD) Phred score ≥20 was used to filter predicted damaging mutations. To remove polymorphisms, we retained only mutations with allele frequency <0.01% in the Exome Aggregation Consortium (ExAC). Novel damaging somatic mutations were discovered in epigenetic regulatory genes, including *DOT1L* (n=4), with >50% of patients harboring mutations in this pathway. Receptor tyrosine kinase (RTK)/Ras/MAPK signaling pathway mutations were found in ~80% of patients, including novel mutations in *ROS1* (n=4), which mediates phosphorylation of *PTPN11*, and in the VEGF-receptor *KDR* (n=4). We detected an extraordinary level of tumor heterogeneity, with microclonal (mutant allele fraction, MAF <10%) *KRAS*, *NRAS*, *FLT3* or *PTPN11* hotspot mutations evident in 31/57 (54.4%) patients. Multiple *KRAS* and *NRAS* codon 12 and 13 microclonal mutations significantly co-occurred within tumor samples (P=4.8x10^{-4}), suggesting ongoing formation of, and selection for, *Ras* mutations. We also discovered a high frequency of likely causal germline mutations, confirmed via Sanger sequencing. At least 25% of HD-ALL patients carried one or more rare (<0.01% allele frequency in ExAC) and predicted damaging germline mutations, including in known ALL predisposition genes, DNA repair genes, or within known hotspot mutation loci that had previously been reported only in tumor genomes. Future work is required to investigate whether tumor microheterogeneity should impact therapeutic regimens and to elucidate the biological function of epigenetic dysregulation in HD-ALL. Whole-exome sequencing of more patients will be required to comprehensively assess high-penetrance predisposition variants underlying HD-ALL.

Biomarkers elucidating epithelial-mesenchymal plasticity of breast cancer stem cells. *D. Dhawan[1,2].* 1) Institute of Life Sciences, Ahmedabad University, Ahmedabad, Gujarat, India; 2) Pangenomics, Ahmedabad, Gujarat, India.

The continued expression of adhesion molecules and the intact basal lamina results in the cancerous epithelial cells being confined to a primary site. However, as the cancer progresses some cells are believed to undergo an epithelial-mesenchymal transition (EMT) event, leading to increased motility, invasion and, ultimately, metastasis of the cells from the primary tumor to secondary sites within the body. Like stem cells, these disseminated cancer cells need the ability to self-renew in order to establish and maintain a heterogeneous metastatic tumor mass. Identification of the specific subpopulation of cancer stem cells amenable to the process of metastasis is highly desirable. In this study, we have isolated and characterized cancer stem cells from luminal and basal breast cancer cell lines (MDA-MB-231, MDA-MB-453, MDA-MB-468, MCF7 and T47D) on the basis of cell surface markers CD44 and CD24; as well as Side Populations (SP) using Hoechst 33342 dye efflux. The isolated populations were analysed for epithelial and mesenchymal markers like E-cadherin, N-cadherin, Sfrp1 and Vimentin by Western blotting and Immunocytochemistry. MDA-MB-231 cell lines contain a major population of CD44+CD24- cells whereas MCF7, T47D and MDA-MB-231 cell lines show a side population. We observed higher expression of N-cadherin in MCF7 SP as compared to MCF7 NSP (Non-side population) suggesting that the SP cells are mesenchymal like cells and hence express increased N-cadherin with stem cell-like properties. There was an expression of Sfrp1 in the MCF7 NSP as compared to no expression in MCF7 SP, which suggests that the Wnt pathway is expressed in the MCF7 SP. The wound healing assays showed a significant difference in the time taken for wound closure between the MCF7 SP and the MCF7 NSP suggesting the ability for metastasis in the SP of MCF7. The mesenchymal marker Vimentin was expressed only in MDA-MB-231 cells. Hence, understanding the breast cancer heterogeneity would enable a better understanding of the disease progression and therapeutic targeting.

RAD51C and *RAD51D* **mutation screening in South African breast and/or ovarian cancer families.** *C.M. Dorfling, J. Eloff, E.J. van Rensburg.* Genetics, University of Pretoria, Pretoria, South Africa.

Most known breast cancer susceptibility genes have important roles in DNA repair by homologous recombination. Pathogenic mutations in *BRCA1* and *BRCA2* have been shown to occur in ~70% of South African high-risk breast and/or ovarian cancer families. The remaining families may be explained by other genes in the DNA repair pathway that also confer increased breast and ovarian cancer risk, such as *RAD51C* and *RAD51D*. To investigate the role of *RAD51C* and *RAD51D* in breast and ovarian cancer predisposition in South African breast and/or ovarian cancer families, we screened 74 patients from 65 families (51 breast cancer specific, 12 breast and ovarian cancer, two ovarian cancer specific) for germline mutations in these genes. Direct Sanger sequencing was performed on all coding regions of *RAD51C* and *RAD51D*, including the 5'UTR and the exon-intron boundaries. Six previously reported *RAD51D* mutations were identified; three intronic, one synonymous and two non-synonymous variants. Seven previously reported *RAD51C* variants were detected; one frameshift, two non-synonymous, three intronic and one 5'UTR variant. The truncating *RAD51C* mutation (c.93delG, p.Gly31GlyfsX9) was identified in a breast cancer only family. This truncating mutation was also described in breast and ovarian cancer families from Finland. Originally pathogenic *RAD51C* mutations were identified in families with both breast and ovarian cancer. Later studies suggested that *RAD51C* mutations contribute to a smaller fraction of breast and ovarian cancer families compared to ovarian cancer only families. Thus, our finding of a pathogenic *RAD51C* mutation in a breast cancer specific family is rare. In conclusion, no pathogenic *RAD51D* mutations were identified whereas pathogenic *RAD51C* mutations were identified in ~2% (1/51) of breast cancer specific families and overall 1.5% (1/65) in high-risk cancer families from South Africa.

2709F

Association of plasma exosome miRNAs with survival in advanced clear cell type kidney cancer. *M. Du[1], K. Giridhar[2], J. Zhu[1], M. Kohli[2], L. Wang[1].* 1) Department of Pathology and Cancer Center, Medical College of Wisconsin, Milwaukee, WI, USA; 2) Department of Oncology, Mayo Clinic, Rochester, MN, USA.

Background. Clinical characteristics are currently used for prognostication of advanced stage kidney cancer. Since these can be inaccurate in individual patients, we evaluated plasma exosomal miRNAs for prognosis in clear cell type renal cell cancer (ccRCC). **Methods.** ccRCC patients were enrolled on a tertiary hospital based repository between 9/2011 and 12/2015 and plasma was collected and processed uniformly for all patients. Exosomal RNA was isolated from plasma and RNA sequencing was performed in 43 ccRCC patients. Cox regression and Kaplan-Meier survival analyses were performed to evaluate the association of miRNAs with overall survival. Expression for significantly associated candidate exosomal miRNAs with overall survival were evaluated in TCGA ccRCC dataset with 508 patients. **Results.** RNA sequencing of plasma in the 43 ccRCC patients generated approximately 3.72 million mappable reads per patient. Of those with normalized read counts>8 RPM (reads per million), 93.6% were mapped to miRNAs for a total of 322 miRNAs, 6.2% were mapped to piwiRNAs, and 0.2% was other RNAs including mRNA, tRNA and rRNA. Cox regression analysis identified 20 exosomal miRNAs in plasma that were associated with overall survival (p < 0.05). Of these, lower expression of miR-190 was significantly associated with poor overall survival in plasma (p=0.0007, HR=0.051) and in tumor tissues from TCGA (p=1.05E-06, HR=0.67). Lower expression of miR-30d was also associated with poor overall survival in plasma (p=0.034, HR=0.31) and in TCGA tumor tissues (p=0.022, HR=0.75). In addition, we found that at least three miRNAs were associated with overall survival in plasma but not in TCGA dataset. Higher expression of miR-133b and miR-378h were associated with poor overall survival (p=0.032, HR=2.27 and p=0.006, HR=4.48, respectively). Lower expression of miR-26a-1-3p was associated with poor overall survival (p=0.001, HR=0.018). **Conclusion.** Multiple plasma exosomal miRNAs were determined as promising prognostic biomarkers for advanced ccRCC patients. These markers, if validated, could be incorporated to current clinicopathologic parameters to improve prognostic information on individual patients. Prospective validation is needed for further evaluation of these candidate miRNAs.

Routes to prostate cancer progression and identification of new drug targets: Results from the CRUK-ICGC prostate initiative. *R. Eeles[1], D.C. Wedge[2], G. Gundem[2], T.J. Mitchell[2], M. Ghori[2], J. Zamora[2], A. Butler[2], H. Whitaker[3], Z. Kote-Jarai[1], C. Massie[3], L.B. Alexandrov[3], A. Warren[4], C. Verrill[5], D. Berney[6], N. Dennis[1], S. Merson[1], M. Fraser[7], P. Boutros[8], R. Bristow[7], C. Sander[9], F. Hamdy[10], U. McDermott[2], B. Al-Lazikani[1], P. Workman[1], A.G. Lynch[3], G.S. Bova[11], C. Foster[12], D.S. Brewer[13], D. Neal[2], C.S. Cooper[13].* 1) Div of Genetics & Epidemiology, Inst Cancer Res, Sutton, Surrey, United Kingdom; 2) Wellcome Trust Sanger Institute, Cambridge, United Kingdom; 3) Cancer Research UK, Cambridge Institute, Cambridge, United Kingdom; 4) Cambridge University Hospitals NHS Foundation Trust, Addenbrookes Hospital, Cambridge, United Kingdom; 5) Oxford University Hospital NHS Foundation Trust, Oxford, United Kingdom; 6) Barts Cancer Centre, Barts and the London School of Medicine, London, United Kingdom; 7) Princess Margaret Cancer Centre, Toronto, Canada; 8) Ontario Institute for Cancer Research /MaRS Centre, Toronto, Canada; 9) Dana-Farber Cancer Institute, Boston, USA; 10) University of Oxford, Oxford, United Kingdom; 11) University of Tampere & FimLab Laboratories, Tampere, Finland; 12) HCA Healthcare, London, United Kingdom; 13) University of East Anglia, Norwich, United Kingdom.

Prostate cancer (PCa) is a challenge to treat because, while some cases are indolent, others progress and cause morbidity and mortality. We sequenced the whole genomes of 112 primary and metastatic PCas to 50X and their associated germline DNA to 30X through the CRUK - ICGC prostate cancer project. We then combined these data with publically available sequence data from prostate cancers in the TCGA. We identified 18 novel putative driver genes. Through the temporal dissection of aberrations and the stratification of tumours by ETS status and primary/metastatic site, we identified driver mutations specifically associated with steps in the progression of PCa. Using the CanSAR analysis of mutations which is a bioinformatic tool to predict which products may be susceptible to current drug targets, we identified 8 targets of current drugs, 6 targets of investigational drugs and 26 compounds that may be active and should be considered as trial candidates in future clinical trial design in this disease.

2711T

Morning fatigue in cancer patients receiving chemotherapy is associated with differential expression and methylation of regions associated with immune function/inflammation and energy metabolism. *E. Flowers[1], C. Miaskowski[1], J. Mastick[1], B. Cooper[2], S. Paul[2], K. Kober[1].* 1) Physiological Nursing, University of California, San Francisco, San Francisco, CA; 2) University of California, San Francisco, San Francisco, CA.

Fatigue is the most common symptom associated with cancer treatment. However, due to the lack of understanding of the mechanisms that underlie fatigue, no effective interventions are available. Investigation of the molecular mechanisms that are associated with higher levels of fatigue in oncology patients undergoing chemotherapy (CTX) may guide the development of more effective treatments. The objective of this study is to examine differential gene expression and methylation in a subset of breast cancer patients experiencing lower (n=14) versus higher (n=30) levels of morning fatigue. Oncology outpatients (n=582) were assessed over two CTX cycles. Morning fatigue was assessed using the Lee Fatigue Scale (LFS). In this sample, we previously described three latent classes of patients with distinct morning fatigue trajectories over two cycles of CTX (i.e., low (32%), high (51%), and very high (17%)). Gene expression and methylation were assayed from peripheral blood for 44 breast cancer patients prior to a dose of CTX with the Illumina HumanHT-12 and HumanMethylation450 arrays. No differences were found in demographic or clinical characteristics between the low (n=14, mean LFS score 4.5) and higher fatigue (n=30, mean LFS score 6.1) groups. Differences in gene expression were found between the low and higher fatigue groups for 97 genes and 135 differentially perturbed KEGG pathways. The pathways are involved in inflammation and immunity, energy metabolism, and circadian rhythm. In addition, 1585 preliminary differentially methylated positions (pDMPs) were found between the low versus higher fatigue groups. Genes annotated for these pDMPs (n=1188) were significantly enriched in 63 KEGG pathways. Three pathways overlapped with those enriched in the gene expression analysis, including chemokine signalling pathway, antigen processing and presentation, and circadian rhythm. These findings suggest that the severity of morning fatigue in oncology patients is associated with changes in gene expression and epigenetic markers, and support currently hypothesized mechanisms for fatigue. The development of interventions that target these mechanisms may be useful to treat oncology patients undergoing CTX.

2712F

Association of *2R/3R* **polymorphism of the thymidylate synthase gene with non-response to chemotherapy in colon cancer patients from Mexican population.** *K. Gómez-Mariscal[1,5], G.M. Zúñiga[2], L.E. Figuera[3], A.M. Puebla[4], M.P. Gallegos-Arreola[5].* 1) Universidad de Guadalajara, Guadalajara, Jalisco, Mexico; 2) Laboratorio de Mutagénesis , Centro de Investigación Biomédica de Occidente (CIBO),, Instituto Mexicano del Seguro Social (IMSS); 3) División de Genética, CIBO, IMSS; 4) Laboratorio de Inmunofarmacología, Centro Universitario de Ciencias Exactas e Ingenierías (CUCEI), UdeG; 5) Laboratorio de Genética Molecular, División de Genética, CIBO, IMSS. Guadalajara, Jalisco, México.

The polymorphism *2R/3R* of Thymidylate Synthase gene (*TYMS*) has been associated with susceptibility to colon cancer (CRC) in different populations. Also has been a play an important role in the conversion of dUMP to dTMP, which in turn may result in differences in the outcome of CRC chemotherapy. This study determined the association of *2R/3R* polymorphism with non-response to chemotherapy in CRC patients from Mexican population. DNA of 47 patients with CRC with 5-fluorouracil or capecitabine with chemotherapy treatment (5-FU) was extracted. The *2R/3R* polymorphism was determined by polymerase chain reaction (PCR) and wild genotype (*2R/2R*) was identified by 210bp band, the heterozygous genotype (2R/3R) by 210 and 238bp; and polymorphic genotype (*3R/3R*) by 238 bp. the PCR products were separated on a 6% polyacrylamide gel. Patients were sub-grouped by chemotherapy status: response (RC), non-response (NRC), and partial response (PRC). Results: genotype 3R*/3R* of *VNTR* polymorphism no was associated with NRC and PRC (p>0.05). Conclusion: Our results indicate that the *2R/3R TYMS* polymorphism no was associated with non-response chemotherapy in CRC patients of analyzed sample from Mexican population.

2713W

Association of *-31T<C* **polymorphism of the IL-1β gene with susceptibility to colon cancer patients from Mexican population.** *M.P. Gallegos-Arreola[1], L.E. Figuera[2], A.M. Puebla-Pérez[3], G.M. Zúñiga[4].* 1) Laboratorio de Genética, División de Genética, Centro de Investigación Biomédica de Occidente (CIBO), IMSS,; 2) División de Genética, CIBO, IMSS; 3) Laboratorio de Inmunofarmacología, Centro Universitario de Ciencias Exactas e Ingenierías (CUCEI), Universidad de Guadalajara (U de G); 4) Laboratorio de Mutagenesis, CIBO, IMSS. Guadalajara, Jalisco. México.

In different kind of cancers have been investigated that the cytokine-mediated immune and inflammatory responses to play an important role in their pathogenesis. The present study investigated the association of *-31T<C* polymorphism of interleukin-1β (IL1β) with colon cancer (CRC) patients from Mexican population. DNA of 230 CRC patients and 220 healthy controls from general population was extracted. The *-31T<C* polymorphism in the 5′-untranslated region (5′-UTR) was determined by polymerase chain reaction (PCR) and the 272bp fragments of PCR were digested with AluI restriction enzyme, the products were separated on an 6% polyacrylamide gel. The genotype frequencies of *-31T<C* polymorphism were 23% and 29% of *T/T*; 62% and 51% of *T/C*; and 15% and 20% of C/C from patients and controls respectively. The comparative analysis of association shown that heterozygous genotype was associated with susceptibility of CRC patients [odds ratio OR 1.5 Confidence intervals CI95% 1.1-2.2), p=0.02]. Conclusion: Our results indicate that the *-31T<C* polymorphism of *IL1β* was associated with CRC patients from Mexican population.

Rare germline loss-of-function variants in melanoma susceptibility genes in familial melanoma. *A.M. Goldstein[1], Y. Xiao[1], H. Bennett[1], M. Rotunno[1], K. Jones[1,2], A. Vogt[1,2], L. Burdette[1,2], B. Zhu[1,2], M. Yeager[1,2], S.J. Chanock[1], M.A. Tucker[1], X.R. Yang[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, DHHS, Bethesda, MD, USA; 2) Cancer Genomics Research Laboratory, Leidos Biomedical Research, Frederick National Laboratory for Cancer Research, Frederick, MD, USA.

Approximately 10% of cutaneous malignant melanoma (CMM) cases occur in a familial setting and known high-risk CMM genes account for melanoma risk in less than 40% of melanoma-prone families, suggesting the existence of additional high-risk genes or a polygenic mechanism involving multiple genetic modifiers such as variants in intermediate-risk and low-risk genes. The goal of this analysis was to systematically characterize rare germline loss-of-function (LOF) variants in established melanoma high-risk, intermediate-risk, and low-risk genes among CMM patients in 76 American melanoma-prone families without known mutations (144 CMM cases) using data from whole-exome sequencing. Rare variants were defined as <0.1% in the 1000 Genomes Project (1,092 subjects), ESP (6,500 subjects), 500 healthy in-house population-based controls of European ancestry, and ≤1 family from our in-house database of >900 cancer-prone control families (excluding CMM and pancreatic cancer families). Among the 42 known melanoma genes evaluated, we identified nine LOF variants. Six of them remained of interest after technical validation and further evaluation in about 800 population-based CMM cases and 800 controls, including two variants in *TYRP1* and one each in *TYR*, *PLA2G6*, *POT1*, and *TINF2*. Of particular interest, a stopgain variant in *TYR* was present in 5 of the 6 sequenced CMM cases/obligate gene carriers in one family and a single sporadic CMM case. The variant was only observed in 3 out of 66,390 alleles among non-Finish Europeans in The Exome Aggregation Consortium (ExAC) database and not seen in any other public control databases or our population-based controls. This stopgain variant is classified as a disease-causing mutation in the Human Gene Mutation Database with the associated phenotype being *OCA1* albinism. A start gain variant in the 5'UTR region of *PLA2G6* was seen in all three examined cases in one family. It was not present in any evaluated public databases or our in-house controls. A stopgain variant in *POT1* was seen in one family in a single CMM case and a family member with dysplastic nevi. A frameshift variant in *TINF2* was observed in two of three cases in a family and the two *TYRP1* variants (one stopgain and one frameshift) were each observed in a single case in two different families. Our results suggest that rare LOF variants in known CMM susceptibility genes may contribute to CMM predisposition in some melanoma-prone families without known genetic causes.

2715F

Loss of selective constraints drives damage to mitochondrial genomes in cancer. *S. Grandhi[1], B. Colleen[1], M. Wesley[1], N. Ying[1,2], L. Thomas[1,2,3].* 1) Department of Genetics and Genome Sciences, Case Western Reserve University, Cleveland, Ohio, USA; 2) Genomic Medicine Institute, Lerner Research Institute, Cleveland Clinic, Cleveland, Ohio, USA; 3) 3Center for Proteomics and Bioinformatics, Case Western Reserve University School of Medicine, Cleveland, Ohio, USA.

Although mitochondrial genomes (mtDNA) accumulate elevated levels of mutations in cancer cells, the origin and functional impact of these mutations remain controversial. Here, we queried whole-genome sequence data from 1,916 patients across 24 cancer types to characterize patterns of mtDNA mutations and elucidate the selective constraints driving their fate. Tumor mitochondrial genomes show a distinct mutational signature and are disproportionately enriched for protein-altering changes, in contrast to the strong purifying selection found in the human germline and somatic normal cells. Moreover, protein-altering mtDNA variants that are initially present at low frequencies in normal cells preferentially expand in the altered tumor environment, suggesting selective advantage. Dramatic shifts in selective pressures suggest that tumor cells exploit the dynamic and transient nature of normal mitochondria by tuning levels of damaged mitochondrial genomes to facilitate the tumorigenic process.

2716W

Pathogenic/likely pathogenic variants in non-high risk genes in persons with multiple primary cancers. *S.A. Jackson, L.R. Susswein, J.L. Mester, K.A. Barker Grill, R.T. Klein, K.S. Hruska.* GeneDx, Gaithersburg, MD.

One criterion for hereditary cancer susceptibility testing is a personal history of multiple primary cancer diagnoses. With the evolution from single gene to multiplex testing, moderate-risk and newer cancer susceptibility genes are often included on panels with historical high-risk genes. As a clinical diagnostic laboratory, we aimed to characterize the distribution of pathogenic or likely pathogenic variants (P/LPVs) across genes and risk categories among individuals with multiple primary cancers undergoing multi-gene cancer panel testing. We retrospectively reviewed personal history and testing results from approximately 11,000 individuals who underwent Comprehensive Cancer Panel testing in our diagnostic laboratory between August 2013 and March 2016. This next-generation sequencing and deletion/duplication panel includes 17 genes associated with highly penetrant hereditary cancer syndromes, 3 causing a moderate increase in cancer risk, and up to 12 recently described in association with cancer risk. Cancers of unlikely hereditary etiology (cervical, lung, non-melanoma skin) were excluded from analysis. Cases were also excluded if prior analysis of one or more genes on this panel had been performed at this or another laboratory, or if an individual only had a single P/LPV in *MUTYH*. Of the 127 total individuals with at least one P/LPV and multiple primary cancers, 62 (48.8%) harbored a variant in a newer or moderate-risk gene. Among 121 individuals heterozygous for a single P/LPV, 52.1% (63/121) occurred in a high-risk gene, with BRCA1/2 accounting for over half (37/63, 58.7%); 38.8% (47/121) occurred in a moderate-risk gene, with most (29/47, 61.7%) in CHEK2; and 9.1% (11/121) involved a newer cancer risk gene. In addition, six individuals were found to have two P/LPVs: two with P/LPVs in high risk genes and four involving one high- and one moderate-risk gene. Although a diagnosis of multiple primary cancers may appear more consistent with a highly-penetrant hereditary cancer syndrome as the underlying etiology, a large portion of P/LPVs were identified in newer or moderate-risk genes. Furthermore, four individuals with a high-risk P/LPV also had a moderate-risk P/LPV, which would have gone undetected had testing been limited to analysis of high-risk genes. These results strongly support evaluation of moderate-risk and newer cancer susceptibility genes in individuals with a personal history of multiple primary cancers.

2717T

A microRNA target site polymorphism in *SLC7A6* confer risk of hepatitis B virus-related hepatocellular carcinoma. *D. Jiang[1,2,3,4], X. Ma[2], Q. Xiao[5], C. Conran[1], S. Zheng[1], L. Yu[2,6], J. Xu[1,2,3,4,5,7].* 1) Program for Personalized Cancer Care, NorthShore University HealthSystem, Evanston, IL, Affiliate of University of Chicago Pritzker School of Medicine; 2) State Key Laboratory of Genetic Engineering, Collaborative Innovation Center for Genetics and Development, School of Life Sciences, Fudan University, Shanghai, China; 3) Ministry of Education Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan University, Shanghai, China; 4) Center for genetic Epidemiology, School of Life Sciences, Fudan University, Shanghai, China; 5) Center for Genomic Translational Medicine and Prevention, School of Public Health, Fudan University, Shanghai, China; 6) Institute of Biomedical Science, Fudan University, Shanghai, China; 7) Fudan Institute of Urology, Huashan Hospital, Fudan University, Shanghai, China.

Purpose: Single nucleotide polymorphisms (SNPs) in microRNA (miRNA) binding sites within 3′-untranslated regions (UTRs) of miRNA target genes may influence miRNA–mRNA interaction and contribute to carcinogenesis. In the present study, we aimed to perform a systematic evaluation of the associations between SNPs in putative miRNA binding sites across the whole genome and risk of hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC). **Methods:** We used our recent genome-wide association study (GWAS) on HBV-related HCC including 2,514 chronic HBV carriers with (n=1,161) or without (n=1,353) HCC (Nat Genet 2013;45:72-5) as a discovery stage. We extracted 32,074 SNPs within miRNA target sites from the GWAS data and investigated their associations with risk of HBV-related HCC. Seven promising SNPs were then replicated in four independent case-control populations totaling 6,922 chronic HBV carriers, including 3,161 HCC cases and 3,761 controls. A meta-analysis of the discovery stage and subsequent replications was performed to identify significant SNPs ($P\square1.56\times10^{-6}$ after a Bonferroni correction for multiple tests of 32,074 SNPs). We assessed the correlations between significant SNPs and mRNA expression of genes that harbor the significant SNPs both in tumor and corresponding adjacent normal tissues from 103 HBV-related HCC patients using real-time PCR. We also assessed the binding affinity of predicted miRNAs to their target sites possessing different alleles of the significant SNPs using miRNA mimics and reporter gene assays. **Results:** We found that, among the 32,074 SNPs, rs11350 C>T in the 3′ UTR of *SLC7A6* was the only significant SNP. The C allele of rs11350 was significantly associated with increased HBV-related HCC risk under an additive model (OR=1.40, 95% CI=1.23-1.59, $P_{meta}=2.09\times10^{-7}$) and a dominant model (OR=1.42, 95%CI=1.24-1.62, $P_{meta}=1.82\times10^{-7}$). The rs11350 C allele carriers had higher *SLC7A6* mRNA expression levels in both HCC tissues and corresponding adjacent non-tumor tissues. Additionally, rs11350 was predicted to be within the miR-548d-3p and miR-548x seed binding regions. Further functional analyses showed that the rs11350 C allele weakened the binding capacity of miR-548d-3p to the 3′-UTR of *SLC7A6* compared to the T allele. **Conclusion:** Our findings indicate that rs11350, located at the miR-548d-3p binding site, may alter the expression of *SLC7A6* and contribute to the development of HBV-related HCC in Chinese populations.

Homologous recombination and the SWI/SNF chromatin remodeling pathways are necessary for the repair of formaldehyde-induced double strand breaks. *E. Juarez, A.K. McCullough.* Molecular and Medical Genetics, Oregon Health and Science University, Portland, OR.

The SWI/SNF complex was originally identified as an important player in cancer development when biallelic truncating mutations were identified in malignant rhabdoid tumors, a highly aggressive pediatric cancer. Since then, mutations in other subunits of the SWI/SNF complex have been identified in 20% of cancers, suggesting a vital role in neoplasia. The mechanisms by which mutations in this complex specifically drive tumorigenesis are still unclear. Given the current evidence that SWI/SNF deficiency plays a role in carcinogenesis, and growing evidence that it may be acting as a bono-fide tumor suppressor, we chose to investigate the role of the SWI/SNF complex in DNA repair and genome stability. Tumor suppressor genes are often DNA repair-associated genes and protect the cell from genetic instability that favors tumor progression. Formaldehyde was used to induce DNA-protein crosslinks (DPCs) and subsequent double-strand breaks (DSB), and these studies were performed in yeast cells due to their genetic versatility. Our lab, and others, have identified cellular pathways critical for cell survival following DPC induction. Specifically, we demonstrated via a screen of the *S.cerevisiae* gene deletion library, that components of the Nucleotide Excision Repair (NER) pathway are necessary for cell survival after high-dose acute formaldehyde exposure. Conversely, components of the Homologous Recombination (HR) pathway, and not NER, were necessary for survival following low-dose chronic exposure. In this study we show that components of the SWI/SNF complex are exquisitely sensitive to formaldehyde exposure under chronic conditions, and that double mutants harboring mutations in both the HR and SWI/SNF pathways show an epistatic relationship. Deletion of the SWI/SNF ATPase core subunit, SNF2*,* also resulted in an accumulation of DSBs likely due to a delayed DNA-damage response as supported by abnormal upregulation of MEC1 (ATR) and TEL1 (ATM) gene expression. Moreover, persistent DSBs resulted in a cell cycle arrest in G2/M 24 hours after initial chronic exposure. Finally, formaldehyde exposure also resulted in failed cytokinesis resulting in multinucleated yeast cells. Therefore, we propose that the SWI/SNF complex is working with the HR repair pathway to maintain genome integrity and cell cycle progression, and believe that this interplay may be contributing to its role as a tumor suppressor in cancer development and progression.

Genomic differences between pure ductal carcinoma *in situ* **and synchronous ductal carcinoma** *in situ* **with invasive breast cancer.** *S.Y. Kim[1,3], S.H. Jung[1,3], M.S. Kim[2], I.P. Baek[1,3], S.H. Lee[4], T.M. Kim[5], Y.J. Chung[1,3], S.H. Lee[2].* 1) Microbiology, The Catholic University of Korea, Seoul, South Korea; 2) Pathology, The Catholic University of Korea, Seoul, South Korea; 3) Integrated Research Center for Polymorphism, The Catholic University of Korea, Seoul, South Korea; 4) Hospital Pathology, The Catholic University of Korea, Seoul, South Korea; 5) Medical Informatics, The Catholic University of Korea, Seoul, South Korea.

Although ductal carcinoma in situ (DCIS) precedes invasive ductal carcinoma (IDC), the related genomic alterations remain unknown. To identify the genomic landscape of DCIS and better understand the mechanisms behind progression to IDC, we performed whole-exome sequencing and copy number profiling for six cases of pure DCIS and five pairs of synchronous DCIS and IDC. Pure DCIS harbored well-known mutations (e.g., TP53, PIK3CA and AKT1), copy number alterations (CNAs) and chromothripses, but had significantly fewer driver genes and co-occurrence of mutation/CNAs than synchronous DCIS-IDC. We found neither recurrent nor significantly mutated genes with synchronous DCIS-IDC compared to pure DCIS, indicating that there may not be a single determinant for pure DCIS progression to IDC. Of note, synchronous DCIS genomes were closer to IDC than pure DCIS. Among the clinicopathologic parameters, progesterone receptor (PR)-negative status was associated with increased mutations, CNAs, co-occurrence of mutations/CNAs and driver mutations. Our results indicate that although pure DCIS has already acquired some drivers, more changes are needed to progress to IDC. In addition, IDC-associated DCIS is more aggressive than pure DCIS at genomic level and should really be considered IDC. Finally, the data suggest that PR-negativity could be used to predict aggressive breast cancer genotypes.

Genetic predisposition to breast cancer due to mutations other than *BRCA1* and *BRCA2* founder alleles among Ashkenazi Jewish women. *M.C. King, J.B. Mandell, S. Casadei, S. Gulsuner, M.K. Lee, T. Walsh.* Depts of Genome Sciences and Medicine, University of Washington, Seattle, WA.

Among Ashkenazi Jewish (AJ) breast cancer patients who do not carry one of the three founder mutations of *BRCA1* or *BRCA2*, the likelihood of carrying some other pathogenic mutation in *BRCA1*, *BRCA2*, or another breast cancer gene is not well established. We undertook this assessment in a cohort of 1007 AJ breast cancer patients, not selected for family history or age at diagnosis; previous analyses had identified a *BRCA1* or *BRCA2* founder mutation in 10% (104) of these patients (Science 302:643, 2003). For the present project, we sequenced genomic DNA from these 1007 patients for 28 known and candidate breast cancer genes using BROCA. Of the 903 patients with no founder mutation, 0.8% (7) carried rare truncating mutations in *BRCA1* or *BRCA2*. Of these seven mutations, one is apparently private; the other six appear in one or more European populations. Family history was suggestive for four of the seven mutation carriers. Frequencies of non-founder *BRCA1* and *BRCA2* mutations were higher among patients diagnosed before age 40 (2.9%) compared to those diagnosed at ages 40-49 (1.1%), ages 50-59 (0.4%), or age 60 or older (0.4%). The gene panel also revealed that 3.5% (32/903) of patients carried a pathogenic mutation in another known or candidate breast cancer gene: 29 in *CHEK2* (entirely explained by 1100delC, p.S428F, and c.444(+1)G>A), and one each in *BRIP1, GEN1*, or *NBN*. Frequencies of mutations in *CHEK2, BRIP1, GEN1*, and *NBN* were higher among patients diagnosed before age 60 (4.1%) than at age 60 or older (2.2%), and among patients with a first or second degree relative with breast cancer (4.4%) compared to no such family history (2.5%). These results suggest that among AJ breast cancer patients with none of the *BRCA1* or *BRCA2* founder mutations, about 1% carry another actionable mutation in *BRCA1* or *BRCA2* and 3% to 4% carry an actionable mutation in another breast cancer gene. Finally, we estimate that of all inherited predisposition to breast cancer identified thus far in the AJ population, 73% is due to a *BRCA1* or *BRCA2* founder allele, 5% to another *BRCA1* or *BRCA2* mutation, and 22% to a mutation in another gene. (Supported by the Breast Cancer Research Foundation.).

2721F

DDI2, a novel candidate against sporadic colorectal cancer. *L. Lei[1,2], Y. Yang[1,2], X.J. Zhao[1,2], R.T. Liu[1,2], E.F. Chen[1,2], H.J. He[1,2], J. Dong[1,2], J. Yang[1,2].* 1) Northwest University, Xi'an, ShaanXi, China; 2) Key Laboratory of Resources Biology and Biotechnology in Western China, Ministry of Education.

Identifying and understanding genomic changes in sporadic colorectal cancer (sCRC) is essential for early diagnosis and targeted treatment. Here we analysed 3 cases of sCRC samples in the Chinese Han population by exome sequencing and identified 15 gene candidates, including DNA-damage inducible protein 2 (DDI2). DDI2 is likely to be involved in multiple cellular processes connected to the cell cycle control through ubiquitin-mediated degradative pathways. It is reported that the mRNA expression of DDI2 is lower in malignant than in benign thyroid lesions. However, whether DDI2 is associated with sCRC and the underlying mechanisms have yet to be investigated. In this study, we detected one missense mutation in deep sequencing group of 50 sCRC cases and illustrated lower expression of DDI2 in adenocarcinoma than adjacent normal tissue by immunohistochemistry. Further experiments showed exogenous introduction of DDI2 into LoVo cells suppressed migration, invasion, and cell proliferation in vitro as well as tumor growth in vivo. Taken together, our results suggest DDI2 may serve as a novel candidate against tumor growth for sCRC.

Further dissection on germline defects in Singapore Lynch Syndrome patients without obvious defects in common mismatch repair genes. *Y. Liu, M.H. Chew, C.T.T. Loi, C.L. Tang.* Colorectal Surgery, Singapore General Hospital, Singapore, Singapore.

   Background: Lynch Syndrome (LS) is an autosomal,dominantly inherited syndrome associated with substantial risks for malignancies in colon, rectum, endometrium, stomach, ovaries, small bowel, ureter, billary tract, renal pelvis, brain and skin. LS accounts for approximately 5% of all colorectal cancer cases in Singapore and we have previously identified disease-causing defects in common mismatch repair (MMR) genes (*MLH1* and *MSH2*) in one-third of local LS families. **Objectives**: To verify the association of 9 copy number variation (CNV) regions and 5 single or dinucleotide loci found in previous genome-wide studies with increased risks of LS. **Methodology**: Two sets of case-control samples were used in this study. CNV was analysed through the Nanostring nCounter® System while genotyping was performed using the Sequenome MassARRAY iPLEX™ platform. **Results**: Five out of the 9 CNV regions showed variation in the copy numbers. Within these 5 regions, we identified a handful of potentially implicated genes including *UGT2B4*, *TRIM5* and *ADAM32*, while the others were gene desert areas. As regards genotyp-ing, 4 loci were verified as novel mutations in *MLH1* and *MSH6* genes that were observed only in LS patient group. The remaining locus is a polymorphic site located within the miRNA binding site at 3' UTR of *PRKD3* gene. The patient group exhibited significantly higher minor allele frequency as compared to 185 matched healthy controls (*P*=0.0035). **Discussion**: The susceptibil-ity loci validated in this study will provide insights into pathogenic defects underlying LS in families who do not harbour obvious defects in the common MMR genes. The ultimate benefits will facilitate development of genetic testing for local LS families and subsequent disease management for LS cases and disease monitoring for defect-carriers among family members.

Association of vitamin D levels and risk of ovarian cancer: A Mendelian randomization study. *S. Macgregor[1], J. Ong[1], A. Berchuck[2], P.D.P. Pharoah[3], G. Chenevix-Trench[1], P. Gharahkhani[1], R. Neale[1], P. Webb[1] On behalf of the Ovarian Cancer Association Consortium.* 1) QIMR Berghofer Medical Re-search Institute, Brisbane, Australia; 2) Duke Cancer Institute, Duke University Medical Center, Durham, North Carolina, USA; 3) The Centre for Cancer Ge-netic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK.

   In vitro and observational epidemiological studies suggest that vitamin D may play a role in cancer prevention. However, the relationship between vitamin D and ovarian cancer is uncertain, with observational studies gen-erating conflicting findings. A potential limitation of observational studies is inadequate control of confounding and reverse causality. To overcome this problem, we used Mendelian randomization (MR) to evaluate the association between single nucleotide polymorphisms (SNPs) associated with circulating 25-hydroxyvitamin D (25(OH)D) concentration and risk of ovarian cancer. We employed two SNPs with well-established associations with 25(OH)D concen-tration as instrumental variables for MR: rs7944926 (*DHCR7*) and rs12794714 (*CYP2R1*). We included 31 719 women of European ancestry (10 065 cases, 21 654 controls) from the Ovarian Cancer Association Consortium, who were genotyped using customized Illumina Infinium iSelect (iCOGS) arrays. A two-sample (summary data) Mendelian randomization approach was used, and analyses were performed separately for all ovarian cancer (10 065 cases) and for high-grade serous ovarian cancer (4 121 cases).   The odds ratio for epithelial ovarian cancer risk (10 065 cases) estimated by combining the indi-vidual SNP associations using inverse variance weighting was 1.28 (95% con-fidence interval: 1.03 to 1.58) per 20nmol/L decrease in 25(OH)D concentra-tion. The estimated odds ratio for high-grade serous epithelial ovarian cancer (4 121 cases) was 1.63 (1.20, 2.22). Genetically lowered 25-hydroxyvitamin D concentrations were associated with higher ovarian cancer susceptibility in Europeans. These findings suggest that increasing plasma vitamin D levels may reduce risk of ovarian cancer.

2724F

***MCPH1* is a novel hereditary breast cancer susceptibility gene.** *T. Mantere[1], R. Winqvist[1], S. Kauppila[2], M. Grip[3], A. Jukkola-Vuorinen[4], A. Tervasmäki[1], K. Rapakko[5], K. Pylkäs[1].* 1) Laboratory of Cancer Genetics and Tumor Biology, Cancer and Translational Medicine Research Unit and Biocenter Oulu, Northern Finland Laboratory Centre NordLab Oulu, University of Oulu, Oulu, Finland; 2) Department of Pathology, Oulu University Hospital and University of Oulu, Oulu, Finland; 3) Department of Surgery, Oulu University Hospital and University of Oulu, Oulu, Finland; 4) Department of Oncology, Oulu University Hospital and University of Oulu, Oulu, Finland; 5) Laboratory of Genetics, Northern Finland Laboratory Centre NordLab Oulu, Oulu, Finland.

Breast cancer is strongly influenced by hereditary risk factors, a majority of which still remain unknown. Here, we performed a targeted next-generation sequencing of 796 genes implicated in DNA repair in 189 Finnish breast cancer cases with indication of hereditary disease susceptibility and focused the analysis on protein truncating mutations. A recurrent heterozygous mutation (c.904_916del, p.Arg304ValfsTer3) was identified in early DNA damage response gene, *MCPH1*, significantly associating with breast cancer susceptibility both in familial (5/145, 3.4%, P = 0.003, OR 8.3) and unselected cases (16/1150, 1.4%, P = 0.016, OR 3.3). A total of 21 mutation positive families were identified, of which one-third exhibited also brain tumors and/or sarcomas (P = 0.0007). Mutation carriers exhibited significant increase in genomic instability assessed by cytogenetic analysis for spontaneous chromosomal rearrangements in peripheral blood lymphocytes (P = 0.0007), suggesting an effect for MCPH1 haploinsufficiency on cancer susceptibility. Furthermore, 40% of the mutation carrier tumors exhibited loss of the wild-type allele. These findings collectively provide strong evidence for *MCHP1* being a novel breast cancer susceptibility gene, which warrants further investigations in other populations.

2725W

Case-case analysis of the genetic signature associated with inherited aggressive prostate cancer risk. *M. Mijuskovic[1], D.A. Leongamornlert[1], E.J. Saunders[1], S. Stephens[1], I. Whitmore[1], C. Cieza-Borrella[1], T. Dadaev[1], K. Govindasami[1], C. Haiman[2], D. Conti[2], R.A. Eeles[1], Z. Kote-Jarai[1].* 1) The Institute of Cancer Research, London, United Kingdom; 2) University of Southern California, Los Angeles, USA.

Prostate cancer (PrCa) is the most common malignancy diagnosed in men living in the developed world, with 250,000 deaths per year worldwide. Family history is a strong risk factor for the disease, however only a modest number of contributing moderate penetrance gene variants (e.g. in *BRCA2*) has been described to date. We hypothesized that additional rare germline variants exist that may be relevant to the patient outcome and can improve clinical management of the disease. To enrich the presence of rare variants associated with poor outcome, we performed extreme phenotype sampling of patients from the UK Genetic Prostate Cancer Study (UKGPCS), in which ~90% of patients had clinically presenting disease at diagnosis. We selected 144 of the aggressive (metastatic, age < 60 at diagnosis) and 144 non-aggressive (tumor grade ≤ T2b, no metastasis or nodal involvement, Gleason score < 7, age at diagnosis ≥ 60) cases for whole exome sequencing. All cases were of European ancestry, unrelated and had clinical follow-up data available. Samples were block randomized based on aggressive status and DNA extraction method and sequenced using Agilent SureSelectXT V5 to 20X median target coverage. Variants were called using GATK 3.5 and annotated against the GENCODE v19 transcript set. Rigorous data cleaning was performed that included the assessment of genotype quality, contamination, batch quality, sample identity and case-case confounding. The final filtered dataset included 139 aggressive and 141 non-aggressive cases with a total of 151,562 exonic/splice variants. We identified 97,889 rare variants (minor allele frequency ≤ 1%), among which 5,307 were predicted to be protein truncating (1,613 frameshift indels, 1,189 nonsense mutations, 2,494 splice site mutations, 8 start codon deletions and 3 stop codon insertions). 29 variants were found in 60 genes from the BROCA cancer risk panel, and they were overrepresented among samples with the aggressive phenotype (p=0.0031). The most frequently truncated genes from this set were *BRCA2* (1.8%), *ATM* (1.4%) and *NBN* (1%). Besides these, we found an additional 61 rare protein truncating variants in genes with a role in various DNA repair pathways. We furthermore describe the exome-wide gene and pathway-based association analysis of germline signature of aggressiveness which will aid future genetic profiling and screening for clinically significant PrCa. .

LGR5 **is a potential prognostic marker in young Egyptian rectal cancer patients.** *H. Morsy[1], A. Gaballah[2], M. Samir[3], M. Shamseya[4], H. Mahrous[1], A. Ghazal[2], W. Arafat[5], M. Hashish[1].* 1) Human Genetics Department , Medical Research Institute, Alexandria, Egypt; 2) Microbiology Department, Medical Research Institute, Alexandria, Egypt; 3) Clinical and Experimental Surgery Department, Medical Research Institute, Alexandria, Egypt; 4) Clinical and Experimental Internal Medicine Department, Medical Research Institute, Alexandria, Egypt; 5) Clinical Oncology and Nuclear Medicine Department, Faculty of Medicine, Alexandria University.

Objectives: The aim of the study was to delineate the gene expression profile of *LGR5* in rectal cancer (RC) tissues among young Egyptian patients. The study aimed at investigating the possible link between this CSCs related gene and clinical outcome, including response to neoadjuvant chemo-radiotherapy (CRT). Methods: The study was conducted on 30 young Egyptian RC patients, who were recommended to undergo neoadjuvant CRT. Paired tumor and non-tumor adjacent mucosal tissues were obtained from patients by routine biopsy techniques. Total RNA was extracted followed by reverse transcription, then quantitative PCR was performed using SYBR green. Expression levels of *LGR5* in tumor relative to adjacent non-tumor tissues were calculated using the comparative Cq method after normalization for the expression of *ACTB*. Patients were followed up for assessment of response to neoadjuvant CRT based on revised RECIST 1.1. Results: Overexpression of *LGR5* in human RC tissues compared to non- tumor tissues was detected.Furthermore, correlation analysis showed that higher expression of *LGR5* was correlated with more depth of tumor invasion, LN metastasis, advanced cTNM stage and mesorectal fascia involvement. On the other hand, it was not correlated with gender, age, tumor site nor pathological features. These results suggest that *LGR5* may not only play an important role in the progression of RC but also serve as a potential unfavorable prognostic biomarker for RC. In addition, high *LGR5* expression level was associated with poor response to CRT. ROC curve analysis showed that *LGR5* expression is an excellent predictor for response to neoadjuvant therapy. Conclusions: 1- High *LGR5* expression is, most likely, indicative of poor prognosis among young Egyptian RC patients. 2- *LGR5* expression level is proposed to be a novel predictive marker of resistance to neoadjuvant CRT in young Egyptian RC patients.

2727F

Latinas and breast cancer: Discovery of mutations in non-*BRCA1/2* **high and moderate penetrance breast cancer susceptibility genes.** *S.L. Neuhausen[1,4], J.N. Weitzel[1,4], A. Adamson[1], S. Tao[4], T.P. Slavin[1,4], C. Ricker[3], B. Nehoray[4], M. Rosenblatt[2], D. Senitzer[4], S. Sand[1,4], L. Steele[1], D. Hu[2,5], S. Huntsman[2,5], D. Castillo[1], E. Ziv[2,5].* 1) Beckman Research Institute of City of Hope, Duarte, CA; 2) UCSF Hellen Diller Comprehensive Cancer Center, San Francisco, CA; 3) USC Norris Comprehensive Cancer Center, Los Angeles, CA; 4) City of Hope Comprehensive Cancer Center, Duarte, CA; 5) UCSF Institute for Human Genetics, San Francisco, CA.

Latinos represent the largest and fastest-growing minority population in the US, yet they have been under-studied in terms of genetic susceptibility to breast cancer. Mutations in *BRCA1* and *BRCA2* (*BRCA*) explain approximately 25% of their familial breast cancer. The benefit of sequencing other breast cancer susceptibility genes in Latinas has not been defined. Seven hundred and seven *BRCA*-negative Latina women with breast cancer diagnosed under age 50 years, bilateral breast cancer, or diagnosed with both breast and ovarian cancers, and/or with at least two first- or second-degree relatives diagnosed with breast cancer under age 70 years were selected from the City of Hope Clinical Cancer Genomics Research Network and UCSF clinical cancer genetics program. Whole exome sequencing was performed on an Illumina 2500HT using customized Agilent Clinical Exome Capture libraries with a target of 70x coverage. Sequencing data were aligned to HG-19 and variants annotated with ANNOVAR. This report focuses on 13 known (*ATM, BARD1, BRIP1, CDH1, CHEK2, MRE11A, NBN, PALB2, PTEN, RAD51C, RAD51D, STK11, TP53*) and 9 (*BLM, FANCC, FANCM, NF1, RAD50, RECQL, RINT1, XRCC2*) suspected high- and moderate-penetrance breast cancer susceptibility genes. We identified pathogenic mutations in 45 women in 17 genes including *PALB2* (N=14); FANCM (N=6); *BARD1* (N=4), FANCC (N=3); *ATM, BLM, CHEK2, RAD50,* RECQL (N=2)*;* and *BRIP1, CDH1, MRE11A, NF1, PTEN, STK11, SLX4,* and *XRCC2* (N=1). Of the 30 pathogenic mutations identified, 5 were splicing, 15 were frameshift leading to truncation, and 10 were nonsense; 25 (83%) had not been reported previously in Clinvar. No likely pathogenic mutations were observed in *NBN, RAD51C, RAD51D, RINT1,* and *TP53*. Two recurrent mutations were identified, including a frameshift mutation in PALB2 (n=8; 1.1%) and a nonsense mutation in FANCM (n=4; 0.6%). In addition, of the non-synonymous variants in these genes, 63 were classified as damaging by a majority (5 of 8) of mutation classification algorithms, with 9 classified as damaging by all 8 callers. Overall, excluding non-synonymous mutations, 7.2% of Latinas carried a known or likely pathogenic mutation in 17 of the 22 genes. These mutation carriers may benefit from receiving this additional risk information to enhance decision making.

2728W

Whole-genome analysis of paediatric cancer from cases with a family cancer history: Early insights from Victoria, Australia. *T. Nguyen-Dumont[1], B. Feng[2], H. Tsimiklis[1], D. Amor[3], E. Algar[4], E. Milne[5], L.G. Spector[6], J. Ng[7], E. Smibert[8], A. Lonie[9], B.J. Pope[9,10], D.J. Park[1,9], G.S. Dite[11], M.C. Southey[1], J.A. Heath[1,12], J.L. Hopper[11].* 1) Genetic Epidemiology Laboratory, The University of Melbourne, Melbourne, Australia; 2) Department of Dermatology and Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, USA; 3) Murdoch Childrens Research Institute, Melbourne, Australia; 4) Monash Health and Hudson Institute, Clayton, Australia; 5) Telethon Kids Institute, University of Western Australia, Perth, Australia; 6) Department of Pediatrics, University of Minnesota, Minneapolis, Minnesota, USA; 7) The Royal Children's Hospital and The Royal Women's Hospital, Melbourne, Australia; 8) The Royal Children's Hospital, Melbourne, Australia; 9) Victorian Life Sciences Computation Initiative, The University of Melbourne, Melbourne, Australia; 10) Department of Computing and Information Systems, The University of Melbourne, Melbourne, Australia; 11) Centre for Epidemiology and Biostatistics, University of Melbourne, Melbourne, Australia; 12) Sidra Medical and Research Center, Doha, Qatar.

Approximately 1000 children and adolescents are diagnosed with cancer in Australia every year. However, less than 10% of all childhood tumours are associated with a known cancer predisposition syndrome. We hypothesized that whole genome analysis of DNA from affected children from families with multiple occurrences of early-onset cancers may be a valuable approach to identifying candidate genes or pathways that are associated with increased risk for childhood cancers. We performed whole genome sequencing (WGS) on 30 probands enrolled in the Victorian Paediatric Cancer Family Study (VPCFS), a population-based sample of 379 children diagnosed with cancer under the age of 15 years recruited from the two paediatric cancer hospitals for the state of Victoria, Australia. The probands for WGS were selected on the basis of sample availability and having one or more relative diagnosed with early onset cancer. Cancer in the selected probands included leukaemia (ALL and AML), Wilms tumours and brain tumours, and were diagnosed at a median age of 5 years (range, 1 to 14 years). Fifteen cancers were reported in first degree relatives and 166 cancers in second and third degree relatives. Of 181 cancers observed in the families, 17, 37 and 59 were diagnosed before the age of 30, 40 and 50 years, respectively. WGS was performed on the HiSeq XTen using blood-derived DNA. The analysis pipeline was based on the GATK best practices v3.3. We applied the PERCH (Polymorphism Evaluation, Ranking and Classification for a Heritable trait) framework for prioritisation of findings from WGS. Preliminary analysis of selected candidate genes, including *TP53, BRCA1, BRCA2, APC, DNMT3A, CTR9, NSD1, PMS2, NF1, RB1* and *RUNX1*, did not reveal any potentially pathogenic variant as defined by ClinVar. Comprehensive data analysis, including copy number variation and large rearrangements, is in progress. Germline DNA was extracted from all remaining VPCFS participants who provided a blood sample (n=745) for further screening by targeted-sequencing of genes of interest, identified from the WGS analysis and from the literature. Fresh frozen and paraffin embedded pathology material for all the cancers (where a biopsy or surgical resection was undertaken) are available for follow-up analyses. We anticipate that this dataset will reveal important insights into cancer aetiology and lead to improved cancer prevention, effective cancer screening and optimal clinical care.

Genetic and epigenetic changes in breast cancer tumors with BRCAness profile. *D. Plaseska-Karanfilska[1], M. Jakimovska[1], I. Maleva Kostovska[1], K. Popovska-Jankovic[1], K. Kubelka-Sabit[2], M. Karagjozov[2], L. Stojanovska[3], A. Arsovski[3].* 1) Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, R. Macedonia; 2) Acibadem-Sistina Hospital, Skopje, R. Macedonia; 3) Re-Medika General Hospital, Skopje, R. Macedonia.

BRCAness refers to shared tumor characteristics between sporadic and BRCA-mutated cancers. Different genetic and epigenetic mechanisms might be responsible for the development of *BRCA*ness phenotype. Recently, it was proposed that BRCAness is associated with the presence of homologous recombination repair defect in the tumor in the absence of germline *BRCA1* or *BRCA2* mutations. In a subset of BRCAness *BRCA1* promoter hypermethylation is present, but the molecular causes in the remaining tumors are unknown. We aimed to investigate the relevance of copy number alterations (CNAs) and promoter methylation (PM) in BRCAness breast cancers. We studied a total of 251 fresh frozen breast tumor tissues. The samples were assessed for BRCAness, CNAs and PM by Multiplex Ligation-dependent Probe Amplification (MLPA). Twenty six BC tissues (10,4%) showed BRCAness profile. Triple negative tumors represented 41,7% of BRCAness group and 2,8% of non-BRCAness group (p=1x10^{-6}). *BRCA1/2* germline mutations were present in 23,1% (3/13) of the BRCAness tumors. *BRCA1* promoter methylation was observed in 7.69% (2/26) of *BRCA*ness tissues. *TIMP3* gene promoter was methylated in 23% of *BRCA*ness tumors and 1.8% in non-BRCAness tumors (p=1,2x10^{-4}). Statistically significant positive associations were observed between BRCAness profile and duplications and/or amplifications of *CCNE1, EMSY, MTDH* and *EGFR* and deletion of *ADAM9* gene. Amplification of *FGFR1* gene was negatively associated with BRCAness profile. Our study showed that *BRCA1/2* mutations and *BRCA1* hypermethylation explain around 30% of breast cancers with BRCAness profile. It also suggests that CNAs and PM of other cancer genes might be involved in the development of BRCAness profile.

Association of *1494del6* **polymorphism of the thymidylate synthase gene with non-response to chemotherapy in breast cancer patients from Mexican population.** *A.M. Puebla-Pérez[1], G.M. Zúñiga[2], L.E. Figuera[3], M.P. Gallegos-Arreola[4].* 1) Departamento de Farmacología, Laboratorio de Inmunofarmacología, Universidad de Guadalajara; 2) Laboratorio de Mutagénesis, Centro de Investigación Biomédica de Occidente (CIBO), Instituto Mexicano del Seguro Social (IMSS); 3) División de Genética, CIBO, IMSS; 4) Laboratorio de Genética Molecular, División de Genética, CIBO, IMSS. Guadalajara, Jalisco, México.

The polymorphism *1494del6* of Thymidylate Synthase gene (*TYMS*) has been associated with susceptibility to breast cancer in different populations despite to decreased levels of mRNA. Also plays an important role in the conversion of dUMP to dTMP, which in turn may result in differences in the outcome of breast cancer chemotherapy. This study determined the association of *1494del6* polymorphism of the *TYMS* gene with non-response to chemotherapy in breast cancer patients from Mexican population. DNA of 518 patients with breast cancer with FEC chemotherapy treatment (5-fluorouracil- epirubicin-cyclophosphamide) was extracted. The *1494del6* polymorphism (6 bp insertion/deletion) in the TS 3′-untranslated region (3′-UTR) was determined by polymerase chain reaction (PCR) and the 152bp fragments of PCR were digested with DraI restriction enzyme, the products were separated on an 8% polyacrylamide gel. Patients were sub-grouped by chemotherapy status: response (RC), non-response (NRC), non-response by recurrence (NRRC) and partial response (PRC). Results: genotype *Del/Del* of *1494del6* polymorphism was associated with NRC [odds ratio OR 2.54 Confidence intervals CI95% 1.26-5.12), p=0.0089]; NRRC [OR 2.19 (CI95% 1.09-4.66), p=0.0214)] and PRC [OR 3.59 (IC95% 1.52-8.47), p=0.0035)] to respect at RC. Conclusion: Our results indicate that the *1494del6* polymorphism of *TYMS* was associated with non-response chemotherapy in breast cancer patients from Mexican population.

Exome sequencing and methylation analysis in monozygotic twins discordant for acute lymphocytic leukemia. *A. Russo[1,2], E. Casalone[1,2], S. Guarrera[1,2], K. Mareschi[3,4], F. Fagioli[3], G. Matullo[1,2].* 1) Human Genetics Foundation, Turin, Italy; 2) Department of Medical Sciences, University of Turin, Italy; 3) Stem Cell Transplantation and Cellular Therapy Laboratory, Paediatric Onco-Haematology, City of Science and Health of Turin, Italy; 4) Department of Public Health and Paediatrics, University of Turin, Italy.

Acute Lymphocytic Leukemia (ALL) is the most common type of cancer diagnosed in children. Although the 11q23 rearrangement is the most common cytogenetic abnormality in infant ALL, studies demonstrate that this rearrangement is not sufficient for leukemogenesis. In order to characterize somatic mutational and epigenetic profiles of one patient with infant ALL at diagnosis, blood DNA was collected from the affected child at diagnosis and remission, from her healthy monozygotic twin sister, and from their healthy parents. Five DNA samples underwent DNA methylation analysis on the Illumina HumanMethylation450 BeadChip. Data were analyzed according to standard procedures (MethyLumi, Bioconductor). Whole exome sequencing was also performed using Agilent's SureSelectQXT kit and the Illumina NextSeq500 platform. Reads were aligned to the human reference genome h19 and the Genome Analysis Toolkit was used for variant calling. SnpEff and Variant Effect predictor were used to annotate and prioritize variants. We searched for stretches of contiguous CpGs (A-Clustering method). We identified about 80 differentially methylated regions (DMRs) with methylation "deltas" between the co-twins ranging from 20% and 80% at an individual CpG level. The affected child showed consistent hypermethylation as compared to the sister: out of the ~80 DMRs, only a 3 CpGs region on chromosome 15 was less methylated in the proband. Interestingly, when comparing the affected child with herself at remission, the previously observed hypermethylation (methylation levels at diagnosis) was reverted to the levels observed for the healthy sister, for all the loci. Preliminary analysis of exome sequencing data showed 12 *de novo* single nucleotide variants (SNVs) with a population frequency less than 1%, in heterozygous state in the diseased child that were absent in both parents and healthy sister. Two out of 12 SNVs were missense variants annotated by the SIFT and PolyPhen predictors as "deleterious/damaging". The two SNVs were respectively located in the *PADI4* gene, which encodes for a protein involved in a process that may be important for tumorigenesis, and in *BNIP3L,* a gene that was found to be differentially expressed between sensitive and resistant blasts in acute myeloid leukemia. These preliminary results provide insight into new somatic mutations that together with DMRs may be potentially involved in ALL onset.

2732T

Breast cancer risk factors: Focusing on men. *R. Scarpitta[1], L. Maresca[1], L. Spugnesi[1], I. Zanna[2], D. Palli[2], M.A. Caligo[1].* 1) Section on Medical Genetics, University of Pisa, Pisa, Pisa, Italy; 2) Molecular and Nutritional Epidemiology Unit Cancer Prevention and Research Institute (ISPO), Florence, Italy.

Breast cancer (BC) is a complex multi-factorial disease. Recent molecular insights have evidenced the strong complexity of breast cancer genetics. Currently known susceptibility alleles have different frequencies and confer different disease-associated risk. The strongest risk factor is represented by inherited high-penetrance mutations involving BRCA1/2 genes, which can explain only up to 15% of all cases. Moderate- and low-penetrance polymorphic variants should importantly contribute to BC risk, probably interacting with environmental and life style factors, particularly occupational and dietary carcinogen exposures. The main goal of this project is to contribute to clarify the etiology of breast cancer by investigating how occupational and dietary carcinogen exposures might modify the penetrance of rare alleles in DNA repair genes.Our hypothesis is that the combined effects of various factors can be better investigated in male breast cancer (MBC), which represents a clean model of BC since they lack in reproductive-history related variables.Fifty MBC cases were recruited and information on their cancer family history, lifestyle habits, and working history were collected using standardized questionnaires (EPIC). DNA samples were subjected to Next Generation Sequencing for a panel of 24 genes involved in DNA repair and breast cancer predisposition.Our preliminary results show that MBCs are mostly accounted for high-penetrance mutations in BRCA genes. A rare synonymous and three predicted pathogenic missense variants were detected in BRCA1. BRCA2 is the most frequently mutated gene: 9 variants were detected (4 SNVs, 2 frameshift deletion, 2 splicing variants, 1 stop-gain). A novel frameshift mutation, one pathogenic missense mutation and two predicted pathogenic missense variants were found in BRIP1. PALB2 was found mutated only in a case (1 SNV). These variants could act as moderate penetrance alleles influencing the interaction between BRIP1 and PALB2 and their functional partner, BRCA1 and BRCA2, respectively. In low- penetrance genes, 11 additional VUS (variant of unknown significance) have been identified in 8 genes: *CDH1* (1 SNV), *CHEK2* (1 SNV), *ERCC1* (1 SNV), *MLH1* (2 SNVs), *MSH2* (1 SNV), *MUTYH* (1 SNV), *NBN* (2 SNVs), *PMS2* (2 SNVs).Although these data must be confirmed statistically, and correlated to the environmental variable, those results may help to further improve our knowledge and provide new insights into the characterization of BC.

2733F

A family-based, genome-wide association study of young-onset breast cancer: Inherited variants and maternally mediated effects. *M. Shi[1], K. O'brien[1], D. Sandler[2], J. Taylor[2], D. Zaykin[1], J. Keller[3], A. Wise[1], C. Weinberg[1].* 1) Biostatistics Br, NIEHS, Res Triangle Park, NC; 2) Epidemiology Br, NIEHS, Res Triangle Park, NC; 3) Westat Inc., Durham, NC, USA.

Young-onset breast cancer shows certain phenotypic and etiologic differences from older-onset breast cancer and may be influenced by some distinct genetic variants. Few genetic studies of breast cancer have targeted young women and no studies have examined whether maternal variants influence disease in their adult daughters through prenatal effects. We conducted a family-based, genome-wide association study of young-onset breast cancer (age at diagnosis <50 years). A total of 602 188 single-nucleotide polymorphisms (SNPs) were genotyped for 1279 non-Hispanic white cases and their parents or sisters. We used likelihood-based log-linear models to test for transmission asymmetry within families and for maternally mediated genetic effects. Three autosomal SNPs (rs28373882, P=2.8 × 10[-7]; rs879162, P=9.2 × 10[-7]; rs12606061, P=9.1 × 10[-7]) were associated with risk of young-onset breast cancer at a false-discovery rate below 0.20. None of these loci has been previously linked with young-onset or overall breast cancer risk, and their functional roles are unknown. There was no evidence of maternally mediated, X-linked, or mitochondrial genetic effects, and no notable findings within cancer subcategories defined by menopausal status, estrogen receptor status, or by tumor invasiveness. Further investigations are needed to explore other potential genetic, epigenetic, or epistatic mechanisms and to confirm the association between these three novel loci and youngonset breast cancer.

2734W

Genetic progression of high grade prostatic intraepithelial neoplasia to prostate cancer. *S. Shin[1,2], S.H. Jung[1,2], H.C. Park[1,2], H. Cho[1,2], S.H. Lee[3], Y.J. Chung[1,2].* 1) Microbiology, The Catholic University of Korea, Seoul, South Korea; 2) Integrated Research Center for Genome Polymorphism, The Catholic University of Korea, Seoul, South Korea; 3) Pathology, The Catholic University of Korea, Seoul, South Korea.

Although high grade prostatic intraepithelial neoplasia (HGPIN) is considered a neoplastic lesion that precedes prostate cancer (PCA), the genomic structures of HGPIN remain unknown. To identify the genomic landscape of HGPIN and the mechanisms for its progression to PCA, we analyzed 20 regions of paired HGPIN and PCA from six patients using whole-exome sequencing and array-comparative genomic hybridization to compare somatic mutation and copy number alteration (CNA) profiles of paired HGPIN and PCA. The number of total mutations and CNAs of HGPINs were significantly fewer than those of PCAs. Mutations in FOXA1 and CNAs (1q and 8q gains) were detected in both HGPIN and PCA ('common'), suggesting their roles in early PCA development. Mutations in SPOP, KDM6A, and KMT2D were 'PCA-specific', suggesting their roles in HGPIN progression to PCA. The 8p loss was either 'common' or 'PCA-specific'. In-silico estimation of evolutionary ages predicted that HGPIN genomes were much younger than PCA genomes. Our data show that PCAs are direct descendants of HGPINs in most cases that require more genomic alterations to progress to PCA. The nature of heterogeneous HGPIN population that might attenuate genomic signals should further be studied. HGPIN genomes harbor relatively fewer mutations and CNAs than PCA but require additional hits for the progression. Our results provide a clue to explain the long latency from HGPIN to PCA and provide useful information for the genetic diagnosis of HGPIN and PCA.

Male breast cancer (MBC) is a rare disease, whose etiology appears to be largely associated with genetic factors. Inherited high- and moderate- penetrance mutations in known predisposing genes, including *BRCA1*, *BRCA2* and *PALB2*, accounts for only 10-15% of all cases. Thus, a fraction of MBCs is expected to be caused by genetic risk factors yet to be identified. Recently, a case-control study showed that the *FANCM* c.5791C>T nonsense mutation (rs144567652) was associated with familial breast cancer (BC) risk, supporting the hypothesis that *FANCM* could be a novel moderate risk factor for the disease (Peterlongo P. *et al.*, *Hum Mol Genet.* 2015;24(18):5345-55). Interestingly, among the mutation positive families, one presented both female and male BC cases, suggesting that the c.5791C>T might be associated with MBC risk. Aimed at testing whether this mutation may explain a fraction of MBCs, we performed a case-control study including 489 *BRCA1/2* mutation negative MBCs, of which 33% had a first-degree family history of breast/ovarian cancer, and 800 controls from the ongoing Italian Multicenter Study on MBC. Genotyping of *FANCM* c.5791C>T mutation in peripheral-blood DNA samples was carried out using a custom TaqMan SNP genotyping assay. The *FANCM* c.5791C>T mutation was found in 1out of 800 controls (0.13%), a man aged 75 and with no personal history of cancer, and in none of the 489 MBC cases. Overall, our results, based on a country-based series, suggest that *FANCM* c.5791C>T mutation have not a major role in MBC predisposition in cases unselected for family history. Although based on the largest series of *BRCA1/2* mutation negative MBC reported to date, this study may be statistically underpowered to detect association between a rare mutation and risk of disease in MBC. Additional studies based on large MBC series from other countries, possibly enriched for familial cases, could clarify further the role of *FANCM* c.5791C>T mutation in MBC predisposition.   Study supported by *Italian Association for Cancer Research* (AIRC IG16933) to L.O.

Exome sequencing of oral squamous cell carcinoma reveals molecular subgroups and novel therapeutic strategies. *S. Su[1], W. Fan[1], W. Chung[1], S. Yang[2].* 1) Chang Gung Memorial Hospital, Keelung, Taiwan; 2) Chung Shan Medical University, Taichung, Taiwan.

Oral squamous cell carcinoma (OSCC), an epithelial malignancy affecting a variety of subsites in oral cavity, is prevalent in Southeast Asia. The survival rate of OSCC patients has not improved over the past decades due to its heterogeneous etiology, genetic aberrations, and treatment outcomes. Improvement in therapeutic strategies and tailored treatment options is an unmet need. To unveil the mutational spectrum, whole-exome sequencing of 120 OSCC from male individuals in Taiwan was conducted. Analyzing the contributions of the five mutational signatures extracted from the dataset of somatic variations identified four groups of tumors that are significantly associated with demographic and clinical parameters. In addition, known (*TP53, FAT1, EPHA2, CDKN2A, NOTCH1, CASP8, HRAS, RASA1,* and *PIK3CA*) and novel (*CHUK* and *ELAVL1*) genes that are significantly and frequently mutated in OSCC were discovered. Further analyses of mutation status with cancer progression revealed that *PIK3CA* mutations tend to appear at tumors with large size. Through defining the catalog of targetable genomic alterations (somatic mutations and copy number variations), 58% of the tumors were found to carry at least one aberrant event potentially aimed by US Food and Drug Administration (FDA)–approved agents. Strikingly, while targeting the P53-cell cycle pathway (*TP53* and *CCND1*) by the drugs studied in phase I-III clinical trials, those possibly actionable tumors are predominantly located at the tongue, suggesting that tumors at the specific anatomical site are likely more sensitive to current targeted therapies. Our work revealed molecular OSCC subgroups that reflect etiological and prognostic correlation as well as defined the extensive landscape of major altered events in the coding regions of OSCC genome. These findings provide insights into design of clinical trials for targeted therapies and genomically driven stratification of OSCC patients with differential therapeutic efficacy. .

2737W

Genomic analysis of breast cancer genes in the Women's Health Initiative: Creation of a public genomics resource. *T. Walsh[1], S. Gulsuner[1], M. Lee[1], S. Casadei[1], G. Anderson[2], J. Van den Akker[3], D. DeSloover[3], R. O'Connor[3], T. Sittler[3], E. Gil[3], M-C. King[3].* 1) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 2) Fred Hutchinson Cancer Research Center, Seattle, WA; 3) Color Genomics, Burlingame, CA, 94010.

BRCA1, BRCA2, and multiple other genes are known to harbor mutations that significantly increase risk of breast cancer, with risks and allele frequencies that vary by gene and by mutation. A powerful way to distinguish pathogenic from benign variants in these genes is to characterize variant frequencies among appropriate controls; that is, among older women who have not developed breast cancer, then to compare variant frequencies between controls and breast cancer cases. Although public databases include exome sequences of many thousands of individuals, very few of those sequences are from older women known to be free of breast and ovarian cancer. We have sequenced germline DNA from 7000 European American (EA) and 3000 African American (AA) women who were participants in the Women's Health Initiative (WHI) and were at least 70 years old and had not had cancer as of last follow-up contact. Twenty-eight known and candidate breast and/or ovarian cancer genes were sequenced to high depth of coverage (>200x) and SNVs, indels, copy number variants, and complex rearrangements identified. Analysis of the first 4300 individuals reveals premature truncations, canonical splice site mutations, and experimentally validated loss-of-function missenses at a combined carrier frequency <0.001 for each of BRCA1 (one individual with M1775R), CHEK1, CTNNA1, GEN1, MRE11A, PALB2, RAD51B, RAD51C, RAD51D, RINT1, TP53 (one individual with R175C) and XRCC2; between 0.001 and 0.005 for each of ATM, ATR, BARD1, BRCA2, BRIP1, FAM175A, NBN, and SLX4; and >0.005 for each of CHEK2, FANCM, and RECQL. Thus far, unambiguously pathogenic mutations have not been identified in BAP1, CDH1, PTEN, or STK11. Our goal is to create a public resource of frequencies of all variants, pathogenic or benign, for both EA and AA populations, from these 10,000 cancer-free WHI participants. Investigators can then compare allele frequencies among these controls to frequencies among breast cancer patients in any EA or AA case series. The resource is also intended to provide investigators, health care providers, and consumers with background frequencies, among older cancer-free women, of variants detected in these genes by genetic testing from any source.

2738T

Synthetic lethality between *ATRX* mutations and *MYCN* amplification in neuroblastoma. *M. Zeineldin[1], J. Jeon[1], L. Griffith[1,2], S.M. Federico[1], X. Chen[1], J. Easton[1], J. Wu[1], S. Mao[1], Y. Liu[1], A. Naranjo[3], A. Pappo[1], M.D. Hogarty[4], M.A. Dyer[1,2].* 1) St. Jude Children's Research Hospital, Memphis, TN; 2) Howard Hughes Medical Insitute; 3) University of Florida, Gainesville, FL; 4) Children's Hospital of Philadelphia, Philadelphia, PA.

Neuroblastoma (NB) is a devastating pediatric tumor that is responsible for 15% of cancer related death in children. The chromatin remodeler ATRX is frequently mutated in NB and in a range of other pediatric and adult tumors. The tumorigenecity of *ATRX* mutations are not completely understood. Interestingly, *ATRX* mutations seem to be mutually exclusive with *MYCN* amplification; the later is also recurrently detected in NB. However, most of genetic studies of NB were conducted using a, relatively, small number of tumors. To study the genetic basis of NB and the mutual exclusivity between *ATRX* mutations and *MYCN* amplification, we did whole exome sequencing for 475 tumors and the matching normal tissues available from 353 patients from different age and clinical stage groups. In addition, intragenic *ATRX* deletions were examined by deep sequencing using custom-designed probe capture. We found *MYCN* amplification in 28 (5.9%) tumors and *ATRX* mutations in 19 (4%) other tumors, with no single tumor with both *MYCN* amplification and *ATRX* mutations. We also tested the mutual exclusivity between *ATRX* mutations and *MYCN* amplification in cultured cell lines. We found that induction of *MYCN* overexpression results in cell death and cell cycle changes in cell lines with *ATRX* mutations. We also detected reduced colony formation in two NB cell lines with *MYCN* amplification when ATRX was down-regulated using *ATRX*-specific *shRNA*. In addition, we tried to knock out *ATRX* in NB cell lines with MYCN amplification using CRISPR-Cas9 technology. In one of these cell line, IMR-32, no single clone with *ATRX* deletion was detected out of 142 clones screened. In another cell line, SK-N-BE(2), only one clone with *ATRX* mutation was detected out of 42 clones generated. Notably, in SK-N-BE(2) cells with CRISPR-induced *ATRX* mutations, the MYCN protein level was significantly reduced and the cells stopped growing and differentiated. We also mapped the epigenetic landscape of 8 different cell lines with and without *ATRX* mutations, 10 xenograft NB tumors orthotopically maintained in immune-compromised mice and a primary tumor with mutated *ATRX* using ChIP-Seq and bisulfite sequencing. Collectively, these data confirm synthetic lethality between *ATRX* mutations and *MYCN* amplification in NB cells and shed light on the molecular pathogenesis of *ATRX* mutations in NB. .

Absence of selection for somatic mutations in mitochondrial DNA of diffuse large B-cell lymphomas. *A.G.X. Zeng[1], A.C.Y Leung[2], A.R Brooks-Wilson[1,3].* 1) Canada's Michael Smith Genome Sciences Centre, BC Cancer Agency, Vancouver, British Columbia, Canada; 2) Department of Statistics, University of British Columbia, Vancouver, British Columbia, Canada; 3) Department of Biomedical Physiology and Kinesiology, Simon Fraser University, Burnaby, British Columbia, Canada.

Diffuse Large B-Cell Lymphoma (DLBCL) is an aggressive and heterogeneous cancer. A subset of DLBCLs shows a gene expression pattern consistent with enhanced oxidative phosphorylation (oxphos) activity, suggesting that mitochondrial metabolism may play a role in this cancer. Mitochondrial DNA encodes subunits of oxphos complexes. Mitochondria have been linked to carcinogenesis primarily through aberrant production of reactive oxygen species (ROS). We characterized the mitochondrial genomes of 39 DLBCL cases using whole-genome data from the Cancer Genome Characterization Initiative, accessed through dbGaP. We analyzed germline variants not accounted for by haplogroup status (private variants) and somatic mutations present in tumor but not in peripheral blood DNA. Prevalence of heteroplasmies was assessed by comparing the heteroplasmic fractions (HF) of private variants (n = 137) and somatic mutations (n = 63) with a two sample t-test. Private variants were predominantly homoplasmic with some low-level heteroplasmies; somatic mutations were almost exclusively heteroplasmic (p < 0.001). While the frequency of G:C > T:A substitutions – the main consequence of ROS-mediated DNA damage – is higher in somatic mutations than private germline variants, they constituted only 8% of somatic mutations, suggesting that ROS plays a limited role in mtDNA mutagenesis in DLBCL. The mutational load of each functional region within the mitochondrial genome was compared using a chi-square test of homogeneity: private germline variants were more common within the D-Loop than expected by chance (p = 0.01), while the distribution of somatic mutations across the mitochondrial genome did not differ from that expected by chance. The HF of each heteroplasmy in the peripheral blood DNA was compared to the HF of its corresponding position in the tumor using paired t-tests. Heteroplasmic variants with a HF above 5% (n = 27) in peripheral blood showed a lower HF in the corresponding tumor (p < 0.001) and display a general trend towards fixation of the major allele regardless of whether it was a reference or variant allele, showing that changes in heteroplasmy during tumorigenesis appear random. In contrast with some studies on other cancers, we do not see evidence for positive selection for somatic mutations in DLBCL. Together, our observations suggest that somatic mutations in mitochondrial DNA are passengers rather than drivers, and that oxphos function is maintained in DLBCL.

Genetic characterization and prognostic implications of Korean patients with Lynch syndrome. *K. Park[1], J. Park[2], D. Chang[3], H. Kim[4], J. Kim[5].* 1) Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 2) Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea; 3) Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; 4) Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; 5) Department of Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea.

　　Background: Lynch syndrome (LS) is caused by a genetic mutation that disrupts the mismatch repair (MMR) pathways. The overall survival in patients with LS seems to be different according to the mutation type in MMR genes. Currently, it is unclear whether the mutation type influences the tumor-free interval (TFI) in LS. The aims of this study were to investigate the mutation features and epidemiologic trends of LS in Korean and to evaluate the prognostic impacts of different mutation types. **Methods:** In total, 286 unrelated patients with cancers were enrolled from 341 consecutive individuals underwent a genetic workup (*MLH1, MSH2,* and *MSH6*) in the Cancer Genetics Clinic of the Samsung Medical Center in Korea from 2004 to 2015. Histopathologic findings and microsatellite instability data as well as clinical information such as tumor spectrum, family history and survival time were collected. Epidemiologic time trends of LS in Korea were evaluated. **Results:** A total of 118 patients were found to have mutations (41%). We identified 76 different mutations (47 in *MLH1*, 24 in *MSH2*, and 5 in *MSH6*) including 20 novel mutations and one founder mutation (c.1024delinsAA in *MSH2*). Truncation mutations such as frameshift and nonsense mutations were associated with shorter TFI compared to other mutation types (median of 3,129 days vs. 5,877 days, HR = 2.313, 95% CI = 1.101-4.858, *P* = 0.0396). There have been the epidemiologic changes in Korean LS patients between the period of 1995-2004 and that of 2004-2005; advanced age at diagnosis (*P* < 0.0001), presence of history of multiple tumor manifestations (*P* = 0.0019), increased mutation detection rate (*P* = 0.0022), and increased nonsense mutations and splicing mutations (*P* < 0.0001) **Conclusion:** This study shed light on the genetic features of Asian patients with LS as well as prognostic implications of different mutation types. This study will provide good guidance for genetic counseling and stratification of the surveillance program depending on mutation types.

Evaluation of copy number variants as modifiers of breast and ovarian cancer risk for *BRCA1* pathogenic variant carriers. *L.C. Walker[1], L. Marquart[2], J.F. Pearson[1], G.A.R. Wiggins[1], T.A. O'Mara[2], G. Chenevix-Trench[2], A.C. Antoniou[3], F.J. Couch[4], A.B. Spurdle[2], Consortium of Investigators of Modifiers of BRCA1/2 (CIMBA).* 1) University of Otago, Christchurch, New Zealand; 2) QIMR Berghofer Medical Research Institute, Queensland, Australia; 3) University of Cambridge, Strangeways Research Laboratory, Cambridge, UK; 4) Mayo Clinic, Rochester, Minnesota, USA.

　　Genome-wide studies of patients carrying pathogenic variants (mutations) in *BRCA1* or *BRCA2* have reported strong associations between single nucleotide polymorphisms (SNPs) and cancer risk. To conduct the first genome-wide association analysis of copy number variants (CNVs) with breast or ovarian cancer risk in a cohort of 2500 *BRCA1* pathogenic variant carriers, CNV discovery was performed using multiple calling algorithms and Illumina 610k SNP array data from a previously published genome-wide association study. Our analysis, which focused on functionally disruptive genomic deletions overlapping gene regions, identified a number of loci associated with risk of breast or ovarian cancer for *BRCA1* pathogenic variant carriers. Despite only including putative deletions called by at least two or more algorithms, detection of selected CNVs by ancillary molecular technologies only confirmed 40% of predicted common (>1% allele frequency) variants. These include four loci that were associated (P<0.05) with breast cancer (*GTF2H2, ZNF385B, NAALADL2, PSG5*), and two loci associated with ovarian cancer (*CYP2A7, OR2A1*). The most significant finding was an association of a validated CNV deletion at the *CYP2A7* locus (19q13.2) with decreased ovarian cancer risk (Relative Risk=0.50, P=0.007). Genomic analysis found this deletion coincides with a region displaying strong regulatory potential in ovarian tissue, but not in breast epithelial cells. This study provides evidence that CNVs can modify risk of breast or ovarian cancer in *BRCA1* pathogenic variant carriers.

Increased number in rare of germline variants in melanoma suscepti-bility genes in Spanish Giant Congential Melanocytic nevi patients. *C. Badenas[1], G. Tell[2], V.P. Martins da Silva[2], K. Jagirdar[3], M. Potrony[2], D.L. Duffy[4], H.P. Soyer[1,5], S. Puig[2], R.A. Sturm[3], A. Vicente[6], M.A. Gonzalez-Ensenyat[6], J. Malvehy[2], J.A. Puig-Butille[1].* 1) Molecular Genetics Service. Melanoma Units. CIBERER, Hospital Clinic de Barcelona, Barcelona, Spain; 2) Dermatology Service. Melanoma Units. CIBERER. Hospital Clinic de Barcelona, Barcelona, Spain; 3) Dermatology Research Centre, School of Medicine, The University of Queensland, Translational Research Institute, Brisbane, QLD, Australia; 4) QIMR-Berghofer Medical Research Institute, Brisbane, QLD, Australia; 5) Department of Dermatology, Princess Alexandra Hospital, Brisbane, QLD, Australia; 6) Clinic of Dermatology, Hospital Universitari Sant Joan de Déu, Barcelona, Spain.

   Introduction: Giant congenital melanocytic nevi (GCMN) are rare melano-cytic benign tumors associated with presence of neurocutaneous melanosis and higher risk of melanoma and other malignancies. The genetic cause of GCMN is likely to be the acquisition of postzygotic alterations. However, there are evidences of predisposition for the GCMN development. We hypothesized that germline variants in melanoma susceptibility genes (*MC1R, ATM* and *MITF*) have a role on this predisposition. **Materials and Methods**: Analysis of *MC1R* gene was performed in 21 patients by Sanger sequencing. Evaluation of ATM variants and p.E318-MITF variant was performed in 16 patients by CoreExome genotype platform (Illumina). *ATM* variants were evaluated by its ExAC Browser European frequency (EB-E freq) and its functional effect (Polyphen and Shift information) **Results**: *MC1R* variants were detected in 57.1% (12/21) GCMN patients. Statistically significant differences between patients and control population (N=296) in terms of number of alleles or type (Red hair vs non-Red hair alleles) were not detected. However, we observed a higher prevalence of patients harboring at least one *MC1R* variant (19%) compare to control population (9.8%). Moreover, 18.7% (3/16) GCMN patients carry rare *ATM* coding variants such as p.L1420F (EB-E freq= 0.019; benign/tolerated), p.V410A (EB-E freq= 0.003; benign/deleterious) and p.S333F (EB-E freq= 0.001; possibly damaging/deleterious). In contrast, the p.E318K-MITF was not detected in the set of GCMN patients. **Conclusions: t**he study suggests that GCMN patients have a higher incidence of *MC1R* variants and rare *ATM* variants. Study of a large number of patients is necessary to confirm such findings.

The role of CI-994, a histone deacetylase inhibitor, on the differentiation of acute myelogenous leukemia cell lines. *N. Bhambra[1,2], M.A. Blanco[2].* 1) Department of Molecular Genetics, University of Toronto, Toronto, Canada; 2) Department of Newborn Medicine, Boston Children's Hospital, Boston, MA.

   Histone deacetylase (HDAC) inhibitors cause chromatin remodeling and inhibit the expression of otherwise highly expressed genes. HDAC inhibitors hold great promise as a cancer treatment due to their proven ability to induce differentiation in proliferative and cancerous cell lines. The induction of cellular differentiation in cancerous cells is of interest, because it reduces the ability of these cells to proliferate, and thus limits tumor growth. HDAC inhibitors and other drugs shown to induce cellular differentiation hold great promise as cancer therapies, as they cause significantly less cell death and are less toxic to patients than conventional chemotherapies. One such HDAC inhibitor is CI-994. Using flow cytometry and cell viability counts, our research shows that after treatment of human and mouse acute myelogenous leukemia (AML) cell lines with CI-994, cell populations show increased levels of cellular differen-tiation and a minimal reduction in cell viability. Some cell lines show a good balance between differentiation and cell viability. Although our results are not uniformly successful across all cell lines tested, our findings are promising. Our findings indicate that further research needs to be done on the exact mechanism of CI-994 in cellular differentiation. Future experiments will exam-ine the role of CI-994 on the remodeling of chromatin in these and other cell lines, and examine specifically the genes it may be suppressing.

Novel rare variants underpin prostate cancer susceptibility genome wide. *N. Emami[1], T. Hoffmann[2,3], J. Mefford[4], K. Lindquist[6], C. Cario[1], C. Tai[2], E. Wan[3], S. Wong[3], J. Gollub[6], A. Finn[6], D. Aaronson[7], J. Presti[7], L. Habel[8], J. Shan[8], D. Ranatunga[8], C. Chao[9], N. Ghai[9], E. Jorgenson[8], L. Sakoda[8], M. Kvale[3], P. Kwok[3], C. Schaefer[8], N. Risch[1,2,3,4,8], S. Van Den Eeden[5,8], J. Witte[1,2,3,4,5].* 1) Program in Biological and Medical Informatics, UCSF, San Francisco, CA; 2) Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; 3) Institute for Human Genetics, UCSF, San Francisco, CA; 4) Program in Pharmaceutical Sciences and Pharmacogenomics, UCSF, San Francisco, CA; 5) Department of Urology, UCSF, San Francisco, CA; 6) Affymetrix, Inc., Santa Clara, CA; 7) Department of Urology, Kaiser Oakland Medical Center, Oakland, CA; 8) Division of Research, Kaiser Permanente Northern Califoria, Oakland, CA; 9) Department of Research and Evaluation, Kaiser Permanente Southern California, Pasadena CA.

The impact of rare genetic variants on common disease susceptibility remains an area of wide interest and controversy. Although it has been hypothesized that rare variants with high effect sizes may contribute substantially to the missing heritability of complex human traits, the difficulty of tagging and confidently imputing rare variants has hindered the investigation of this hypothesis in genome wide association studies (GWAS). Furthermore, while next generation sequencing technologies have enabled us to bypass the challenge of rare variant imputation, the financial cost of sequencing seriously limits our ability to broadly pursue the discovery of trait-associated rare variants, which require many thousands of subjects to be sequenced in order to be detected at a genome-wide significance level. Previously we described the design of a custom Affymetrix Axiom microarray for directly assaying putatively functional rare variants and fine mapping loci previously associated with prostate cancer (PrCa), a highly heritable, common disease with appreciable missing heritability. Using our custom array, 416,047 markers were genotyped in a population of 8,480 prostate cancer cases and 8,128 controls nested within the Kaiser Permanente Research Program on Genes, Environment, and Health (RPGEH), ProHealth and California Men's Health Study. This approach revealed dozens of novel PrCa susceptibility variants, exonic, intronic, and intergenic, in the rare (MAF less than 1%) and intermediate (MAF greater than 1% and less than 5%) minor allele frequency ranges. Many of these variants have been uncovered at loci not previously associated with PrCa risk, including 3p14, 5q14, and 14q21. Furthermore, novel rare susceptibility variants were also discovered at previously reported PrCa loci, including 11q23 and 19q13, where the prostate-specific antigen gene KLK3 is located. Conditional analyses simultaneously modeling both novel rare variants and previously published GWAS variants suggest the presence of multiple independent signals of PrCa risk. While further study may clarify the extent to which rare variants drive heritability and synthetic associations at PrCa susceptibility loci genome-wide, our results represent preliminary evidence that rare variants may explain a significant fraction of the missing heritability for PrCa risk.

2745F

Whole exome sequencing in multigenerational mixed cancer families identifies a putative risk variant in the *PDIA2* gene. *R.M. Jones[1], P.E. Melton[1], A. Rea[1], E. Ingley[2], M.L. Ballinger[3], D.J. Wood[4], D.M. Thomas[3], E.K. Moses[1].* 1) The Curtin UWA Centre for Genetic Origins of Health and Disease, Faculty of Health Sciences, Curtin University and Faculty of Medicine, Dentistry & Health Sciences, The University of Western Australia; 2) Harry Perkins Institute of Medical Research, Western Australia; 3) The Kinghorn Cancer Centre, Garvan Institute of Medical Research, New South Wales, Australia; 4) School of Surgery, University of Western Australia.

The use of whole exome sequencing (WES) in families represents an optimal study design for the identification of rare genetic variants involved in the risk of cancer. We investigated 3 multi-generational cancer-cluster families from the International Sarcoma Kindred Study in order to identify putative deleterious exonic genetic variants that predispose individuals for sarcoma and other cancers. We performed WES using Ion Ampliseq Exome RDY at 100X on genomic DNA extracted from peripheral blood samples from 9 family members with cancer and 10 unaffected family members. Sequences were aligned to hg19 and called using the Torrent Variant Caller. We identified 94,449 SNVs across all 19 germline samples including 47,296 intronic, 19,295 missense (nonsynonymous, stop gain and stop loss), and 20,270 synonymous variants. To reduce multiple testing, variants from WES were filtered to prioritise those detected in 101 known cancer genes plus 25kb upstream and downstream (1,216 variants). These variants, along with pedigree and phenotype information, were imported into SOLAR and analysed using measured genotypes. We investigated all 3 families together and each family independently. Outcome variables used were sarcoma, cancer, age of onset of sarcoma, and age of onset of cancer. Our analysis revealed an association between a variant (rs45614840, c.1464C>G / p.T119R) in *PDIA2* at 16p13.3 and onset of all cancer patients in a single family, (p = 0.00028). This variant is only present in 4 family members with cancer (1 sarcoma, 1 prostate, 2 melanomas) and not found in any unaffected family members or members of the other families. Bioinformatic interrogation revealed that this variant has an allele frequency of 0.0479 in 1,000 Genomes and is located in exon 2 of *PDIA2*. Variants in *PDIA2* have been previously reported in 45 cancer cases in the Cancer Genome Atlas, with 12 in melanoma cases and the rs45614840 variant has been previously reported in two lymphoma cases. Our results demonstrate the first association of *PDIA2* with familial cancer. Our findings support the hypothesis that familial clustering of cancer is caused by heritable factors that can influence multiple cancer types.

2746W

Whole exome sequencing in 75 high-risk families with validation and replication in two case-control studies identifies three previously unknown prostate cancer susceptibility genes. *D.M. Karyadi[1], M. Geybels[2], E. Karlins[1,3], B. Decker[1], L. McIntosh[2], A. Hutchinson[3], S. Kolb[2], S.K. McDonnell[4], B. Hicks[3], S. Baheti[4], L.M. FitzGerald[5], M.S. DeRycke[6], S. Riska[4], M. Yeager[3], D.J. Schaid[4], S.J. Chanock[3], S.N. Thibodeau[6], S.I. Berndt[3], J.L. Stanford[2,7], E.A. Ostrander[1].* 1) Cancer Genetics and Comparative Genomics Branch, NHGRI/NIH, Bethesda, MD; 2) Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA; 3) Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, MD; 4) Department of Health Sciences Research, Mayo Clinic, Rochester, MN; 5) Cancer Epidemiology Centre, Cancer Council Victoria, Melbourne, Victoria, Australia; 6) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 7) Department of Epidemiology, School of Public Health, University of Washington, Seattle, WA.

Prostate cancer (PCa) is genetically heterogeneous and predicted to be caused by a continuum from common, low-penetrant to rare, high-penetrant variants. While genome-wide association studies have been successful in defining at least 100 loci associated with PCa risk in Europeans, these loci likely represent common, low-penetrant variants and, to date, only a few moderately to highly penetrant PCa risk variants have been implicated and validated. To identify low-frequency variants with moderate penetrance, we leveraged whole exome sequence (WES) data with array-based SNP haplotypes from 75 hereditary PCa families. We performed rigorous disease model-based variant filtering, choosing variants with population frequency ≤ 2% that are predicted to be protein damaging, which reduced the candidate variants to 22,242. Selecting variants that are more frequent in the high-risk families versus the general population, and also segregate in at least three families reduced eligible variants to 998. We then varied three metrics: high-risk family frequency ratio, number of families segregating the variant, and average affected carrier frequency in order to identify the most compelling candidates for follow-up. Analysis of these 341 candidate risk variants in a population-based, case-control study of 2,495 men identified nine variants nominally associated with PCa risk with predicted protein consequences in *SWSAP1*, *HOXB13*, *D2HGDH*, *CHAD*, *EPHA8*, *TANGO2*, *BRD2*, *PPP6R2* and *OR5H14*. These nine variants were taken forward to test for replication in an independent nested case-control study of 7,121 men, which showed that two variants were associated with PCa in subset analyses. Meta-analysis combining the two case-control studies highlighted four variants that were significantly associated with risk, only one of which was previously identified. Co-occurrence of at least two of the variants increased risk by 5.47-fold (P = 0.02). Unlike other cancers, where high-risk families define one set of risk alleles and case-control studies another, our study clearly shows that PCa is unique; the complete mutation profile is a continuum. We conclude that well-defined, disease model-based filtering methods, followed by validation and replication in multiple case-control studies can successfully identify moderately penetrant mutations, which until now remained largely undiscovered.

2747T

A genome-wide association study of carcinoembryonic antigen (CEA) levels according to smoking status in Korean population. *S.M. Jeong, J.M. Yun, H.T. Kwon, J.H. Park, B. Cho.* Department of Family Medicine, Seoul National University Hospital, Seoul, South Korea.

Carcinoembryonic antigen (CEA) is known as an indicator of cancer progression and therapeutic responsiveness. Although high concentration of CEA is usually observed in people with several cancers, it is also known as being influenced by smoking through the mechanism increasing mRNA and protein expression of CEA in normal lung tissue compared with non smokers. There was a study in China that reported the significant association between four loci and plasma CEA concentration. We evaluated CEA-level associated single nucleotide polymorphisms (SNPs) by smoking status in Korean. We performed a genome-wide association study of CEA in 1,949 participants who underwent routine health check-ups at Seoul National University Hospital from December 2009 to December 2013 with 4,414,664 SNPs after genomic imputation. We analyzed the association between SNP and CEA level in current smokers as well as in total subjects. CEA level in current smoker (1.98 ± 1.00 ng/ml) was significantly higher than in non smoker (1.51 ± 0.68 ng/ml) (Mean ± SD). We identified two SNPs with significant association with CEA level after adjusting smoking status in all subjects. In accordance with previous study, rs8176749 at 9q34.2 in *ABO* gene was identified showing most significant association with CEA concentration in all subjects (p = 1.71×10^{-14}) and non smoker (p = 5.92×10^{-13}). The result suggests that ABO blood type may have different effects on CEA level. The ABO blood type is reported to be related to prognosis and survival of several malignancies. In current smokers, rs2140345 at 3q13.2 in *ZBTB20* gene was associated with high CEA level (p = 6.20×10^{-10}). *ZBTB20* gene is known to be associated with poor prognosis of hepatocellular carcinoma and cell proliferation in non-small cell lung cancer in previous reports. In conclusion, rs2140345 in current smokers was associated with increased levels of CEA in Korean adults. Our study suggests that smoking may "turn on" the effect of rs2140345 on serum CEA level by certain genetic mechanism.

2748F

Identification of novel genetic variant on *KLKP1* associated with prostate-specific antigen level: A genome-wide association study in the Korean population. *T.G. Yoo, B. Cho, J.H. Park, H.T. Kwon, J.M. Yun.* Department of Family Medicine, Seoul National University Hospital, Seoul, South Korea.

Measuring serum levels of prostate-specific antigen (PSA) is a useful screening test for prostate cancer in Korea. However, PSA levels may be influenced by several factors including genetic components, which lead to poor sensitivity and specificity for detecting prostate cancer. In this study, we aimed to conduct a genome-wide association study (GWAS) in the Korean population to identify genetic variation correlated with PSA levels. We performed a GWAS among 1936 Korean men, aged 20 or above, who had no medical history of cancer and underwent routine health examination at Seoul National University Hospital from December 2009 to December 2013. DNA samples were genotyped in Infinium HumanCore v1.0 BeadChip (Illumina, USA). After imputing genotypes, we were able to analyze a total of 4,414,664 single nucleotide polymorphisms (SNPs). Multivariable linear regression analysis was performed to investigate the association between genetic variants and log-transformed PSA levels, adjusted for age. We detected 10 SNPs on chromosome 1q32.1 (*NUCKS1*, *RAB29*, and *SLC41A1* locus) and 19q13.41 (*KLK3*, *KLK2*, and *KLKP1* locus) that showed statistically significant associations with $p \leq 1 \times 10^{-6}$. The SNPs that showed strongest signals in each region were rs823136 located on 1q32.1 ($p=4.65 \times 10^{-9}$) and rs1058205 located on 19q13.41 ($p=1.92 \times 10^{-15}$). For rs823126, PSA levels are 1.08 ± 0.02 ng/ml in major allele homozygote, 1.19 ± 0.04 ng/ml in heterozygote, and 1.92 ± 0.24 ng/ml in minor allele homozygote (mean±SE). For rs1058205, PSA levels are 1.26 ± 0.03 ng/ml in major allele homozygote, 1.09 ± 0.02 ng/ml in heterozygote, and 0.95 ± 0.04 ng/ml in minor allele homozygote (mean±SE). *KLK3*, encoding the PSA protein, has been proven to have strong association with PSA levels beyond ethnicity. *KLKP1*, which is expressed at lower levels in advanced prostate cancer compared to benign prostate hyperplasia, is a novel finding in our GWAS. We suggest that personalizing a cutoff value for PSA level, using the genetic markers identified in this study, could improve the validity of diagnosing prostate cancer.

Analysis of *cis*-eQTLs in normal and tumor-derived pancreatic tissues reveals functional insights, including for the 9q34.1/*ABO* pancreatic cancer risk locus. *L. Amundadottir[1], S. Lykke-Andersen[2], B. Zhu[3], W. Xiao[4], J.W. Hoskins[1], A. Jermusyk[1], X. Zhang[5], L. Rost[1], I. Collins[1], J. Jia[1], H. Parikh[1], T. Zhang[1], L. Song[3], B. Zhu[5], W. Zhou[5], G. Matters[7], R. Kurtz[8], M. Yeager[5], T. Jensen[2], K. Brown[1], W. Bamlet[9], S. Chanock[6], N. Chatterjee[10], B. Wolpin[11], J. Smith[12], S. Olson[13], G. Petersen[9], J. Shi[3], M. Zhang[1], TCGA Research Network.* 1) NIH/NCI/DCEG/LTG, National Institute of Health, Bethesda, MD; 2) Department of Molecular Biology and Genetics, Aarhus University, DK-8000 Aarhus, Denmark; 3) Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, Maryland 20892, USA; 4) Division of Bioinformatics and Biostatistics, National Center for Toxicological Research, FDA, Jefferson, Arkansas 72079, USA; 5) Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, Maryland, USA; 6) Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, Maryland 20892, USA; 7) Department of Biochemistry and Molecular Biology, The Pennsylvania State University College of Medicine, Hershey, PA 17033, USA; 8) Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, New York 10065, USA; 9) Division of Epidemiology, Department of Health Sciences Research, Mayo Clinic, Rochester, Minnesota 55905, USA; 10) Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland 21205, USA; 11) Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, Massachusetts, USA; 12) Division of Gastroenterology and Hepatology, Georgetown University Hospital, Washington, DC 20007, USA; 13) Department of Epidemiology and Biostatistics, Memorial Sloan-Kettering Cancer Center, New York, New York 10065, USA.

Objective: To elucidate the genetic architecture of gene expression in pancreatic tissues. **Design**: We performed expression quantitative trait locus (eQTL) and allele specific expression (ASE) analyses using RNA-sequence data and 1000 Genomes (1000G) imputed GWAS genotypes from 95 fresh frozen histologically normal pancreatic tissue samples. Data from 115 pancreatic tumor-derived tissue samples from The Cancer Genome Atlas (TCGA) was included for comparison. **Results**: We identified 38,615 *cis*-eQTLs (corresponding to 484 Genes) in histologically normal tissues and 39,713 *cis*-eQTL (corresponding to 237 Genes) in tumor tissues (FDR<0.1), with the strongest effects seen near transcriptional start sites (TSS). Approximately 23% and 42% of genes with significant *cis*-eQTLs (eGenes) appeared to be specific for tumor and normal derived tissues, respectively. Significant enrichment of *cis*-eQTL variants was noted in noncoding regulatory regions marked by modified histones, DNAse hypersensitivity and bound transcription factors, in particular for pancreatic tissues (1.53-3.12 fold, $P \leq 0.0001$), indicating tissue-specific functional relevance. A common pancreatic cancer risk locus on 9q34.2 in the *ABO* gene (rs687289) was associated with *ABO* expression in histologically normal ($P=5.8 \times 10^{-8}$) and tumor-derived ($P=8.3 \times 10^{-5}$) pancreatic tissues. The high linkage disequilibrium (LD) between this variant and the O blood group generating deletion variant in exon 6 of *ABO* suggested that nonsense-mediated decay (NMD) of the "O" mRNA could explain the eQTL. However, knock-down of crucial NMD regulators did not influence decay of the *ABO* "O" mRNA, indicating that a gene regulatory element influenced by pancreatic cancer risk alleles may underlie the eQTL. **Conclusions**: We have identified *cis*-eQTLs representing potential functional regulatory variants in the pancreas and generated a rich dataset for further studies on gene expression and regulation in pancreatic tissues.

Partitioning of genetic variation for breast cancer using two genome-wide association studies containing genetically enriched cases.

O.C. Leavy[1], L. Palla[1], J. Peto[1], D.F. Easton[2], F. Dudbridge[1]. 1) Dept Non-communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom; 2) Dept Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom.

   Breast cancer is the most common type of cancer in women worldwide. Over recent years genome-wide association studies (GWAS) have identified over 70 individual genetic markers associated with breast cancer risk. However much of the heritability for this disease remains to be explained. Much of this remaining heritability may be explained by a collection of genetic markers that individually have a small effect on disease risk. Polygenic scoring has been used to examine whether a combination of genetic variants affect disease risk. We studied two GWAS datasets: the UK2 study and the British Breast Cancer Study (BBCS), both containing women who have at least two close relatives that have developed breast cancer with most of the cases in the BBCS dataset being bilateral breast cancer cases. Methods given by Dudbridge (2013) and Palla and Dudbridge (2015) can be used to estimate the genetic variance explained by an entire GWAS using polygenic scoring and information on internal training and replication datasets. We estimated the genetic variance explained to be between 16% and 21% on the liability scale for the two GWAS. Interestingly, the estimated genetic variance explained by markers related to breast cancer on the iCOGS array is 3%, with all markers on the array explaining 6%. These results indicate that much of the heritability can be explained by markers across the genome that are currently not reaching genome-wide significance. Partitioning the genetic variance by minor allele frequency (MAF), chromosome and SNP annotation can further improve our understanding of how genetic variation is spread across the genome. We use genome partitioning to show evidence of a linear relationship between the genetic variation explained by a chromosome and chromosome length. We show that, for both GWAS, a large proportion of the genetic variance (94%) is explained by common SNPs with MAFs > 0.1. The results from partitioning the genetic variance for each GWAS by SNP annotation suggest that proportionally the UK2 SNPs mapping to an intergenic region explain more genetic variance, whereas the BBCS SNPs mapping to gene regions explain more of the genetic variance. The results from this analysis give insight into the genetic architecture of breast cancer and provide evidence that, similarly to other complex diseases, a large proportion of the genetic variation of breast cancer can be explained by common markers.

Unilateral vestibular schwannoma in a patient with PIK3CA-related segmental overgrowth: Co-occurrence of mosaicism for two rare disorders.

J.R. Mills[1], A.M. Moyer[1], A.B. Poplawski[2], L. Messiaen[2], D. Babovic-Vuksanovic[1,3]. 1) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 2) Department of Genetics, University of Alabama at Birmingham Birmingham, AL; 3) Department of Clinical Genomics, Mayo Clinic.

   A 28-year-old female with a history of PIK3CA-related segmental overgrowth presented to Mayo Clinic Rochester with headaches and was found to have a 5.4 cm left-sided vestibular schwannoma, as well as three small meningiomas. At birth, she was large, had macrocephaly, and by 6-months of age she was noted to have generalized body asymmetry, with her right side being larger than her left. Her hemihypertrophy persisted and required multiple surgeries. She has no significant family history. She underwent surgical resection of the presumed unilateral vestibular schwannoma, which was pathologically confirmed.   According to the current NIH consensus diagnostic criteria for neurofibromatosis 2 (NF2), the presence of a unilateral vestibular schwannoma along with three meningiomas is sufficient for a clinical diagnosis of NF2. While prior genetic analysis of DNA extracted from blood revealed the presence of a mosaic heterozygous c.2740G>A (p.Gly914Arg) *PIK3CA* mutation present at ~10% allele frequency, confirming the diagnosis of PIK3CA-related overgrowth; however, no mutations in *NF2* were detected. Although vestibular schwannoma has not previously been reported in PIK3CA-related segmental overgrowth, meningiomas have been associated, raising the question of whether this patient's vestibular schwannoma and meningiomas represent coincidental NF2 or additional manifestations of her overgrowth syndrome. Therefore, we tested the vestibular schwannoma for *NF2* mutations.   In the vestibular schwannoma we identified a heterozygous *NF2* mutation c.784C>T (p.Arg262*) and partial loss of 22q, including *NF2*, *SMARCB1*, and *LZTR1* genes, confirming *NF2* involvement in the development of the vestibular schwannoma. No other *SMARCB1* or *LZTR1* mutations were identified. We also confirmed the presence of the *PIK3CA* (p.Gly194Arg) mutation in this tumor. This finding suggests that two hits in *NF2* are necessary for development of vestibular schwannoma, despite the functional overlap between the *NF2* tumor suppressor function and the PI3K-signaling pathway. While this patient's vestibular schwannoma most likely represents mosaic NF2, we cannot exclude the possibility that her meningiomas are a result of the *PIK3CA* mutation and the unilateral vestibular schwannoma represents a sporadic tumor. Identification of *NF2* mutations in this patient supports the clinical diagnosis of mosaic NF2 and highlights the possibility of co-occurrence of mosaicism for multiple rare disorders in a single patient. .

Pharmacogenomic prediction of anthracycline-induced cardiotoxicity.
F. Aminkeng[1], A. Bhavsar[2], S. Rassekh[3], M. Rieder[4], J. Stortz[4], F. Dionne[5], G. Groenweg[3], M. Hayden[1], B. Carleton[3], C. Ross[2], The Canadian Pharmacogenomics Network for Drug Safety Consortium. 1) Medical Genetics, The University of British Columbia, Vancouver, British Columbia, Canada; 2) Faculty of Pharmaceutical Sciences, The University of British Columbia, Vancouver, British Columbia, Canada; 3) Pediatrics, The University of British Columbia, Vancouver, British Columbia, Canada; 4) Pediatrics, University of Western Ontario, London, ON, Canada; 5) Centre for Clinical Epidemiology and Evaluation, Vancouver, BC, Canada.

Background/Rationale Cancer is a leading cause of morbidity and mortality. Over 14.1 million people are diagnosed every year and it accounts for approximately 15% of all deaths. Anthracyclines are used to treat over 70% of childhood and 50-90% of adult breast cancer patients each year, and have significantly contributed to the improved 5-year survival rates to over 80%. Their use is limited by cardiac toxicity and congestive heart failure in 57% and 20% of treated patients, respectively. Uncovering the genetics and pathophysiology of anthracycline-induced cardiotoxicity (ACT) will inform treatment decisions and future drug development. *Methods* Patients were recruited and clinically characterized by the Canadian Pharmacogenomics Network for Drug Safety. *Results Pharmacogenomic Discovery*: We recently published the first GWAS (740 000 SNPs) of ACT and discovered a new gene (*RARG*) and a new variant (rs2229774, p.Ser427Leu) in children ($P = 5.9 \times 10^{-8}$, OR (95%CI) = 4.7 (2.7–8.3)). We showed that *RARG* transcriptionally regulates *Top2b* expression, an activity that is impaired by the rs2229774 variation, thereby providing new insights into the pathophysiology of ACT (*Aminkeng F et al. Nature Genetics. 2015 Sep; 47(9):1079-84*). We are analyzing the results of another GWAS (1.7 million SNPs) of ACT in 565 adult breast cancer patients. Preliminary results suggest a role of *RARG* rs2229774 in ACT in adult breast cancer patients (*Aminkeng F et al, Manuscript in preparation*). We have shown in a separate study that pharmacogenomic testing improves ACT prediction beyond currently implemented clinical risk factors and can inform treatment decisions (*Aminkeng F et al, Manuscript in preparation*). Implementation: We developed comprehensive, evidence-based, clinical practice guidelines for ACT pharmacogenomic screening (*Aminkeng F et al. Br J Clin Pharmacol. 2016 May 16. doi: 10.1111/bcp.13008*). We conducted a comprehensive health economic evaluation to examine the cost-effectiveness of ACT pharmacogenomic testing and showed that pharmacogenomics screening reduces morbidity and mortality and saves cost (*Dionne F, Aminkeng F et al, Manuscript in preparation*). We are currently implementing point-of-care genetic testing to enhance treatment decisions and 150 childhood cancer patients have been screened in British Columbia (*Manuscript in preparation*). *Conclusion* Pharmacogenomic prediction of anthracycline-induced cardiotoxicity informs oncology treatment decisions and is cost effective.

2753T

Novel genetic variants in carboxylesterase 1 predict early-onset capecitabine-related toxicity. *U. Amstutz[1], S. Hamzic[1], D. Kummer[1], S. Milesi[1], D. Mueller[1], S. Aebi[2], M. Joerger[3], C.R. Largiadèr[1].* 1) University Institute of Clinical Chemistry, Inselspital Bern University Hospital, University of Bern, Bern, Switzerland; 2) Division of Medical Oncology, Cantonal Hospital Lucerne, Lucerne, Switzerland; 3) Department of Medical Oncology and Hematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland.

Background: Capecitabine (Cp), an oral prodrug of 5-fluorouracil, is commonly prescribed to treat gastrointestinal and breast tumors. However, dose-limiting adverse effects occur in 20-35% of patients at standard doses, in particular hand-foot syndrome and diarrhea. The aim of this study was to evaluate, for the first time, the association of genetic variability in all enzymes of the Cp activation pathway with early-onset toxicity from Cp-based chemotherapy. **Patients & Methods:** The coding and exon-flanking regions of the cytidine deaminase gene (*CDA*) were sequenced in 144 Cp-treated patients, in whom Cp-related toxicities in the first two chemotherapy cycles were recorded. For the other investigated genes (*CES1*, *CES2*, *TYMP*, *UPP1*, and *UPP2*), sequencing of coding and exon-flanking regions was performed in a discovery subset of 48 patients (24 with severe Cp-related toxicity, 24 with no or mild toxicity), and associated candidate variants were subsequently genotyped in the full cohort. **Results:** We identified a haplotype in the carboxylesterase 1 gene (*CES1*) associated with Cp-related toxicity ($OR_{additive}$ = 2.3, 95% CI: 1.25-4.32, $P_{adjusted}$ = 0.008; $OR_{recessive}$ = 16.6, 95% CI: 2.78-98.7, $P_{adjusted}$ = 0.002). This common haplotype (frequency = 14%) encompassed five noncoding variants, including an expression quantitative trait locus (rs7187684) for *CES1*. In addition, the association of two common linked *CDA* promoter variants (c.1-451C>T: $OR_{dominant}$ = 4.29, 95% CI: 1.30-14.2, $P_{adjusted}$ = 0.017; and c.1-92A>G: $P_{adjusted}$ = 0.015; $OR_{dominant}$ = 4.40; 95% CI 1.34-14.5) with increased risk of Cp-induced diarrhea was replicated. For all other investigated genes, no significant association of genetic variants with Cp-related toxicities was detected. **Conclusions:** This is the first study to identify an association of genetic variation in *CES1* with Cp-related toxicity. Given that a variant (rs2244613) of the same *CES1* haplotype was previously associated with trough concentrations and bleeding from the CES1-metabolized anticoagulant dabigatran, this finding provides important evidence for the existence of a common regulatory *CES1* variant with possible clinical relevance for carboxylesterase-metabolized drugs..

2754F

Genetic variation in *SLC16A5* confers protection from cisplatin-induced ototoxicity in adult testicular cancer patients. *B.I. Drogemoller[1,2,13], J.G. Monzon[3,13], A.P. Bhavsar[1,2], A.E. Critchley[11], Z. Chen[8], L.R. Brunham[4,12], M.R. Hayden[2,7], C.J.D. Ross[1,2,5,14], K.A. Gelmon[9,14], B.C. Carleton[4,5,14].* 1) Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; 2) Child & Family Research Institute, Vancouver, BC, Canada; 3) Tom Baker Cancer Centre, Calgary, AB, Canada; 4) Department of Pediatrics, Division of Translational Therapeutics, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada; 5) Pharmaceutical Outcomes Programme, BC Children's Hospital, Vancouver, BC, Canada; 6) Audiology and Speech Pathology Department, BC Children's Hospital, Vancouver, BC, Canada; 7) Department of Medical Genetics, Centre for Molecular Medicine and Therapeutics, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada; 8) Medical Oncology and Hematology, Department of Medicine, Princess Margaret Cancer Centre – University Health Network and University of Toronto, Toronto, ON, Canada; 9) BC Cancer Agency, Vancouver, BC, Canada; 10) Princess Margaret Cancer Centre and University of Toronto, Toronto, Ontario, Canada; 11) Neuro-Otology unit, Vancouver General Hospital, Vancouver, BC, Canada; 12) Department of Medicine, Centre for Heart Lung Innovation, University of British Columbia, Vancouver, British Columbia, Canada; 13) These authors contributed equally to this work; 14) These authors jointly supervised this work.

Background: Cisplatin, a chemotherapeutic agent used to treat many cancers, is highly effective in the treatment of testicular cancer. Cisplatin-induced ototoxicity (CIO), which occurs in 10-25% of adult patients, is an important complication that can affect testicular cancer survivors. Although clinical variables are associated with CIO, they do not completely explain the observed inter-individual variability and we hypothesize that pharmacogenomic variants also contribute to the occurrence of CIO.   Methods: Discovery (n=96, 23 cases and 73 controls) and replication cohorts (n=92, 14 cases and 78 controls) of adult testicular cancer patients previously treated with cisplatin were recruited and extensive clinical and demographic data were collected to facilitate case-control designation. All samples were genotyped for 7,907 variants using a custom pharmacogenomic genotyping panel. Logistic regression was performed to identify variants that were significantly associated with CIO and functional validation assays were utilized to substantiate these findings. Results: Association and fine-mapping analyses identified one significantly associated variant in *SLC16A5* (combined cohort: $P = 2.17 \times 10^{-7}$; OR = 0.06; 95% CI: 0.02-0.22) that conferred protection against CIO. Functional validation of this transporter gene revealed that *in vitro SLC16A5*-silencing significantly altered cellular responses to cisplatin treatment ($P < 0.0001$), thereby providing suggestive evidence of a role for *SLC16A5* in the development of CIO. Conclusions: This study has identified a strong association with a synonymous variant in *SLC16A5* and protection against CIO for the first time. This variant could be used to better predict which patients are at risk of CIO before therapy begins. These findings also provide insight into the molecular mechanisms of CIO in adult cancer patients with implications for potential otoprotectant strategies.

Exome sequencing of cancer related genes to identify genetic markers for sensitivity to cytotoxic anticancer drugs. *C. Udagawa[1], T. Tokino[2], Y. Sasaki[2], B. Shiotani[1], Y. Ohnishi[3], H. Suemizu[3], H. Zembutsu[1].* 1) National cancer center, Tokyo, Japan; 2) Sapporo Medical University School of Medicine, Sapporo, Japan; 3) Central Institute for Experimental Animals, Kawasaki, Japan.

Exome sequencing of 409 cancer related genes was conducted in 59 DNAs extracted from human tumor xenografts, of which sensitivity to nine cytotoxic anticancer drugs had been examined, in a nude mice model. We classified these xenografts into high (> 50%) and low (≤ 50%) variant allele frequency (VF) groups, and examined the difference in sensitivity to the anticancer drugs between the two groups using Welch's t test. The number of SNVs showing association with the anticancer drugs (P<0.05) were 211, 182, 167, 136, 126, 188, 179, 131 and 153 in MMC, CPM, ACNU, DDP, ADR, VCR, VLB, 5FU and MTX, respectively. 13 SNVs of them showed significant association (P<0.05) with five drugs or more, and one of them was located in a gene which is an essential component of NF-κB signaling. The most convincing candidate SNV was on a tumor suppressor gene, and xenografts with high VF of the SNV were more sensitive to ADR compared with xenografts with low VF ($P=8.66 \times 10^{-5}$). These data could contribute useful information for identifying biomarkers for drug sensitivity that may eventually provide "cancer precision medicine".

2756T

Estimating the joint distribution of rare variants, polygenic risk and family history to support analysis of the prospective benefits of risk-based mammographic screening. *M.C. Wolfson[1], S. Gribble[1], A. Antoniou[2], D. Easton[2], N. Pashayan[3], A. Lee[4], J. Simard[5]. 1) Epidemiology, University of Ottawa, Ottawa, Ontario, Canada; 2) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, England; 3) Dept of Applied Health Research, University College London, London, England; 4) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Carre and Department of Oncology, University of Cambridge, Cambridge, UK; 5) Genomics Center, CHU de Québe, Université Laval Research Center, Quebec City, Quebec, Canada.*

The vast majority of breast cancer screening in Canada and other countries is based on a woman's age, e.g. starting age 50. However, women with some genotypes can be at high risk of breast cancer at earlier ages. Knowing genetic risk at an earlier age could enable organized screening programs cost-effectively to offer routine mammographic screening at earlier ages / higher frequencies to high risk women, and later ages / lower frequencies to low risk women. Multiple rare but moderate to high risk mutations for breast cancer, together with many more common single nucleotide polymorphisms (SNPs) conferring lower risks, have now been identified. The combined effects of multiple SNPs can be summarised into a polygenic risk score (PRS). These known variants explain ~45% of familial aggregation to breast cancer, so that detailed family history (FH) still provides substantial incremental information on risk.A significant health policy question is whether population-based assessment using such genetic information for risk-based rather than primarily age-based breast cancer screening would be warranted. However, no data exist for a representative population sample of the joint distribution of rare breast cancer genetic variants and PRS and FH.As part of the Genome Canada/CIHR/Genome Quebec-funded PERSPECTIVE project, a Genetic Mixing Model (GMM) has been developed to estimate this joint distribution. GMM is an interacting agent microsimulation model, simulating nuptiality, nulliparity, parity-specific fertility, and genetic inheritance for populations > 1M individuals, drawing on the underlying genetics of the BOADICEA algorithm (Lee et al. Genet Med (2016)). GMM is part of a larger simulation model to assess cost-effectiveness of risk stratified vs. current primarily age-based organized breast cancer screening programs in Canada.The GMM-simulated joint distribution of rare variants, PRS, and FH provides estimated proportions of women identified as high risk for breast cancer (e.g. >3x average for age). Of the three factors, the PRS identifies the most women at high-risk, followed by FH. In terms of clinical application for breast cancer risk stratification, these results suggest that SNP data are most important on a population basis, followed by FH. Testing for rare genetic variants like BRCA1/2, while important for younger women with a strong FH of breast cancer, are not most important in assessing genetic breast cancer risk on a realistic population basis.

2757F

Large-scale rare variants association studies in hereditary cutaneous and ocular melanoma uncover new risk gene with tumor suppressor activity. *M. Artomov[1,2,3], A.J. Stratigos[4], I. Kim[5], C.N. Njauw[6], K. Shannon[7], E.S. Gragoudas[5], A.M. Lane[5], M. Lauss[8], R. Kumar[8], B. Miao[6], G. Jonsson[8], M.J. Daly[1,2], H. Tsao[6,7]. 1) ATGU, Massachusetts General Hospital, Boston, MA, USA; 2) Broad Institute, Cambridge, MA, USA; 3) Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA, USA; 4) 1st Department of Dermatology, University of Athens School of Medicine, Andreas Sygros Hospital, Athens, Greece; 5) Retina Service, Massachusetts Eye and Ear Infirmary, Boston, MA, USA; 6) Department of Dermatology, Wellman Center for Photomedicine, MGH, Boston, MA, USA; 7) Melanoma Genetics Program, MGH Cancer Center, MGH, Boston, MA, USA; 8) Department of Oncology, Clinical Sciences, Lund University, Lund, Sweden.*

Extraordinary progress has been made in our understanding of common variants in all aspects of medicine. However, the contribution of rare coding variants to inherited disease predisposition is not as well characterized. With the advent of routine whole exome sequencing, this next frontier has become more amenable to exploration. Here we performed an exome-wide, gene-based association study of familial cutaneous melanoma (CM; n=273) and ocular melanoma (OM; n=99) cases along with 7,629 ancestry-matched controls. We established a novel analytical framework for a large-scale exome-based rare variant association study in hereditary cancer cohort. Strong signals were detected for *CDKN2A* and *BAP1* in the CM and OM cohorts, respectively. In addition, multiple candidates exhibited some evidence of association (P<10[-4]); these were then subjected to replication with germline CM and OM sequences available for individuals in The Cancer Genome Atlas (TCGA) project. One of these novel secondary candidates, *EBF3*, was replicated in TCGA and then subjected to proof-of-concept functional credentialing and found to have properties of a *bona fide* tumor suppressor gene. Taken together, these results represent the largest rare variant germline association study in cancer to date, delineate the mutational landscape of hereditary cutaneous and ocular melanomas and implicate *EBF3* as a possible predisposition gene and a novel tumor suppressor in melanoma.

2758W

Linkage analyses reveal significant signals on multiple chromosomes for familial lung cancer. *J.E. Bailey-Wilson[1], A.M. Musolf[1], C.L. Simpson[1,2], M. de Andrade[3], D. Mandal[4], C. Gaba[5], P. Yang[3], M. You[6], E.Y. Kupert[6], M.W. Anderson[6], A.G. Schwartz[7], S.M. Pinney[8], C.I. Amos[9], Genetic Epidemiology of Lung Cancer Consortium.* 1) Computational and Statistical Genomics Branch, NIH/NHGRI, Baltimore, MD; 2) University of Tennessee Health Science Center, Memphis, TN; 3) Mayo Clinic, Rochester, MN; 4) Louisiana State University Health Sciences Center, New Orleans, LA; 5) University of Toledo Dana Cancer Center, Toledo, OH; 6) Medical College of Wisconsin, Milwaukee, WI; 7) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 8) University of Cincinnati College of Medicine, Cincinnati, OH; 9) Geisel School of Medicine, Dartmouth College, Lebanon, NH.

Lung cancer has been the leading cancer killer of men since the 1950s and of women since 1987 and will kill an estimated 158,000 Americans in 2016. Lung cancer risk is known to increase with environmental exposures such as cigarette smoking; there is also a substantial genetic risk. We analyzed genotypes on about 240,000 SNPs (Illumina HumanCore-1 2v1-0 array) on 190 individuals from 26 extended families with a family history of lung cancer (Genetic Epidemiology of Lung Cancer Consortium). An affected-only model assuming autosomal dominant inheritance with 80% penetrance in carriers and 1% penetrance in non-carriers was used in three types of linkage analyses. Two-point linkage was performed using TwoPointLods; multipoint analyses were run using SIMWALK2 and regional-based linkage was run using SEQLinkage and MERLIN. SEQLinkage builds multiallelic regional haplotype-based markers (similar to microsatellites in information content) using rare variants (here MAF≤0.15) within a gene or a portion of a gene. Two-point linkage analyses were then performed on the regional markers using MERLIN. We found 7 regional markers (genes) with heterogeneity LOD (HLOD) scores that were genome-wide significant (HLOD≥3.4) on chromosomes 2, 3, 6p, 8, 16, 18, and 20. Four of the five genes with highest HLODs have been implicated in cancer, with three specifically in lung cancer. The highest HLOD (3.97) was on chromosome 18 at the PTPRM gene, which has been reported to control methylation patterns in pulmonary tumors. Both PTPRT (HLOD=3.8) and NRG1 (HLOD=3.5) have been found to be involved in lung cancer as well, and the CNTN6 gene (HLOD=3.87) has been implicated in familial prostate cancer. Two-point analyses were not genome-wide significant. Multipoint analyses showed a signal on chromosome 18 near PTPRM but no multipoint HLODs were genome-wide significant. This is most likely due to the fact that multipoint analyses require pruning of SNPs to remove LD, resulting in a very sparse map. The regional approach has been shown to control Type I error while improving power when using rare variants. Because both locus and allelic heterogeneity are quite common in familial cancers, it is reasonable to expect that different families contain different high risk variants. Here, we report significant linkage peaks to multiple chromosomes for familial lung cancer. Targeted sequencing of the regions of interest is needed to identify the actual source of a particular linkage peak.

2759T

Role of stochasticity in tumor formation in mice and humans with germline p53 mutations. *C. Chan[1,2], H. Ke[1], Y. Sun[1], A. Levine[3].* 1) Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 2) Department of Medicine, Rutgers Robert-Wood Johnson Medical School, New Brunswick, NJ; 3) Institute for Advanced Study, Princeton, NJ.

Germline p53 mutations predispose mice and humans to a high risk of getting a wide spectrum of tumors with a lifetime risk of getting cancer greater than ninety percent. Yet, genetically identical mice with the same p53 mutation will get tumors in a wide distribution of age as well as tumor types. We observe a similar disparate phenotype in a pair of human identical twins who have germline p53 mutation. We create a probabilistic model using epidemiological data to show how stochasticity can produce much of the heterogeneity in phenotypes. Moreover, the model provides some insights into the process of tumorigenesis with germline p53 mutations.

2760F

Targeted next-generation sequencing panel for detection of mutations in breast cancer. *Y. Chang[1], Y. Hsu[1], S. Su[2], H. Chen[3], Y. Huang[4], S. Yu[5], J. Chen[6], H. Chen[1], K. Li[1].* 1) Institute of Statistical Science, Academia Sinica, Taipei, Taiwan, Taiwan; 2) Center of Biotechnology, National Taiwan University, Taipei, Taiwan; 3) Graduate Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan; 4) Department of Computer Science and Information Engineering, National Chung Cheng University, Taipei, Taiwan; 5) Department of Clinical Laboratory Sciences and Medical Biotechnology, National Taiwan University, Taipei, Taiwan; 6) Institutes of Biomedical Sciences and Molecular Biology, National Chung Hsing University, Taichung, Taiwan.

The detection of mutations can improve our ability to detect high-risk patients who experience relapse and die early. There were 147 breast cancer patients sequenced by Raindance Hotspot targeted sequencing. The average age of all 147 breast cancer patients included in the study was 51.7 years, with a range of 21–77 years. Breast cancer samples categorized as ER positive, HER2 positive, PR positive and triple negative subtypes. The average sequencing depth is 5222X (range 2900x-8633x) and the coverage is around 100%. A total 235 variants in 43 genes were detected in 147 patients by high depth Illumina sequencing. 219 single nucleotide variations were found in 42 genes in from 147 patients and 16 indel mutations in 13 genes from 84 patients. After filtering the 1000 genome database and synonymous SNPs, we focused on the 54 somatic functional point mutations. The functional point mutations contained the 54 missense mutations in 22 genes. We found 37 novel functional mutations (filter by 1000 genome and dbSNP database) in 37 patients and 7 patients were with 2 novel functional mutations. Additionally, we performed the patient with the number of missense somatic mutations predicted the overall survival for the breast cancer patients (log-rank P = 0.036).

2761W

Whole-exome association study of colorectal cancer. *J. Chen[1], Y. Yu[1], F. Hu[1], H. Hu[1], E. Vilar[2], C. Huff[1].* 1) Epidemiology, UT MD Anderson Cancer Center, Houston, TX; 2) Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX.

Although familial studies have identified a number of high-risk colorectal cancer genes, the role of rare variants conferring an intermediate risk of colorectal cancer remains uncertain. To further evaluate the contribution of rare exonic variation to colorectal cancer susceptibility, we conducted a whole-exome case-control study among individuals of European ancestry involving 398 colorectal cancer cases from TCGA and 3507 controls from the National Database for Autism Research. We controlled for technological stratification resulting from heterogeneous sequencing platforms using the XQC toolkit and conducted gene-based association tests using VAAST2.1. Our results replicated five established colorectal cancer susceptibility genes at p <0.05: *MLH1, APC, POLD1, PMS1,* and *MLH3*. We also report effect size estimates for two classes of rare variants in each of these genes: Likely Gene-Disrupting (LGD) (nonsense, frame-shift and canonical splice-site mutations) and non-LGD variants predicted to be damaging by VAAST and PolyPhen-2. Our results yield insights into the role of rare non-LGD risk variants among established colorectal cancer susceptibility genes and provide a foundation for future exome association studies in colorectal cancer.

2762T

Search for genetic factor association with prostate specific antigen level based on genome-wide association study. *E.K. Choe[1], J.Y. Cho[2], Y. Lee[3], J. Lee[4], E.Y. Cho[4], J.Y. Lee[4], H.J. Choi[5].* 1) Surgery, Seoul National University Hospital, Healthcare System Gangnam Center, Seoul, South Korea; 2) Department of Radiology, Seoul National University Hospital, Healthcare System Gangnam Center, Seoul, Korea; 3) Seoul National University Hospital, Healthcare System Gangnam Center, Seoul, Korea; 4) DNA Link, Inc., Seoul, Korea; 5) Department of Anatomy, Seoul National University College of Medicine.

Background: Serum prostate specific antigen (PSA) level is a well-known tumor marker for prostate cancer as a screening tool. However, the genetic determinants of PSA level in healthy and prostate cancer population is not well known. We investigated the genetic markers associated with elevated serum sPSA level in these two populations and its clinical implications. Methods and Findings: Genome-wide association study (GWAS) was conducted in 4,124 healthy Korean male adults (discovery set 2841, replication set 1283) using the Affymetrix Axiom® Customized Biobank Genotyping Arrays for PSA levels with age adjustment. Subgroup analysis in population who had prostate biopsy for increased PSA level (n=65) were done. Results: We detected 11 genome-wide significant signals associated with PSA levels. The top SNP associated with log PSA levels was rs72434280 in SLC45A3 (p value, discovery set=2.97×10^{-20}, replication set = 7.31×10^{-10}). 4 SNPs (rs2735839, rs266849, rs16856139, rs10993994) that has been reported to be associated with PSA levels previously were validated in our population (P=7.57×10^{-20}, P=1.83×10^{-14}, P=1.35×10^{-11}, P=1.45×10^{-10}, respectively). With 11 Candidate SNPs associated with elevated PSA levels, case control study (50 biopsy negative vs 15 cancer proved) in PSA >3ng/ml group , whose biopsy reports were available, was performed after age adjustment. rs266849-G, rs2411332-A and rs2735839-A were associated with false negative increase in PSA levels (normal biopsy result as reference, Odds ratio (OR) =0.215, 95% Confidence interval (CI) = 0.049~0.956, P=0.04; OR=0.1252, 95% CI=0.027~0.572, P=0007; OR=0.054, 95% CI= 0.0008~0.383, P=0.003, respectively). However, the remaining 8 SNPs were not significantly associated with the biopsy result. Conclusions: We found new 7 candidate SNPs associated with elevated PSA levels in healthy males. 4 SNPs previously reported, were validated in Korean population. In males with increased PSA levels, genotyping rs266849 (19q13.33), rs2411332 (19q.33) and rs2735839 (19q.33, KLK3 gene) could be informative to decide the indication of prostate biopsy.

2763F

Comparative analysis of *ATRX* mutations in cancers and ATR-X syndrome. *A.S. Harutyunyan[1], S. Khazaei[1], K. Rossokhata[1], N. Ibrahim[1], M. Osmond[1], B. Krug[1], J. Majewski[1], N. Jabado[1,2].* 1) Department of Human Genetics, McGill University, Montreal, Quebec H3Z 2Z3, Canada; 2) Department of Pediatrics, McGill University, Montreal, Quebec H3Z 2Z3, Canada.

Mutations in the chromatin remodeler alpha-thalassemia mental retardation X-linked *(ATRX)* gene have recently been identified in gliomas and several other cancers. To better understand their contribution to cancer pathogenesis, we have analyzed *ATRX* mutational spectra in gliomas, other cancers and ATR-X syndrome using sequencing of pediatric gliomas combined with publicly available data (mainly from The Cancer Genome Atlas (TCGA) database). Comparison of somatic and germline variants identified distinct distributions of *ATRX* mutations. Mutations are most frequent in cancers of neural origin (glioma, neuroblastoma, pancreatic neuroendocrine tumors, pheochromocytoma, paraganglioma, adrenocortical carcinoma) and are mainly truncating, while other cancers and ATR-X syndrome predominantly carry missense mutations. Furthermore, the germline missense *ATRX* mutations mainly localize in two functional domains of the protein, ADD domain and ATPase/MecP2 domain, while somatic missense mutations in neural cancers cluster in the ATPase/MecP2 domain. This suggests that these domains play different functional roles in germline and somatic contexts. In gliomas, *ATRX* mutations define a molecular subtype of tumors and are strongly associated with somatic mutations in *TP53*, *IDH1/2* and *H3F3A*. In adult gliomas, the subgroup with *ATRX-TP53-IDH1/2* mutations markedly decreases in frequency with more advanced grades (46% in grade II vs. 30% in grade III vs. 4% in grade IV), while the association of the three mutations remains equally strong. In pediatric gliomas, *ATRX* mutations co-occur preferentially with *H3F3A* (encoding histone H3.3) mutations, particularly the G34R mutation, and are never present in histone H3.1 (*HIST1H3B*, *HIST1H3C*) mutant tumors. Our findings provide a better understanding of the type, location and role of *ATRX* mutations in cancers and ATR-X syndrome. The specificity of variants to particular domains of *ATRX* may provide insight into disease mechanisms. The results of the current study allow us to conclude that *ATRX* mutations have a prominent role in the pathogenesis of neural cancers, while their functional role in other tumors is questionable and the observed rare missense mutations are most likely "passenger" mutations.

   Background: Increasing evidence suggests that long non-coding RNAs (lncRNAs) have key regulatory functions in chromatin remodeling and gene expression, and a few dysregulated lncRNAs have been linked to breast cancer. However, inference of the biological and pathological roles of lncRNAs in breast cancer development remains a challenge. **Results:** We analyzed RNA-sequencing (RNA-seq) data in tumor and normal breast tissue samples from 18 breast cancer patients and 18 demographically matched healthy controls, respectively. We identified 598 lncRNAs and 2,980 mRNAs that were differentially expressed between tumor and normal breast tissue. Genome-wide co-expression analysis of lncRNAs and mRNAs revealed two distinctive correlation patterns associated with breast cancer, reflecting different underlying regulatory mechanisms: 1) 516 pairs of lncRNAs –mRNAs have differential co-expression patterns, in which the correlation between lncRNA and mRNA expression differs in tumor and normal breast tissue; 2) 291 pairs of lncRNAs – mRNAs have dose-response co-expression patterns, in which the correlation is similar in tumor and normal breast tissue, but the expression level of lncRNA or mRNA differs in the two tissue types. We further validated our findings in an additional dataset of 744 breast tumors and 104 adjacent normal tissues from TCGA and annotated the function of lncRNAs using TANRIC. One novel lncRNA, *AC145110.1* on the 8p12 region, was found differentially co-expressed with 127 mRNAs in tumor and normal breast tissue. This lncRNA was also found to harbor a known breast cancer risk locus rs9693444, and was highly correlated with clinical outcomes of breast cancer. Functional enrichment and pathway analyses identified distinct biological functions for different patterns of co-expression regulations. **Conclusions:** Using normal breast tissue from healthy women as a desirable baseline for the first time, we identified breast cancer-associated lncRNAs and further explored their potential roles on gene regulation in a genome-wide co-expression analysis. Our data suggested that lncRNAs might be involved in breast tumorigenesis through the modulation of gene expression in multiple pathologic pathways.

Analysis of shared heritability and functional enrichment based on genome-wide association studies for five common cancers. *X. Jiang[1], H. Finucane[1,2], F. Schumacher[3], A. Price[1], D. Hunter[1], D. Conti[3], G. Casey[3], T. Sellers[4], D. Easton[5], S. Gruber[3], M. Jerkins[6], R. Eeles[7], Z. Kote-Jarai[7], S. Benlloch[7], A. Olama[7], C. Haiman[3], P. Pharoah[5], C. Amos[8], P. Kraft[1], S. Lindstrom[9] for BCAC, CORECT/Colon CFR, TRICL, OCAC and PRACTICAL/ELLIPSE.* 1) Program in Genetic Epidemiology and Statistical Genetics, Harvard T.H. Chan School of Public Health, Boston, MA; 2) Department of Mathematics, Massachusetts Institute of Technology, Cambridge, MA; 3) Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA; 4) H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL; 5) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge; 6) Centre for Molecular, Environmental, Genetic and Analytic Epidemiology, Melbourne School of Population and Global Health, University of Melbourne, Australia; 7) The Institute of Cancer Research; 8) Department of Community and Family Medicine, Geisel School of Medicine at Dartmouth, Hanover, NH; 9) Department of Epidemiology, University of Washington.

   Breast, colorectal, lung, ovarian and prostate cancer constitute more than 50% of all annual new cancer diagnoses in the US. These cancers have a significant inherited component but the extent to which their inherited basis is shared is not known. We used GWAS summary statistics from over 560,000 individuals of European ancestry (279,000 cases, 281,000 controls) across these five cancers, generated through the OncoArray initiative. We applied LD score regression to estimate pairwise genetic correlation among all five cancers. In addition, we partitioned the heritability of each cancer by functional annotations, through: 1) a baseline model using 52 publicly available main annotations that are not specific to any cell types; 2) a cell-type specific model including 220 cell-type specific annotations for four histone marks. We identified significant genetic correlations between breast cancer and lung (rg=0.17, se=0.05), colorectal (rg=0.15, se=0.06) and prostate cancer (rg=0.08, se=0.03), but not between any other pairs of cancer types. Functional enrichment analysis across the five cancers revealed that conserved regions are highly enriched, with 2.6% of SNPs explaining an average of 34.5% of the heritability (12.7-fold enrichment, 95%CI: 9.4-16.0). In addition, coding regions, transcription start sites, transcription factor binding sites and DNase I hypersensitive sites showed strong enrichments across multiple cancer types. In contrast, repressed regions exhibited depletion for all five cancers (0.29, 95%CI: 0.01-0.56). Cell-type specific analysis using histone marks revealed similarities between breast, colorectal and prostate cancer, where we observed high enrichments in multiple tissue types including breast and colon. We did not observe any statistically significant cell type-specific results for either lung or ovarian cancer. Our results indicate that solid tumors arising from different tissues share some common germline genetic influences. In addition, these analyses highlight conserved, coding and regulatory regions as functional components of the genome that are significant contributors to cancer heritability across multiple cancer types.

2766F

Cross-cancer pleiotropic analysis of lung cancer in African Americans.

C.C. Jones[1,2], Y. Bradford[3], C.I. Amos[4], W.J. Blot[5,6], S.J. Chanock[7], C.C. Harris[4], A.G. Schwartz[8], J.K. Wiencke[9], X. Wu[10], M.C. Lung cancer (LC) is one of the most commonly diagnosed cancers in the United States. Genome-wide association studies (GWAS) have successfully identified several loci associated with LC risk. However, despite higher incidence and mortality rates in African Americans, few LC GWAS have been conducted in African Americans. Given the high burden of multiple testing intrinsic to GWAS, studies have shifted toward examining variants selected based on biological plausibility. One such method of selecting variants involves the investigation of pleiotropy, which occurs when a single variant or locus affects more than one phenotype. Here, we sought to examine the pleiotropic effects of SNPs previously associated with other cancers with lung cancer risk. African American lung cancer cases (N=1,410) and controls (N=2,843) from 5 independent studies were genotyped on the Illumina 1M-Duo array and standard quality control filters were applied; imputation was performed using IMPUTE2 and the 1000G cosmopolitan reference panel (June 2014). SNPs were extracted from the National Human Genome Research Institute - European Bioinformatics Institute (NHGRI-EBI) GWAS Catalog based on the search term "neoplasm". Manual review filtered out any study in which the outcome was not cancer risk, resulting in 984 SNPs from 220 studies. We examined 916 SNPs, of which 629 were directly genotyped and 287 were imputed (info score >0.8, minor allele frequency >0.01). For each SNP, we performed logistic regression using SNPTest, adjusting for age at diagnosis, sex, smoking status, global African ancestry, and study site. Two SNPs, rs2853677 (in *TERT* on chromosome 5p15) and rs1051730 (in *CHRNA3* on chromosome 15q25), were significantly associated with LC risk (odds ratio (OR) = 1.27, 95% confidence interval (CI): 1.13-1.41 and OR = 1.37, 95% CI: 1.18-1.60, respectively) applying a false discovery rate of 5%. Both SNPs have been previously associated with LC risk in African Americans. The current analysis examined only the variants directly reported in the NHGRI-EBI GWAS catalog. However, because linkage disequilibrium (LD) patterns are known to differ between racial/ethnic populations, it is possible that SNPs discovered in European or Asian populations do not tag the causative SNP in African Americans. Consideration of LD differences between populations will allow for the discovery of associations not captured by examining the reported SNP alone.

Integrative Bayesian network analysis of prostate tissue lincRNA-mRNA expression profiles reveals potential regulatory mechanisms of prostate cancer risk loci.

N.B. Larson, S. McDonnell, Z. Fogarty, M. Larson, S. Riska, S. Baheti, A.A. Nair, D.J. Schaid, S.N. Thibodeau. Mayo Clinic, Rochester, MN.

Large-scale GWAS have identified 107 loci associated with risk of developing prostate cancer (PRCA). However, most of these loci do not lie in close proximity to protein coding genes and are presumed to be regulatory in nature. Downstream regulation of protein coding genes related to PRCA development may be mediated by *cis*-acting transcriptional regulation of nearby long intergenic non-coding RNAs (lincRNAs), which correspond to a host of regulatory functions such as chromatin remodeling and transcriptional co-activation. LincRNAs have previously been identified as diagnostic and prognostic biomarkers for a number of cancers, although their role in cancer development and progression is poorly understood. To explore this hypothesis, we leveraged an eQTL dataset of 471 samples of normal prostate tissue from prostate/bladder cancer patients with available RNA-Seq and imputed Illumina Infinium 2.5M genotype data. We first conducted an initial *cis*-eQTL screening of 1,169 lincRNAs within 1.1 Mb of 8,073 SNPs in high linkage disequilibrium (r^2>0.5) with previously identified PRCA risk-associated variants, identifying 173 significant lincRNAs (FDR<0.05) to be putatively *cis*-regulated. We then constructed an undirected Bayesian regulatory network from the expression profiles of the cis-regulated lincRNAs along with a total of 17,154 expressed protein-coding mRNAs using semi-interleaved HITON-PC, identifying 24,006 connections between 12,930 transcripts (156 lincRNAs, 12,774 mRNAs). Examination of 158 unique lincRNA-neighboring mRNAs within the regulatory network revealed significant enrichment for Gene Ontology terms related to tissue development and morphogenesis, consistent with previous functional studies of lincRNAs. GLAD4U disease gene-set analysis also revealed enrichment for male urogenital disease genes. Previous studies have indicated potential *cis*-acting transcriptional mechanisms for lincRNAs on neighboring mRNAs; however, 65% (114/176) of identified lincRNA-mRNA connections involved transcript pairs on different chromosomes. One negatively correlated *trans* connection between lincRNA CTD-2194D22.2 and putative oncogene *CAPRIN2* [MIM: 610375] was largely explained by *cis*-associated SNP rs12655062. Notably, CTD-2194D22.2 was also connected to upstream PRCA gene *IRX4* [MIM: 606199], which has previously been shown to be *cis*-regulated by rs12655062. Our findings suggest dysregulation of lincRNA expression may play a role in genetic predisposition to PRCA.

Purpose: The racial disparity in prostate cancer incidence in the United States is well documented, with African American (AA) men at highest risk of disease. To identify germline genetic variation that could explain some of this disparity, our previous admixture mapping study identified a novel region on chromosome 7 where local ancestry was associated with risk of disease. Association mapping that combines both single nucleotide polymorphism (SNP) genotype and local ancestry information was used to further identify prostate cancer susceptibility variants in this region that explain the admixture association, and independent data sets were interrogated for validation. Methods: Genotype data from 420 AA prostate cancer cases and 244 AA controls for the two studies (Henry Ford Health System, Detroit, MI, & Howard University, Washington, DC) that were part of original admixture mapping study were obtained from the African Ancestry Prostate Cancer GWAS consortium (AAPC). Admixture linkage was confirmed using an affected-only test and association mapping within the region was conducted using the MIX-score method to identify the SNP(s) most likely to explain the admixture linkage. Validation testing was conducted in the remainder of the AAPC subjects and an independent sample of African Americans from a recent Kaiser Permanente prostate cancer GWAS (KP). Results: The admixture linkage signal spanned a 25 Mb region from 7q31.1 (112.27Mb) to 7q34 (137.90Mb). Within this region, there were four SNPs with MIX-score p-values less than the Bonferroni corrected significance threshold. The highest level of significance was attained at SNP rs13221538 (p=4.11*10-8), located in an intron of the cadherin-like and PC-esterase domain-containing protein 1 (*CPED1*, not characterized in OMIM) gene and the minor allele was associated with a lower risk. In the validation studies, rs13221538 showed suggestive evidence for validation (p=0.053) but with an association estimate in the opposite direction from the discovery sample. An imputation-based meta-analysis of the AAPC and KP studies revealed an additional low frequency variant (rs73228923; p=5.68*10-7) within the glutamate receptor, metabotropic, 8 (*GRM8* [MIM 601116]) gene, with consistent associations in both AAPC and KP studies. Conclusions: Follow-up association mapping of a novel admixture region on chromosome 7 has identified new variants associated with prostate cancer risk.

Multiple-gene research and its clinical evaluation in Chinese high-risk breast cancer. *G. Li[1,2], X. Zhang[3], X. Wang[1], K. Shao[1], J. Xie[3], B. Xia[3], Y. Zhao[4], B. Cao[1], J. Geng[5], F. Liu[3], S. Zhu[1,2], M. Dean[6], D. Pang[1,7], Y. Hou[1,2].* 1) BGI-Research, BGI-Shenzhen, China; 2) Department of Biology, University of Copenhagen, Denmark; 3) Department of Breast Surgery, Harbin Medical University Cancer Hospital, China;; 4) Department of Epidemiology, Public Health College of Harbin Medical University, China; 5) 5 Department of Pathology, Harbin Medical University Cancer Hospital, China; 6) National Cancer Institute, USA;; 7) Translational Medicine Research and Cooperation Center of Northern China, Heilongjiang Academy of Medical Sciences, China.

Background: Currently, dozens of susceptibility genes have been defined for breast cancer. Though several researches have proved the clinical utility of multiple-gene sequencing in assessment of people with hereditary cancer risk, little clinical approach is available. Especially, there is limited such research in China, which country counts for approximately one fifth of world population. Here, we use a multiple-gene sequencing assessment to identify the variant spectrum and evaluate the clinical utility of this assessment in Chinese with high risk of breast cancer. **Method:** Breast cancer patients, who meet the enrollment criteria of NCCN guidelines of breast and/or ovarian cancer genetic assessment were informed and involved in this research. DNA was extracted from patient's peripheral blood. The coding regions of 115 hereditary cancer susceptibility genes were captured and sequenced using next generation sequencing platform. Single Nucleotide Polymorphism and small Insertion/deletion variants were defined and analyzed. Variants were classified into pathogenic, variants of uncertain significance (VUS) and benign according to ACMG recommendation for interpretation of sequence variants. VUS which locate in BRCA1 RING and BRCT domain had functional analysis. **Result:** Totally, 586 breast cancer patients participated in the research. From which, 121(20.6%) patients carried pathogenic variants, including 61(10.4%) with *BRCA1/2* pathogenic variants only, 53(9.0%) with other genes pathogenic variants only and 7(1.2%) with *BRCA1/2* and other gene pathogenic variants simultaneously, meanwhile, there were 29.6% and 73.1% novel spots in 27 BRCA1 and 33 *BRCA2* pathogenic variant spots respectively. 1163 VUS spots from 115 hereditary cancer susceptibility genes were identified in 586 patients. There were 70(11.9%) patients carried *BRCA1/2* VUS, 5 BRCA1 VUS had done functional analysis, and 1 was identified as pathogenic. Additionally, other gene pathogenic variant carriers in 11 families accepted clinical screening such as breast ultrasound, gastroscopy, fibercolonoscopy and serum tumor marker detection. Positive gastroenteric precancerous lesions have been observed in 3 families with *ATM*, *PMS2*, *ATM* and *PALB2* pathogenic variants respectively. **Conclusion**: Overall, based on this research, we have revealed a comprehensive susceptibility variations spectrum and firstly evaluated clinical utility of a multiple-gene sequencing assessment in Chinese with high risk of breast cancer.

2770W

Assessing hereditary risk of breast cancer - Effectiveness of current clinical guidelines. *L.A. Littlejohn[1,3], J. Gibb[2], D. Goudie[3], J. Berg[1,3].* 1) Clinical Genetics, University of Dundee, Dundee, Angus, United Kingdom; 2) Department of Pathology, Ninewells Hospital and Medical School, Dundee, Angus, United Kingdom; 3) Department of Clinical Genetics, Ninewells Hospital and Medical School, Dundee, Angus, United Kingdom.

Family history of breast cancer is one of the most common indications for referral to Clinical Genetic Services. Currently, UK National Institute of Health and Care Excellence (NICE) guidelines use family history to stratify by absolute risk for developing breast cancer between age 40 and 50. Patients are divided into low/population risk (LR, 10yr risk <3%), medium risk (MR, 10yr risk 3-8%) and high risk (HR, 10yr risk >8%). Risk stratification is separate from *BRCA1 & 2* mutation status. Women at increased cancer risk are offered screening at or prior to age 40. Accurate stratification of risk is essential for effective patient management. Family history data was obtained for all unaffected women with a family history of breast cancer aged ≤50, referred to Tayside clinical genetics between 2000 and 2010. All patients were risk stratified *de novo* according to NICE criteria. Patients who developed breast cancer were identified. Known *BRCA1 & 2* mutation carriers were excluded from initial analysis. 1410 women had 15,414 patient-years of follow up. 30 invasive breast cancers developed in the group, 13 in MR and 13 in HR women. Excluding *BRCA* carriers, more cancers developed in MR and HR groups. LR vs MR: *p*=0.048 (Fisher's exact test) and LR vs HR: *p*=0.029. Inclusion of *BRCA* carriers led to a greater degree of significance, (*p*=0.003 and 0.007 respectively). Excluding *BRCA* carriers, Kaplan-Meier analysis demonstrated the highest rate of breast cancer between ages 40-49 in the HR group followed by MR; log-rank scores: LR vs MR *p*=0.025, LR vs HR *p*=0.021. There was no significant difference in the rate of cancers between MR and HR groups (Log rank *p*=0.840). Combining the MR+HR groups for invasive disease gave a sensitivity of 86.7% and specificity of 63.6%, with a positive predictive value of 2.88%. The 10 year incidences of invasive cancer between 40-49 in MR and HR patients were 2.4% (0.04-0.44%) and 3.6% (0.7-6.5%) repectively. NICE guidelines appear to identify patients at increased risk of breast cancer aged 40-49 with reasonable sensitivity. Discrimination between moderate risk and high risk groups was poor. The 10-year incidence of breast cancer observed in this group did not meet the values suggested by NICE for clinical benefit and cost effectiveness. Improving discrimination between those at MR and HR will help to better target screening resources. Family history criteria required to meet these thresholds may need to be revised.

DeBakey Veterans Affairs Medical Center, Baylor College of Medicine, Houston, TX, USA; 6) Human Genome Sequence Center, Baylor College of Medicine, Houston, TX , USA; 7) Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX, USA; 8) Department of Thoracic/Head and Neck Medical Center, MD Anderson Cancer Center, Houston, TX, USA; 9) Department of Biomedical Data Science, Geisel School of Medicine, Dartmouth College, Lebanon, NH, USA; 10) Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Background: Genome-wide association studies (GWAS) are widely used to map genomic regions contributing to lung cancer (LC) susceptibility but they typically do not identify the precise disease-causing genes/variants. To identify causative LC variants, we focused on common and rare functional variants in exon and regulatory regions of 109 GWAS loci associated with LC, chronic obstructive pulmonary disease (COPD), lung function and smoking behavior. **Methods:** Using an extreme-phenotype approach, we selected: resistant-smokers with normal lung function defined as post-bronchodilator FEV1 ≥ 80% predicted, FEV1/FVC ≥ 0.7, 15+ pack-years, n = 318; and susceptible-smokers with LC, 10+ pack-years, n = 247. Normal DNA was sequenced utilizing VCRome 2.1 (depth 200X over exonic regions). Promising candidates were validated in an independent set of 510 susceptible-smokers with LC and 155 resistant-smokers with normal lung function, genotyped using the MEGA panel, a high-density custom exome-array. **Results:** We discovered 30 common regulatory polymorphisms ($P \leq 1.0 \times 10^{-6}$) and 19 rare non-synonymous substitutions (occurring in 3+ susceptible-smokers and zero resistant-smokers) associated with LC risk. The top deleterious rare variants were 10q25 *CCDC147* p.Arg696Cys (occurring in eight susceptible-smokers in validation), 10q23.33 *IFIT3* p.Leu390Arg and 11p14.1 *BDNF* p.Thr2Ile (occurring in one susceptible-smoker in validation). These mutations were very rare (MAFs < 0.005). Gene-burden tests revealed strong association of common regulatory variants in 10q23.33 and LC risk ($P \leq 1.0 \times 10^{-5}$). **Conclusion:** Our results support the risk-conferring role of *CCDC147* and *IFIT3* in LC and demonstrate that exome sequencing analysis may pinpoint disease-causing functional variants in genomic regions initially identified by GWAS.

2772F

Genome-wide association study identifies new susceptibility regions associated with Ewing sarcoma risk. *M.J. Machiela[1], E. Karlins[1], W. Zhou[1], J. Khan[2], S. Ballet[3], E. Lapouble[3], V. Laurence[3], J. Michon[3], G. Pierron[3], L. Mirabello[1], L. Morton[1], G. Armstrong[4], L.L. Robison[4], S. Bhatia[5], R. Hoover[1], M.A. Tucker[1], F. Tirode[3], O. Delattre[3], S.J. Chanock[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD, USA; 2) Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA; 3) Institut Curie, Paris, France; 4) Department of Epidemiology and Cancer Control, St. Jude Children's Research Hospital, Memphis, TN, USA; 5) Institute for Cancer Outcomes and Survivorship, University of Alabama at Birmingham, Birmingham, AL, USA.

Ewing sarcoma is an aggressive pediatric bone tumor predominantly observed in individuals of European ancestry. A defining characteristic of Ewing sarcoma is a fusion of a member of the ETS transcription factor family, usually the *FLI1* gene, with *EWSR1* resulting in an aberrant transcription factor that promotes cell transformation. A previous genome-wide association study identified candidate risk loci at 1p36.22, 10q21 and 15q15. A functional study of the 10q21 region has since localized the association signal to variation in a GGAA repeat motif that when bound by *EWSR1-FLI1* functions as an active regulatory element of *EGR2*. We performed an expanded genome-wide association study of 700 Ewing sarcoma cases (162 within the Childhood Cancer Survivor Study) and 1,400 ancestry matched controls. Our analysis strengthened previously published association signals at 1p36.22, 10q21 and 15q15 as well as identified two novel candidate loci: a locus on chromosome 6 and a locus on chromosome 20. The chromosome 6 locus is tagged by rs7742053 (OR=1.83, 95% CI=1.50-2.24, P-value=3.88×10^{-9}) while the chromosome 20 locus is tagged by rs12106193 (OR=1.98, 95% CI=1.65-2.37, P-value=1.33×10^{-13}). Notably, the estimated effect sizes of these associations are of greater magnitude than that observed in adult cancers. Extended haplotypes in these associated regions suggest a set of plausible candidate genes for future functional analyses. An additional promising Ewing sarcoma associated locus tagged by rs10627880 was identified on chromosome 3 (P-value=7.79×10^{-8}), but the locus did not achieve the genome-wide significance threshold and thus requires further replication and investigation. Collectively, our findings replicate prior Ewing sarcoma genetic associations and provide evidence for novel Ewing sarcoma susceptibility regions.

Epithelial ovarian cancer (EOC) is a rare but deadly disease for which there is notably poorer survival in women of African Ancestry (AA) compared to women of European Ancestry (EA). Previous EA-based genome-wide association studies (GWAS) have identified 30 common, low penetrant EOC susceptibility alleles. Using the custom-designed 533,631 SNP array, the Illumina OncoArray and imputation to ~8 million genetic variants in the 1000 Genomes Phase 3, we conducted a GWAS in 767 AA EOC cases, including 213 confirmed high-grade serous ovarian cancer (HGSOC) cases, and 1,305 AA controls from the Ovarian Cancer Association Consortium (OCAC). We identified novel susceptibility loci at 4q13.3 for all EOC (lead SNP rs4286604, chr 4 bp 70,442,165, 15 kb 3' of *UGT2A1*, P=2.1x10^{-8}, MAF=0.27) and 4p16.1 for HGSOC (lead SNP rs149394398, chr 4 bp 8,878,796, 5 kb 5' of *HMX1*, P=5.0x10^{-9}, MAF=0.09). These SNPs were not genome-wide significant in the larger OCAC EA GWAS including up to 23,543 EOC cases and 29,444 controls, although an alternate SNP near *UGT2A1* showed regional significance in EA (rs7667921, chr 4 bp 69,665,106, P=1.5x10^{-5}). The *UGT2A1* region SNP identified in EA women in not in linkage disequilibrium (LD) with the lead SNP identified in AA women (R-squared<0.02 in1000G EUR and AFR). *UGT2A1* belongs to the UDP-glycosyltransferase family and plays a role in regulation of the Vitamin D receptor (*VDR*) gene, representing an important pathway previously identified in relation to risk of EOC in AA. Of the 30 SNPs identified in previous EA EOC GWAS, we observed nominally significant associations (P<0.05) with consistent direction of effect for six SNPs in AA women. Additional analysis of these loci revealed regionally significant association at 8q21.13 in AA (rs1451991, chr 8 bp 82,862,754, 100 kb 5' of *SNX16*, P=2.6x10^{-6}, MAF=0.382) at a SNP distinct from that identified in EA (rs11782652, R-squared<0.01 in 1000G EUR and AFR). *SNX16* promotes degradation of EGFR after EGF signaling, further linking it to the *VDR* pathway. Overall, our investigation presents evidence of (1) variants for EOC shared among EA and AA women, (2) susceptibility loci representing distinct underlying variants in EA and AA, and (3) novel EOC risk loci of importance for AA women, possibly representing genes related to the Vitamin D Receptor (*VDR*). Our findings underscore the importance of further genetic studies to identify variants and pathways associated with pathogenesis of EOC in AA women.

2774T

Novel pleiotropic risk loci for melanoma and nevus count. *N.G. Martin[1], G. Zhu[1], D.L. Duffy[1], G.W. Montomery[1,9], N.K. Hayward[1], S. MacGregor[1], M. Law[1], D. Glass[2], M. Falchi[2], V. Mackey[7], L. Jacobs[4], T.E. Nijsten[4], F. Lui[4], M.H. Kayser[4], X. Li[5], J. Han[5], S. Chanock[5], D. Hunter[5].* 1) Genetic Epidemiology, QIMR Berghofer Medical Research Institute, Queensland, Australia; 2) Department of Twin Research & Genetic Epidemiology, St Thomas Hospital Campus, Kings College, London, UK; 3) MRC Integrative Epidemiology Unit and MRC Centre for Causal Analyses in Translational Epidemiology,; 4) Erasmus MC, University Medical Centre, Rotterdam, the Netherlands; 5) Channing Laboratory, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA; 6) Section of Epidemiology and Biostatistics, Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, UK; 7) Centre for Ophthalmology and Visual Science (incorporating Lions Eye Institute), The University of Western Australia Perth, Australia; 8) Child Health Research, University of Western Australia, Perth, Australia; 9) Queensland Brain Institute, Brisbane, Australia; 10) University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia.

The main clinical interest in total number of acquired melanocytic nevi on the skin is its strong correlation with melanoma risk. We have previously described genomewide association scans (GWAS) in Australian and British samples that identified loci influencing both nevus count and melanoma. Here we report a meta-analysis of 10 nevus GWAS from Australia, the Netherlands, United Kingdom and the United States, comprising a total of 23,570 phenotyped individuals. We confirmed known loci, including *MTAP*, *PLA2G6*, and *IRF4*. We detected two novel SNPs are at a genome-wide level of significance in their own right, near *LMX1B* on chromosome 8, and intergenic near *PTBP2* on chromosome 1. On combining the nevus results with those from a recent melanoma meta-analysis, SNPs near *GPRC5A*, *CYP1B1*, and *SYNE2* reached genome-wide significance. Several other loci, such as *PPARGC1B*, previously implicated in melanoma risk, reached a suggestive level of significance when evidence from nevi and melanoma was combined. While some loci act on nevus count and melanoma risk via the "nevus pathway", others are pure nevus or pure melanoma loci.

2775F

Whole-exome sequencing identifies a high frequency of germline deleterious variants in cancer predisposition genes in individuals with osteosarcoma. *L. Mirabello[1], R. Koster[1], B. Zhu[1], M.    Osteosarcoma (OS), the most common malignant bone tumor in children and adolescents, occurs at a higher than expected frequency in individuals with certain cancer predisposition syndromes. Sporadic OS is significantly more common and its genetic etiology is poorly understood. We conducted an evaluation of rare exonic variants in 552 unselected OS cases compared with 1072 cancer-free controls using whole-exome sequencing (WES) to estimate the prevalence and burden of rare deleterious germline variants. WES of OS cases (extracted from either blood or buccal cells) included 347 European (EUR), 51 African (AFR), 61 admixed, 43 Hispanic, and 49 Brazilian ancestry patients. We evaluated rare (MAF <0.01) non-silent genetic variants that passed quality control filters. We performed burden tests comparing 347 EUR cases with 1001 EUR controls sequenced at the same time; initial analyses evaluated potentially pathogenic rare variants in 126 established cancer predisposing genes (CPG). A total of 12.5% of cases had a predicted pathogenic or high impact variant in an autosomal dominant (AD) CPG (29 of 92 AD CPGs); a significantly higher rare variant burden was present in the EUR cases compared to controls (P_{burden}=3.7x10^{-05}). *TP53* had the highest prevalence of pathogenic mutations (4.9% of patients, excluding variants of uncertain significance); the highest frequency was in individuals of AFR (7.8% of AFR cases) and EUR ancestry (5.7% of EUR cases; P_{burden}=1.05x10^{-09}). *COL7A1* and *BRCA2* had the next highest frequencies of rare AD CPG variants in cases but were not significantly higher than the controls. *RB1*, *MEN1* and *CDKN2A* had a significantly higher rare variant burden in the EUR cases (P=0.01). 6.5% of cases had a predicted pathogenic mutation in an autosomal recessive (AR) CPG (19 of 28 AR CPGs; P_{burden}=5.4x10^{-03}). Variants in these AR genes were heterozygous, suggesting they could be risk factors for OS. Two male patients had a mutation in an X-linked CPG (*DKC1* and *GPC3*; 2 of 6 X/Y-linked CPGs). Overall, 107 OS cases (19.4%) had a predicted pathogenic or high impact mutation in a CPG, which was significantly higher than the controls (P_{burden}=2.4x10^{-07}; even after excluding *TP53*, P_{burden}=6.2x10^{-04}). Our data suggest that additional CPGs not previously associated with OS could be important and merit further follow-up. .

2776W

A polygenic risk score analysis of body mass index and the risk of non-Hodgkin lymphoma. *A. Moore[1], E. Kane[2], L.R. Teras[3], A. Monnereau[4], C.F. Skibola[5], N. Wong Doo[6,7], Z. Wang[8], M.    Background: Currently, some studies report an association between increasing body mass index (BMI) and the risk of non-Hodgkin lymphoma (NHL). Some studies also report differences in the association by sex, timing of BMI measurement, and NHL subtype. **Methods**: To investigate the association between BMI and NHL, we used a polygenic risk scores (PRS) to estimate the association between the genetically inferred BMI and risk of NHL. Using data from eight NHL GWAS, including 10,629 cases and 9,505 controls of European ancestry, we constructed both unweighted and weighted PRS using the 97 SNPs previously-identified with genome-wide significance in association with BMI in the GIANT consortium. The unweighted PRS was the sum of the imputed dosage of BMI-increasing alleles. The weighted PRS was the sum of the weighted dosage of BMI-increasing alleles, where weights were the previously reported regression coefficients for each SNP by the GIANT consortium. We used logistic regression to evaluate PRS associations with four NHL subtypes and then combined individual study results in a fixed-effects meta-analysis for each subtype: diffuse large B-cell lymphoma (DLBCL, n=3,857), follicular lymphoma (FL, n=2,847), chronic lymphocytic leukemia (CLL, n=3,100), and marginal zone lymphoma (MZL, n=825). We adjusted for sex, age at NHL diagnosis, and population stratification. **Results**: We did not find evidence of an association between either the unweighted or the weighted BMI PRS and the risk of individual NHL subtypes (p>0.05). When stratified by sex, there was evidence for an association between the continuous weighted PRS and DLBCL risk among males (OR$_{fixed}$ per one-unit increase in PRS=1.50, 95% CI=1.07-2.11, p=0.019). No association was observed among females for DLBCL (OR$_{fixed}$= 0.93, 95% CI=0.64-1.37, p=0.727). Additional analyses will explore the risk association with PRS for waist-to-hip ratio and other obesity-related traits. **Conclusions**: Although the established BMI loci only explain a small fraction of the variance in BMI, this study complements previous epidemiologic studies and supports an association between increased genetic BMI and the risk of DLBCL among males. This analysis also supports the importance of studying NHL subtypes individually and the possibility of sex differences in etiology of NHL.

2777T

Familial lung cancer is significantly linked to six genes on 6q24-25. *A.M. Musolf[1], C.L. Simpson[1], M. de Andrade[2], D. Mandal[3], C. Gaba[4], P. Yang[2], M. You[5], E.Y. Kupert[5], M.W. Anderson[5], A.G. Schwartz[6], S.M. Pinney[7], C.I. Amos[8], J.E. Bailey-Wilson[1].* 1) National Human Genome Research Institute, National Institutes of Health, Baltimore, MD; 2) Mayo Clinic, Rochester, MN; 3) Louisiana State University Health Sciences Center, New Orleans, LA; 4) University of Toledo Dana Cancer Center, Toledo, OH; 5) Medical College of Wisconsin, Milwaukee, WI; 6) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 7) University of Cincinnati College of Medicine, Cincinnati, OH; 8) Geisel School of Medicine, Dartmouth College, Lebanon, NH.

   Lung cancer is the leading cancer-related cause of death in the United States, accounting for about 27% of all cancer deaths. Though lung cancer risk has long been known to be highly affected by the environment (particularly tobacco smoking), there is evidence for a genetic component as well, supported by familial aggregation and segregation studies. We had previously performed multipoint linkage analysis on families with a strong family history of lung cancer from the Genetic Epidemiology of Lung Cancer Consortium and found significant linkage to the 6q24-25 region. We performed targeted sequencing on 75 individuals in the 9 most strongly linked families. Two-point linkage analysis was calculated via paramlink. We also performed regional linkage analysis using SEQLinkage, which built haplotypes to create regional multiallelic markers corresponding to a gene or piece of a gene. These markers were then analyzed for two-point linkage by MERLIN.   We report 7 significant regional HLOD scores (HLOD> 3) across 6 genes: *ZBTB2*, *PARK2*, *CNKSR3*, *EZR-AS1*, *PHACTR2*, and *ADGB*. Both *PHACTR2* and *PARK2* have been implicated directly in lung cancer, and *ZBTB2*, *CNKSR3*, and *ADGB* have been implicated in other cancers. The antisense RNA gene *EZR-AS1* has not been implicated in cancer; though its target has been and noncoding RNAs in general have been found to be involved in various cancers. We did not find any genome-wide significant two-point LOD scores, but we did find several suggestive (HLOD>1) signals. Interestingly, many of these signals were located in known regulatory regions, enhancers, or TF binding sites of the top genes in the regional analyses.   It is not particularly surprising that we found multiple significant signals within 6q24-25. This region is rich with good candidate genes (including those found to be significant) and these families are linked to the region. Also allelic and locus heterogeneity is quite common in hereditary cancers so it is not unreasonable that different families might be segregating different high-risk variants in this region.   Thus, we report that the significant linkage signal previously discovered at 6q24-25 is at least partially explained by the narrowed region encompassing the 6 genome-wide significant genes reported here. Functional analysis of candidate variants in this region is needed to confirm which variants/genes (in conjunction with smoking) substantially increase risk of lung cancer in these high-risk families. .

2778F

Field synopsis of genetic variations and colorectal cancer: Unified 2016 update. *C. Nyiraneza[1], Z. Montazeri[1], E. Theodoratou[2], W. Zheng[3], H. Campbell[2], J. Little[1].* 1) University of Ottawa, Ottawa, Ontario, Canada; 2) University of Edinburgh, Edinburgh, United Kingdom; 3) Vanderbilt University School of Medicine, Nashville, TN, United States.

Background: According to current predictions of global demographic changes, the WHO estimates a 77% increase in colorectal cancer (CRC) incidence and 80% increase in CRC-related deaths by 2030 (Bray etal., 2012). Identifying genetic variants that influence susceptibility to disease potentially can inform the development of approaches for primary and secondary prevention. Two groups have published field synopses on genetic variants associated with CRC, in JNCI in 2012 and Gut in 2013. These groups are now working together on an update. **Methods:** We have searched all published (and some unpublished) genetic association data –including candidate gene and GWAS- for CRC to the end of 2015. Furthermore, we have access to 4 GWAS datasets. We are conducting meta-analyses. We have reached a consensus on the operationalization of the Venice guidelines on the credibility of genetic association, which had differed between the two previous field synopses. **Results:** More than 200 genes in about 770 SNPs were identified as putatively associated with CRC. For 450 SNPs, there was a single study only; for 90 SNPs, two studies; and for 230 SNPs, 3 or more studies. Meta-analysis will be carried out for SNPs with 3 or more studies, and credibility of association assessed according to the Venice criteria. **Conclusions:** The identification of genetic variants with influence on CRC risk may reflect an importance of genes involved in CRC risk. Our data should help results of genetic associations studies to be placed in context and interpreted appropriately and should help direct future research effort.

2779W

Genetic characterization of somatic alterations in radiation-associated chronic lymphocytic leukemia. *J. Ojha[1], A.J. de Smith[1], S. Gonseth[1], M. Zhou[1], H.M Hansen[1], .J. Nakamura[1], P.M. Bracci[1], K.M. Walsh[1], S.C. Finch[6], R.F. Reiss[2,3], M. Little[5], I. Dyagil[4], S.N. Gudzenko[5], D. Bazyka[4], J.L. Wiemles[1], L.B Zablotska[1].* 1) Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA; 2) Department of Pathology and Cell Biology; 3) Department of Medicine, College of Physicians and Surgeons, Columbia University, New York, New York, USA; 4) National Research Center for Radiation Medicine, Kyiv, Ukraine; 5) Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Department of Health and Human Services, Bethesda, Maryland, USA; 6) Robert Wood Johnson Medical School, Camden, New Jersey, USA.

Chronic lymphocytic leukemia (CLL) was the predominant leukemia in the recent study of cleanup workers of the Chernobyl nuclear accident in Ukraine. Significantly elevated radiation risks were reported for CLL, with CLL cases characterized by early age of onset, advanced Rai staging at diagnosis and shorter survival with higher doses. In this study we analyzed the effects of radiation exposure on leukemogenesis in Chernobyl cleanup workers. We performed targeted deep sequencing of 538 cancer-associated genes in tumor DNA from 17 radiation-exposed cleanup workers (Ex) and 28 unexposed general population Ukrainian CLL cases (UnEx), and compared the results with 100 western CLL cases (W-CLL) (publically available data from previous sequencing studies, matched on age males only). *POT1* was the most frequently mutated gene in Ex cases (25%) followed by *NOTCH1* (16%)*, RB1 (*16%), and *ATM, APC, MED12, SF3B1, KMT2C* (2% each). Total number of point mutations was comparable in Ex (range 3-12, median 9), UnEx (range 2-12, median 8) and W-CLL (range 2-11, median 8) cases. Copy number alterations (CNAs) were screened via CNVkit. The most common CNAs in exposed cases were -13q14, -11q (12% each), -17p and +12q (6% each). Total number of lesions (mutations & CNAs) among exposed cases was strongly associated with type of work performed in the Chernobyl zone (p=0.013), number of doctor visits prior to diagnosis, and several time-dependent variables (combined R-square= 0.96). Additionally, progressively stronger association of total lesions with radiation dose of increasing latency periods (p=0.11 for lag=15 years) was observed. We estimated telomere length (TL) using Tel-Seq algorithm and identified significantly longer TL in Ex compared to UnEx cases (p=0.009, adjusted for age). In addition, lifestyle risk factors such as alcohol consumption and smoking, type of cleanup work performed was also associated with differences in TL. The higher prevalence of *POT1* (25%, 0% and 3%) and *ATM* (11%, 3% and 8%) mutations in exposed Chernobyl workers compared to UnEx and W-CLL cases, respectively, suggests that mutations in telomere-related genes may be critical to radiation-associated leukemogenesis. As *POT1* mutation was also associated with poorer patient survival, the relationship between telomere maintenance, radiation exposure, and CLL prognosis merits further investigation.

A genetic analysis of longitudinal prostate-specific antigen concentrations. *S. Rashkin[1], T. Hoffmann[1,2], L. Sakoda[3], E. Jorgenson[3], L. Habel[3], J. Shan[3], D. Ranatunga[3], C. Chao[4], N. Ghai[4], D. Aaronson[5], J. Presti[5], C. Schaefer[3], N. Risch[1,2,3], S. Van Den Eeden[3,6], J. Witte[1,2,6].* 1) Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA; 2) Institute for Human Genetics, University of California San Francisco, San Francisco, CA; 3) Division of Research, Kaiser Permanente Northern California, Oakland, CA; 4) Department of Research and Evaluation, Kaiser Permanente Southern California, Pasadena, CA; 5) Department of Urology, Kaiser Oakland Medical Center, Oakland, CA; 6) Department of Urology, University of California San Francisco, San Francisco, CA.

Prostate-specific antigen (PSA) measures have been used to screen for prostate cancer as increased PSA concentrations are indicative of prostate cancer. However, PSA concentration can vary between individuals due to various factors, leading to only moderate accuracy of PSA testing with a universal threshold. It has been proposed that PSA screening for prostate cancer can be improved by incorporating information from genetic markers influencing PSA concentrations independent of prostate cancer to determine individual-specific screening thresholds.   Studies have been conducted examining the relationship between PSA concentrations and genetic variation, but most use PSA levels measured at a single point in time or simplify longitudinal measurements to a single summary statistic. However, knowledge of how genetics affects PSA concentrations over time may better aid in determining a personalized screening threshold for an individual by incorporating how PSA is likely to change for an individual over time independent of prostate cancer to determine if an increase in PSA over time falls within normal bounds for that individual.   Here, we explore the genetic basis of changes in PSA concentrations over time in Kaiser Permanente health plan members. A previous genome-wide association study in this dataset (28,503 non-Hispanic white Kaiser Permanente health plan members and 18,615 men from replication cohorts) compared each SNP to the median PSA level over time (at least nine measures per man) and found multiple SNPs associated with PSA levels, and many of the novel SNPs were not associated with prostate cancer. We now improve on this analysis with a study looking at the longitudinal measures and trends over time by using longitudinal regression analysis to model PSA concentration.

2781F

Genetic variation in the eicosanoid pathway is associated with non-small-cell lung cancer (NSCLC) survival. *L.N. Sausville[1,2], C.C Jones[3,4], M.C. Aldrich[3,4], W.J. Blot[5,6], A. Pozzi[7,8], S.M. Williams[1,2].* 1) Genetics, Dartmouth College, Hanover, NH., United States; 2) Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH, United States; 3) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN, United States; 4) Department of Thoracic Surgery, Vanderbilt University Medical Center, Nashville, TN, United States; 5) Division of Epidemiology, Vanderbilt University School of Medicine, Nashville, TN, United States; 6) International Epidemiology Institute, Rockville, MD, United States; 7) Department of Biochemistry, Vanderbilt University Medical Center, Nashville, TN, United States; 8) Department of Medicine, Division of Nephrology and Hypertension, Vanderbilt University Medical Center, Nashville, TN, United States.

Globally lung cancer results in more deaths worldwide than any other cancer, indicating a need for better treatments. Members of the eicosanoid metabolism pathway represent promising therapeutic targets, as several enzymes involved in the generation of these lipids are dysregulated in many cancers and their inhibition reduces lung cancer growth in mouse models. However, genetic variations of enzymes involved in eicosanoid metabolism have not been adequately examined for association with lung cancer. The goal of this study was to determine whether genetic variations altering eicosanoid producing enzyme function and/or expression are associated with differences in lung cancer survival.   We examined the association of genetic variation within eicosanoid metabolism genes and lung cancer mortality in 395 non-small-cell lung cancer (NSCLC) cases from the Southern Community Cohort Study (SCCS). A total of 103 SNPs in 19 genes, both common and rare SNPs, were examined for association with NSCLC mortality. Analyses revealed no single common genetic variant or collapsed rare genetic variants within one gene associated with NSCLC survival across the entire study population. However, significant subgroup effects were observed. Rare variants in *ALOX15B* (arachidonate 15-lipoxygenase, type B) were associated with worse survival in women (HR = 2.630, p-value = 0.002), and the common variant rs12529 in *AKR1C3* (prostaglandin F synthase) was associated with improved survival in African Americans (HR = 0.726, p-value = 0.009). The lack of genetic associations among all NSCLC cases and the association among women only for rare variants in *ALOX15B* may, in part, explain the better NSCLC survival observed among women. These results raise the possibility that that some subgroups within the NSCLC population may benefit from drugs targeting eicosanoid metabolism.

2782W

Fanconi anemia gene variants predispose to hereditary pancreatic cancer. *T.P. Slavin, S. Neuhausen, M. Niell-Swiller, C. Rybak, I. Solomon, K. Blazer, A. Adamson, Y. Yate-Ching, K. Yang, S. Sand, D. Castillo, J. Herzog, X. Wu, S. Tao, S. Raja, T. Chavez, V. Chung, G. Singh, J.N. Weitzel.* City of Hope, Duarte, CA.

Approximately 5-10% of all pancreatic cancers have a single gene hereditary component. Hereditary pancreatic cancer susceptibility has been associated with familial atypical multiple mole and melanoma syndrome, hereditary breast and ovarian cancer syndrome, Lynch syndrome, Peutz-Jeghers syndrome, von Hippel-Lindau syndrome, hereditary pancreatitis, and *ATM* and *PALB2*-related cancer. Adults with pancreatic cancer of any histology and a germline DNA sample (n= 54), were selected from the Clinical Cancer Genomics Cancer Research Network (CCGCRN) registry. Germline next generation sequencing was completed using a targeted 706 gene capture kit with full exon coverage for candidate (~600 genes), and previously characterized, hereditary cancer susceptibility genes. The majority (70%) of samples sequenced had previously uninformative clinical testing. Five individuals were previously identified to have a pathogenic mutation through clinical testing. Forty-nine research participants were sequenced and analyzed. Results showed 32 American College of Medical Genetics and Genomics pathogenic (P), likely pathogenic (LP), or protein truncating variants of unknown significance in 27 participants. Seventeen out of 54 participants were found to be carriers of a P or LP variant (31% of the sample set). Participants with P or LP variants had a younger mean age of pancreatic cancer diagnosis (53.9 vs 57.2 years, T-test p-value <0.0001). Seventy percent of those with a P or LP variant had a first, second, or third degree family member with cancer (Chi-square p-value <0.0001). Eight out of 54 participants (15%) had pathogenic or likely pathogenic variants in the hereditary breast cancer signaling pathway (*ATM*, *ATR*, *BRCA2*, *FANCA*, *FANCF*, *FANCM*, and *RAD50*; p-value 5.55E-15); all of these participants had adenocarcinomas or presumed adenocarcinomas. This study describes the spectrum of identified pancreatic cancer susceptibility in the CCGCRN registry. Further exploration into germline hereditary pancreatic cancer susceptibility should include evaluation of the hereditary breast cancer signaling pathway, and particularly the Fanconi anemia genes.

Association of high-evidence gastric cancer susceptibility loci and somatic gene expression levels with survival. *H. Sung[1], H. Nan[2], C. Giffin[3], L. Song[1], H. Su[1], C. Wang[1], T. Ding[4], D. Parisi[3], A. Goldstein[1], P. Taylor[1], P. Hyland[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, MD; 2) High-dimension Data Analysis Group, Basic Research Laboratory, Center for Cancer Research, NCI, NIH, Bethesda, MD; 3) Information Management Services, Inc, Calverton, MD; 4) Shanxi Cancer Hospital, Taiyuan, Shanxi, People's Republic China.

Objective: Eleven high-evidence SNPs at nine loci for gastric cancer (GC) risk have been reported, but their association with survival remains unknown. **Design**: SNP associations and hazard ratios for GC survival overall and by anatomic location and histology were examined among 1,147 incident cases from the Shanxi Upper Gastrointestinal Genetics Project. We further examined if SNPs were expression quantitative trait loci (eQTL) in normal and tumor gastric tissues, and whether tumor *versus* normal somatic mRNA differences in126 cases were associated with survival. **Results**: No SNPs were associated with GC survival overall. However, specific associations with survival for: gastric cardia adenocarcinomas (GCA), *MUC1/MTX1/*1q22 rs2070803 (HR$_{\text{AA vs. GA+GG}}$=2.16; 95% CI=1.24-3.78; P_{FDR}=8.4E-02) and *LTA/TNF/*6p21.33 rs1799724 (HR$_{\text{TT+CT vs. CC}}$=1.30; 95% CI=1.07-1.57; P_{FDR}=8.4E-02), and diffuse-type GC, *PSCA/JRK/*8q24.3 rs2294008 (HR$_{\text{TT vs. CT+CC}}$=1.99; 95% CI=1.33-2.97; P_{FDR}=1.3E-02) were observed. Rs2294008T was an eQTL for *PSCA*, upregulating mRNA in normal gastric (beta=0.60; P=5.7E-21) and GC (beta=0.30; P=8.9E-03) tissues. Also, diffuse-type GC cases with the highest *PSCA* mRNA had much shorter survival than cases with the lowest mRNA (median survival of 0.47 years in the highest quartile *versus* 3.73 years in the lowest quartile; HR=9.70; 95% CI=2.46-38.4; P=1.2E-03). Similar, but less striking survival effects were observed for *MTX1* in GCA and for *JRK* in diffuse GC tissues. **Conclusion:** Our results suggest that three high-evidence GC risk loci also have prognostic importance in GC subtypes. Since PSCA protein is also a target for immunotherapy in other cancers, future clinical studies are needed to validate PSCA as a therapeutic target for GC.

2784F

Heritability of aggressive prostate cancer. *C. Tai[1], T.J. Hoffmann[1,2], L.C. Sakoda[3], E. Jorgenson[3], L.A. Habel[3], J. Shan[3], D.K. Ranatunga[3], C.R. Chao[4], N.R. Ghai[4], D. Aaronson[5], J. Presti[5], C. Schaefer[3], N.J. Risch[1,2,3], S.K. Van Den Eeden[3,6], J.S. Witte[1,2,6].* 1) Department of Epidemiology & Biostatistics, UCSF, San Francisco, CA; 2) Institute for Human Genetics, UCSF, San Francisco, CA; 3) Division of Research, Kaiser Permanente Northern Califoria, Oakland, CA; 4) Department of Research and Evaluation, Kaiser Permanente Southern California, Pasadena CA; 5) Department of Urology, Kaiser Oakland Medical Center, Oakland, CA; 6) Department of Urology, UCSF, San Francisco, CA.

Prostate cancer has been documented to be one of the most heritable cancer phenotypes with reported estimates ranging from 0.42 to 0.58. However many known prostate cancer loci are not strongly associated with aggressive prostate cancer phenotypes such as biochemical recurrence or high-grade cancer. Previous efforts have been largely underpowered or not replicated. Therefore, it is unclear whether more aggressive prostate cancer phenotypes are as heritable as overall prostate cancer and whether we can identify SNPs specific for aggressive prostate cancer. Using the Kaiser Permanente Genetic Epidemiology Research on Adult Health and Aging (GERA) cohort, this study aimed to determine how much of the phenotypic variance could be explained with a GWAS panel with 650,000 SNPs in 4,720 cases Non-Hispanic white prostate cancer with Gleason scores, of which recurrence could be determined in 3,583 cases. We evaluated two aggressive phenotype definitions, high-grade disease (Gleason score ≥ 7 or ≥ 8 compared to <7 or <8) and biochemical recurrence (defined separately for radiation and surgery treated cases, and compared to non-recurrent cases). Analyses were adjusted for age, BMI, and ancestry principal components. Heritability was estimated in unrelated individuals based on a pairwise relatedness cutoff of 0.025. We found the heritability for high-grade disease to be 0.09 (SE=0.27) and 0.67 (SE=0.48) for Gleason ≥ 7 and ≥ 8, respectively. The heritability for biochemical recurrence among cases with radiation treatment was 0.17 (SE=0.54). These estimates provide a starting point to identifying SNPs specific for aggressive disease and suggest that aggressive prostate cancer is heritable.

2785W

Role of *GSTM1* and *GSTT1* copy number variations in differentiated thyroid cancer risk in Europeans from metropolitan France and Melanesians from New Caledonia. *C. Tcheandjieu, E. Cordina-Duverger, M. Sanchez, P. Guenel, T. Truong.* CESP-Centre for research in Cancer Epidemiology and Population Health, Cancer Epidemiology: genes and environment, Inserm U1018, Universite Paris Sud, Universite Paris Saclay, Villejuif, France.

GSTM1 and *GSTT1* encode for enzymes that are involved in the detoxification of various compounds including carcinogens. A dose-effect relationship has been reported between copy number variations (CNVs) of these genes and their enzyme activity. In this study, we analyze whether they influenced the risk of differentiated thyroid carcinoma (DTC) and whether they modify the association between DTC risk and lifestyle risk factors including body mass index (BMI), tobacco smoking, alcohol intake and reproductive factors such as age at menarche, oral contraceptive and parity. We analyzed *GSTM1* and *GSTT1* CNVs in 505 cases and 622 controls of European descent and in 156 cases and 114 controls of Melanesian descent from 2 population-based case-control studies conducted in Metropolitan France and in New-Caledonia. Overall, *GSTM1* and *GSTT1* CNVs were not associated with DTC risk. However, the association between DTC risk and BMI and alcohol drinking in both populations were modulated by the presence or the absence of these genes. The OR contrasting BMI≥ 30 and BMI<25 kg/m² was stronger among *GSTT1*-null subjects (OR= 2.17 (95%CI: 0.86–5.47) in Europeans and OR= 7.63 (95%CI: 2.21–27.64) in Melanesians than among those with non-null genotype ((OR 1.25 (95%CI: 0.87–1.81) and 1.30 (95%CI: 0.48-3.54), respectively). This association was even more striking in *GSTM1*-null and *GSTT1*-null subjects with an OR and 95%CI of 4.09 (0.98-17.13) in Europeans and 13.28 (2.79-63.17) in Melanesians. We reported an inverse association between alcohol drinking and DTC risk (OR (95%CI)= 0.71 (0.53–0.94) in Europeans and 0.58 (0.31–1.11) in Melanesians), which was stronger among subjects with *GSTM1*-null, *GSTT1*-null or *GSTM1*-null/*GSTT1*-null genotypes. The ORs and 95%CI comparing ever vs never drinking alcohol in Europeans were 0.50 (0.32–0.76) in *GSTM1*-null subjects; 0.61 (0.29–1.28) in *GSTT1*-null subjects; and 0.28 (0.08–1.02) in *GSTM1/GSTT1*-null subjects; the corresponding ORs in Melanesians were 0.70 (0.37–1.32); 0.36 (0.13–1.04) and 0.24 (0.07–0.81). In Europeans the risk of DTC associated with age at menarche >13 years was stronger in *GSTT1* non-null than in *GSTT1* null genotype (p-interaction=0.02), and the risk of DTC associated with parity was stronger in *GSTT1*-null than in non-null genotype (p-interaction=0.02). Our results suggest a possible modification effect of *GSTM1* and *GSTT1* genotypes in the association between DTC risk and BMI, alcohol consumption and some reproductive factors.

Prediction of years of life after diagnosis of breast cancer using multi-layer omic and clinically relevant covariates: Two studies using METABRIC and TCGA. *A. Vazquez[1], A. Gonzalez[1], Y. Veturi[2], G. de los Campos[1,3].* 1) Epidemiology and Biostatistics, Michigan State University, Lansing, MI; 2) Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL; 3) Department of Statistics and Probability, Michigan State University, East Lansing, MI.

High-throughput technologies provide large volumes of data from multiple 'omics', including the genome, epigenome, transcriptome, proteome, metabolome and other omics. These data hold valuable information for prediction of disease outcomes. However, integrating high-dimensional multi-layer omic data into risk assessment models can be statistically and computationally challenging: inputs are multi-layer and high-dimensional and the underlying biological processes may involve complex interaction patterns between omics (e.g., gene expression by treatment). We describe a statistical framework (BGAM=Bayesian Generalized Additive Model) to incorporate multi-layer omics into disease risk assessment. BGAM integrates into a unified framework, ideas from Generalized Additive Models, Bayesian shrinkage and variable selection methods, and Reproducing Kernel Hilbert Spaces. We used BGAM in two independent datasets, the Molecular Taxonomy of Breast Cancer Consortium (METABRIC, n=1977) and The Cancer Genome Atlas (TCGA, n=285), to predict (three-year) survival after diagnosis of breast cancer. The information used includes clinical covariates (COV) and genome-wide multi-layer omic profiles from the primary tumor, including gene expression (GE), copy number variants (CNV), and for TCGA methylation (MET). GE and MET alone offered more predictive power than any of the commonly used COV including stage and cancer subtype. The best performing models were those combining COV+GE (CV-AUC for these models were 0.797 and 0.721 for METABRIC and TCGA, respectively). COV+MET also achieved high predictive accuracy (0.672 in TCGA). Use of whole-omic profiles gave significantly higher CV-AUC than prediction based on well-known GE of oncogene signatures alone. The improvement in prediction with CNV was low but positive in both data sets. We also found that GE is most predictive for patients in early stage and without nodal metastasis than for late cancers, achieving 5 (to 7) points of increment in CV-AUC beyond COV. We demonstrate in two independent data sets that the use of whole-genome GE and MET profiles can yield substantial gains in prediction accuracy relative to predictions based on commonly used COV or GE from oncogenes. In summary, we believe that for patients in early stage and without nodal metastasis there is great potential and value for the use of whole-genome GE and MET with COV for prediction of breast cancer outcomes.

Variants associated with telomere length give rise to multiple cancer associations. *J.S. Witte, R.E. Graff, J.D. Hoffman.* Epidemiology & Biostatistics, Univ California,San Francisco, San Francisco, CA.

Telomeres are repeating DNA-protein structures that mark the end of chromosomes and extremes of their length have been implicated in cancer risk. Recent genome-wide association studies have identified multiple genetic variants associated with telomere length. Our goal was to evaluate these genetic variants with respect to multiple cancers in the UK Biobank cohort. We combined genome-wide significant variants associated with telomere length into a polygenic risk score (PRS) by weighting each variant by the beta coefficient for its association with telomere length and summing across all variants. We then tested the telomere length PRS against the risk of cancer overall and of 14 individual cancers. Telomere PRS was significantly associated with the diagnosis of one cancer relative to controls with no diagnoses (p = 1.31e-9; beta = 0.324). Telomere PRS was also significantly associated with diagnosis of multiple cancers versus controls with no cancers (p = 2.82e-3; beta = 0.498). Examination of the PRS with respect to individual cancers identified significant associations with kidney cancer (p= 1.68e-3; beta = 1.18), melanoma (p = 2.73e-4; beta 0.615), testicular cancer (p = 0.028; beta = -0.875), and breast cancer (p = 0.043;beta = 0.217). Overall, our results implicate SNPs associated with longer telomere length in the risk of cancer. That the observed beta for the risk of multiple cancers was larger than that for the risk of a single cancer suggests that telomere length may have an impact on susceptibility to developing multiple different cancers. It should also be noted that we found shorter rather than longer telomere length to be associated with testicular cancer risk, highlighting potential differences in the role telomeres may play in the carcinogenesis of specific cancers.

Identifying functional differentially methylated regions in colorectal cancer. *H. Xu, S. Ghosh, V. George.* Dept Biostatistics & Epidemiology, Augusta University, Augusta, GA.

DNA methylation is critical in the regulation of gene expression and abnormality in DNA methylation has been involved in my human diseases, especially cancers. Substantial efforts have been put into identifying differentially methylated regions (DMRs) between disease and normal samples. However, due to the limited sample size, the large number of CpG sites, and the complexity in gene regulation, many of the resulting DMRs may not be functional in terms of regulating gene expression. As more data with both gene expression and DNA methylation are available, we propose an integrated approach to identify functional differentially methylated regions (fDMRs) based on meta-analysis that combines evidence from both types of genomic data. We evaluated our method through simulation studies. Results from simulation study showed that our integrated approach had well control of type-I error rate. It had improved power compared with the sequential analysis approach. We applied our data to the DNA methylation and gene expression data on colorectal cancer from the Cancer Genome Atlas and identified several fDMRs.

Integration of multi-omic layers for estimation and prediction of genetic variation in glioblastoma multiforme. *Y.L. Bernal Rubio[1], K.H. Wu[1], C. Griguer[2], J.P. Steibel[3,4], A. Gonzalez Reymundez[1], G. de los Campos[1,5], A.I. Vazquez[1].* 1) Department of Epidemiology and Biostatistics, Michigan State University, East Lansing, MI; 2) Department of Neurosurgery, University of Alabama at Birmingham, Birmingham, AL; 3) Department of Animal Science, Michigan State University, East Lansing, MI; 4) Department of Fisheries and Wildlife, Michigan State University, East Lansing, MI; 5) Department of Statistics, Michigan State University, East Lansing, MI.

Glioblastoma multiforme (GBM) is the highest grade and the most malignant form of an astrocytoma tumor (grade IV), which is characterized for being the most common and lethal primary brain tumor. Although standard treatments for GBM patients have improved, the targeting of treatments remains a challenge and patient survival is still very low. The availability of high throughput multi-omic data has opened new research opportunities that can lead to a better understanding of the genetic architecture of GBM and the factors that determine survival of GBM patients. This information could be used to identify genetic signatures that are predictive of survival and response to treatment. In this study we used survival data, clinical information and multi-omic profiles from GBM patients provided by TCGA consortium (n = 476). Censoring rate was 24.5% and, among uncensored observations, 53.5% of the records had time to death lower or equal than one year. Clinical covariates (CLIN) included: age at diagnosis, race, gender, pathological diagnosis method, Karnofsky performance score (KPS) and treatments, which were coded as chemotherapy Yes/No and using dummy variables that indicated the use of 18 different drugs (TRT). Omic information included gene expression profiles (GE, assessed at the tumor using RNA-seq), SNP genotypes (SNP) and methylation β-values (METH). We used Bayesian mixed models to estimate the proportion of variance explained by CLIN and omic profiles. Prediction accuracy of each of the models was assessed using cross-validations (CV) area under the ROC curve (AUC). AGE, KPS and CHEMO had significant ($p<0.05$) effects on survival, with AGE having the lowest p-value (4.1e-10) and largest effect among the CLIN covariates used. Among the omics, METH was the one that explained the largest fraction of variance in survival (23.4%, when considered simultaneously with CLIN, TRT, GE and SNP in a bayesian mixed model). Although TRT did not explain a very large fraction of variance of survival time, in CV TRT improved prediction of short term survival. For long term survival, METH had higher AUC than GE and SNP. A principal component analysis showed a differentiation in METH according to age at diagnosis, suggesting a possible effect of the age on methylation β-values and a concomitant effect of METH on survival of GBM patients.

2790F

Network analysis facilitates the prediction of ovarian cancer progression. *U. Ozbek[1], C. Conley[3], J. Peng[3], P. Wang[2].* 1) Department of Population Health Sciences and Policy, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Department of Statistics, University of California, Davis, CA.

Ovarian cancer is the fifth leading cause of cancer death. It's estimated that there will be 22,280 new cases and 14,420 deaths of ovarian cancer in the US in 2016. To improve the treatment of ovarian cancer patients, it is of great importance to accurately predict patients' disease progression. In this study, our goal is to use network analysis to derive genomic signatures useful to predict the progression of ovarian cancer. We hypothesize that hub genes in gene regulatory network play important roles in shaping the cell phenotypes and are particularly useful for predicting patients' disease progression. To test this hypothesis, we first construct a regulatory network among DNA copy number alterations (CNA) and RNA expressions based on 293 ovarian cancer genomic profiles from The Cancer Genome Atlas using our newly developed novel statistical tool, SpaceMap. This new tool derives conditional dependence relationships among DNA copy number alterations and the RNA expression levels using a set of multivariate linear regressions with novel penalty terms to incorporate the network structures. Based on the inferred regulatory network, we identify a collection of hub genes that are influenced directly by CNA and are interacting with a large number of other genes. We then evaluate the prediction power of these hub genes for patient survival outcome and find these hub genes are in general more information than other non-hub genes. We expect such a strategy could lead to better prediction models for disease outcome in clinical practice. The candidate hub genes could also lead to novel drug targets to improve the patient disease outcome.

Methods for fine-mapping with chromatin and expression population data. *M. Roytman[1], G. Kichaev[1], B. Pasaniuc[1,2,3].* 1) Bioinformatics IDP, UCLA, Los Angeles California, USA; 2) Department of Pathology and Laboratory Medicine, UCLA, Los Angeles California, USA; 3) Department of Human Genetics, Geffen School of Medicine, UCLA, Los Angeles California, USA.

Discerning the genetic basis of complex traits is a fundamental problem in biology. Genome-wide association studies (GWAS) have revealed that the majority of variants associated with disease lie in noncoding regulatory sequences. However, the primary mechanisms by which these variants act are poorly understood. One proposed mechanism is that regulatory variants may affect histone modifications in local regions which in turn have downstream effects on transcription. Recent studies have identified thousands of QTLs associated with local and distal histone modifications. In addition, chromatin states defined by histone marks are known to associate with functional elements and changes in gene regulation. However, this proposed chain of causality has yet to be established. In this project we present a statistical framework designed to detect such interactions in the genome. Given a locus centered around a gene, containing potentially thousands of SNPs and hundreds of chromatin peaks, our method uses a joint likelihood model to assign posterior probabilities to each possible causal path through this architecture. In simulations we show that our integrative method outperforms the naïve approach, whereby the effects of SNPs on chromatin and of chromatin on expression are fine-mapped independently and posteriors are multiplied together, reducing the size of the 90% credible set from 52 paths to 11 paths. Thus, by integrating three levels of data - genomic, chromatin, and expression - into one probabilistic model, our method improves our ability to detect the genomic variants influencing gene expression as well as the chromatin peaks through which they act.

2792T

Identification of breast cancer subtype-specific DNA methylation signatures using both mean and variance signals. *Y. Wang, S. Wang.* Department of Biostatistics, Mailman School of Public Health Columbia University, New York, New York, USA.

DNA methylation plays an important role in gene expression and cancer progression. Studies have found that DNA methylation levels between different cancer subgroups could differ not only in means but also in variances. We recently proposed a semiparametric test based on exponential tilt model (ETM) to detect both mean and variance differences in case-control designs. Elastic-net is a widely used variable selection method in the analysis of high dimensional DNA methylation data where neighboring CpG sites are highly correlated. Here, we extend on the ETM method that considers both mean and variance signals and add the elastic-net regularization that encourages a grouping effect of highly correlated methylation sites. We analyzed four subtypes of the breast invasive carcinoma (BRCA) Illumina HM450K DNA methylation data of 187 tumor samples and 59 normal samples from The Cancer Genome Atlas (TCGA) project, and identified subtype-specific DNA methylation loci for Luminal-A (LumA), Luminal-B (LumB), basal-like (Basal) and human epidermal growth factor receptor 2 (HER2) subtypes, respectively. The combined signal approach identified additional CpG sites that were missed when using mean signal only. Among the candidate genes identified by variance signal only in LumA, LumB, Basal and HER2 subtypes, many of them have also been reported to be differentially methylated in other cancers. Hence, the inclusion of variance signal in addition to the mean signal helps to achieve a better discrimination in breast cancer subtypes.

2793F

A novel region-based bayesian approach for genetic association with Next Generation Sequencing (NGS) data. *J. Xu[1,2], W. Xu[1,3], H. Massam[4], M. Escobar[1], L. Briollais[1,2].* 1) Dalla Lana School of public Health, University of Toronto, Ontario, Canada; 2) Lunenfeld-Tanenbaum Research Institute, Sinai Health System, Toronto, Ontario, Canada; 3) Princess Margaret Cancer Center, University Health Network, Toronto, Ontario, Canada; 4) Department of Mathematics and Statistics, York University, Toronto, Ontario, Canada.

The discovery of rare variants through sequencing studies is becoming a very challenging issue in the field of human genetics and could help deciphering the genetic basis of many complex human diseases. Because rare variants occur too infrequently in the general population, single-variant association tests lack power in NGS analyses. We proposed here a novel region-based statistic based on a Bayes Factor (BF) approach to assess the evidence of association between a set of rare variants located in same chromosomal region and a disease outcome. Marginal likelihood functions are computed under the null and alternative hypotheses assuming a binomial distribution for the rare variants count in the region and either a beta prior distribution or a mixture of Dirac and beta distributions for the probability of observing a rare variant at a specific locus. The hyper-parameters for the prior specification are determined empirically from the data. A permutation test is used to assess the distribution of the BF under the null hypothesis of no association. Our simulations studies showed that the new BF statistic outperforms popular methods such as the Burden test and SKAT (Sequence Kernel Association Test) under most situations. Our real application to a study of lung cancer from Toronto including 258 cases and 257 matched controls suggests interesting genes such as CHEK2 associated with the cancer outcome. Sensitivity analyses and further developments of the BF approach to multi-region NGS analysis will also be discussed.

2794W

Comparison and easy implementation of methods for cosegregation analysis. *J.M.O. Ranola[1], E.A. Rosenthal[2], Q. Liu[3], B.H. Shirts[1]*. 1) Laboratory Medicine , University of Washington, Seattle, WA; 2) Medical Genetics, Medicine, University of Washington, Seattle, WA; 3) Engineering, University of Washington, Seattle, WA.

Cosegregation analysis provides crucial information in evaluating the pathogenicity of variants of unknown significance in known pathogenic genes. However, proper cosegregation analysis has required training in the correct use of available software. Genetics professionals without such training often get around this hurdle by using less robust methods, which usually consider only affected carriers.   We compared two robust methods, full-likelihood Bayes factors (FLB)(Thompson et al 2003) and co-segregation likelihood ratios (CSLR) (Mohammadi et al 2009), with the simpler method of counting meioses. The two robust methods rely on similar underlying statistical models, but allow somewhat different assumptions of variant frequency, use different methods to define penetrance, and handle age of onset in different ways. We compared all three methods using 2742 simulated 3-generation pedigrees with pathogenic or benign variants in *BRCA1* or *MLH1*. We show that CLSR and FLB methods generated median likelihood ratios (LR) of 1.31 and 1.18 for pathogenic *BRCA1* variants, respectively, with ~1% having relatively strong evidence for pathogenicity (LR > 1.3) for both methods. CSLR and FLB methods generated median LR of 0.93 and 0.88 for benign *BRCA1* variants respectively, with ~2% having strong evidence against pathogenicity (LR < -1.3) for both methods. Meiosis counting generated a median Bayes factor of 1 for both pathogenic and benign variants, with Bayes factor >1 for 20% of pathogenic and 1% of benign *BRCA1* variants. CSLR generates results that are generally 10% higher than FLB results for all *BRCA1* variants. We found similar results for simulated pedigrees with pathogenic and benign *MLH1* variants . In classifying benign variants, only CSLR and FLB methods are able to quantify the evidence against pathogenicity. Both CSLR and FLB methods perform better with larger families for both pathogenic and benign variants. Meiosis counting performs worse with larger family size for benign variants.   To facilitate the use of more robust cosegregation analysis methods we present a web tool (analyze.myvariant.org) for the calculation of FLB using FASTLINK backend calculations, which can be used for large pedigrees (N<600). We also present the CoSeg R package, available at R-forge, which can be used to simulate pedigrees using demographic parameters, implement the CSLR method, and count meioses in small to medium sized pedigrees (N<50).

2795T

Single nucleotide polymorphisms of multidrug resistance gene 1 *(MDR1)* **and risk of chronic myeloid leukemia.** *Y. Kassogue[1,2], H. Dehbi[2], M. Quachouh[3], A. Quessar[3], S. Benchekroun[3], S. Nadifi[3]*. 1) University of Sciences, techniques and Technologiques of Bamako, Bamako, Mali; 2) Genetics and Molecular Pathology Laboratory, Medical school of Casablanca, University Hassan II, Morocco; 3) Department of Onco-Hematology, Ibn Rochd University Hospital, Casablanca, Morocco.

Abstract Multi-Drug résistance gene 1 (*MDR1*) is known for its involvement in the detoxification through the active transport of toxic compounds from diverse origins outside the cells. These compounds could cause injury to cell DNA, which might lead in cancer like chronic myeloid leukemia (CML). Individual inherited genetic differences related to polymorphism in detoxification enzymes could be an important factor not only in carcinogen metabolism but also in susceptibility of cancer. The present study aimed to investigate the association of three single nucleotide polymorphisms (SNPs) of the *MDR1* gene in the susceptibility of CML. We successively have determined the genotype profiles of 1236C→T (exon 12); 2677G→T (exon 21) and 3435C→T (exon 26) SNPs by PCR-RFLP in 88 patients and 99 unrelated healthy controls. Logistic regression was used to assess the effect of each SNP on the development of CML. Interestingly, in exon 12 the 1236TT was significantly associated with the susceptibility of CML when compared to the wild type 1236CC (OR: 2.7; 95% CI: 1-7.32, p = 0.041). Additionally, the recessive model 1236TT vs. 1236CC/CT showed a risk of 3.3 fold (p = 0.011) with CML. In exon 26, the 3435CT genotype was associated with a reduced risk of CML (OR: 0.5; 95% CI: 0.3-1, p = 0.042). In exon 21, the 2677GT genotype seems to have a protective effect (OR: 0.6; 95% CI: 0.32-1.1, p = 0.074). Diplotype analysis has demonstrated no effect in susceptibility of CML, but 1236CT/3435CC and 1236CC/2677GT were associated with a protective effect. The haplotypes analysis showed no particular trend (global association p = 0.33). Our findings demonstrate that 1236TT in exon 12 might contribute in the susceptibility of CML, while the 3435CT in exon 26 as well as 1236CT/3435CC and 1236CC/2677GT combinations might be protective factors. **Keywords:** *MDR1* gene; Polymorphism; Haplotype, CML.

Genome-wide gene x smoking interaction analysis in lung adenocarcinoma. *Y. Li, X. Xiao, Y. Han, D. Qian, C. Amos.* Biomedical Data Science Department, Dartmouth College, Hanover, NH.

Purpose: Genome-wide association studies (GWAS) have successfully identified multiple genetic susceptibility genes associated with lung cancer but they only explain limited proportion of the heritability of lung cancer. Smoking is an important environmental risk factor associated with lung cancer and the interactions between smoking and genes have been suggested to play an important role in lung carcinogenesis. Our study is a genome-wide interaction analysis aiming to reveal smoking-gene interactions not identified in GWAS. Methods: The discovery data on 409398 SNPs came from four subset data-sets with a total of 20891 individuals with Caucasian ancestry including 13910 controls and 6981 patients with lung adenocarcinoma. A logistic regression model was used to test the interaction between additive SNP genotype and binary smoking status adjusting for the first three principal components. Potential signals were validated using independent genotype data from 3160 individuals including 2223 controls and 937 cases. Interaction analysis using imputed genotype at the candidate region was used as additional validation. Results: six significant SNPs with p value less than 0.1 from each subset analysis and less than 3.16×10^{-5} from analysis using all the data were detected at gene ZC3H11A/ZBED6 on chromosome 1 in discovery study. And the most significant SNP rs7540041 had a p value of 4.74×10^{-6} in analysis using all the discovery data (p values for subset 1-4: 2.69×10^{-2}, 4.05×10^{-3}, 5.63×10^{-2} and 1.83×10^{-2}, Odds Ratio varied from 1.47 to 1.97). The validation study produced p value of 0.071(OR=1.57) and 0.059 (OR=1.89) at top SNP rs7552670 and rs7540041, respectively. Imputation analysis further identified additional 28 significant SNPs at ZC3H11A/ZBED6 gene. When we combined both discovery and replication data sets, the p values at these two SNPs were 8.46×10^{-7} and 2.44×10^{-7}, respectively; the estimated interaction ORs were 1.49 (95% CI: (1.27, 1.74)) and 1.59 (95% CI: (1.33, 1.89)) at rs7552670 and rs7540041, respectively. The association analysis stratified by smoking status showed that rs7552670 and rs7540041 were protective factor (OR=0.78 and 0.73, respectively) for lung cancer in nonsmokers and risk factor (OD=1.16 for both of the two SNPs) in smokers. All the results in our study suggest the interaction between ZC3H11A/ZBED6 gene and smoking status in lung adenocarcinoma development.

Genetic factors play an important role in the etiology of Colorectal Cancer (CRC), with an estimated 12-35% of CRC risk being explained by heritable factors. Recently, genome-wide association studies (GWAS) have successfully discovered over 50 common variant loci with weak to moderate effects on CRC risk. These genetic factors in aggregate explain only a small fraction of familial risk of CRC, suggesting that a large fraction of risk loci have not yet been identified. Given that most of the reported CRC risk loci are located in noncoding regions we hypothesized that additional common variant risk loci are likely to exert weak effects on CRC risk through cis-regulation of gene expression. We performed a gene-level association test using the recently published method PrediXcan, which uses transcriptome regulation data to characterize tissue-specific variant function. Prediction models were developed for mRNA levels in 169 transverse and 124 sigmoid colon transcriptomes using data from the GTEx project. Predicted expression in 15,506 cases and 13,079 controls from GECCO-CCFR were tested for association with CRC in up to 11,996 genes. In total, 20 genes, representing 12 unique loci, showed statistically significant CRC association at the false discovery rate = 0.2. We identified six novel loci at 2q35, 7q22.1, 12q24.13, 16q24.3, 17p11.2, 19p13.11. These results implicate both known genes/pathways (Wnt signaling, DNA repair), as well as new genes in biologically relevant pathways (e.g. chemokine receptors and MTOR signaling). If replicated, these novel findings provide new biological insight into CRC pathogenicity.

HERVnGoSeq: Identifying and mapping unfixed HERV elements in the genome and application in cancer genomics. *S.S. Francis[1,2], A.D. Wallace[2], J.A. Wendt[3], L.F. Barcellos[3], J.F. Costello[2], M.R. Wrench[2], J.L. Wiemels[2].* 1) Epidemiology , University of California, San Francisco, San Francisco , CA; 2) University of Nevada, Reno; 3) University of California, Berkeley.

   Objectives: Approximately 8% of the human genome is comprised of viral DNA. Human endogenous retroviruses (HERV) are expressed in a variety of cancers including glioblastoma (GBM). The totality of the genomic effects of HERV insertions is not fully understood. However, human and non-human studies show that ERVs have exerted strong evolutionary pressure. We seek to understand the diversity of HERV insertions in humans and to assess their role in complex diseases including cancer. **Methods:** We initiated a large-scale bioinformatics screen of HERVs in the complete 1000 Genomes dataset of 2557 whole genome (WGS) samples from individuals worldwide as baseline and The Cancer Genome Atlas (TCGA) GBM subjects n=52tumor/52 normal. We developed a custom bioinformatic pipeline for detecting HERV insertions, HERVnGoSeq, which uses a 2-stage approach, wherein the first stage nominates HERV LTR chimeric reads that mark the integration point into the genome and maps locations. The second phase of creates synthetic sequences of all insertion points (novel and those in hg19) for re-screening of raw reads. HERVnGoSeq was performed on Amazon's Elastic Computing Cloud. To map additional putative HERV integrations sites a novel GWAS based mapping approach was conducted to identify genomic positions. **Results:** The analysis was designed to detect all HERVs, yet only HERV-K was variable between humans. We identified 1788 putative HERV-K insertion sites across 2557 genomes, including 251 that are not represented in the reference genome. Many of these novel insertions were not mappable by sequence homology yet we successfully mapped >67 previously unreported sites to genomic coordinates using a novel GWAS based approach to identify SNPs associated with given insertions. We observed no HERV-K differences between TCGA GBM germ-line and tumor samples. Hierarchical clustering of TCGA GBM subjects revealed two distinct groups based solely on HERV insertions; the two groups differed significantly by age at diagnosis (mean age= 55.4, 64.2 years p=0.001) independent of ancestry. **Conclusion:** We discovered heterogeneous HERV-K insertions within and between diverse human populations where we mapped >67 previously unreported HERV-K insertions to genomic coordinates. In the TCGA GBM data, we show that two groups of GBM cases based on variable HERV-K insertions had significantly different ages at diagnosis. Further investigation of HERV-K as a germ-line risk factor for GBM is warranted.

The *R* package genMOSS for Genome-wide Association Studies (GWAS). *L. Briollais.* Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.

   The analysis of GWAS data has long been restricted to simple models that cannot fully capture the genetic architecture of complex human diseases. As a shift from standard approaches, we present here the *R* package genMOSS that implements a Bayesian graphical model approach and stochastic search algorithm for multi-SNP analysis from GWAS data. This approach is applicable to a wide range of genetic association problems, including GWAS, fine-mapping studies and SNP-SNP interaction analyses. More specifically, genMOSS is able to: 1) Assess the joint effect of multiple SNPs that can be linked or unlinked and interact or not; 2) Explore the multi-SNP model space efficiently using the Mode Oriented Stochastic Search (MOSS) algorithm and determine the best models. 3) Include prior information on SNPs to enhance the detection of genetic associations. We illustrate the *R* package through several applications to cancer genetic studies including GWAS, fine mapping studies and gene network analysis.

2800W

Identifying potentially significant causative chromosomal regions from GWAS data. *R.T. Relator, J. Sese.* Artificial Intelligence Research Center, National Institute of Advanced Industrial Science and Technology, Tokyo, Japan.

The goal of genome-wide association studies is to find chromosomal positions associated with common, complex diseases. Conventional association tests include single locus analysis, focusing on identifying important mutations related to the disease by assessing them individually. However, especially for common diseases, many non-significant small peaks often appear, and no causative mutations could be found. Here we focus on identifying potential causative "regions" in diseases, which would be overlooked when variants are considered individually. We propose a chromosomal sweeping approach for using the Limitless Arity Multiple-testing Procedure (LAMP). We divide chromosomes into sub-regions while taking into consideration linkage disequilibrium information, and focus on each region for analysis. By doing this, we can exploit all SNP combinations for assessment without sacrificing computational cost or statistical value since LAMP can handle any combinations of SNPs and is known to be less conservative in controlling the family-wise error rate than the usual multiple testing procedures such as Bonferroni correction. We applied our method to postmenopausal breast cancer GWAS data [Nat Genet. 2007 Jul; 39(7):870-4], including 2,287 subjects and around 550,000 SNPs. While the paper identified the importance of the mutations around the FGFR2 gene in chromosome 10 for the disease, our method also detected a wide area in the HLA region in chromosome 6 to have a high relationship to this cancer type. Our technique may contribute to identifying new regions that are possibly relevant to diseases by re-analysis of existing GWAS datasets.

Kenny[2].* 1) Genetics, Stanford University, Stanford, CA, CA; 2) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York NY; 3) Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle WA; 4) Department of Structural Biology, Stanford University School of Medicine, Stanford CA; 5) Division of Nephrology, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York NY; 6) Department of Epidemiology, University of North Carolina, Chapel Hill NC; 7) Department of Statistics & Biostatistics, Rutgers University, New Brunswick NJ; 8) Department of Genetics, Rutgers University, New Brunswick NJ; 9) Division of Genomic Medicine, NHGRI, NIH, Bethesda MD; 10) Division of Clinical Research & Data Management, NIMHD, NIH, Bethesda MD; 11) Department of Preventive Medicine, University of Southern California Keck School of Medicine, Los Angeles CA.

During the past decade, major advances in genomics have resulted in the identification of more than 6,000 genetic disorders. However, implementing these findings into clinical care poses a difficult challenge. Vast quantities of rare variants in human populations make questions of causality, penetrance, and expressivity for any particular variant difficult to ascertain. This problem is compounded by theory and observations from population genetics that rare variants are typically population-restricted. Therefore, the characterization of clinically relevant variants (CRVs) in multi-ethnic cohorts is a critical step in advancing global precision medicine efforts. To address this gap in knowledge, the PAGE Study was formed as a multi-center collaboration, to characterize trait-associated genetic variation in ancestrally diverse populations within the United States. Through PAGE-II, we genotyped over 50,000 individuals with ancestry from more than 100 global populations, linked to deep phenotypic data, including diagnostic and procedural codes, radiologic, labs, epidemiologic and disease data. Using the newly-designed Illumina Infinium Multi-Ethnic Genotyping Array (MEGA) including tens of thousands of CRVs, we report population-stratified frequencies for pathogenic variants of ACMG- and pharmacogenomics-prioritized genes, including *BRCA1/2, TP53, PTEN*, and *CFTR*. These include 1,736 ClinVar-annotated pathogenic variants observed more than once in PAGE, and either not found, or monomorphic, in the Exome Aggregation Consortium (ExAC) browser. We observe 27 variants in *BRCA1*, 40 variants in *BRCA2*, and 67 variants in *CFTR*, all of which are annotated as pathogenic in ClinVar and segregating in the PAGE-II populations above a singleton threshold. Additionally, we identify 167 ClinVar-pathogenic alleles at a frequency above 5% in at least one population. We expect the outcome of this work to enable genomic interpretation, assess resources for defining pathogenicity, including ClinVar, ACMG, PharmGKB, and influence current practices around incidental findings and return of genetic findings to study participants. Population-specific allele frequencies of CRVs will ultimately be incorporated into the NHGRI-sponsored PAGE, ClinVar and ClinGen initiatives. Screens of CRVs such as in PAGE provide needed insight into the segregation of variants contributing to clinical conditions worldwide.

Simultaneous genetic regulatory networks inference and genomic hub identification through conditional graphical models. *C.J. Conley[1], P. Wang[2], J. Peng[1].* 1) Statistics, University of California, Davis, CA; 2) Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY.

Models for integrative genomics applications face diverse challenges such as data heterogeneity and limits on scaling dimensionality, computation, and biological interpretation. All these challenges are present while learning genetic regulatory networks from RNA expression data or protein expression data and simultaneously identifying which DNA copy number alterations perturb these networks. For this purpose we developed a sparse conditional graphical model (CG model), called Spacemap, which integrates a response data type (e.g. RNA/protein expression) and a predictor data type (e.g. DNA copy number alterations) through a penalized multivariate regression framework. Specifically, Spacemap infers an undirected network among response nodes in tandem with a directed graph encoding how predictor nodes perturb the responses. Thus, Spacemap predicts the cis- and trans- regulatory structure of genomic perturbations on a response network and points to genomic hubs driving the responses. Spacemap also scales in dimensionality to infer networks with a few thousand of nodes. In a simulation study, Spacemap is shown to improve power in network inference over models where the two types of nodes are not differentiated as well as a likelihood-based CG model. We apply Spacemap to characterize gene regulatory patterns among RNAs and proteins conditioned on DNA copy number alterations using RNAseq and deep protein profiling data of 77 breast cancer tumors from the TCGA-CPTAC studies . In both the inferred mRNA and protein co-expression networks, many known cancer genes involved in cell cycle were found to be directly perturbed by DNA copy number alterations. Specifically, the copy number alterations of a genome region in 5q34 was found to influence a large number of RNAs and proteins in these tumors. Results from this analysis cast new light on the gene regulatory mechanisms in breast cancer.

SlopeCCA — Sparse CCA with false discovery rate control. *A. Gossmann[1], Y.-P. Wang[2].* 1) Mathematics, Tulane University, New Orleans, LA; 2) Biomedical Engineering, Tulane University, New Orleans, LA.

Canonical correlation analysis (CCA) is a classical statistical technique, which is used to make sense of the cross-correlation of two sets of measurements collected on the same set of samples (e.g., two genomic assays for the same set of cancer cells, or fMRI imaging and DNA sequencing data for the same mental illness patients). More precisely, given two sets of random variables, CCA identifies linear combinations of each, which have maximum correlation with each other. Like many classical statistical techniques, CCA fails in high-dimensional settings, when the number of variables in either of the two cross-correlated datasets strictly exceeds the number of samples. To counteract this issue, several methods for sparse canonical correlation analysis (sparse CCA) have been proposed, where sparse linear combinations of variables from the two datasets are identified to maximize the correlation. However, commonly used sparse CCA methods determine the level of sparsity of the canonical vectors either based on criteria of model fit (danger of overfitting), or according to a preconceived sparsity level (questionable validity). Motivated by Sorted L1 Penalized Estimation (SLOPE), a sparse regression method that offers false discovery rate (FDR) control, we propose a definition of FDR for the canonical vectors, and a sorted l1 penalized CCA (slopeCCA) method. We prove that under certain conditions our method keeps the FDR of the canonical vectors below a user-specified target level. Additionally, FDR control is shown in other less restrictive settings via a simulation study. To our knowledge, this is the first attempt to provably control FDR in a sparse CCA model. As a demonstration of slopeCCA on real genomic data, we apply the method to data from The Cancer Genome Atlas (TCGA), in order to identify significant relationships between gene expressions and miRNA levels on Glioblastoma Multiforme tumor samples.

2804T

Genetic ancestry affects the predictive power of PRS in Latinas. *S.D. Sawyer[1], L. Fejerman[1], E. John[2], L. Kushi[3], G. Torres-Majia[4], D. Hu[1], S. Huntsman[1], C. Haiman[5], E. Ziv[1].* 1) Medicine, University of California, San Francisco, CA., United States; 2) Cancer Prevention Institute of California, Fremont, CA, United States; 3) Kaiser Permanente Northern California, Oakland, CA, United States; 4) Instituto Nacional de Salud Pública, Cuernavaca, Mexico; 5) University of Southern California, Los Angeles, CA, United States.

   Introduction: Genome-wide association studies (GWAS) have identified >90 single nucleotide polymorphisms (SNPs). Individually, these SNPs are weak predictors of breast cancer, but when combined in a polygenic risk score (PRS) they may be useful to identify high risk women whom would benefit from more aggressive screening and prevention. GWAS for breast cancer were mostly conducted in Europeans and PRS based on these results may not perform as well in other populations. We sought to examine and optimize the predictive performance of PRS for breast cancer in Latinas. **METHODS:** We used data from 1679 Latina breast cancer cases and 5743 controls from four studies: San Francisco Bay Area Cancer Study, Northern California Breast Cancer Family Registry, Kaiser Permanente Research Program on Genes, Environment and Heath, Mexico Breast Cancer Study and Health Multiethnic Cohort. Samples were typed on genome-wide SNP arrays and imputed. We included 103 SNPs previously associated with breast cancer ($p < 5 \times 10^{-8}$) in at least one population. The PRS was calculated using a log-additive model. We developed PRS's using both published odds ratios (ORs) and refitting ORs in our own data. Discrimination for each PRS was measured by receiver operating characteristic area under the curve (AUC). **RESULTS:** The PRS based on 75 SNPs (PRS75) using published ORs was significantly associated with breast cancer in Latinas ($p = 2.2 \times 10^{-26}$) and had an AUC of 0.584 (95% CI 0.569-0.600), which was lower than a published AUC of 0.615 in a European study (Mavaddat et al JNCI 2015). An expanded PRS of 103 SNPs (PRS103) using published ORs did not improve the AUC=0.593 (95% CI 0.578-0.608). PRS75 performed better (p=0.035) among Latinas in the high quartile of European Ancestry (AUC=0.611, 95% CI 0.532-0.592) compared to Latinas in the lowest quartile of European (and higher Indigenous American) ancestry (AUC=0.562, 95% CI 0.532-0.592). Next we developed a PRS with the same SNPs, refitting the ORs for Latinas. We calculated the ORs in a training subset (2/3) of our data, and tested the PRS using those ORs in a validation subset (1/3). The discrimination of PRS75 using Latina ORs was AUC=0.585 (95% CI 0.559-0.612) and extended PRS103 was AUC=0.595 (95% CI 0.568-0.621). **CONCLUSION:** PRS using published OR's performs better in Latinas with higher European ancestry. Fine mapping may boost the predictive power of the PRS in Latinas. Results will be used in a trial of breast cancer screening in California.

A spectrum of common and rare germ-line variation in a group of Puerto Rican women with double and triple negative tumors. *H. Diaz-Zabala[1], N. Arroyo[1], W. Luo[2], M. Dean[2], J. Matta[1], J. Dutil[1].* 1) Ponce Health Sciences University - School of Medicine, Ponce, PR; 2) Laboratory of Translational Genomics, National Cancer Institute, Frederick, MD, USA.

   Introduction: Germ-line variants are known to predispose to sporadic and inherited forms of breast cancer. Rare and common germ-line variants can modify breast cancer risk with different effect sizes and may be the basis to explain susceptibility to molecular subtypes of breast cancer. **Objective:** This study aims to identify the proportion of rare and common germ-line variants that are present in a group of breast cancer cases with triple and double negative tumors. **Methods:** Targeted sequencing with an Ion AmpliSeqä Cancer Hotspot Panel was used to genotype germ-line variants in a group of 52 Puerto Rican breast cancer cases with confirmed triple and double negative pathology reports. Germ-line variant discovery from amplicons was performed using GATK Haplotype Caller. Variant annotation and functional prediction in protein sequence was performed using Golden Helix SNP & Variation Suite (SVS) package. **Results:** A total of 668 germ-line variants was detected in 52 triple and double negative breast cancer cases. Most identified variants were intronic, synonymous and rare with allelic frequencies <1.5% in the general population. Rare variants with damaging effects in protein sequence were identified in *ATM*, *CDKN2A*, *MET*, *EGFR* and *APC*. **Conclusion:** In this study, we identified a spectrum of rare and common germ-line variants in a group of Puerto Rican breast cancer cases with triple and double negative tumors. Predisposition effects of these germ-line mutations need to be addressed in future studies.

Rodriguez[8], M. Cruz-Correa[9], I. Komenaka[10], P. Ashton-Prolla[11], B. Alemar[11], J.N. Weitzel[1]. 1) Clinical Cancer Genetics - Laboratory, City of Hope, Beckman Research Institute, Duarte, California, USA; 2) Departamento de Investigacion y de Tumores Mamarios del Instituto Nacional de Cancerologia, México City, México; 3) Centro de Cancer de Mama del Hospital Zambrano Hellion, Tecnologico de Monterrey, San Pedro Garza Garcia, Nuevo Leon, México; 4) Unidad de Genómica y Secuenciación Masiva, Subdirección de Investigación Básica, Instituto Nacional de Cancerología, México City, México; 5) Instituto Nacional de Cancerología, División de Investigación, México Universidad de Guadalajara, Instituto de Génetica Humana, México; 6) Departamento de Mamas, Partes Blandas y Piel, Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru; 7) Departamento de Fisiología, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Jalisco, México; 8) Centro de Oncologia, Clínica del Country, Bogotá, Colombia; 9) Division of Gastrointestinal Oncology, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico; 10) Department of Surgery, Maricopa Medical Center, Phoenix, Arizona; Arizona Cancer Center, University of Arizona, Tucson, Arizona, USA; 11) Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.

    Germline mutations in the *BRCA1* or *BRCA2* (*BRCA*) gene predispose to an increased lifetime risk of breast and ovarian cancer. In Latin America the prevalence and contribution of *BRCA* mutations to the overall cancer burden is not well understood. This is primarily due to limited access to genetic cancer risk assessment (GCRA) and testing. To address this disparity we have implemented an efficient, cost-effective testing strategy for at risk individuals. Utilizing a combination of Sequenom MassARRAY technology, Ion Torrent semiconductor sequencing, and PCR-based methodologies for copy number variation (CNV) detection, 1,489 individuals have been screened by our laboratory to date. Patients were prospectively accrued from Mexico (Mexico City and Guadalajara), Peru (Lima), Colombia (Bogota), Puerto Rico, and Arizona (Maricopa). A retrospective cohort (n = 66) from Brazil (Porto Alegre) was also included. The overall mutation rate was ~13%. Primary screening with a high-frequency Hispanic mutation Panel (*HISPANEL*) on the Sequenom MassARRAY platform, combined with a 3-primer PCR assay (3-PA) for the recurrent *BRCA1* exon9-12del CNV, yielded ~55% of overall positives (~61% in Mexico) at an estimated cost of ~$20 per case. *HISPANEL* negative cases were fully sequenced for *BRCA* on the Ion Torrent PGM platform, using a commercially available Community Panel pilot tested by our laboratory for the AmpliSeq *BRCA* Global Consortium. *BRCA* sequencing yielded ~35% of all positives at an additional cost of ~$80 per case (materials only). Positive cases were confirmed by Sanger sequencing. Sequence negative cases were further evaluated by Multiplex Ligation-dependent Probe Amplification (MLPA) for *BRCA1* CNVs, at a cost of ~$25 per case. The *BRCA2* gene was not evaluated by MLPA due to the rarity of CNVs in this gene relative to *BRCA1*. CNVs represented ~25% of all positives, with the Mexican founder mutation, *BRCA1* exon9-12del (detected by 3-PA), accounting for ~59% of all CNVs. The remaining ~41% of CNVs were detected by MLPA alone. This is consistent with previous reports of *BRCA* CNVs in Hispanic populations. Data from this ongoing study are being used to construct a population specific variant database delineating mutation frequency, spectrum, and variants of uncertain significance (VUS) by region. This information will be leveraged to customize the *HISPANEL* into a rapid, inexpensive, high-throughput screening tool with high sensitivity for populations beyond Mexico and the U.S.

2807T

Genetic association between ND3 gene polymorphisms and the risk of gastric cancer.
E. Jin[1], J. Hong[1,2]. 1) Clinical Trials Center, Chungnam National University Hospital, Daejeon, South Korea; 2) Department of Pharmacology, College of Medicine, Chungnam National University, Daejeon, South Korea.

    Recently, several studies have been reported that mitochondrial DNA alterations are related with cancer development and progression. In this study, we performed case-control association studies to evaluate the relevance between mitochondrial NADH-dehydrogenase subunit 3 (ND3) gene polymorphisms and the risk of gastric cancer (GC) in the Korean population. A case-control study was conducted with 377 GC patients and 363 controls. We genotyped 6 SNPs such as rs28358278, rs2853826, rs201397417, rs41467651, and rs28358275 in ND3 gene using direct sequencing. χ^2 tests were used to estimate the Hardy-Weinberg equilibrium of each SNP and the association between the GC and control. Binary logistic regression was conducted to estimate the GC risk by odds ratios (OR) and 95% confidence intervals (CI). Variant, rs41467651 was significantly associated with an increased gastric cancer risk of GC and diffuse-type GC (OR = 2.08, P = 0.006 and OR = 2.64, P = 0.002, respectively). Our data suggests that rs41467651 polymorphism of ND3 gene may influence ND3-mediated signaling pathway, particularly in the development of diffuse-type GC in the Korean population.

Acquisition of clonal driver mutations in VHL syndrome clear-cell renal cell carcinomas. *A.D. Mitchell[1], S.S. Fei[1], C.D. Vocke[2], C. Boniface[1], W.M. Linehan[2], P.T. Spellman[1].* 1) Department of Molecular & Medical Genetics, Oregon Health & Science University, Mail Code: CL6S, 2730 SW Moody St, Portland, Oregon 97201, USA; 2) Urologic Oncology Branch, Center for Cancer Research, National Cancer Institute, Building 10 Room 1-5940, Bethesda, Maryland 20892, USA.

VHL Syndrome is a rare genetic disorder with a dominant mode of inheritance, which predisposes one to benign and malignant neoplasms of varying origin, including renal cell carcinomas. Individuals with VHL Syndrome, who develop renal cancer, commonly present with multiple, malignant clear-cell renal carcinomas (ccRCC). These are synchronous tumors, meaning they initiate, mature and evolve, at the same time and within the same germline environment. Synchronous tumors are an extremely rare occurrence across all types of cancer. Thus, VHL Syndrome ccRCC provides one of the few presentations of cancer to study the somatic genetic features of tumors while controlling for time and environment. We previously observed modest differences in the number of somatic genetic driver events within Fuhrman grade 2 and grade 3 VHL syndrome ccRCC tumors from whole-genome sequencing. The Fuhrman grading system is assigned by pathologist based on the shape and size of the nucleus of tumor cells, as well as the prominence of nucleoli. Tumors are classified into one of four possible grades, or more generally into two grade classes: low and high. High Fuhrman grade ccRCC tumors have an increased ability for metastasis and lower survival rate. Thus, high Fuhrman grade ccRCC tumors are generally more aggressive and more evolved. We have performed resequencing of exomes at ~200X coverage on five grade 3 and five grade 2 ccRCC tumors from three VHL syndrome patients. Resequencing these tumor exomes has provided sufficient power to call variants of low allele frequency across all driver genes. We applied methods to assess clonality within these tumors to determine which SNVs are more likely to be true drivers of tumor evolution with respect to Fuhrman grade. We show that high Fuhrman grade tumors contain more nonsynonymous driver gene variants than low Fuhrman grade tumors. Clonal driver SNVs were only identified in high Fuhrman grade tumors, which suggests driver SNVs may influence the progression of Fuhrman grade in VHL Syndrome ccRCC tumors. .

2809W

Association of variants rs822396, and rs1501299 of *ADIPOQ*, rs1342387 of *ADIPOR1*, rs1862513, of *RETN* and rs35749351of *CAP1* genes with breast cancer risk in Mexican obesity women: Preliminary results. *A. Muñoz-Palomeque[1], M.A Guerrero-Ramírez[2], R.C Rosales Gómez[3], M.G López-Cardona[1,3], J.C Catón-Romero[4], H. Montoya Fuentes[3], T.A García-Cobian[1], S.A Gutierrez-Rubio[1].* 1) Departamento de Fisiología, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Colonia Independencia, Guadalajara, Jalisco, Mexico; 2) Dr Valentín Gómez Farías, ISSSTE Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Zapopan, Jalisco, Mexico; 3) UMAE Hospital de Especialidades del Centro Médico Nacional de Occidente, IMSS Hospital de Especialidades, Instituto Mexicano del Seguro Social, Guadalajara, Mexico; 4) CIBO centro de Investigación Biomédica del Occidente, IMSS Instituto Mexicano del Seguro Social, Guadalajara, Mexico4Unidad de Medicina Genómica y Genética, Hospital.

Clinical studies suggest that breast cancer (BC) and obesity are related, the adiponectin and resistin has been associated with BC, and however, the result has been inconclusive. Various studies suggest that adiponectin has anti-tumour effects but in obesity this protein is decreased, on the other side resistin may act directly by signalling through TLR4 and CAP1, which activates the JAK / STAT and MAPK pathway, proteins directly involved in the initiation, promotion, and progression of tumors (Codoñer-Franch & Alonso-Iglesias 2015; Lee, et al., 2014). In the present study the SNPs rs1862513 of *RETN*, rs822396, and rs1501299 of *ADIPOQ*, rs1342387 of *ADIPOR1* gene and rs35749351 of *CAP1*. Were selected with the aim to determine the association between these variants with BC in Mexican women with obesity. DNA samples from 56 women with breast cancer and 106 healthy women were genotyped. To measure adiponectin, resistin, TNF-α, and IL-6 levels in serum were determined using the following enzyme-linked immunosorbent assay and the reference group. The allelic frequency of the rs35749351 SNP of *CAP1* in the general population were of G allele frequency it was of 399 to 13 for A allele. Furthermore, in reference group, the allele frequency was 185 G alleles and 9 A allele. On another hand, all alleles were G (n=3) in population breast cancer women. In the rs1862513 SNP of *RETN* to general population group, the allele frequency was similar to 154 of the G allele vs. 146 C allele. Were observed allelic frequencies were equal to the frequencies found in the general population frequency of 51% for the G allele and 49% for the C allele. Frequencies allelic in the rs822396 SNP of *ADIPOQ* of 168 individuals from the general population were for A allele 259 and for 77 of the G allele. Also, the allelic frequencies of the reference group that shows the most abundant of 152 for A allele vs. 36 of G allele. Finally, allelic frequencies of the variant for 6 individuals in women with breast were observed 1:1. An assay of ELISA was performed to measure the concentration of TNF-α in serum. Twenty-nine sera from reference and 2 sera from women with breast cancer were analyzed, where differences between the two groups and higher levels of this cytokine in the serum of women with breast cancer were found.   .

Development of functional assays for identifying *BRCA1* **and** *BRCA2*
mutation carriers. *A. Salmon[1], T. Zehavi-Harel[1], G. Yahav[2], D. Fixler[2], Y.
Shimshon[3], M. Divon-Salmon[3].* 1) Dept Oncology, Hadassah Med Ctr, Jeru-
salem, Israel; 2) 3Bar-Ilan University, Faculty of Engineering and Institute of
Nanotechnology and Advanced Materials; 3) Department of Molecular Biology,
Ariel University, Ariel, Israel,.

   Worldwide, more than one million women are diagnosed with breast cancer
every year, making it the most common female malignancy in the developed
world. Germline mutations in BRCA1 and BRCA2 genes account for 4-6% of
all breast cancer cases and mutation carriers have a lifetime risk of up to 80%
for developing breast cancer and 40% for developing ovarian cancer. From a
clinical point of view, identification of BRCA1 and BRCA2 mutation carriers of-
fers an opportunity to early identify or prevent the development of malignancy;
therefore the ability to determine which women are more likely to carry BRCA1
or BRCA2 mutations is of great importance. The available diagnostic tests
for mutation analysis of BRCA1 and BRCA2 are time- and labor-intensive,
expensive, and do not allow the identification of all the functional mutations.
We utilized various simple, inexpensive and sensitive methods for identifying
BRCA1 and BRCA2 healthy mutation carriers, by using easily obtainable
lymphocyte cells from peripheral blood. First, we used the Fluorescent life
time imaging microscopy (FLIM) method which allows recognizing different
cell populations, in order to distinguish between lymphocytes of BRCA1 and
BRCA2 mutation heterozygous carriers and non-carrier women. Secondly,
using the RNA-seq technology, we performed expression profiling analysis of
normal and BRCA1/2 mutation heterozygous lymphocytes. Our results demon-
strate that cells originated from *BRCA2*-mutation carriers have significantly
lower FLT values compared with *BRCA1* and control cells. Using RNA-seq
analysis we were able to detect distinguished gene expression pattern in
BRCA1/2 mutation heterozygous lymphocytes compared to control. Together,
these two techniques may be utilized in the future to detect BRCA1/2 carriers,
particularly those bearing unknown functional mutations.

2811F

Polymorphism in the *XPD* **gene affects the risk of bladder cancer:**
A case-control study a meta-analysis and TSA. *M. Sankhwar[1], S.N.
Sankhwar[1], S. Bansal[2], S. Rajender[2].* 1) Urology, King George Medical Univer-
sity, Lucknow, Uttar Pradesh, India; 2) Division of Endocrinology, Central Drug
Research Institute, Lucknow, India.

   Purpose: DNA repair of bulky adducts is essential for a normal life. Among
the repair proteins, the XPD protein is interesting because it is a major player
in the nucleotide excision repair pathway and is also involved in transcription
initiation and in the control of the cell cycle and apoptosis. Lys751Gln and
Asp312Asn of XPD gene have been extensively studied in relation to cancer.
We have analyzed these polymorphisms in Indian bladder cancer patients and
conducted a meta-analysis to generate a pooled estimate about the effect of
these variations on bladder cancer. **Material and methods:** The polymor-
phisms was analysed using polymerase chain reaction-restriction fragment
length polymorphism (PCR-RFLP) in 234 case and 258 control samples, fol-
lowed by Chi square test for statistical analysis. The meta-analysis included a
total of 33 studies (twenty one for lys751gln and twelve for asp312asn) studies
comprising of 11,115 cases and 13,800 controls for. Forest plot and funnel plot
were used to interpret statistical significance of association and publication
bias, respectively. Egger's test was performed to confirm funnel plot symmetry
statistically. TSA was performed to validate the findings of meta- analysis.
Results: The results of our case control study showed significant association
between D312N polymorphism and bladder cancer risk (OR-2.85, CI-1.91-
4.25, P<.0001). Smoking and tobacco chewing were found to be a risk factor
for bladder cancer for D312N. XPD gene were not found to be in significant LD
(D'=0.157, LOD=2.66, r^2=0.021) with each other. Haplotypes CG and AA were
found to be significantly higher in the cases (35.7% and 42.1%, respectively)
Meta-analysis results of XPD for the both the polymorphisms also showed
strong association in all the models for D312N dominant (GA+AA vs GG: OR-
1.35, CI-1.15-1.57, P-0.000) and K751Q dominant (AC+CC vs AA: OR=1.12,
CI=1.00-1.25, P=0.03) in overall population as well as Americans and Indian
at higher risk for D312N on ethnicity basis which is further confirmed by TSA.
Conclusion: XPD substitutions increase bladder cancer risk in Indo-European
populations of Uttar Pradesh and also in other populations across the world.

2812W

Frequency of mutations in multi-gene panel testing of 3,600 individuals for hereditary breast and ovarian cancer risk. *A.Y. Zhou[1], J. van den Akker[1], K.A. Smith[1], R. O'Connor[1], S. Kim[1], D.E. DeSloover[1], T. Walsh[2], E. Gil[1], T. Sittler[1].* 1) Color Genomics, Burlingame, CA; 2) University of Washington, Seattle, WA.

Current published guidelines recommend genetic testing for breast and ovarian cancer risk to individuals with a strong personal or family history of these cancers. However, little is known about the genetics of the individuals that fall outside of these restrictive recommendation criteria. Here, we describe the demographics and characteristics of 3,595 individuals who received the Color Test by physician order. In this cohort, 282 pathogenic or likely pathogenic mutations were identified and reported. The proportion of individuals who carried a pathogenic or likely pathogenic mutation (mutation carrier rate) was 7.7% (276/3595; 95% CI: 6.9%-8.6%), similar to reports from other laboratories. Among 1,421 individuals who would not have been recommended for testing under current NCCN guidelines, the mutation carrier rate was 3.9% (95% CI: 3.0%-5.0%). Among 561 Medicare-eligible individuals, 455 would not have met current recommendations for testing under Medicare guidelines. This cohort presented with a mutation carrier rate of 6.2% (95% CI: 4.3%-8.8%). Among 434 Ashkenazi Jewish individuals, 42 pathogenic or likely pathogenic mutations were identified and almost 50% of these mutations (20 of 42) were outside the three known Ashkenazi Jewish founder mutations in BRCA1 and BRCA2. The mutation carrier rates, reported here, in cohorts of individuals who would not have qualified for current published guidelines for testing is much higher than the presently estimated rate in the general United States population. Additionally, the number of pathogenic mutations identified outside of the three Ashkenazi Jewish founder alleles in the Ashkenazi Jewish cohort indicates that testing for just these three alleles is insufficient in this population. Taken together, the results of this study demonstrate the importance of broadening the offering of genetic testing for all populations.

2813T

Germline *CDH1* mutations are a dominant cause of diffuse gastric cancer in the New Zealand Māori population. *C. Hakkaart[1], S. Chen[2], R. Day[1], L. Ellison-Loschmann[2], M. Gray[2], P. Harawira[3], J. Koea[4], N. Pearce[5], A. Sporle[6], T. Whaanga[2], P. Guilford[1].* 1) Biochemsitry Department, University of Otago, Dunedin, New Zealand; 2) Centre for Public Health Research, Massey University, Wellington, New Zealand; 3) Kimihauora Health Centre, Tauranga, New Zealand; 4) Waitemata District Health Board, Auckland, New Zealand; 5) London School of Hygiene and Tropical Medicine, London, England; 6) Department of Statistics, University of Auckland, Auckland, New Zealand.

Gastric cancer is a multifactorial disease with a complex interplay of both inherited and environmental factors contributing to its emergence. The two main histological subtypes of gastric cancer are: intestinal, which is more common and is closely associated with environmental factors; and diffuse, which is less common and is though to have a strong genetic component. In New Zealand, Māori have a notably elevated rate of gastric cancer compared to non-Māori and are one of the few populations worldwide with an overall higher incidence of the diffuse type of the disease. Genetic predisposition to gastric cancer has been well documented in New Zealand with multiple families being diagnosed with the inherited cancer syndrome Hereditary Diffuse Gastric Cancer (HDGC), which is caused by germline mutations in the tumour suppressor gene *CDH1*. *CDH1* mutation carriers have 70% lifetime risk of developing diffuse gastric cancer and females have an additional 40% risk of developing lobular breast cancer. As part of a study examining the known risk factors of gastric cancer in Māori we are using next generation sequencing and MLPA to search for germline mutations in germline *CDH1*. Our aim is to determine the prevalence of pathogenic *CDH1* mutations in the Māori gastric cancer population and understand the impact this is having on the rate of gastric cancer in New Zealand. We have sequenced blood DNA collected from an unselected series of 94 Māori gastric cancer patients diagnosed between 2009 and 2013 and more than 204 healthy matched controls. 18% of all patients and 34% of patients with the diffuse subtype carried pathogenic germline mutations in *CDH1*. This incidence increased to 66% for diffuse gastric cancer patients aged less than 45 years. These results show genetic predisposition to gastric cancer is a dominant cause of early onset diffuse gastric cancer in New Zealand Māori and that this is a major contributor to the high incidence relative to New Zealand Europeans.

2814F

A computational framework for genotyping and early detection of lung cancer. *E. Adetiba[1,2], O.O. Olugbara[1,2].* 1) Department of Information Technology, Durban University of Technology, P.O. Box 1334, Durban, 4001, South Africa; 2) ICT and Society Research Group, Durban University of Technology, P.O. Box 1334, Durban, 4001, South Africa.

A wide ranging and collaborative efforts of scientists and researchers from around the world have successfully unravelled the human genome sequences. The completed human genome sequences are about three billion characters in length. In addition, the sequences of other organisms such as virus, bacteria, archaea, fungi, mouse and several plants have been deciphered. These efforts have generated huge biological data which keep growing at an astronomical rate. Meanwhile, the analysis and interpretation of these genomic data are major challenges facing researchers and scientists in fields as diverse as information engineering, computer science, physics, mathematics, molecular biology, medicine, pharmacy, agriculture and genetics. This is consequent on the big prospects that such interpretation holds for human development in areas such as creation of new diagnostic tools, innovation of therapeutic procedures, design of novel drugs and production of genetically modified crops. We report and discuss the preliminary results of the prototype of a computational framework we developed for genotyping, screening and early detection of lung cancer mutations. To develop the framework, we extracted lung cancer biomarker genes from the COSMIC database. The extracted genes have been implicated to carry various mutations (such as deletion and substitution) that are responsible for the initiation and advancement of lung cancer. Some of these genes are tumor suppressor p53, kirsten rat sarcoma viral oncogene homolog, epidermal growth factor receptor, cyclin-dependent kinase inhibitor 2A, lysine-specific methyltransferase 2C and host of others. The computational components of the framework are Z-curve affine transform, histogram of oriented gradient and Gaussian radial basis function neural network. The neural network was trained and validated using the extracted features from the biomarker genes. A graphical user interface was developed for ease of use and the experimental results show a high classification accuracy of lung cancer genomes into the appropriate biomarker genes and mutation types. The computational framework can be interfaced with next generation sequencing platforms like Illumina MiSeq to detect lung cancer mutations in at risk persons and those with an early onset of the disease. This will assist oncologists to make timely recommendations for targeted molecular therapies and ultimately reduce the rate of mortality due to lung cancer.

2815W

Recurrent somatic copy number variation analysis identifies risk genes that modulate the survival of young women with breast cancer. *C. Chi[1], R. Ajwad[1,2], Q. Kuang[1], L.C. Murphy[1,3], P. Hu[1,4].* 1) Department of Biochemistry and Medical Genetics, University of Manitoba, Winnipeg, MB, Canada; 2) Department of Computer Science, University of Manitoba, Winnipeg, MB, Canada; 3) Research Institute in Oncology and Hematology, Winnipeg, MB, Canada; 4) Department of Electrical and Computer Engineering, University of Manitoba, Winnipeg, MB, Canada.

Breast cancer (BC) diagnosis in young women (<45 years old) has come forth as an independent factor with higher recurrence risk and death than their older counterparts, and it has been suggested that it may exhibit its own unique biology. Copy number variations (CNVs) have led many to consider them as an alternate paradigm for the genetic basis of human diseases, as these large variations may encompass key genes that contribute to carcinogenesis and disease progression. Although many complex diseases have been linked to CNVs in the genomic DNA, prior studies have yet to document age-related changes in somatic CNVs for young women with BC. We hypothesize that recurrent somatic CNV regions uniquely found in young women with BC will harbor cancer-susceptibility genes that modulate the survival of these young women. We aim to find recurrent somatic CNV regions that are identified from BC microarray data and associate the CNV status of the encompassed genes to the survival of young women with BC. We have developed a new interval graph-based algorithm for identifying recurrent somatic CNVs in cancer using a maximal clique detection technique. The algorithm guarantees that the identified CNV regions are the most frequent and identifies the delineated minimal regions. By applying the algorithm to the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) CNV data consisting of 2000 breast tumour samples (equally divided into a Discovery set with 130 young women and a Validation set with 125 young women), we have identified 5 validated recurrent CNV regions (three amplifications and two deletions) that are uniquely found in young women with BC. There regions encompass 6 corresponding candidate genes (amplification regions: *AMY1A*, *KIAA1267*, *SIRPB1* and deletion regions: *OR4F5*, *GSTM1*, *GSTM2*). Interestingly, the frequency at which these CNVs occur ranges from 8.5% (*AMY1A*) to 30.8% (*SIRPB1*) in the Discovery set and from 10.4% (*AMY1A*) to 46.4% (*SIRPB1*) in the Validation set. Overall, the frequency of these genes between the young group and the old group is significantly different (p value < 5e[-10]). The amplification status of gene signature (*AMY1A*, *SIRPB1*) in young women with BC is associated with disease-specific survival in the Discovery set (hazard ratio=1.78; p value=0.058). Together, identification of the deletion and amplification events that may be prognostic in young women with BC can be used in genomic-guided treatment.

2816T

Low memory, fast, specific, sensitive, multi-reference sequence classification using Bloom filter maps. *J. Chu[1,2], H. Mohamadi[1,2], S. Yeo[2], B. Vandervalk[1,2], G. Jahesh[1,2], C. Yang[1,2], S. Jackman[1,2], R. Warren[2], I. Birol[1,2,3].* 1) The University of British Columbia, Vancouver, BC, Canada; 2) Canada's Michael Smith Genome Sciences Centre, British Columbia Cancer Agency, Vancouver, BC, Canada; 3) Simon Fraser University, Burnaby, BC, Canada.

Background Sequence classification is traditionally performed by alignments of sequencing reads onto a reference sequence set. Although alignment methodologies have the potential to map the location of these reads precisely, this information is not a prerequisite for classification and thus perform more computation than is needed. To address these shortcomings, we previously proposed an efficient classification method, BioBloom Tools (BBT) (Chu et al. 2014), that uses a low memory, probabilistic set membership query data structure called a Bloom filter. Using a Bloom filter, sequences are queried to determine whether they are or are not members of a set of sequences composed of a list of references. The accuracy and speed of BBT has proved useful towards mass screening of whole genome shotgun data from human tumors and was instrumental studying large cohorts, such as the Cancer Genome Atlas (TCGA) project on genomic characterization of papillary thyroid carcinoma (Agrawal et al. 2014). Though effective when using a small number of filters, determining the specific reference of a queried sequence requires inefficient usage of multiple Bloom filters. Here we present a new data structure we call a Bloom map, which can efficiently associate queries to a specific reference. Methods A Bloom filter works by implicitly storing sequences by obtaining a set of numbers derived from a nucleotide sequence (via a process called "hashing"), rather than storing the sequence itself. These numbers are used to set bit locations in an array from 0 to 1. To determine if a sequence is part of a filter we hash the sequence and lookup these locations to see if they are set. Conceptually, a Bloom map is a Bloom filter that contains not just presence of a set bit but an index identifier for each bit set, allowing us to look up a corresponding array that stores which genome this sequence originally came from. Results We benchmarked the performance of our tool on a simulated metagenomic dataset mimicking 1 million 2x150bp Illumina reads from all the complete genomes within the NCBI bacterial database. We correctly classified the genus of 97.3% reads utilizing 61 GB of RAM in under 2 minutes using 8 CPU cores. Conclusions Here we present an efficient low memory multi-reference sequence classification tool with broad applications contamination screening, pathogen detection, metagenomics, and preprocessing for targeted assembly from shotgun sequence data.

2817F

Resolution of complex genomic structures arising from integrated duplication, inversion, and translocation events with barcoded linked-read sequencing. *S. Greer[1], B. Lau[1], J. Chen[2], C. Xia[2], H. Ji[1,2].* 1) Stanford Genome Technology Center, Stanford University, Stanford, CA; 2) Dept of Med/Oncology, Stanford University, Stanford, CA.

Structural variants (SVs) represent an important source of somatic variation in cancer genomes, often affecting critical oncogenes and tumor suppressors to become tumorigenic. Despite the large-scale availability of whole genome sequence (WGS) data, accurate detection of SVs remains a challenge. Moreover, the resolution of complex SV structures is still near impossible. We recently demonstrated the use of linked-read sequencing (LRS) to resolve haplotypes of both normal and cancer genomes (GX Zheng, BT Lau, et al. Nature Biotechnol. 2016). This phasing technology uses droplet-partitioned barcodes to tag high molecular weight DNA molecules over 150 kb in size, enabling the resolution of haplotypes spanning multiple megabases. In this study, we used LRS to resolve the structure of complex SVs that are undetectable with traditional WGS. With LRS, SVs that bring together non-adjacent genomic elements will share the same droplet partition barcode and thus can be directly detected and robustly quantified. We performed LRS on two ovarian (left and right) metastases from a patient with diffuse gastric cancer. Detection of SVs in these samples from traditional WGS data yielded many events with limited accuracy and unknown linkage. In contrast, LRS data provided a means to resolve the structures of oncogenic SVs. In the right metastasis, we were able to temporally link multiple SV events into a single resolved structure in the *FGFR2* locus. This rearrangement involved a 30 Mb deletion, followed by inversion-translocation of the deletion-flanking regions, and subsequent tandem duplication of the remaining 1 Mb region encompassing the previous events. We performed this analysis on the left metastasis and also resolved in the *FGFR2* locus an intrachromosomal translocation event coupled with a tandem duplication, but at a location distinct from that of the right metastasis. The unique SV structures between metastases was clear with LRS data but would have been impossible to resolve using traditional WGS, highlighting the utility of LRS as a revolutionary method for SV analysis.

2818W

Improved detection of genetic variants through a non-aligning k-mer approach. *L.L. Hansen, A. Fire.* Pathology, Stanford, Stanford, CA.

Next generation sequencing (NGS) has impacted virtually all aspects of molecular biology. One prominent application of NGS technology is the sequencing of whole genomes or targeted genomic regions (exomes), with the objective of identifying genetic variants. The flood of sequencing data being applied to variant discovery has created a corresponding need for computational tools that can accurately detect variants of all types and sizes. In order to obtain a complete picture of variation, current approaches rely on complex computational pipelines combining different methods, each restricted to identifying a particular type or size of variant. Even so, some types of variants remain difficult to call, too large for small indel callers and too small for structural variant callers. In addition, the majority of existing techniques require the alignment of reads to a reference genome prior to calling variants, adding to computational expense and introducing potential alignment biases. To address these issues, we have developed a method to call variants that allows for direct comparison of sequence library(ies) with a reference genome or to each other without requiring the alignment of reads to a reference genome. Our approach allows us to detect in one method a large subset of variants, including small single nucleotide variants (SNVs), small indels, and large structural variants regardless of size. This includes medium sized structural variants (15-100 bp), which traditionally have been especially difficult to detect using currently available approaches. We are also able to identify both germline and somatic variants. Briefly, our method is based on comparative indexing of DNA words unique to one read library compared to another and/or to a reference genome. This allows us to identify reads that share the same variant because they share the same unique word(s). We then assemble reads containing the same variant into a contig, and align the contig to the reference genome, allowing us to accurately call the variant type and position. Our method will work on any variant that generates unique sequence(s), independent of variant size or type. Performance tests on gold standard datasets indicate our method outperforms popular existing small indel and SNV callers and in addition will call all sizes and types of structural variants.

2819T

Clinically actionable genetic variants in cancer-predisposing genes: A survey of 300 patients with whole-genome sequencing and lifetime electronic health records. *M.M. He[1,2,3], K.Y. He[4], Q. Li[5], K. Wang[5,6].* 1) Center for Human Genetics, Marshfield Clinic Research Foundation, Marshfield, WI 54449, USA; 2) Biomedical Informatics Research Center, Marshfield Clinic Research Foundation, Marshfield, WI 54449, USA; 3) Computation and Informatics in Biology and Medicine, University of Wisconsin-Madison, Madison, WI 53706, USA; 4) Department of Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, OH 44106, USA; 5) Zilkha Neurogenetic Institute, University of Southern California, Los Angeles, CA 90089, USA; 6) Department of Psychiatry, University of Southern California, Los Angeles, CA 90089, USA.

Statement of purpose: Discovery of clinically actionable genetic variants across cancer-predisposition genes using whole-genome sequencing (WGS) data and electronic health records (EHRs) may improve our understanding of carcinogenesis, direct personalized patient care, and facilitate genetic counseling for patients and families. Our objective is to identify clinically actionable germline mutations in cancer-predisposing genes using patients' WGS data and comprehensive clinical data derived from their EHRs. Methods used: We analyzed genetic mutations in 60 autosomal dominant cancer-predisposition genes in 300 deceased patients with nearly complete long-term (over 30 years) medical records. Germline mutations in these 60 genes are associated with autosomal dominant cancer-predisposition syndromes [1]. To infer biological insights from massive amounts of WGS data and comprehensive clinical data in a short period of time, we developed an in-house analysis pipeline within a software framework called SeqHBase [2] to quickly classify genetic pathogenicity based on the latest ACMG guidelines [3]. The clinical data of the carriers of pathogenic and/or likely pathogenic variants were reviewed to assess their clinical conditions using their lifetime EHRs. Summary of results: Among the 300 participants, 7 (2.3%) carried a presumed pathogenic or likely pathogenic variants (including 3 novel loss-of-function variants) in one of the 60 cancer-predisposing genes. When assessing extensive clinical data, each of the 7 patients had one or more different cancers, which are fully consistent with their genetic profiles. This work demonstrates that genetic mutations in autosomal dominant cancer-predisposing genes could be potentially used in clinical diagnosis, prevention, and personalized treatments, showcasing the power of combining WGS and EHR to improve healthcare. Inferring expressed genes by whole-genome sequencing of plasma DNA.
E. Heitzer[1], P. Ulz[1], G.G. Thallinger[2,3], M. Auer[1], K. Kashofer[4], S.W. Jahn[4], L. Abete[4], G. Pristauz[5], E. Petru[5], J.B. Geigl[1], M.R. Speicher[1]. 1) Institute of Human Genetics, Medical Unversity of Graz, Graz, Austria; 2) Institute of Molecular Biotechnology, Graz University of Technology, Graz, Austria; 3) Bio-TechMed OMICS Center Graz, Graz, Austria; 4) Institute of Pathology, Medical University of Graz, Graz, Austria; 5) Department of Obstetrics and Gynecology, Medical University of Graz, Graz, Austria.

The analysis of cell-free DNA (cfDNA) in plasma represents a rapidly advancing field in medicine. cfDNA fragments have been associated with the release of DNA from apoptotic cells after enzymatic processing since the distribution of their lengths has a mode near 166 bp in most analyses, a size which corresponds approximately to the DNA wrapped around a nucleosome (~147 bp) plus a linker fragment (~20 bp). Recently evidence that cfDNA reflects nucleosome footprints was reported. Therefore, we investigated whether plasma DNA is able to reflect expression-specific nucleosome occupancy at promoters. Furthermore, we assessed if plasma DNA possesses the sensitivity and accuracy to predict whether genes are expressed or not, and furthermore, we determined if blood samples from patients with cancer are informative for expressed cancer driver genes. We performed whole-genome sequencing (WGS) of plasma DNA and identified two discrete regions at transcription start sites (TSS) where the nucleosome occupancy results in different read-depth coverage patterns in expressed and silent genes. By employing machine learning for gene classification, we found that the plasma DNA read depth patterns from healthy donors reflected the expression signature of hematopoietic cells. In cancer patients with metastatic disease, we were able to classify expressed cancer driver genes in regions with somatic copy number gains with high accuracy. We could even determine the expressed isoform of genes with several TSSs as confirmed by RNA-Seq of the matching primary tumor. Taken together our data suggest that read depth analyses of plasma DNA can reveal functional data such as the expression status of genes due to the nucleosome occupancy pattern at promoter regions and, furthermore, that even the expression status of cancer-related genes can be deduced from the blood of patients with cancer. Due to the increasing application of molecularly driven therapeutics, which rely on accurate and timely measurements of critical biomarkers, our results are of utmost significance, as they provide a new view on the genomes of the cells which release their DNA into the circulation. Furthermore, our approach is applicable during a disease stage at which most clinical studies in oncology are conducted. This significantly expands upon the currently existing options for cfDNA analysis. .

Efficient human genome sequence assembly with ABySS v2. *S.D. Jackman, B.P. Vandervalk, H. Mohamadi, J. Chu, R.L. Warren, S. Yeo, L. Coombe, G. Jahesh, A. Hammond, I. Birol.* BC Cancer Agency Genome Sciences Centre, Vancouver, BC, Canada.

Assembling genome sequencing reads into larger contiguous sequences before comparison to a reference genome improves variant calling in highly polymorphic loci, such as HLA, and in identifying variants that are difficult to infer directly from aligned short-read sequencing data, such as large indels and structural variants. ABySS was the first genome assembler to scale to assembling the human genome using Illumina sequencing. Since then read lengths on the platform have quintupled from 50 bp to 250 bp. Paired-end sequencing of a typical library of ~500 bp DNA fragments with two 250 bp reads fully describes the sequence of the fragments, and so one can derive 500 bp pseudo-reads from the Illumina platform. Assembly software must continue to evolve to fully benefit from these improvements in sequencing technology. ABySS v1 required a terabyte of memory to assemble a human genome and employed the message passing interface (MPI) to aggregate memory across multiple machines. In the version we are reporting here, ABySS v2, we have implemented algorithms that employ a Bloom filter, a probabilistic data structure, to represent the sequence content of experimental data to be assembled. This data structure reduces the memory footprint of ABySS v2 by ten fold, making it possible to assemble a human genome in 100 GB of RAM, which is often available on a single server. As read lengths increase, the optimal value of the fundamental assembly parameter k, which describes the minimum required overlap between reads for assembly, also increases. Therefore, the memory footprint of assembly algorithms that use typical data structures, such as a hash table, increases linearly with k. The memory use of a Bloom filter, on the other hand, is independent of k, allowing ABySS v2 to scale with increasing read lengths with no increase in required memory. Here, we demonstrate the assembly of a human genome using 100 GB of RAM with a scaffold NGA50 of 4.4 Mbp using a single library of each Illumina paired-end and mate-pair sequencing. We also investigate the use of 10x Genomics Chromium data to further improve the scaffold contiguity of this assembly. We note that routine assembly of highly contiguous human genomes using high-throughput sequencing data with moderate computing resources presents an enabling technology for personalized medicine applications. These include analyzing structural variations in highly rearranged cancer genomes at a resolution not afforded by alternative methods.

2822T

Inferring clonal sequences and phylogenies from personal tumor genome profiles. *S. Kumar, K. Gomez, O. Murrillo, S. Miura.* Institute for Genomics and Evolutionary Medicine, Temple University, Philadelphia, PA.

   Tumor progression involves evolution of clone cells that arise through cell division, mutate and spread in tumors. Genetic profiling has revealed the presence of extensive variation in tumor samples from individual patients; however, existing methods have difficulty in estimating clone genotypes and clone frequencies from heterogeneous tumor samples. We show that the clone cell genotypes present in each tumor sample can be accurately inferred from the analysis of multiple tumor sample profiles with our new CloneFinder method. CloneFinder uses molecular evolutionary principles to deduce clone genotypes at a single-nucleotide resolution along with the frequency of each clone in each sample. It performs better than existing methods and is scalable for the analysis of a large number of samples. Application of CloneFinder to more than 60 empirical datasets revealed that a vast majority of tumor samples contain at least one ancestral clone, that ancestral clones occur at high frequencies, and that many tumors are a mixture of very early and recently evolved clones. Therefore, our new method provides new insights into the clonal structure of tumors and their evolution within a personal life time.

Prediction of prostate cancer recurrence by voting feature intervals. *M. Leclercq[1,2], A. Bergeron[1], Y. Fradet[1], A. Droit[2].* 1) Centre de recherche du CHU de Québec-Université Laval; 2) Centre de recherche du CHU de Québec - Université Laval, Médecine moléculaire, Faculté de médecine, Université Laval.

   Introduction: The emergence of high-throughput genomic technologies in the recent years has allowed a better understanding of the genomic landscape of prostate cancer (PCa). The analyses of hundreds of prostate tumors showed important genomic heterogeneity. However despite these extensive studies, the prognostication of prostate tumors has not yet been greatly improved. There are accumulating evidences that a detailed analysis of the intra-tumoral immune response could help to the stratification and prognostication of tumors. The objective of this study was to apply a machine learning approach to identify an immune signature that could help predict PCa progression. **Methods**: Tumor mRNAseq and clinical dataset of 489 PCa patients from The Cancer Genome Atlas project were used for these analyses. The tumor infiltration by immune cells was assessed using the CIBERSORT approach. The infiltration of immune cells along with the expression profiles of 1418 immune response-related genes were analyzed with clinical data by machine learning approaches to identify features able to predict biochemical recurrence (BR) after surgery. **Results**: Using correlation-based feature subset selection we identified 5 genes (*PPBP, KEL, HRH4, CEACAM6* and *CXCL11*), two clinical features (Gleason grade and pathologic T) and the abundance of a subset of immune cells (gamma delta T cells), that have an individual predictive ability with low inter-correlation to predict BR. Supervised learning by voting feature intervals classifier on these features predicted BR at 70% accuracy (AUC: 75.8%, 10 fold cross validation) with a 71.8% specificity and 69.4% sensitivity. While some other classifiers provided better accuracy, none provided a sensitivity higher than 40%. **Conclusion**: We believe that these results will help to better understand the spontaneous immune response against PCa, critical for the design of new emerging immunotherapies based on highly specific biomarker combination.

Variant EXplOreR : Integrative environment for functional understanding of complex trait susceptibility loci. Application in breast cancer fine-mapping analysis. *A. Lemaçon[1], J. Allen[2], P. Soucy[1], J. Beesley[3], P. Kraft[4,5], G. Bader[6], A. Dunning[7], K. Michailidou[2,7], G. Chenevix-Trench[3], R. Milne[9,10], K.B. Kuchenbaecker[2,11], A.C. Antoniou[2], D. Easton[2,8], J. Simard[1], A. Droit[1], BCAC, CIMBA.* 1) Genomics Center, Centre Hospitalier Universitaire de Québec Research Center, Lav, Quebec, Quebec, Canada; 2) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK; 3) Cancer Division, QIMR Berghofer Medical Research Institute, Brisbane, Australia; 4) Program in Genetic Epidemiology and Statistical Genetics, Harvard T.H. Chan School of Public Health, Boston, MA, USA; 5) Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, USA; 6) The Donnelly Centre, University of Toronto, Toronto, Canada; 7) Department of Electron Microscopy/Molecular Pathology, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus; 8) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, UK; 9) Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global health, The University of Melbourne, Melbourne, Australia; 10) Cancer Epidemiology Centre, Cancer Council Victoria, Melbourne, Australia; 11) The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, UK.

Recent pan-genomic studies of common genetic variations conferring susceptibility to breast cancer have revealed over 180 independent loci, the vast majority located in the non-coding genome. For the purpose of determining the biological relevance of those risk loci in breast cancer risk prediction, we want to finely characterize each locus. In the context of our collaborations within the Breast Cancer Association Consortium (BCAC) and the Consortium of Investigators of Modifiers of BRCA1/2 (CIMBA), approximately 570K have been genotyped using the OncoArray (a custom Illumina chip which includes 260K "backbone" SNPs providing a genome-wide coverage of most common variants, together with SNPs of interest), leading to the imputation of 22 million genetic variants. These association results have been merged in a single file also including, for each variant, epidemiological data and the overlap status with more than 130 bio-features (introns, exons, TFBS...) used as potential genomic causality predictors. The huge dimension of the generated matrix (more than 3 billion entries), renders it impossible to manually handle all these valuable data. Therefore, we developed a bioinformatic tool named VEXOR, for Variant EXplOreR, which is designed to address this big data challenge. VEXOR is a platform-independent browser-based integrative environment for functional annotation in R, based on the Shiny package. This interface provides a comprehensive analytical framework to characterize the role of variants driving susceptibility signals in regions defined by GWAS. The matrix is connected to 1) publicly available functional annotations through UCSC Browser, 2) genetic diversity information (1000 Genomes third phase MAF, Linkage Disequilibrium) 3) effect prediction tools (VeP, HaploReg), 4) functional scoring tools (CADD, RegulomeDB) 5) prioritization algorithm (PAINTOR), 6) pathway information (GeneMANIA) 7) regulation data (Enhancers, Super-enhancers, IM-PET) and finally 8) relevant experimental data such as chromosomal interactions (Hi-C, 3C, 5C, ChIA-PET) and expression data. Thus, the user is provided with a proximal and distal context for each variant to assist in the prediction of putative functional effects. VEXOR is a versatile and scalable tool designed to help the understanding of the functional context in fine-mapping analyses of complex traits. It is now available to the scientific community on the Compute Canada Portal (http://romix.genome.ulaval.ca/vexor).

2825T

Identification of regulatory non-coding cancer drivers based on functional impact. *E. Liu, A. Fundichely, P. Dhingra, E. Khurana.* Weill Cornell Medical College, New York, NY.

The majority of variants identified in cancer whole-genome sequencing (WGS) data are located in non-coding regions. Mutation recurrence is a strong indicator of functional cancer driver and highly recurrent mutations have been identified in non-coding regions, such as the TERT promoter and the long noncoding RNA, MALAT1. However, the lack of large sample sizes and inaccurate background mutation rate estimation decrease the statistical power for recurrence-based methods to differentiate cancer driver mutations from passenger mutations in non-coding regions. We have developed a computational method to integrate the signals from variants with high functional impact with the recurrence of variants across multiple tumor samples while controlling for multiple possible covariates, such as, replication timing, histone modification marks, and open chromatin regions, to identify candidate non-coding drivers. The functional impact score is a weighted scheme that uses the properties of ENCODE elements (including nucleotide sequence conservation, transcription-factor (TF) motif disruption or gain, and network properties). By analyzing mutations in 14 different tumor types encompassing 1161 tumor WGS samples, we not only confirm well-known functional non-coding hotspots, but also detect several novel non-coding candidate elements that may target similar oncogenic pathways in the tumor samples without known functional cancer mutations. This analysis may help match patients to suitable clinical trials as well as provide crucial biological insights necessary for the translation of noncoding variants to the clinic.

Pan-cancer analysis using public research datasets can yield new clinical insights into the care of pediatric cancer patients. *O. Morozova[1], A. Tai-Shah[2], Y. Newton[1], S. Salama[1,3], I. Bjork[1], T. Goldstein[1], A. Resnick[4], S. Mueller[4], E.A. Sweet-Cordero[2], D. Haussler[1,3].* 1) Genomics Institute, University of California Santa Cruz, Santa Cruz, CA; 2) Division of Hematology and Oncology, Department of Pediatrics, Stanford University School of Medicine, Stanford, CA; 3) Howard Hughes Medical Institute, Chevy Chase, MD; 4) Pacific Pediatric Neuro-Oncology Consortium (PNOC).

Precision medicine programs are entering clinical care for adult cancer patients, but their application in pediatrics has been more limited. To address the need for innovative approaches to precision medicine in pediatric oncology, we launched California Kids Cancer Comparison (CKCC), a demonstration project for the California Initiative to Advance Precision Medicine. CKCC evaluates the efficacy and potential clinical utility of real-time pan-cancer genomics analysis, as applied to the most difficult-to-treat pediatric cancer patients, treated prospectively on clinical genomics trials at California hospitals. In our pan-cancer approach, each patient's RNA-sequencing profile and/or mutational profile is compared to over 10,000 tumor profiles from public research datasets, such as The Cancer Genome Atlas (TCGA) and Therapeutically Application Research to Generate Effective Treatments (TARGET) projects. The comparisons are conducted using our in-house Tumor Map tool, which examines nearest neighbors of each individual tumor to reveal tumor-specific pathway perturbations. We also implemented a gene expression outlier analysis that can identify pathways and genes with transcripts that are significantly over or under represented in a given patient, as compared to either the whole pan-cancer reference cohort or tumors that are most closely related to the patient's cancer based on the Tumor Map. Together, our analysis approaches are used to identify new therapeutic directions that were not previously apparent. These therapeutic directions can be further investigated by the medical teams, and confirmed using CLIA tests. Since April 2016, we have analyzed data from 12 patients, treated at University of California San Francisco and Stanford. In 12 out of 12 cases, our pan-cancer analyses found potential additional therapeutic directions. These therapeutic directions included existing clinical trials or FDA-approved drugs that could be administered off-label at the discretion of the physician. In 3 of these cases, all at Stanford, the pan-cancer analyses, together with CLIA certified validation tests, have provided key insights that have guided therapeutic decisions. Our study provides a framework of how very large, public genomic datasets collected from adult and pediatric patients in research and clinical settings can be used to provide new therapeutic opportunities for individual pediatric patients prospectively.

A *de novo* assembly pipeline to detect structural variants from RNA-seq data in clinical genomics. *K.M. Nip[1,2], R. Chiu[1], J. Chu[1,2], H. Mohamadi[1,2], G. Jahesh[1,2], I. Birol[1,3].* 1) Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada; 2) Bioinformatics Graduate Program, University of British Columbia, Vancouver, BC, Canada; 3) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada.

High-throughput RNA sequencing (RNA-seq) is being vigorously explored as a clinical genomics tool. It is widely used for gene fusion detection and gene expression analysis. Circumventing the short read length of RNA-seq data, de novo assembly allows reliable detection of long-range rearrangements and facilitates capturing the exact sequence of the rearranged transcriptomic product. We present a bioinformatics pipeline, TAP, that performs assembly-based detection of transcript-level rearrangements. Since most clinical applications involve a known gene set that are actionable or confer knowledge about a disease of interest, TAP can be utilized to operate on a user-defined gene list to ensure a quick turnaround. TAP consists of three stages: (1) de novo assembly, (2) alignment to reference, and (3) variant detection. First, read pairs are binned with BioBloomTools for each gene of interest. Then, these read sets are assembled in parallel with Trans-ABySS. The assembled transcripts are then aligned to the reference genome with GMAP. Finally, PAVFinder is used to identify variants such as gene fusions, indels, internal and partial tandem duplications (ITDs and PTDs), and alternative splicing such as novel exon skipping. TAP's performance was assessed with the Illumina RNA-seq data of AML patients from the LEUCEGENE project. In our first test set of 4 samples, TAP was able to detect all *NUP98-NSD1* fusions and *FLT3*-ITDs of various sizes. In our second test set of 2 samples, TAP was able to detect *RUNX1-RUNX1T1* and *CBFB-MYH11* fusions and *FLT3*-ITDs. Some cancer genes involved in gene fusions are known to be promiscuous with different partners. One of the features of TAP is its ability to detect fusion events as long as one gene partner is present in the target list. We tested this feature by running TAP using a single *KMT2A* Bloom filter on 9 representative samples, each carrying a *KMT2A* fusion with a different gene partner. TAP was able to detect all the gene fusions. The RNA-seq data in our test set contains over 100 million read pairs. Our target gene list consists of 595 genes from the COSMIC Cancer Gene Census. The runtime for the TAP pipeline on the test sets is around 2 hours on average using a machine with 24 CPUs and 48GB of RAM running CentOS 6. We conclude that TAP's runtime and accuracy are suitable for potential clinical genomics applications.

ChARMDiff: **Discovery of combinatorial chromatin state difference in multiple cell types and conditions.** *S. Park, S. Kim.* Department of Bioinformatics and Life Science, Soongsil University, Seoul, R.O.Korea.

Various chromatin modifications, identified in large-scale epigenomic analyses, are associated with distinct phenotypes of different cells and disease phases. To improve our understanding of these variations, many computational methods have been developed to discover novel sites and cell-specific chromatin modifications. However, the discovery of combinatorial patterns of differential chromatin modifications across tissues, cell types, and disease phases, is a non-trivial task and remained unaddressed. In this regard, we report *ChARMDiff*, a new computational approach based on association rule mining, which is pattern discovery of *de novo* differential chromatin modifications and characterize globally occurred patterns of combinatorial chromatin state difference between multiple cell types and conditions. By applying *ChARMDiff* to two pairs of epigenomes in normal and cancer cells i.e., GM12878 and K562 from ENCODE and from normal and hepatocellular carcinoma tissues of hepatitis B virus X -transgenic mice. We find that genes in distinctive chromatin modification pattern are enriched in the significant canonical pathways accounted for the pathogenesis of leukemia and human hepatocellular carcinoma and are differentially expressed. *ChARMDiff* provides a scalable framework that can easily be applied to find various levels of combination patterns, which should reflect a range of globally common to locally rare chromatin modifications. Our approach provides new insights into the resolution of the histone code hypothesis to characterize epigenetic variations in distinct phenotypes of different cells, disease phase and experimental conditions.

2829F

Analysis of genetic variation data and its relationship to protein sequence and 3D structures. *A. Prlic[1], T. Kalro[1], R. Bhattacharya[2], C. Christie[1], P.W. Rose[1], S.K. Burley[3,4].* 1) RCSB Protein Data Bank, San Diego Supercomputer Center and Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California San Diego,, La Jolla, CA 92093, USA; 2) Bioinformatics and Medical Informatics, San Diego State University, San Diego, CA 92182, USA; 3) RCSB Protein Data Bank, Department of Chemistry and Chemical Biology, Center for Integrative Proteomics Research and Institute for Quantitative Biomedicine, Rutgers, The State University of New Jersey, Piscataway, NJ 08854, USA; 4) Rutgers Cancer Institute of New Jersey, New Brunswick, NJ 08903, USA.

   Statement of purpose: Knowledge of the 3D structure of a protein at the atomic-level, provides deep insights into the molecular mechanisms underpinning normal cellular or biochemical function and potential roles in disease. To enable analyses of changes in protein sequence and structure resulting from genetic variation, we have developed novel tools that facilitate mapping of any genetic location onto corresponding protein sequence isoforms and 3D protein structures available from the Protein Data Bank archive. Our tools permit annotation of large sets of genetic variation data by correlating genomic location and sequence variation data with more than 60 external resources and protein 3D structural data housed within the data-warehouse that supports the RCSB PDB website (rcsb.org). Novel visualisation tools provide graphical depictions of the mapping of genetic variation to protein sequence and 3D structural features.**Methods used:**We developed a mapping for every nucleotide in a known human gene (as available from the HGNC; genenames.org) at a specific position in the reference genome to the mRNA and the relevant codon together with the corresponding residue of the protein isoform, plus 3D atomic coordinates. A user interface is available for manual analysis (http://www.rcsb.org/pdb/chromosome.do). The data can also be used for batch-analysis of a large number of genetic locations (e.g., for SNV analysis), using Apache Spark via 'DataFrames'.**Summary of Results:**Annotations for ~19,000 human genes are freely available from public sources. Using our analysis tools, any genomic location can be mapped to UniProt and the PDB archive of 3D structures (if available), together with a collection of additional protein-level annotations. At present, ~5200 distinct human genes can be mapped onto ~8100 experimentally-determined structures housed within the PDB archive. Extending this approach to computed homology models of human gene products will allow us to map up to 50% of all human genes on 3D structural models, when an experimental structure of the human protein is not yet available.

2830W

Landscape of somatic mutations in the normal-appearing airway cancerization field of early-stage non-small cell lung cancer. *P. Scheet[1,2], S. Sivakumar[1,2], C.L. McDowell[3], Y.A. Jakubek[1], W. Lang[3], L. Xu[3], C. Chow[4], J. Wang[5], J. Fujimoto[3], J. Fowler[1], G.E. Davies[6], I.I. Wistuba[3], E. Ehli[6], H. Kadara[3,7].* 1) Department of Epidemiology, MD Anderson Cancer Center, Houston, TX; 2) The University of Texas Graduate School of Biomedical Sciences, Houston, TX; 3) Department of Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX; 4) Department of Thoracic/Head & Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX; 5) Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX; 6) Avera Institute for Human Genetics, Sioux Falls, SD; 7) The American University of Beirut, Beirut, Lebanon.

   Lung cancer is the second most prevalent form of cancer among men and women in the United States. It is also the leading cause of cancer mortality resulting in 1 of every 4 cancer deaths. Non-small cell lung cancer, a predominant form of lung cancer, is primarily composed of adenocarcinomas (LUAD) and squamous cell carcinomas (LUSC). "Field cancerization" theory predicts that normal appearing tissues surrounding a tumor will exhibit a "field effect" -- typically, though not absolutely, induced by smoking -- with the closer tissues showing more alterations than those farther away from the tumor. This is thought to extend to, and include, overlap with alterations in the tumor, as well. However, due to the histological complexity of LUADs, previous studies provide evidence for both linear and nonlinear progression of these tumors. Yet, the precise mechanism remains unknown. To investigate this phenomenon, we performed a genome-wide assessment of mutation profiles from targeted sequencing of 48 cases with 500 multi-region samples of the field, specifically comprising the lung tumor (LUAD and LUSC), small and large airways, nasal epithelium, as well as adjacent normal lung and blood. For 28 cases, core needle biopsy samples (CNBs) from different regions of the tumor were also profiled. We aim to compare the field cancerization of the two subtypes, assess the impact of smoking, and test for intratumor heterogeneity among the CNBs. After rigorous filtering, we obtained 267 samples with variant calls, mostly in CNBs and tumor tissues, as expected. The tumor samples showed a higher proportion of C:G>A:T variants, consistent with smoking status. We also observed concordance of mutation calls across multiple within-patient tumor/CNB samples as well as airway samples. Our initial findings identified six cases with variants in small airways comprising lung cancer drivers such as KRAS, STK11, TP53 and KEAP1; four cases showed overlapping genes with their matched tumor samples as well. We also identified variants in the normal lung (RB1, RET, IDH2), nasal epithelium (AKT1) and large airway (TP53, TSHR, SETD2, CDKN2A). These novel findings in normal-appearing tissues of the respiratory epithelium offer insights into the earliest mutational events in their progression to tumors or in local/ regional metastasis, especially in LUADs. Our results offer insights into early progression events and their potential utility as biomarkers or targets for chemoprevention of NSCLCs.

2831T

GFusion: A novel algorithm to identify fusion genes from cancer RNA-seq data. *X. Song, Q. Chen.* Nanjing University of Aseronautics and Astronautics, Nanjing, Jiangsu, China.

   Background: Cancer related fusion genes have attracted the attention of many scientists. With the development of next generation sequencing, computationally identifying fusion genes from RNA-seq data is a primary step in studying fusion genes in cancer. However, it remains a challenge to identify fusion genes with higher sensitivity and specificity. The current tools only used unmapped reads or discordant pairs, and neglected the mate reads information of the unmapped reads spanning fusion boundaries, leading to lots of spurious fusion genes are discovered and defined as fusions. Here, we present a novel fusion gene detection tool, GFusion, a powerful and efficient fusions detection method for both paired-end and single-end RNA-seq data, to predict fusion genes by comprehensive analysis of realigned split reads or spanning fragments. **Methods**: In this work the GFusion pipeline performs multiple alignments and strict filtering algorithm to improve sensitivity and reduce the false positive rate. The main steps of GFusion procedure involves with following seven steps: Initial alignment, Creation of anchors, Aligning and locating anchors, Locating fusion boundaries, Confirming fusion models, Aggregating candidate fusions, Constructing fusion index and realigning. One of powerful features in GFusion is that it focuses more on the mapped mate reads and split reads. GFusion requires the anchor length more than 20bp to minimize impact of short sequence multi-mapping. **Results**: GFusion successfully detected 26 from 30 previously reported fusions in four cancer datasets (three breast cancer cell lines BT474, SKBR3, MCF7 and a normal breast cell line). We also demonstrated the effectiveness of GFusion using 24 million 76bp paired-end reads simulation data which contains 42 artificial fusion genes, among which GFusion successfully discovered 37 fusion genes. Compared with existing methods (FusionSeq, FusionMap, Tophat-fusion), GFusion presented higher sensitivity and lower false positive rate. The GFusion pipeline can be accessed freely for non-commercial purposes at: http://bioinfo.nuaa.edu.cn/GFusion.html.

Germline mutations in cancer-predisposing genes: Clinically actionable genetic variants in 300 patients. *A.P. Tafti[1], K.Y. He[2], M.M. He[1,3,4].* 1) Center for Human Genetics, Marshfield Clinic Research Foundation, Marshfield, WI 54449, USA; 2) Department of Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, OH 44106, USA; 3) Biomedical Informatics Research Center, Marshfield Clinic Research Foundation, Marshfield, WI 54449, USA; 4) Computation and Informatics in Biology and Medicine, University of Wisconsin-Madison, Madison, WI 53706, USA.

Statement of purpose: Detection of clinically actionable genetic variants across cancer-predisposing genes using whole-genome sequencing (WGS) data and electronic health records (EHRs) may expand our understanding of carcinogenesis, direct personalized patient care, and enable genetic counseling for patients and families. Our objective is to identify clinically actionable germline mutations in cancer-predisposition genes using patients' WGS data and comprehensive EHRs. Methods used: We analyzed genetic mutations in 565 cancer-predisposition genes in 300 deceased patients with complete lifetime medical records. The 565 genes include 60 autosomal dominant cancer predisposition genes, 29 autosomal recessive genes, 58 tumor suppressor genes, 23 kinase genes, and additional 395 cancer-associated genes [1]. To infer biological insights from massive volume of WGS data and comprehensive clinical data in a short amount of time, we developed an in-house analysis pipeline within a software framework called SeqHBase [2] to quickly classify genetic pathogenicity based on variant biological function, frequency, ClinVar, and the latest ACMG guidelines [3]. Clinical data of the carriers of pathogenic and/or likely pathogenic variants were reviewed to assess their clinical conditions using their lifetime EHRs. Summary of results: We identified 33 pathogenic and/or likely pathogenic variants including 12 novel loss-of-function variants. Among the 300 participants, 44 (14.7%) carried one or more presumed pathogenic or likely pathogenic variants in at least one of the 565 cancer-predisposing genes. More importantly, 38 patients (12.7% of the population) had a genetic profile likely to cause a cancer predisposition syndrome. When assessing extensive clinical data, a majority (38/44; over 86%) of the 44 patients had different types of cancers. This work shows an estimate of clinically actionable genetic mutations in cancer predisposing genes, which could be potentially used for clinical diagnosis, prevention, and/or personalized treatments, expected from WGS. Identifying statistically significant SNP combinations from GWAS dataset with confounding variable. *A. Terada[1,2,3], D. du Verle[2,3], K. Tsuda[2,3,4], J. Sese[3,5].* 1) PRESTO, JST, Kawaguchi, Saitama, Japan; 2) Dept of Comp. Biol. and Med. Sci., The Univ. of Tokyo, Kashiwa, Chiba, Japan; 3) BRD, AIST, Koto-ku, Tokyo, Japan; 4) NIMS, Tsukuba, Ibaraki, Japan; 5) AIRC, AIST, Koto-ku, Tokyo, Japan.

Epistatic interactions are associated with complex phenotypes in humans, and detecting the combinatorial effect of SNPs is key to understand causal factors of disease. While various statistical analysis methods have been proposed to detect combination of SNPs significantly associated with a target trait, few methods can simultaneously address the following two issues: (1) difficulty of investigating high-order combination of SNPs (2) risk of spurious results due to confounding variables (e.g. age and gender). Recently, a multiple testing procedure, named Limitless Arity Multiple-testing procedure (LAMP) [Terada et al, 2013], was proposed to address this first issue of combinatorial effect discovery. However, because LAMP cannot consider the effect of confounding variables (the second issue), it may produce spurious results in GWAS. In our research, we propose a novel multiple testing procedure so as to evaluate statistical significance of combinations under confounding variables. Using a new testability bound based on the exact logistic regression model for stratified dataset, our algorithm can efficiently compute the significance with no combination size limit. We applied our method to a postmenopausal breast cancer GWAS dataset [Hunter et al., 2007] containing 2434 individuals. We analyzed 4432 exon SNPs, using age as a confounding variable. Our method confirmed a combination of 6 SNPs statistically significantly associated with breast cancer occurrence, independently of the effect of age.

Inferring escape and reversion rates of cancer neo-antigens in response to T-cell mediated immune presence. *M. Tutert[1], L. Shlush[5], A. Mitchell[5], J. Dick[1,4,5], P. Awadalla[1,2,3,4].* 1) Informatics and Bio-computing, Ontario Institute for Cancer Research, Toronto, Canada; 2) Department of Pediatrics, University of Montreal, Montreal, Quebec, Canada; 3) St. Justine Research Hospital, Montreal, Quebec, Canada; 4) Department of Molecular Genetics, University of Toronto, Ontario, Canada; 5) Princess Margaret Cancer Centre, University Health Network, Toronto, Ontario, Canada.

Neo-antigens are peptides that arise from somatic mutations in the human genome, which induce an anti-tumour immune response and have long been targets of cancer therapies. An immune response is dependent on successful recognition of the presented epitope to T-cells. Hence, mutations in the sequences surrounding epitopes can inhibit immune presentation or recognition and thereby influence the response of the antigen-processing pathway, enabling tumours to escape the immune system response. Inversely, epitopes are also able to revert and mutate into forms that are instead recognized by the immune response. Current methods for identifying immunologically active epitopes are based on DNA sequencing of tumours, but these methods often fail to capture the selective pressure by the immune system on sequences surrounding potential epitopes, as well as account for the variable expression due to the highly polymorphic human leukocyte antigen (HLA) genes. For this study, we use Pancan cancer analysis of whole genome (PCAWG) and exploit Acute Myeloid Leukemia (AML) genomic data including whole genome (WGS), exome and transcriptome sequencing from plasma blood taken at patient diagnosis and relapse, and whole genome sequencing of T-cells. Using existing bioinformatics pipelines, HLA typing based on WGS for these patients was performed and cross-referenced against matched RNA-sequencing data for HLA allele expression. Additionally, a subsequent mutation detection pipeline used these inferred alleles to examine detection of mutations in HLA genes. A hidden Markov model (HMM) approach was then taken to account for immune-mediated evolution of epitopes. Since selective pressure for immune escape causes a reduction in the frequency of a wild-type amino acid, we find that the expression of an HLA allele in the host provides a much better model for epitope prediction than looking at sequence data alone. This can be combined with a phylogenetic HMM which is able to make probabilistic epitope predictions based on sequence evolution. Additionally, ordinary differential equation models (ODE) were used in combination with these phylogenetic models to integrate available sequence data and estimate escape and reversion rates for list of epitopes of each patient. This model applies dynamic programming, phylogenetic, statistical and ODE-based modelling to examine epitope parameters in an effort to understand the dependence on epitopes selective pressure by the immune system.

Identification of germline copy number variations in hereditary prostate cancer cases using whole-exome sequencing analysis. *K. Wood[1], M. Baddoo[2], D. Mandal[1].* 1) Department of Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) Tulane Cancer Center, Tulane University, New Orleans, LA.

Family history is one of the most prominent predictors of prostate cancer (PCa) risk, and approximately 10% of PCa cases are attributable to inheritable genetic factors. Next-generation sequencing (NGS), including whole-exome sequencing (WES), provides reliable large scale data that can be used for variant identification in PCa. Genomic copy number variations (CNVs) have been detected in prostate tumors, but changes in copy number have not been studied in germline DNAs from hereditary PCa (HPC) cases. The goal of the present study is to use a CNV-specific algorithm to identify CNVs in WES data on Louisiana HPC families. We hypothesize that CNVs in actionable genes contribute to high-risk PCa cases. We have WES data on 3 affected cases from 3 different high-risk HPC families (≥5 PCa affected/family) from Louisiana. Two of the cases are African Americans and one is Caucasian, and the age at diagnosis ranges from 51 to 60 years of age. A CNV-specific calling algorithm implemented in CANOES was used on WES data in order to successfully call the CNVs. CANOES works by reading the WES data files into R programming language, calling CNVs in the samples by modeling read counts using a precise distribution, and plotting all the CNV calls. Following the detection of CNVs, the variants were visualized using Integrative Genomics Viewer (IGV), which is used to visualize genomic variants, including changes in copy number. CANOES called a total of 446 germline CNVs from the WES data, and 278 of the CNVs were confirmed using IGV. Of the 278 CNVs, 84 were in exonic regions of genes, including the exonic regions of 7 cancer-related genes. Four of these 7 cancer-related genes have previously been associated with prostate tumors, including *SPAG11A*, *DMBT1*, *POTEM* and *CKMT1B*. To our knowledge, this is the first time these 4 genes have been found to be altered in the germlines of PCa-affected individuals. In future studies, we will apply the same bioinformatics pipeline to germline WES data for additional PCa cases and unaffected relatives from the same families and from other HPC families. The identification of germline CNVs within HPC families will contribute to the impending need of cancer biomarker identification in the era of precision medicine, and will allow us to facilitate PCa screening in HPC families.

TASRcloud: **Targeted** *de novo* **assembly of candidate genes on the cloud.** *Z. Xue, R.L. Warren, E. Gibb, D. MacMillan, R. Chiu, J. Chu, I. Birol.* Genome Sciences Centre, BC Cancer Agency, Vancouver, BC, Canada.

The steep decline in DNA sequencing costs over the last decade has enabled the genome and transcriptome sequencing of large patient cohorts, such as those from The Cancer Genome Atlas (TCGA). Traditionally, laboratories were downloading and using these data on an individual basis, which is often a substantial undertaking and an inefficient practice. We present *TASRcloud*, a novel targeted de novo sequence assembly methodology on the NCI Cancer Genomics Cloud Pilots. Application of targeted *de novo* assembly approaches to large sample cohorts is often overlooked. When a researcher is interested in a specific gene or sequence, a complete assembly becomes unnecessarily complicated and confounding. The retrospective targeted reconstruction of transcripts in large cohorts leverages pre-existing big data as a near-inexhaustible sequence source for focused discovery. The targeted sequence assembly approach uses established bioinformatics software that are already in use at the Institute for Systems Biology (ISB) Cloud Pilots in Seattle, including BioBloom Tools (BBT), and award-winning *de novo* genome assembler ABySS. Over 50% of human genes are estimated to produce two or more transcript isoforms via alternative polyadenylation (APA) [1], indicating that shifts in 3' untranslated region (UTR) lengths may represent a general mechanism for regulating gene expression by post-transcriptional processing. In cancer, a global shortening of 3' UTRs has been observed [2], suggesting a mechanism by which certain genes in cancer pathways may escape the regulatory effects of other molecules. We report on a specific application of *TASRcloud*, by conducting a comprehensive pan-cancer survey of tumor-associated APA events by targeted reconstruction of candidate 3'-UTRs, and demonstrate the utility of cloud computing resources for targeted cancer genomics studies by leveraging TCGA data via the NCI Cancer Genomics Cloud Pilots program. Visualization and analysis of cancer genomics data with omics tools. *C. Yan, Y. Hu, Q. Chen, D. Meerzaman.* NCI, Rockville, MD.

Next generation sequencing technologies have generated large amounts of multidimensional genomics data to obtain the complete landscape of tumor alterations. Visualization and network analysis tools are commonly used to uncover the complex interrelationships among mutation, expression, copy number and methylation profiles. We have developed two R packages OmicCircos and OmicPath to generate high-quality circular plots and network graphics in Bioconductor environment. OmicCircos has been downloaded for more than 10,000 times in the past three years. With implementation of users' suggested functions, we updated OmicCircos with the advanced zoom and text manipulation capabilities. OmicPath is a novel R package to perform pathway analysis, construct de novo network and run systematic functional annotation. It performs multiple statistical analyses on several pathway databases such as PID, KEGG, and user-defined networks. OmicPath provides an easy way to examine the network topology characteristics of expression and mutation profiles in cancers. The utilization of these packages will contribute to a better understanding of cancer molecular etiology.

mTCTdb: An integrative resource for mutation-dependent targeted cancer therapy. *H. Yao[1], M. Li[1], Z. Liu[1], H. Xu[1], P. Sham[1], J. Wang[2].* 1) Center for Genomic Sciences, LKS Faculty of Medicine, The University of Hong Kong , Hong Kong, China; 2) Department of Health Sciences Research and Center for Individualized Medicine, Mayo Clinic, Scottsdale, AZ 85259, USA.

Recent advances on next-generation sequencing technologies have enabled efficient and accurate detection of somatic alterations from tumor tissue or liquid biopsy of a cancer patient. These personalized tumor mutation profiles provide valuable information for targeted cancer therapy, which identifies the optimal drug(s) or treatment(s) to patient. However, mutation-dependent drug response information, or rather mutation therapeutic implications more generally, have not been well collected and structured. Here we developed an integrative database to provide researchers and clinicians with a combination of mutation information, mutation therapeutic implications and corresponding drug information. Mutation information were obtained from various mutation annotations and functional prediction algorithms. Drug information were collected from databases including DrugBank, DGIdb, TTD, ClinicalTrials.gov and then corrected manually through FDA and literature. Mutation therapeutic implications were acquired both from database such as CIViC and our manual curation. Mutation-oriented drug recommendations are offered in two levels, including direct evidence and gene-drug relationship based prioritization. Given a specific mutation, our resource could provide comprehensive mutation annotation and corresponding therapeutic information, which will benefit both clinicians and researchers. The link of this database will be provided by the end of June, 2016.

Predicting genome-wide DNA methylation of repetitive elements. *Y. Zheng[1,2], L. Liu[1,3], W. Zhang[1,3], B. Joyce[1,4], Z. Zhang[1,5], W. Kibbe[6], L. Hou[1,3].* 1) Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL; 2) Health Sciences Integrated PhD Program, Northwestern University Feinberg School of Medicine, Chicago, IL; 3) Robert H. Lurie Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL; 4) 3Robert H. Lurie Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, Illinois 60611, USA Division of Epidemiology/Biostatistics, School of Public Health, University of Illinois at Chicago, Chicago, IL; 5) Driskill Graduate Program in Life Sciences, Northwestern University Feinberg School of Medicine, Chicago, IL; 6) Center for Biomedical Informatics and Information Technology, National Cancer Institute, Rockville, MD.

DNA repetitive elements (REs) account for over 55% of the human genome, half of which can cause genomic instability by proliferating and inserting themselves into new genomic locations. DNA methylation is an epigenetic defense mechanism that suppresses RE mobility and thus maintains genomic stability. Accumulating evidence shows that methylation greatly varies across specific REs, suggesting distinct locus-specific roles. However, whole-genome RE methylation sequencing is challenging and remains prohibitively expensive for large population studies. The widely used surrogate approach of measuring global methylation by simply averaging methylation levels at various RE loci throughout the human genome may lead to massive information loss and substantially inhibit our ability to further elucidate the distinct biological roles of DNA methylation in locus-specific RE. We developed a random forest-based algorithm to computationally predict genome-wide, locus-specific RE methylation levels. With this algorithm we predicted methylation levels of two major REs, Alu or LINE-1, and verified them using cross-platform validation. By applying this algorithm to TCGA data, we identified that both hypo- and hyper-methylated Alu and LINE-1 could occur in tumor tissue, potentially involving different biological pathways. We also observed that using the mean value of Alu or LINE-1 methylation was less effective in discriminating tumor from normal tissue. Our work may lead to an improved understanding of the role played by DNA methylation of REs in human diseases.

2840T

An FFPE-based prognostic signature to predict metastasis in stage I/II microsatellite stable colorectal cancer. *C.H. Blöcker[1], Y.S. Low[2], J.R. McPherson[1], S.A. Tang[2], Y.Y. Cheng[1], J.Y.S. Wong[2], C. Chua[3], T.K.H. Lim[4], C.L. Tang[2], M.H. Chew[2], P. Tan[1,5], I.B. Tan[3], S.G. Rozen[1,5], P.Y. Cheah[1,2,6].* 1) Programme in Cancer & Stem Cell Biology, Duke-NUS Medical School, National University of Singapore, Singapore; 2) Department of Colorectal Surgery, Singapore General Hospital, Singapore; 3) National Cancer Center, Singapore; 4) Department of Pathology, Singapore General Hospital, Singapore; 5) The Precision Medicine Institute of SingHealth and Duke-NUS, Singapore; 6) Saw Swee Hock School of Public Health, National University of Singapore, Singapore.

PurposeApproximately 25% of early stage (I/II) patients with colorectal cancer (CRC) develop metastases despite curative surgery. Here, we aim to develop a formalin-fixed and paraffin embedded (FFPE)-based predictor of metastases in early stage, microsatellite-stable CRC patients.**Patients and Methods**In designing the predictor, we first considered genome-wide mRNA and miRNA expression and the mutation status of 20 genes as assayed in 150 fresh-frozen tumors. Based on microarray analysis of mRNA levels, we selected 193 potentially informative genes for analysis using NanoString nCounter arrays on the FFPE samples corresponding to the frozen tumors. Neither mutation status nor miRNA expression improved estimated prediction compared to prediction based on the mRNA levels of 193 genes alone. Furthermore, addition of genes beyond the top 19 did not improve prediction. The final predictor, ColoMet19, based on these 19 genes' mRNA levels assayed by nCounter in FFPE samples, had an estimated positive predictive value of 0.72 in the tumors on which it was developed.**Results**We tested ColoMet19 on an independent test set of 131 tumors with known metastasis status, and obtained a population adjusted positive predictive value of 0.73 and a negative predictive value of 0.82. Predicted-positive patients had poorer metastasis-free survival (hazard ratios 1.92 and 2.05 in the design and testing data, respectively).**Conclusion**The positive predictive value evaluated in the test set indicates that early stage CRC patients who are positive by ColoMet19 have a 73% risk of developing metastases. This risk is much higher than that of node-positive CRC patients, who are generally treated with adjuvant chemotherapy. Thus, early stage CRC patients who test positive by ColoMet19 may be considered for adjuvant therapy after surgery.

Integrating genome and transcriptome data to predict functional driver mutations in breast cancer. *K. Chen, Z. Wang, K. Ng, T. Chen, T. Kim, K.R. Shaw, F. Meric-Bernstam, G.B. Mills.* The University of Texas MD Anderson cancer center, Houston, TX.

Accurate prediction of the functional effects of genetic variation in cancer is critical for realizing the promise of precision medicine. Due to genetic heterogeneity across patients, predicting driver mutations using population genomic approaches remains challenging. We developed a novel Bayesian method, termed xDriver that integrates functional properties of mutations (such as evolutionary conservation) with quantitative traits (such as mRNA expressions) to achieve accurate, context-sensitive prediction of driver mutations. We demonstrate using 752 breast cancer samples in The Cancer Genome Atlas that our integrative approach is able to significantly improve the accuracy of driver mutation identification over existing approaches that do not perform such integration. In particular, our approach is able to enhance the functional prioritization of so-called "tail" (rare) mutations and more accurately delineate driver mutations specific to cancer subtypes (such as *PIK3CA* mutants associated with lymph node positive or negative patients). Importantly, scores generated by our model achieve better agreement with *in vitro* functional cell viability data obtained from growth factors-dependent Ba/F3 and MCF10A cell models, compared to predictions from other commonly used algorithms. Our study highlights the importance of integrating quantitative traits in predicting cancer driver mutations and provides a statistically rigorous solution to accelerate cancer target discovery and development.

Translating cancer genomics research bioinformatics to precision oncology: Accurate identification of somatic mutations in cancer patient specimens by NGS in clinical scenarios. *F.M. De La Vega[1,2], S. Irvine[3], D. Ware[3], K. Gaastra[3], Y. Pouliot[1], Y. Bouhlal[1], A. Vilborg[1], D. Mendoza[1], F. Goodsaid[1], A. So[1], L. Trigg[3].* 1) TOMA Biosciences, Foster City, CA, USA; 2) Stanford University School of Medicine, Stanford, CA, USA; 3) Real Time Genomics, Hamilton, New Zealand.

Tumor molecular profiling is rapidly becoming the standard clinical test for selecting targeted therapies in refractory cancer patients. DNA extracted from patient samples is enriched for cancer genes and sequenced to identify actionable somatic mutations therein. A major challenge arises when tumor-derived data is analyzed in the absence of normal tissue data, as it is common in clinical scenarios. The distinction between somatic and germline variants become difficult, leaving clinicians to resort to crude heuristic filtering. We present here a variant calling software, developed under quality system regulation protocols, capable of accurately identifying somatic mutations from targeted next-generation sequencing data. A novel Bayesian Network approach models the distribution of reads harboring germline and somatic mutations, estimates the contamination from normal tissue in the sample, scores somatic mutations, and imputes germline variants, without matching normal tissue data. This approach also allows joint analysis of multiple specimens from the same patient (e.g. FFPE and ctDNA) when available, improving the limit of detection. To improve specificity, our caller can also utilize prior information from different databases including somatic mutations, germline variation, and healthy controls data. We validated our method by analyzing data from the TOMA OS-Seq 131 cancer gene panel using the Illumina platform. To validate our method, we analyzed somatic mutations simulated on a background of data from reference samples, data on a dilution series from two reference samples, and several commercial control and clinical samples. We show that, compared to other commonly used methods, we can achieve higher true positive rate whilst maintaining a false discovery rate of 1%. In conclusion, we observe that our caller outperforms other software and is particularly well suited for the clinical use cases.

2843T

Tracing the origin of disseminated tumor cells in breast cancer using single-cell sequencing. *J. Demeulemeester[1,2], P. Kumar[3,4], E.K. Møller[5,6], S. Nord[5,6], D.C. Wedge[7], A. Peterson[8,9], R.R. Mathiesen[4,10,11], R. Fjelldal[12], M.Z. Esteki[3], A.J. Grundstad[8], E. Borgen[12], L.O. Baumbusch[1,13], A.-L. Børresen-Dale[5,6], K.P. White[8], B. Naume[6,10], V.N. Background Single-cell micro-metastases of solid tumors often occur in bone marrow. These disseminated tumor cells (DTCs) may resist therapy and lay dormant or progress to cause overt bone and visceral metastases. Unfortunately, the molecular nature of DTCs remains elusive, as well as when and from where in the tumor they originate. Here, we apply single-cell sequencing to identify and trace the origin of DTCs in breast cancer. **Results** We sequenced the genomes of 63 single cells isolated by micromanipulation from the bone marrow of six non-metastatic breast cancer patients using established immunocytochemical markers and morphologic characteristics for epithelial tumor cells. Comparison of the cells' DNA copy number aberration (CNA) landscapes with those of the primary tumors and lymph node metastasis established that almost half of the cells classified as tumor cells are indeed DTCs disseminating from the observed tumor. The remaining cells represented non-aberrant 'normal' cells and 'aberrant cells of unknown origin' that have CNA landscapes discordant from the tumor. Genotyping somatic mutations called on bulk tumor exomes in the single-cell sequences confirmed that these cells did not derive from the same lineages as the observed breast cancers. Intriguingly, their prevalence tends to increase with patient age. Evolutionary reconstruction analysis of bulk tumor and DTC genomes enabled ordering of CNA events in molecular pseudo-time and tracing the origin of the DTCs to either the main tumor clone, primary tumor subclones, or subclones in an axillary lymph node metastasis. **Conclusions** Single-cell sequencing of bone-marrow epithelial-like cells, in parallel with intra-tumor genetic heterogeneity profiling from bulk DNA, is a powerful approach to identify and study DTCs, yielding insight into metastatic processes. A heterogeneous and age-correlated population of CNA-positive cells of unknown origin is present in bone marrow.

Interactome-based approach to identification of cancer genes with low mutation frequency. *I. Glotova[1], D. Kural[2].* 1) Seven Bridges Genomics UK Ltd., London, United Kingdom; 2) Seven Bridges Genomics Inc., Cambridge, United States.

Large-scale cancer projects are generating constantly growing amounts of genomic data in many cancer types. One key challenge in the detection of functional cancer driver genes is the identification of genes with low mutation frequency. These genes are usually near significance when scored by driver gene callers, and could be identified as new drivers when more individuals are sequenced for the corresponding tumor. We applied a systems biology approach that integrates mutation data from 32 tumors with a human protein-protein and protein-DNA network (interactome). Using mutation data as input, four driver gene callers were employed for obtaining a list of predicted significant and near significance genes (NSGs) for each tumor: MutSigCV, DOTS-Finder, OncodriveFM and OncodriveCLUST. Simple mapping of known genes (Cancer Gene Census), significant genes and NSGs to the interactome shows that some NSGs do interact with at least one known/significant gene in the corresponding tumor network, and/or are involved in the same pathway(s) with certain known/significant genes. To further analyze the network properties of NSGs, we applied network-based localization measures: module size (largest connected component in a tumor network) and shortest mean distance (mean of all the shortest paths for all gene pairs in a tumor network). Although NSGs increase module size in most tumors that have an observable module, module size was found to be a degree-dependent property in 47% of these cancers (becomes non-significant if node degree is considered). However, mean shortest distance is not degree-dependent and is significantly lower (compared to random networks) in 26 tumors (even when NSGs are added to the tumor network). This observation shows that NSGs have a tendency to agglomerate in the same interactome neighborhood as known and predicted driver genes. Moreover, in 61.5% of tumors the addition of NSGs to the tumor network decreases its mean shortest distance. Thus, if combined with additional data sources like sequence, expression and genotypic data sets, mean shortest distance can be used as a predictive measure for low-frequency driver genes in different cancers. We also analyzed network-based separation between two tumor networks (shows if the gene neighborhoods of two tumors significantly overlap or are separated). NSGs were found to increase the overlap between some tumor neighborhoods, as well as decrease the overlap between others and make it non-significant.

Comprehensive molecular profiling and subtyping of lung adenocarcinoma in Asian population. *S. Hwang[1], J. Byn[2], C. Seo[3], J. Kim[1], Y. Jun[1], Y. Jung[1], C. Park[1], S. Kim[1], P. Kim[1], J. Seo[1], Y. Jang[1], N. Yu[1], Y. Jang[1], M. Lee[1], Y. Jung[1], S. Park[4], J.O. Yang[4], B. Lee[4], J. Lee[3], J. Kim[1], D. Hwang[2], J. Kim[5], S. Lee[1].* 1) Life Science, Ewha Womans University, Seoul, South Korea; 2) New Biology, Daegu-Gyungbuk Institute of Science and Technology, Deagu, South Korea; 3) DNA Link Inc., Business Cluster Center, 150 Bugahyeon-ro, Seodaemun-gu, Seoul, South Korea; 4) Korean Bioinformation Center (KOBIC), Korea Institute of Bioscience and Biotechnology, Deajon, South Korea; 5) Lung Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea.

Lung cancer is the most common cause of global cancer deaths, resulting in over a million deaths each year and adenocarcinoma is the most common subtype of lung cancer. Here we report molecular profiling of 114 lung adenocarcinoma (LUAD) patients in Korea using whole exome sequencing, transcriptome sequencing, and copy number variation analysis. Comparative analysis with ~1,000 cases from previous studies, which are mostly on Caucasian patients, showed a dramatic difference in mutation frequencies of EGFR and KRAS mainly due to the ethnic factor. EGFR mutations were more frequent in Asian patients, whereas mutations in KRAS were more common in Caucasians. In Asian LUAD patients, the major alterations were EGFR mutations or indels such as EGFR L858R and Exon 18 deletion, but many other driver alterations were also identified including fusion events of ALK, ROS, and RET genes and aberrant splicing in MET, TP53 and PTEN genes. Notably, we were able to identify actionable targets and therapies for ~80% of our LUAD patients. We have also developed a new patient stratification strategy combining the mutation and gene expression profiles. Mutation-based patient clustering suggested three subtypes – EGFR-only, EGFR and TP53, and high mutation (including KRAS) groups. The EGFR-only subtype showed significantly better prognosis than two other subtypes (p-value < 0.03). Patient clustering based on mRNA expression, using fold-change value between tumor and matched normal tissues, identified another three subtypes whose signature genes were enriched in the metabolism and PD-1 signaling, oncogenic pathways such as RTK-PI3K-AKT-mTOR, and metastatic processes. These three groups were in partial agreement with the TCGA subtypes of terminal respiratory unit, proximal proliferative, and proximal inflammatory subtypes, respectively. The metastatic subtype showed worse prognosis than two others. The subtypes from mutation-based and expression-based clustering were distinct and complementary. In conclusion, our comprehensive molecular profiling of lung adenocarcinoma among Asian population not only identified the ethnic difference in driver mutations and copy number alterations but also devised a new patient stratification scheme combining mutation and expression profiles, which might be valuable in suggesting personalized precision care for lung adenocarcinoma patients.

2846T

Don't assume infinite sites! Detection of intratumoral divergence of copy number alterations. *Y.A. Jakubek[1], H. Kadara[2,3], P. Scheet[1].* 1) Department of Epidemiology, The University of Texas MD Anderson Cancer Center, Houston, TX; 2) Department of Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX; 3) The American University of Beirut, Beirut, Lebanon.

Increased intratumoral heterogeneity is associated with poor prognosis for cancer patients. Genetic heterogeneity in the context of tumor genomes can generally be classified into two categories: single nucleotide variants (SNVs) and copy number alterations (CNAs); in the later category we include copy neutral loss of heterozygosity. Currently most methods for tumor heterogeneity detection focus on SNVs and net copy number differences among samples from the same tissue or tumor. These methods often apply an infinite sites model for both SNVs and CNAs. While this may often be appropriate for SNVs, we demonstrate its violation for CNAs in highly unstable cancer genomes. Here, we propose a novel method to identify divergent CNAs in multiple SNP DNA microarray data sets from the same tumor. In this context divergent is defined as a CNA identified in multiple samples from the same tumor but with different chromosomal changes giving rise to the CNA. Our algorithm uses B allele frequency (BAF) data from Illumina SNP arrays to detect regions where BAFs from germline heterozygous sites shift in opposite directions between pairs of samples (indicative of divergent tumor clones). We applied our method to data from core needle biopsies extracted from the tumors of 30 non-small cell lung cancer (NSCLC) patients. We observe instances of divergent allelic imbalance changes in 16 of the 30 cases comprising 2% of CNAs tested. Strikingly, one tumor had a rate of 16% divergent CNAs. These divergent genomic alterations represent about half of the total number expected since imbalances of the same haplotype will not be observable in such data. Some of the identified divergent events encompassed entire chromosomal arms (5p, 7q, 18p, 18q, 20p, 21q, 22q). Our method allows for the detection of genomic regions that are divergently lost or gained. This information can help identify CNAs under positive or negative selection in the tumor microenvironment. This approach provides an added dimension to tumor heterogeneity analysis for a more comprehensive characterization of cancer genomes.

GtExCLDB – A database of genotypes and gene expression for cancer cell lines. *I. Jeong, J. Kim, I. Choi, Y. Jun, S. Kim, M. Lee, S. Lee.* Ewha Womans University, Daehyeon-dong, Seodaemun-gu, Seoul, South Korea.

Cancer cell lines are essential resources for biomedical researches such as functional studies and screening experiments for developing therapeutic targets. Proper choice of cell lines that are suitable for experimental purpose is often difficult because the genotype and/or expression data are missing or scattered in diverse resources. Here we report the development of GtExCLDB, an online database resource of human cancer cell lines that provides the genotype and expression information. We have collected the mutation, gene expression, and copy number variation (CNV) data from three representative databases on cell lines – CCLE (Cancer Cell Line Encyclopedia), COSMIC (Catalogue of Somatic Mutations in Cancer), and NCI60. In total, GtExCLDB includes 1,787 cell lines from 170 cancer types and 29 tissues. Mutation, gene expression, and CNV information is available for 1,369, 1,318, and 1,613 cell lines, respectively. Since the microarray platforms are different for each database, we removed the batch effect using Combat software and re-processed the whole data of gene expression and SNP chips. The cell line information was standardized using Cellosaurus from ExPASy. Our user interface supports diverse queries where cancer types, tissues, genotypes, and gene expression conditions can be combined. For example, users can easily identify lung cancer cell lines with EGFR L858R mutation and browse the gene expression or CNVs in specific genomic region for those cell lines. Providing molecular characteristics as well as the clinical information, we believe that GtExCLDB would be a valuable resource for many biomedical researches for functional or screening studies. GeExCLD is available at http://gtexcldb.ewha.ac.kr.

Impact of genetic and epigenetic alterations in prostate cancer on tissue-specific regulatory network. *E. Khurana, P. Dhingra, A. Martinez Fundichely, A. Neil Forbes, E. Minwei Liu, D. Liu, A. Sboner, D. Rickman, M. Rubin.* Weill Cornell Medicine, New York, NY.

Prostate cancer is characterized by multiple recurrent genomic and epigenomic alterations. We investigated the combined effects of single nucleotide variants (SNVs), large structural variations (SVs) and DNA methylation changes on the prostate transcriptional machinery. We integrated whole-genome sequencing (WGS), RNA-seq and DNA methylation data from 521 primary prostate tumor samples with functional genomics data from the ENCODE and Roadmap Epigenomics projects. We developed a three step computational model: (a) construction of prostate regulatory network using DNase I hypersensitivity data, (b) identification of significantly mutated, rearranged and differentially methylated coding and non-coding regions in prostate cancer and, (c) interpretation of the effects of these alterations on prostate regulatory network. We identified 153 transcription factor (TF) hubs in the network, which include known prostate cancer genes (such as ERG) and novel candidates. Our results show that although more regions show significant differential methylation than SVs and SNVs in the regulatory network, a larger number of TF hubs are affected by SVs. This shows SVs are likely to play a stronger role in prostate cancer development by causing larger perturbations in the network as compared to SNVs and methylation changes. We hypothesized this may occur via crosstalk between TF hub expression (modulated by SVs) and DNA methylation changes. Consistent with the prediction, functional validation using Enhanced Reduced Representation Bisulphite Sequencing (ERRBS) shows global methylation changes caused by ERG overexpression. This work provides a novel framework for using tissue-specific regulatory networks to understand the global impact of genetic and epigenetic alterations in tumors.

Identifying transcriptomic mechanisms of gemcitabine resistance and counter-resistance pathways for pancreatic cancer using public data. *R. Kusko[1], Y. Cha[1], J. Perez-Rogers[2], N. Caballero[1], G. Koytiger[1], J. Shankar[1], A. Lysaght[1], B. Weiner[1], S. Kolitz[1], F. Towfic[1], K. Fowler[1], B. Vardarajan[1,3], M. Artyomov[1,4], B. Zeskind[1].* 1) Genomics, Immuneering, Cambridge, MA; 2) Computational Biomedicine, Boston University School of Medicine, Boston, MA; 3) Columbia University, New York, New York; 4) Washington University in St. Louis, St Louis, MO.

Although pancreatic cancer is increasing in incidence, therapeutic options remain limited. Treatment with gemcitabine or a gemcitabine combination therapy is most common, although current combination therapies are challenged by toxicity. The urgent unmet clinical need for promising novel combination therapies to enhance the efficacy of gemcitabine is suggested by the alarmingly high 5 year mortality rate. We studied gene expression data from 3 pancreatic cancer cell line datasets (Klijn et al, Collisson et al, and CCLE) to query druggable genes and pathways which mastermind gemcitabine resistance or encourage gemcitabine sensitivity. First we processed data and removed low quality samples, then utilized a t-test to pinpoint genes differentially expressed (DE) between cell lines that are sensitive vs resistant to gemcitabine as dictated by Collisson et al's IC50 values. The overlap of DE genes between all three studies revealed 83 genes upregulated and 48 genes downregulated in gemcitabine resistant cell lines. Specific genes of interest changing include upregulation of apoptosis suppressor TMBIM6 (p<0.003) and pro-survival gene IL20RA (p<0.003) in resistant cell lines. Enrichment of genes upregulated in resistant cell lines includes GEO Kinase perturbation ERBB3 (p.adj=3.28E-08) and GO cyclin-dependent protein serine/threonine kinase regulator activity (p.adj=0.038). GSEAP was conducted in each dataset separately, and top shared significant pathway results include upregulation of KEGG drug metabolism cytochrome P450 (p.adj<0.0003) as well as Retinol metabolism (p.adj<0.0004). Drugs which downregulate these genes and pathways may enhance the effect of gemcitabine. Enrichment of genes upregulated in sensitive cell lines includes GEO Kinase Perturbation ALK (p.adj=1.16E-05) and IRAK4 (4.93E-06), as well as PPI Hub protein PRKACA. Drugs which enhance these kinases and hub proteins may increase effectiveness of gemcitabine. Ongoing work includes analysis to pinpoint drugs which may appropriately enhance or suppress above mentioned master regulators of resistance. Functional genomic studies are underway to validate key targets. By leveraging publicly available data to detailing a consistent gene set which separates gemcitabine sensitive from resistant pancreatic cancer cell lines, we have characterized numerous potential driver candidates and pathways which could be the key to a novel gemcitabine combination.

An analysis of expression of druggable targets and prostate cancer disease signatures in 2,978 patients with adverse pathology after radical prostatectomy: Initial results from the Decipher GRID. *J. Lehrer, M. Alshalalfa, N. Erho, H. Ashbab, M. Takhar, P. Wood, L. Lam, E. Davicioni.* GenomeDx, Vancouver, BC, Canada.

   INTRODUCTIONProstate cancer patient management has been enhanced with several commercial genomic prognostic tests such as the Decipher® prostate cancer classifier. Unlike other tests, Decipher generates genome-wide expression data for each patient. This data has been anonymized and made available for research in the Decipher GRID™. Here we report an initial analysis further characterizing the genomic landscape of localized prostate cancer patients most at risk for recurrence after radical prostatectomy. **METHODS**We conducted a literature search to identify genes and signatures of potential clinical relevance to prostate cancer. The expression and distribution of 697 genes and 31 prostate cancer disease signatures for metastasis risk, proliferation, luminal/basal, small cell and AR signalling were examined across 2,978 radical prostatectomy tumors with adverse pathology tested with Decipher and available in the GRID. For the 697 genes, expression distribution was characterized and high and low expression were defined using thresholds based on median +/- 1.5*1.48*MAD (median absolute deviation). Genes from 31 published prostate cancer signatures were adapted to the Decipher platform and scores were calculated. **RESULTS**For various druggable targets including immune checkpoint inhibitors (PD1, PDL1) and growth receptors (c-MET, EGFR, HER), between 2-11% of patients had high expression above right threshold. Clustering of scores for 31 signatures revealed several clear groupings of patients. About 20% of patients consistently had high scores for all the metastasis risk signatures and low-average AR signalling scores. About 10% of patients had high scores for the proliferation signatures but low metastasis risk scores. Tumors with low AR signalling scores were enriched with high basal and small cell signature scores whereas most luminal tumors had higher AR signalling. **CONCLUSIONS**Since every patient who has received the Decipher test also has a genome-wide expression profile, the Decipher GRID allows researchers to evaluate on a systematic, population-level the expression of genes and signatures that may guide therapies. Such information may be useful for selection of optimal systemic therapy and inclusion into clinical trials of novel targeted agents. This rich genomic resource is being made available on a research use only basis to prostate cancer researchers and to clinicians seeking to better understand prostate cancer in order to advance precision medicine.

RNA sequencing-based cell proliferation analysis across 19 cancers identifies a subset of proliferation-informative cancers with a common survival signature. *R. Ramaker[1,2], B. Lasseigene[1], A. Hardigan[1,2], S. Cooper[1], R. Myers[1].* 1) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 2) University of Alabama at Birmingham, Birmingham, AL.

   Despite advances in cancer diagnosis and treatment strategies, robust prognostic signatures remain elusive in most cancers. Cell proliferation has long been recognized as a prognostic marker in cancer, but it has not been thoroughly investigated across multiple cancers using tissue-based RNA sequencing. Here we explore the role of cell proliferation across 19 cancers (n=6,581 patients) from The Cancer Genome Atlas project by employing a 'proliferative index' derived from gene expression associated with *PCNA* expression. This proliferative index is significantly associated with patient survival (Cox, FDR<0.05) in 7/19 cancers, which we have defined as 'proliferation-informative cancers' (PICs). In PICs the proliferative index is strongly correlated with tumor stage and nodal invasion. PICs paradoxically demonstrate reduced baseline expression of proliferation machinery relative to non-PICs suggesting that non-PICs may saturate their proliferative capacity early in tumor development and allow other factors to dictate prognostic outcomes. We find that tumor proliferative index is significantly associated with gross somatic mutation burden (Spearman, p=1.76×10^{-23}) as well as protein altering mutations in well-characterized driver genes such as *TP53*, *PIK3K*, and *RB1*. In breast cancer, protein altering mutations in *RELN* were associated with increased proliferative index (FDR<0.1) across all PAM50 subtypes and decreased expression of *RELN* was associated with poor prognosis (p=0.08) in patients with basal breast cancer. This analysis provides a comprehensive characterization of tumor proliferation rates and their association with disease progression and prognosis across cancer types and highlights specific cancers and mutation events that may be particularly susceptible to improved targeting of this classic cancer hallmark. .

Patterns of somatic genomic variation in premalignant lesions inform insights into early pathogenesis of lung adenocarcinomas. *S. Sivakumar[1,2], J. Fowler[1], Y. Jakubek[1], C.L. McDowell[3], W. Lang[3], L. Xu[3], J. Fujimoto[3], E. Ehli[4], Y. Yatabe[5], H. Kadara[3,6], P. Scheet[1,2].* 1) Department of Epidemiology, The University of Texas MD Anderson Cancer Center, Houston, TX; 2) The University of Texas Graduate School of Biomedical Sciences, Houston, TX; 3) Department of Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX; 4) Avera Institute for Human Genetics, Sioux Falls, SD; 5) Department of Pathology and Molecular Diagnostics, Aichi Cancer Center, Nagoya, Japan; 6) The American University of Beirut, Beirut, Lebanon.

Lung cancer is the second most prevalent form of cancer and the leading cause of cancer-related deaths worldwide. Its high mortality is due to late diagnosis and further compounded by a dearth of knowledge about its molecular evolution and pathogenesis, especially for the major histological type, adenocarcinoma (LUAD). Here we profile mutations and gene expression in a cohort of 25 patients with matched tumor, premalignant and normal tissues, to identify signatures indicative of the neoplastic progression of premalignant tissues to invasive LUAD. The premalignant tissues (atypical adenomatous hyperplasia; AAH), are considered precursor lesions to LUAD. We carry out a genome-wide assessment of single nucleotide variants and copy number alteration profiles through a cross-platform analysis comprising Ion Torrent deep targeted sequencing of cancer associated genes and broader-scale whole-genome SNP genotyping arrays in order to identify events in AAHs that overlap or differ from LUADs. We will also assess associations with smoking. As Ion Torrent is challenged to resolve homopolymers, we developed an algorithm that considerably reduced artifacts and is now part of our automated QC variant pipeline for this technology. From our preliminary mutation analysis of 10 patients (6 ever-, 4 never-smokers), we observed 16 genes, including known lung cancer drivers such as EGFR, TRIM24 and ABL2, from a within-patient between-tissue analysis; with up to 9 identical variants shared per patient. Moreover, at the tissue level, we found 22 genes common to AAHs and LUADs, including oncogenes such as EGFR, ABL2, RARA, JAK3 and tumor suppressor genes such as STK11 and SOCS1, offering evidence of AAH progressing to LUAD. Among non-synonymous variants unique to the AAH, we observed mutations in KRAS for two patients, both smokers, which may suggest early stages of a second primary tumor. Other variants unique to AAH include genes such as BRAF, SOX11, CSMD3, CDKN2A, NF1, and MAP2K2, all previously implicated in LUAD. Further, C:G>T:A transitions were the most common among all base substitutions, which is typical of EGFR mutants and non-smoker lesions. Our encouraging results offer a better understanding of the neoplastic progression mechanism in LUAD, thus aiding novel biomarker discovery for their early detection and possible chemoprevention.

Bioinformatics design and analysis approach for targeted NGS tumor immune response expression profiling. *Y. Sun, A. Atkins, A. Pankov, T. Looney, Y. Ku, W. Tom, F. Hyland, J. Au-Young, A. Mongan.* Thermo Fisher Scientific, South San Francisco, CA.

Targeted panel for transcriptional profiling offers increased sensitivity and higher degrees of sample multiplexing for selected gene targets of high interest. In particular, interleukins and other cytokines regulating the immune response are typically expressed at fairly low levels and would be undetectable without the use of targeted panels. Here, we present a 400-gene panel to evaluate the expression of genes involved in immune checkpoints, interferon signaling, cytokine signaling, T and B cell signaling, tumor antigens, and tumor proliferation markers. This panel is designed to be compatible with FFPE samples with low input requirements of 10 ng total RNA. The 400-gene amplicons are designed using AmpliSeq designer (https://www.ampliseq.com/browse.action). When multiple isoforms exist for a gene, the design targets multiple isoforms and allows for the quantitative measurement of the gene expression profile. To streamline the data processing and analysis, we developed an analysis package that automates QC assessment, read alignment, and read counts. Additionally, we implemented a normalization strategy beyond simple accounting for sequencing depth using a composite of 12 housekeeping genes. This approach leads to more accurate estimates of gene expression and fold changes. The analysis package is integrated into the Torrent Suite™ Software for automated sequencing data analysis and analysis report generation. We performed expression profiling analysis on 16 non-small cell lung cancer (NSCLC) FFPE samples, and demonstrated robust detection for expression of key cytokines including interferon gamma.

Regulation of the immune response by long non-coding RNAs in healthy subjects and stage IV melanoma patients. *Y. Zhang[1,2], L. Wang[1,2], S. Felts[3], V. Keulen[3], L. Pease[3].* 1) Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD; 2) Division of Biostatistics and Bioinformatics, University of Maryland Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD; 3) Department of Immunology, Mayo Clinic College of Medicine, Rochester, MN.

Tremendous advancements in genome-wide transcriptome annotation over the last decade have revealed that long non-coding RNAs (lncRNAs) are pervasively transcribed in human genome, which are emerging as key regulators of diverse cellular processes. However, functions and expression profiling of lncRNAs still remain elusive in the human immune system. In this study, we investigated the expression profiles of lncRNAs in CD4+, CD8+ and CD14+ peripheral blood cells from both healthy subjects and stage IV melanoma patients. First, we performed RNA-seq on 134 blood samples from 10 healthy subjects and 10 stage IV melanoma patients. In total, we reconstructed 346,746 RNA transcripts, 781 of which were significantly differentially expressed between healthy subjects and melanoma patients, including 512 in CD4+ cells, 304 in CD8+ cells and 79 in CD14+ cells. Among these RNA transcripts, we further identified 12,946 expressed lncRNAs including 9,296 annotated by GENCODE V23, 3,319 overlapping with known lncRNAs in GENCODE V23, and 331 novel long intergenic non-coding RNAs (lincRNAs) using our computational bioinformatics pipeline. 25 lncRNAs showed differential expression patterns between healthy and melanoma patient groups in at least one of CD4+, CD8+, and CD14+ cells. The co-expression analysis indicated that lncRNAs were correlatively expressed with genes involved in immune response and cancer progression. Our studies suggest that lncRNAs play crucial regulatory roles in human immune system and may shed light on the pathogenesis of melanoma.

A text mining and temporal analysis of cytogenetic data correlated with gene expression profiles reveals a dependence network of chromosome aberrations outlined by early and late cytogenetic events in prognostic subgroups of diffuse large B-cell lymphoma. *R. Garcia, P. Koduru.* UT Southwestern, Dallas, TX. 5323 Harry Hines Blvd, Dallas, TX 75390.

Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous group of neoplasms characterized by distinct morphological, immunophenotypic, cytogenetics and molecular features. In the present study, we examined the Mitelman and NCBI databases to construct a dependence network of recurrent cytogenetic aberrations (RCAs) in prognostic subgroups of DLBCL and correlate findings with gene expression. In addition, a temporal analysis was performed to outline early and late cytogenetic events in tumor progression. The R package containing the *tm* library was used to analyze the cytogenetic nomenclature and obtain chromosome aberrations and the *pvclust* library was used to design a hierarchical cluster of RCAs. Clusters with p-value <.05 were considered significant. Clusters were assigned based on established RCAs in DLBCL subtypes or literature review. To characterize RCAs at the molecular level, a gene expression profile was performed. The GSE26812 dataset from NCBI was used for this purpose and the GEO2R was used to obtain differently expressed genes. To outline clonal evolution, a principal component analysis and temporal analysis was performed in R. We identified 1433 cases of DLBCL. There were 235 RCAs that appeared at least 5 times but only 195 were used. Among these included: +18, t(14;18), -15, -17, -13, t(8;14), -10, -16, -20, -11,-18, add(14)(q32), -19, t(3;14). In terms of a dependence network of RCAs, we identified 61 significant clusters. Of the most prominent included: +18, +16; i(18)(q10),i(21)(q10); +19, +11; add(18)(p11), +i(18)(q10), del(9)(p), del(1)(q42) in ABC-DLBCL and t(14;18), dup(1)q; +X, +12; add(10)(q24), add(12)(q24); add(14)(q32), add(10)(q22); +15, del(1)(q32) in GCB-DLBCL. A cluster containing add(16)(p13) was assigned as PMBCL. Furthermore, our analysis showed correlations between clustered RCAs in DLBCL subtypes and gene expression, mainly described by dosage compensation in some instances or overexpression and under expression in others. Early cytogenetic events in tumor progression included largely translocations and gains of chromosomes, while monosomy of chromosomes was characterized by late events. In summary, our results demonstrate clonal evolution of unique groups of RCAs in DLBCL subtypes that may be used to predict outcome and further stratify DLBCL. Key words: DLBCL, RCAs, text mining, clonal evolution, gene expression.

2856F

Machine learning to prioritize cancer variants for screening of cell free DNA (cfDNA). *C. Cario, L. Leong, J. Witte.* Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, California.

Cell free DNA (cfDNA), a form of 'liquid biopsy', has recently emerged as a promising technology to screen, diagnose, and monitor many types of disease. In the context of cancer, it provides several benefits over traditional biopsy in examining the genetic structure of a tumor that include a simple and non-invasive sampling nature and the ability to detect subclonal variation. One unfortunate complication of cfDNA as a biomarker technology is a weak signal-to-noise ratio that arises primarily from contamination by DNA from healthy tissue. To circumvent this issue, many researchers have narrowed focus to probe a limited set of hand-picked coding variants within a single gene or a small gene panel, trading breadth for depth to improve signal. This approach, while sensible, can lead to detection issues in highly heterogeneous diseases-- like prostate cancer-- in which variants are not universally present at high proportion across patients. It also presents a scenario where bias can be induced when elucidating the underlying biological mechanisms of disease since hand-picked variants often exclude intergenic regions of the genome which may have functional importance. Our group proposes an unbiased approach to the design of a variant panel to screen and monitor heterogeneous cancers. Using prostate cancer to demonstrate this approach, a support vector machine (SVM) is trained on known genome wide tumor variants from the International Cancer Genome Consortium (ICGC) and an equal number of randomly simulated mutations. Using biologic annotation from a dozen databases, the machine learns the weighted combination of annotations most predictive of prostate cancer, and creates a model that can be used to prioritize variants for screening. Through cross validation, we demonstrate superior performance of this SVM directed panel over two hand-curated panels and a frequency-based approach in detection ability. To further assess the performance of this panel, samples from a cohort of over 100 prostate cancer patients undergoing treatment at the UCSF hospital system are being collected to determine the panel's sensitivity and specificity in detecting tumor variants. These results are being compared to identified variants from sequence data of multiple tumor foci in each patient. Clinical applications of the panel, such as the monitoring of residual disease, are also being evaluated.

2857W

Identify circulating DNA's tissue-of-origin in cancer by whole genome sequencing. *Y. Liu[1,2], S. Reed[2], G. Ha[2], S. Freeman[2], V. Adalsteinsson[2], M. Kellis[1,2].* 1) Massachusetts Institute of Technology; 2) Broad institute of MIT and Harvard, Cambridge, MA.

Circulating DNA (ctDNA) has been shown as an emerging non-invasive bio-marker to monitor the tumor progress in cancer patients. In late stage cancer patients, elevated ctDNA has been found not only from tumors, but also from normal tissues. Thus, the identification of ctDNA's tissue-of-origin is critical to understand the mechanism of tumor progression. Recent efforts to identify ctDNA's tissue-of-origin begin to utilize ctDNA's epigenomic status, such as DNA methylation and nucleosome spacing. However, both of these methods have their own limitations: (1) For nucleosome spacing, lack of reference nucleosome maps in different tumor and normal tissues has limited its application to tissue-of-origin deconvolution; (2) For DNA methylation, large DNA degradation during whole genome bisulfite sequencing (WGBS) library preparation, even with current low-input DNA technology, is still the major hurdle for its clinical application, although extensive DNA methylation studies by WGBS in tumor and normal tissues during the last decade have already provided enough reference maps. Very recently, a pioneer study showed significant differences between DNA fragment lengths of methylated and unmethylated ctDNA. Here, taking the advantage of this experimental observation, we developed a computational approach to identify ctDNA's tissue-of-origin by inferring its DNA methylation pattern from fragment information in whole genome sequencing (WGS). We systematically explored the correlation between DNA methylation measured by WGBS and fragment information measured by WGS from ctDNA of the same breast cancer patients. Furthermore, we deconvoluted ctDNA's tissue-of-origin status by using only fragment information from WGS in ctDNA and DNA methylation level from public available tumor and normal WGBS datasets. Overall, our methods here paved the road for ctDNA's application in clinical diagnosis.

2858T

Mammalian species conservation data and the implication for clinical variant classification. *P. Taylor, A. Alvarez-Buylla, Y. Kobayashi, S. Yang, K. Nykamp, S. Topper.* Invitae, San Francisco, CA, USA.

Functionally critical amino acid residues are subject to evolutionary pressure and are expected to be conserved, whereas non-critical positions may be more tolerant to variation. As such, evolutionary conservation data may be a powerful component of predicting the deleterious effect of missense mutations. In practice, however, the predictive power of existing conservation-based in silico algorithms has been inadequate for broad clinical application; the 2015 ACMG guidelines for the interpretation of sequence variants (ISV) consider consensus among multiple algorithms to be only supporting evidence for variant classification. However, the 2015 ACMG ISV also discusses an alternative application for conservation data: the presence of the variant amino acid change in multiple non-human mammalian species is designated strong evidence for a classification of benign. This distinction reflects the assumption that variation within the mammalian clade speaks more directly to questions related to mammalian physiology and is therefore more relevant to the question of human disease. To assess the predictive power of this type of data, we selected 6572 missense variants from our database and examined conservation across 61 non-human mammalian species. We identified 308 missense variants classified as pathogenic (P) or likely pathogenic (LP), and only two (0.6%) of these were present in multiple species; both were in genes associated with cardiovascular defects (*TTR* p.Val142Ile; *KCNH2* p.Ala913Val). By contrast, in silico algorithms predicted eight (2.6%) of the P/LP missense mutations to be tolerated. In 228 of 1427 (16.0%) missense variants classified as benign, the variant amino acid change was present in multiple species, which indicates a clear depletion of these events for deleterious variants. Our analysis confirms and extends the approach proposed in the 2015 ACMG ISV guidelines and suggests that non-conservation among mammalian species may be more accurate than complex in silico algorithms as an indicator that a variant is benign.

Improving somatic mutation identification in highly variable genomic regions using graph-based reference genomes. *H. Gibling[1,2], J.T. Simpson[1,3], P. Awadalla[1,2].* 1) Informatics and Bio-computing, Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 2) Molecular Genetics, University of Toronto, Toronto, Ontario, Canada; 3) Computer Science, University of Toronto, Toronto, Ontario, Canada.

The traditional method of comparing high-throughput sequencing (HTS) reads to a single haploid reference genome is useful for discovering somatic mutations, but less effective in regions of high variability between individuals in a population. One of the most polymorphic regions in the human genome is the major histocompatibility complex (MHC), containing over 200 human leukocyte antigen (HLA) genes which encode proteins that present foreign antigens to immune cells. There are thousands of known HLA alleles throughout the human population. Similarly, over 30 *PRDM9* alleles have been identified thus far, allowing for variation in the location of double strand breaks during meiotic homologous recombination. Variation in cancer HTS data make identifying somatic mutations difficult, and valuable information is lost in unmapped reads, particularly in regions of high variability. Both HLA genes and some alleles of *PRDM9* play roles in cancer development or progression, emphasizing the importance of accurately mapping sequencing reads to these regions when studying somatic mutations. To tackle difficulties in mapping HTS reads to highly variable regions, we exploit the flexible properties of sequence graphs. These graphs represent a genome by combining the reference sequence with known variation within the same data structure. HTS reads can align to variants including single nucleotide polymorphisms, insertions, and deletions by following a path through the graph. This flexibility resolves the issues that arise from mapping to a single haploid reference sequence, including uneven coverage in polymorphic regions and a bias towards overestimating reference allele frequencies. In addition, novel variants detected from HTS reads can be added to the graph to maintain a dynamic reference graph. Using the vg software package, we built two sequence graphs: one for the MHC locus using the reference and alternate haplotypes and SNPs from the 1000 Genomes Project, and one for *PRDM9* using allelic sequences from the polymorphic zinc finger array. Using whole genome sequencing data from the Pan Cancer Analysis of Whole Genomes (PCAWG) project, we intend to evaluate whether reference graphs improve coverage, variant calling, and allele typing compared to traditional mapping methods for these variable regions.

2860W

Discovery of mosaic point mutations in pediatric cancer using whole-exome sequencing of DNA extracted from blood. *E. Karlins[1,2], L. Mirabello[1], M.J. Machiela[1], R.A. Kleinerman[1], J.N. Sampson[1], B.L. Gallie[3,4,5], D.E. Rushlow[5], B. Hicks[1,2], B. Zhu[1,2], M. Dean[1], M. Yeager[1,2], S.J. Chanock[1], M. Tucker[1], S.A. Savage[1], L. Morton[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD, USA; 2) Cancer Genomics Research Laboratory, Leidos Biomedical Research, Frederick National Laboratory for Cancer Research, Frederick, MD 20877, USA; 3) Department of Ophthalmology and Vision Sciences, The Hospital for Sick Children, 555 University Ave., Toronto, ON M5G 1X8, Canada; 4) Departments of Ophthalmology & Vision Sciences, Molecular Genetics and Medical Biophysics, Faculty of Medicine, University of Toronto, Toronto, Canada; 5) Impact Genetics, Bowmanville, Ontario, Canada.

Germline mosaic mutations are known to contribute to pediatric cancer risk. In retinoblastoma it is estimated that ten percent of germline *RB1* mutations are mosaic. When a cancer risk gene is known, as is the case for retinoblastoma, deep sequencing or other techniques can be used to detect mosaic mutations, however when a specific gene is not known, deep sequencing on an exome level to detect mosaic mutations would be extremely expensive. Mosaic mutations are likely to be missed by traditional whole-exome sequencing (WES) variant callers since the mutant allele will be at too low frequency for variant discovery without also generating an excess of false positive variant calls.   Here we explore computational methods for mosaic mutation discovery from WES data using a set of validated blood DNA *RB1* variants from 89 retinoblastoma cases with Illumina WES. Eight of these 89 variants were classified as mosaic by the premier retinoblastoma genetic testing facility, and three of the mosaic mutations were not discovered by traditional exome variant calling. Relaxing variant caller parameters identify these mosaic variants, along with many false positives. We create a model of true positive mosaic variants using sequencing read level metrics as input to the model. Included in the model are metrics that are associated with a WES variant being a true positive and independent of proportion of reference alleles to alternative alleles: position of alternative alleles on the read, mapping quality of reads with alternative alleles, and base quality of alternative alleles as compared to reference alleles, for example. We then apply this model to a test set of 360 osteosarcoma cases with both Illumina WES data and targeted *TP53* Ion AmpliSeq data. For each input variant, the output of the model is a probability of the variant being a true positive. The user can set a probability threshold as desired based on specificity and sensitivity levels appropriate for his or her study.   Our methods can aid variant discovery after WES and rare variant filtering highlight candidate genes. In some instances, adding variants in one or two additional cases may be all that is needed to drive a burden test over the significance threshold. Using techniques like these to discover new variants from existing data can be a cost-effective step before variant validation and help inform decisions on whether to perform follow-up candidate gene deep sequencing.

2861T

AmpliconArchitect: A computational approach to elucidate complex rearrangements in genomes of virus-driven cancers. *V.B. Deshpande[1], N. Nguyen[1], H. Carter[2], R.B. Schwab[3], V. Bafna[1].* 1) Department of Computer Science and Engineering, University of California San Diego, La Jolla, CA; 2) Department of Medicine, Division of Hematology/Oncology and Moores Cancer Center, University of California San Diego, La Jolla, CA; 3) Department of Medicine, Division of Medical Genetics, University of California San Diego, La Jolla, CA.

Viruses have been implicated in 15% of all human cancers (11% of all cancer deaths). The integration of the viral genome into the host genome of a normal cell often precedes its transformation into a tumor cell. Viral integrations are reported to cause copy number amplification and structural variations near the integration site on the human chromosome. Existing tools detect integration sites but are unable to resolve the architecture of the human-viral chimeric amplicon, which consists of complex tandem duplications due to looping/episome formation of the chimeric region. Here we present a novel computational approach, AmpliconArchitect(AA), to automatically identify the amplified genomic regions and reconstruct plausible amplicon architectures. AA takes as input whole genome sequencing (WGS) paired-end reads aligned to a combined human-virus reference, using the following steps: (a) Use discordant read-pair alignments and coverage information to iteratively visit and extend connected genomic regions with high copy numbers. (b) Segment amplified regions using a mean-shift approach to detect copy number changes. (c) Use discordant read-pair clusters to construct a breakpoint graph connecting segments. (d) Compute a maximum likelihood network flow to estimate copy counts of genomic segments. (e) Report paths and cycles in the graph that identify the dominant linear and circular structures involved in the chimeric human-viral amplicon. We applied AA to 21 matched cervical cancer samples (20 TCGA+1 anonymous). All samples contained HPV DNA (HPV 16:11; HPV 18: 7; HPV 33, HPV 45, HPV 70: 1). Host integration was detected in 20/21 tumor samples but in no matched normal sample. All amplicons contained the *E6/E7* oncogenes, and 9/21 samples showed deletion in all or part of the *E2* gene, a key repressor of *E6/E7*. AA reported architecture for 16/21 samples, after discarding samples with low copy counts. Of these 16 samples, 3 displayed a simple viral insertion at the site; 5 displayed a unique simple cycle with one human and one viral segment; and 8 samples displayed complex cycles or heterogeneous mixtures of multiple structures. 13 amplicons contained parts of human genes, with 2 containing truncated forms of the oncogene *ERBB2*. Conclusion: AA is a useful tool to understand amplification, heterogeneity and rearrangements at viral integration sites. This will provide crucial insight into the mechanistic/functional aspects of viral integration in cancers..

Predicting regulatory variants with composite statistic. *J. Wang[1], M.J. Li[2,3], Z. Pan[3,6], Z. Liu[3,5], J. Wu[2], P. Wang[1,3], Y. Zhu[3,4], F. Xu[3,4], Z. Xia[5], P.C. Sham[3,6], J.P.A. Kocher[1], M. Li[3,6], J. Liu[2].* 1) Health Science Research, Mayo Clinic Arizona, Scottsdale, AZ; 2) Department of Statistics, Harvard University, Cambridge, Boston, MA 02138-2901, USA; 3) Centre for Genomic Sciences, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong SAR, China; 4) School of Biomedical Sciences, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong SAR, China; 5) Department of Anaesthesiology, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong SAR, China; 6) Department of Psychiatry and Centre for Reproduction, Development and Growth, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong SAR, China.

Motivation: Prediction and prioritization of human noncoding regulatory variants is critical for understanding the regulatory mechanisms of disease pathogenesis and promoting personalized medicine. Existing tools utilize functional genomics data and evolutionary information to evaluate the pathogenicity or regulatory functions of noncoding variants. However, different algorithms lead to inconsistent and even conflicting predictions. Combining multiple methods may increase accuracy in regulatory variant prediction. **Results:** Here, we first compiled an integrative resource for predictions from eight different tools on functional annotation of noncoding variants. We further developed a composite strategy to integrate multiple predictions and computed the composite likelihood of a given variant being regulatory variant. Benchmarked by multiple independent causal variants datasets, we demonstrated that our composite model significantly improves the prediction performance. **Availability:** We implemented our model and scoring procedure as a tool, named PRVCS, which is freely available to academic and nonprofit usage at http://jjwanglab. org/PRVCS. **Contact:** junwen@uw.edu, jliu@stat.harvard.edu, limx54@gmail. com.

Accelerating medical genomics through functional mapping of clinical genomic variant data to underlying disease biology. *L. Brody, A. Ajetunmobi, V. Dillard, N. Humphreys-Kirilov, R. Doyle.* Genomic Services, Desktop Genetics, London, United Kingdom.

The wealth of data output from next-generation sequencing (NGS) technologies have led to tremendous progress in the study of the evolutionary origins of human genetic variation and its contribution to human disease. In particular, several consortia have been developed to map human genetic variation, providing genome-wide association studies and rare variant analyses in the context of common and rare diseases. However, many of these variant databases do not provide information on the function of these variants and their contribution to the pathophysiology of human diseases. Without elucidating the functional contribution of these variants to cellular activity, these studies will yield little benefit to human health. It is clear that high-throughput characterization of the molecular and cellular activity of genetic variation is becoming increasingly important for understanding the mechanistic function of the human genome. At Desktop Genetics, we have developed an integrated approach for end-to-end NGS data analysis; from variant detection to functional profiling. We have developed a custom bioinformatics pipeline which can be implemented for genome alignment including, single nucleotide polymorphism (SNP), small insertion/deletion (InDel), and copy number variation (CNV) detection of whole genome/exome sequencing (WGS/WES) data from the Illumina platform. Using sequencing data, and our optimized gRNA design rules, we have implemented a bespoke CRISPR genome editing methodology for *in vitro* functional assays in cultured human cells of a defined genotype. CRISPR/Cas9 in conjunction with customizable guide RNA is used to precisely target genetic and epigenetic regions of interest to induce loss-of-function alterations and validate predicted variant function. This may provide a unique approach for downstream variant interpretation and interrogation of their role in the pathogenesis of rare and common genetic diseases.

Consideration for applying machine learning methods to GWAS data to predict disease patients. *P. Ruan, J. Sese.* Artificial Intelligence Research Center, National institute of advanced industrial science and technology, Tokyo, Japan.

The conventional analysis in GWAS computes a P-value on each SNP, and a chromosomal region around a statistically significant SNP is supposed to contain a causal mutation of the target disease. However, GWA studies for common or complex diseases often found many SNPs whose odds ratios are moderate, and summation of them can explain only part of the cause of the disease. To overcome the problem, we here test the use of machine learning methods to the analysis of GWAS. We apply cutting-edge machine learning techniques such as deep learning and gradient tree boosting as well as conventional methods such as Support Vector Machine, random forest and logistic regression to the prediction of disease/non-disease patients. In this study, we use a GWAS dataset consisting of 1, 231 postmenopausal breast cancer patients and 1,203 control subjects. To calculate the accuracies for the method comparison, we perform 100 times of 10-fold cross-validations. In our procedure, SNPs whose P-values are less than 0.05 are selected, and discriminant analysis is performed with the SNPs. Then, accuracies (F-measures) on test data are calculated with the discriminant function. We report the comparison of the prediction accuracies of the results including how the results are different/similar among the machine learning methods and how sensitive to parameters in each technique.

Identification of target lincRNA associated with prostate cancer risk loci. *S. McDonnell, A. Nair, Z. Fogarty, S. Riska, M. Larson, A.J. French, L. Tillmans, M.S. DeRycke, D.J. Schaid, S.N. Thibodeau.* Dept Health Sci Research, Mayo Clinic, Rochester, MN.

Multiple risk loci for prostate cancer have been identified; however determining which genes the loci influence is difficult. Previously we identified 51 regions with significant eQTL signals associated with 88 genes for prostate cancer risk while creating a normal prostate tissue eQTL database from 471 normal prostate tissue samples. Long intergenic non-coding RNAs (lincRNAs) are an abundant class of non-coding RNAs that serve as key regulators for many cellular processes and thus can be potential diagnostic markers and therapeutic targets for diseases such as cancer. Expanding on our earlier work, we have quantified lincRNA in our mRNAseq dataset and performed eQTL analysis correlating expression of lincRNA with 220 prostate cancer (PCa) risk variants. LincRNA were quantified using an Ultrafast and Comprehensive lincRNA pipeline, called UClincR, to identify known and novel lincRNAs using the transcriptome sequencing data. In total, 54,004 lincRNAs were identified; of which 11,212 have median raw count > 7. All PCa-risk SNPs and those SNPs within +/-100Kb and in LD (r^2>0.5) (n=8,073 SNPs) with the PCa-risk SNP were tested against all lincRNA located within 1.1Mb (n=1,169 genes) adjusting for histologic characteristics and lincRNA expression principal components. 64 lincRNA in 23 risk-regions demonstrated a significant eQTL signal using a Bonferroni significance threshold (P≤ 2.5E-07). Future planned studies include expanded analysis of the 64 lincRNA to identify all potential eQTL variants as well as utilizing public datasets to map the significant SNPs to prostate-specific known and predicted regulatory elements, including promoters, enhancers, transcription factor binding sites, transcription start and stop sites.

Statistical approaches for network-driven discovery and interpretation of cancer driver mutations. *J. Reimand[1,2].* 1) Department of Informatics and Biocomputing, Ontario Institute for Cancer Research, Toronto, Canada; 2) Department of Medical Biophysics, University of Toronto, Toronto, Canada.

   Identifying driver mutations in whole genome sequencing data of cohorts of cancer samples is essential to deciphering tumour biology and designing precision treatments. Information on pathways and molecular interaction networks can improve interpretation of cancer mutations and associating mechanism and clinical information. We hypothesize that many cancer driver mutations precisely modify network interfaces encoded in small sites in proteins, RNA and DNA, leading to interaction losses and gains in networks. We have developed novel computational strategies to find network-associated cancer driver mutations and infer their impact on network topology that are complementary to state-of-the-art approaches. Our mutation enrichment algorithm ActiveDriver-2 discovers coding and non-coding cancer driver elements from whole-genome sequencing data. It assumes that frequent mutations such as SNVs and indels in network-associated sequence sites indicate interaction hotspots in cancer. This approach is applicable in signalling pathways and gene regulatory networks where site-specific interactions between proteins, RNA and DNA are known or predicted computationally. ActiveDriver-2 determines genome elements and sites with statistically significant mutation recurrence by accounting for trinucleotide mutation rates using a Poisson regression model. Our machine learning method MIMP further complements this strategy by annotating mutations that erase existing binding sites and/or creating new binding sites and thus cause rewiring of interaction networks. After validating the statistical properties of our model with synthetic genome mutation data, we analysed the collection of 2,800 cancer whole genomes in the ICGC Pan-cancer Analysis Working Group (PCAWG) effort. We revealed mutation hotspots coinciding with network-associated sites, including post-translational modification sites of proteins, microRNA target sites in gene UTRs, and transcription factor binding sites in gene promoters and enhancers, suggesting novel mechanisms of action of cancer mutations. Our study emphasizes the importance of network-related variation in cancer by providing novel interpretation to known cancer mutations, helping find new cancer drivers and risk modifier alleles, and characterising their biological mechanisms.

Inferring evolution structure based on copy number aberration from head and neck cancer via penalized two-way mixture Poisson model. *A. Tai[1], W. Hsieh[1], C. Peng[2], S. Peng[2].* 1) Institute of Statistics, National Tsing Hua University, Hsinchu, Taiwan, R.O.C; 2) Departments of Resource Center for Clinical Research, Chang Gung Memorial Hospital, Taoyuan, Taiwan, R.O.C.

   Somatic evolution describes the accumulation of mutations in the cells during an individual's life time. The mechanism is important for the development of cancer. The development of cancer is a multistep process and it results in tumor heterogeneity, meaning that each tumor might consist of genomes from multiple clones. There are many computational approaches developed to infer the clonal evolution from the sequencing data. Most of them are based on single nucleotide variants (SNVs). However, the accuracy of these algorithms is usually affected by the copy number aberration. How to effectively identify the copy number aberration is an issue that must be addressed. Furthermore, copy number aberration itself forms an even more complicated problem of tumor heterogeneity. We developed a penalized two-way mixture Poisson model to study the cancer evolution based on copy number aberration. In our model, the clonal architecture is automatically resolved by the penalized function in the likelihood and it is a clustering method that can determine the corresponding copy number state. Finally, we applied our model to the sequencing data of head and neck cancer from TCGA to understand the distribution of copy number aberration and clonal structures.

Epigenome-based drug repositioning for acute myeloid leukemia. *A.S. Brown, C.J. Patel.* Biomedical Informatics, Harvard Medical School, Boston, MA.

   Repositioning approved drugs for the treatment of new indications is a promising avenue to reduce the burden of drug development. We recently described a novel repositioning method, ksRepo, that enables investigators to move beyond microarray-based gene expression and utilize a variety of other sources of molecular evidence, such as DNA methylation differences. In this pilot study, we applied ksRepo to DNA methylation information from three independent acute myeloid leukemia (AML) datasets. We ranked genes according to their degree of differential methylation between AML blasts and normal bone marrow aspirates. Next, we used ksRepo to predict drug candidates derived from a list of curated gene-drug interactions from the Comparative Toxicogenomics Database. In addition to recovering the most commonly prescribed frontline therapy, cytarabine, ksRepo also found significance for decitabine, an epigenetic drug commonly used in AML treatment. We further observed enrichment for sex hormone-related drugs among the KS-significant drugs, congruent with recent findings in AML. In conclusion, ksRepo provides a platform for deriving repositioning hypotheses from differential DNA methylation and yields clinically relevant predictions.

Accurate prediction of breast cancer risk based on flow variant analysis of circulating peripheral blood B cells. *K. Upadhyay, M. Syeda, J. Loke, H. Ostrer.* Albert Einstein College of Medicine, Bronx , NY.

   Introduction. About 10% cases of breast cancer occur to women from high-risk families with multiple affected relatives. Heritable mutations in genes in the double strand break (DSB) repair pathway can be detected in over 25% percent of these cases. In up to 40%, a variant of uncertain significance (VUS) is identified and commonly 2 or more VUS are observed. In addition to the issue of prevalent VUS, most sequencing methods are biased in scope and depth, because certain genomic regions can be difficult to capture, amplify or assemble. Previously, we demonstrated that flow variant assays (FVAs) that quantify native and phosphoproteins, protein nuclear localization and protein-protein interactions in the DSB repair pathway were altered in LCLs from individuals with mutations in *BRCA1* and other genes in this pathway. Development of an accurate risk classifier based on logistic regression analysis of multiple FVAs of circulating B cells could improve risk assessment for these individuals and their family members. **Materials and methods.** Nuclear localization and phosphoprotein FVAs were performed on 37 LCLs (discovery cohort) with mutations and benign variants in *BRCA1, BRCA2* and other genes in this pathway and on circulating B cells from 29 women (replication cohort), 20 of whom had breast cancer or ovarian cancer, no *BRCA1* nor *BRCA2* mutation and 2 or more affected relatives, and 9 healthy women with 1 affected relative. Logistic regression classifiers were calculated for 2 FVA and 3 FVA models. Accuracy was calculated for single FVAs and 2 FVA and 3 FVA classifiers in discovery and replication cohorts. In addition, whole genome sequencing was performed on all of the women with breast cancer in the replication cohort. **Results.** Logistic regression classifiers improved the accuracy for prediction of breast cancer risk. The range of accuracies was 86-89% in the discovery cohort for single FVAs, 92% for the 2 FVA classifier and 95% for the 3 FVA classifier. The range of accuracies for single FVAs was 60-90% for single FVAs in the replication cohort, 93% for the 2 FVA classifier and >99% for the 3 FVA classifier. Notably, all women had only VUS. **Conclusion.** The high degree of accuracy of 2 and 3 FVA classifiers suggests that they could be used as an independent risk assessment tool, if validated in larger, independent cohorts. The ready accessibility of analyzing circulating B cells would facilitate clinical use of FVA classifiers for prediction of breast cancer risk.

Gene set analysis methods: A systematic comparison. *R. Mathur[1], A. Motsinger-Reif[1], A. Shojaie[2].* 1) Bioinformatics Research Center, North Carolina State University, Raleigh, NC; 2) Department of Biostatistics, University of Washington, Seattle, WA.

Pathway or gene set analysis is a useful method to summarize and interpret high-dimensional genetic data. While numerous methods have been developed to conduct this type of analysis, the results from these methods are often vastly different. Methods comparison studies have typically utilized benchmark datasets only, limiting true evaluation of the statistical performance of the gene set analysis methods. In this study we have devised a systematic simulation study, based on real data, with a range of effect sizes and pathway characteristics, to conduct an extensive comparison of the most commonly used gene set/pathway tools. Our simulated data is based on the true correlation structure of a Prostate Cancer microarray dataset, with signal introduced in the TGF-β signaling and KRAS pathways. Using this data, we present and compare the power and false positive rates of Significance Analysis of Function and Expression (SAFE), sigPathway, Gene Set Enrichment Analysis (GSEA), and Correlation Adjusted Mean RAnk (CAMERA) methods, using the Molecular Signatures Database (MSigDB) gene set database as the knowledgebase for each method. Our estimated power and false positive rates rigorously evaluate the statistical properties of these approaches, and provide guidance for users on choosing and interpreting these methods.

2871F

Extraction of long-range sequence and phasing information and characterization of structural variation from FFPE samples using a novel *in situ* **digestion and ligation protocol.** *N. Putnam[1], S. Balakrishnan[1], R. Calef[1], P. Hartley[1], J. Stites[1], C. Troll[1], B. Rice[1], M.P. Powers[1], R.E. Green[1,2].* 1) Dovetail Genomics, LLC, Santa Cruz, CA; 2) University of California, Santa Cruz, Santa Cruz, CA.

Presented herein is a novel technique for the generation of megabase-scale phased sequence data via pre-extraction *in situ* DNA preparation from FFPE samples. Until now, FFPE samples typically yielded sub-500bp DNA fragments, confounding the acquisition of long-range sequence information. Long-range sequence information can only be obtained from FFPE tissue in non-repetitive loci where reads overlap unique breakpoints or other unique sequence features. Because the human genome is >50% repetitive, human FFPE samples have to date not provided adequate long-range genome information. In this first of its kind proof-of-principle study we: (i) remove paraffin from FFPE treated cell lines (GM24149, GM24385), (ii) treat tissue fragments *in situ* with restriction endonuclease, (iii) fill-in the resulting recessed 3' termini, and (iv) ligate the resulting ends, creating chimeric molecules. These chimeric molecules preserve the long-range information of the starting molecule due to proximity-based ligation. Sequencing provides data similar to those produced by Hi-C or Chicago™. The data produced demonstrate that phasing and long-range information is preserved from these samples with >90% accuracy up to 1.9 MB. This technique provides a powerful new way to extract genome information for archives of tumor samples and other FFPE samples from bio-banks including the discovery of structural variation, copy-neutral structural variants, and other long-range sequence variants within (or mediated by) repetitive elements.

Identification of cancer antigens in NSCLC using exome sequencing and mutated antigen screening with gBlock Mini-genes. *Y. Bao[1], L. Zhang[2], C. Qian[2], B. Yang[2], B. Yin[2], W. Li[2], B. Ning[2], F. Wang[2], C. Hu[2], H. Loi[1], C. Chen[1], H. Wang[2], R. Wang[2].* 1) Research and Development, Integerated DNA Technologies, Redwood City, CA; 2) Center for Inflammation and Epigenetics, Houston Methodist Research Institute, Houston, TX.

Tumor-specific mutated antigens may serve as ideal targets for immunotherapy and precision medicine. Although several hundreds of cancer antigens have been identified, only a few are suitable for immunotherapy using T cell receptor (TCR) or chimeric antigen receptor (CAR) based therapy. Thus, identification and selection of cancer antigens are vital to develop personalized immunotherapy in cancer. Targeted exome sequencing has made it possible to routinely detect cancer mutations for each patient. Lung cancer is one of the most frequently mutated cancer types. Thus, we hypothesize that patient-specific cancer antigens can be identified and used as immune targets for personalized immunotherapy of advanced lung cancer patients. In this study, exome sequencing of both tumor and isolated T-cell samples in 30 NSCLC patients and MS analysis were used to detect tumor-specific mutations. Following the identification of somatic mutations, 20-30 mutated antigen candidates per patient were screened by transient expression of mutated antigens cloned into an expression vector through gBlock mini-genes to generate fusion proteins. Of 89 CD4+ T cell clones used for the screening, four mutated antigens were identified. Among all the 89 T cell clones, 83 of them have response to 4 neoantigens, and 67 of them recognized one dominated antigen. Our work demonstrates that the method described above can effectively identify potential targets for T cell based cancer immunotherapy.

Sensitive and reliable variant detection from challenging samples. *N. Fang, K. Heitz, R. Tolun.* QIAGEN GmbH, Hilden, Germany.

The rapidly developing next generation sequencing (NGS) technologies provide highly sensitive methods in detecting and characterizing variants in clinical samples. However, clinical samples often come in limited quantity as well as compromised quality. Such samples are not suitable for standard NGS library construction methods, which commonly require hundreds of nanograms of good quality DNA. Examples of such challenging clinical samples are laser capture microdissection (LCM) samples, FFPE samples, and circulating DNA. Here we describe an optimized workflow to efficiently convert small amount of DNA samples into sequencing libraries. The library construction protocol is based on the QIAseq UltraLowInput Library Kit, which has optimized enzyme and buffer formulations that enable high library conversion rate as well as unbiased library amplification from as low as 10pg input DNA. In combination with an optimized hybrid-capture-based target enrichment procedure, the workflow described in this poster enables reliable mutation detection even with low DNA input amount, making it feasible to gain sequence insights from challenging sample types.

2874F

Low level somatic variant detection by Sanger sequencing of formalin-fixed paraffin-embedded (FFPE) samples for Precision Oncology. *A. Gerstner, E. Schreiber, S. Schneider, S. Jackson, K. Varma.* Thermo Fisher Scientific, South San Francisco, CA.

   Deleterious sequence variants play an important role in the initiation and progression of many different cancer types. The detection of germline variants by the gold standard Sanger sequencing has been well established, however, the detection of somatic mutations, especially in heterogeneous tumor samples where variants may be present at a lower level, has been more challenging.To facilitate analysis of somatic mutations in tumor samples, we have developed Sanger sequencing panels that cover the entire coding regions of specific genes (e.g. TP53) as well as an extended panel encompassing 66 frequently detected oncogenic alleles from 18 genes. We have also developed companion software, Minor Variant Finder (MVF), that facilitates detection of low levels of somatic mutations by Sanger sequencing. To demonstrate the workflow of these panels, we analyzed FFPE DNAs from 12 different cancer tissue types. We initially determined variants in these samples using Ion Torrent™ Personal Genome Machine (PGM™) next generation sequencing. We confirmed the identity and variant allele frequency of these variants by Sanger sequencing using 1 ng, 0.5 ng or 0.1 ng DNA. Finally, we made serial dilutions of one of these samples to establish limit of detection (LOD) at as little as 3% of a minor variant in an FFPE sample.Sanger sequencing is the gold standard for confirmation of minor variants detected by NGS. In this study, we show that Sanger sequencing of limited number of targets, in conjunction with the MVF software, can also be an ideal first line screening choice for tumor FFPE samples where limited amount of DNA is available.

Single-cell transcriptome analysis reveals heterogeneity in endometrioid adenocarcinoma tissue. *S. Hashimoto[1,2], Y. Tabuchi[3], T. Torigoe[3], K. Matsushima[4], H. Yurino[1].* 1) Graduate Sch Medicine, Kanazawa University, Ishikawa, Japan; 2) Japan Science and Technology Agency, Core Research for Evolutional Science and Technology (CREST), Tokyo, Japan; 3) Department of Pathology, School of Medicine, Sapporo Medical University, Sapporo, Japan; 4) Department of Molecular Preventive Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.

   The cell populations, such as differentiated states or tissues and organs, are thought to be heterogeneous. Therefore any expression profile based on a tissue sample will blend the true expression profiles of its constituent cells. To overcome this problem, single-cell methods have been developed for both microarrays and RNA-seq. Recently several studies have been reported single cell gene expression strategies. Single-cell gene-expression profiling allows identification and characterization of different cell types and cell subtypes. Furthermore, phenotypic heterogeneity can be studied within the same cell type. To understand the cell population status, single cell analysis is required. Although several studies for single cell gene expression analysis have been reported, number of the observed cells is very limited. Therefore, we have developed novel strategy (Nx1-seq) of single-cell transcriptome analysis for thousands of single cells. In our approach, single cells are deposited in a high-density microwell plate and lysed in situ. mRNA is then captured on barcoding microbeads and reverse transcribed. The diversity of barcode on the beads was made by emulsion PCR using randomly synthesized barcode oligo DNA. The pooling of Nx1-seq data of single cell in two homogeneous cell populations provides rich and highly reproducible transcriptional profiles. In addition, gene expression patterns among libraries with high sequencing reads were close (p=0.92). In this study, we applied Nx1-seq to characterize complex heterogeneous samples in myometrial infiltration side and endometrial side of human endometrioid adenocarcinoma with squamous differentiation tissue by examining thousands of cells per experiment. Endometrial cancer is the commonest pelvic gynaecological cancer in the westernised parts of the world. These results showed the distinction of the cancer cell state with tumorigenicity, the EMT and infiltrated leukocytes in two sides. Finally, we show that established endometrioid adenocarcinoma subtype classifiers are variably expressed across individual cells within a tumor and demonstrate the potential prognostic implications of such intratumoral heterogeneity.

Oncology biomarker development: Simultaneous digital counting of nucleic acids and proteins at 800-plex. *E. Manrao, D. Kim, G. Meredith, P.M. Ross, J. McKay-Fleisch, E. Piazza, C. Ngouenet, M. Liu, P. Danaher, G. Demirkan, B. Filanoski, B. Birditt, G. Geiss, J. Beechem.* NanoString Technologies, Seattle, WA.

With the growth of biomarker discovery, identification of novel cancer signatures has revealed the limitations of relying on a single analyte class to characterize tumors or predict their responses to therapies. NanoString® has developed its nCounter Vantage™ line of products powered by novel 3D Biology™ technology to meet the need for simultaneous analysis of DNA, RNA, and proteins. Based on single-molecule optical barcoding technology, NanoString's products are designed to consume as little as 15,000-25,000 cells while utilizing the experimental power of 800-plex, cross-analyte quantification. We present two case studies of 3D Biology in action. First, we show that the 30-plex nCounter Vantage Protein Solid Tumor Signaling Pathways Panel can be used in conjunction with the 770-plex PanCancer Pathways Panel to monitor expression regulation and protein phosphorylation within clinically relevant samples, including FFPE tissues. Second, we demonstrate that our RNA and protein detection chemistries work in concert with our novel SNV-specific probes for in-depth characterization of genotype-specific expression changes in a cell culture model of BRAF inhibition. Together, these examples highlight the rich data sets and robust discovery potential provided by a 3D Biology approach to cancer biomarker research.

Pharmacogenomic prediction of cisplatin-induced nephrotoxicity in Mexican patients treated for childhood cancer. *M. Medeiros[1,2], F. Aminkeng[2,3,4], C. Jimenez-Triana[1], R. Rivas-Ruiz[5], L. Jaurez[6], M. Palomo[6], P. Clark[7], G. Castañeda-Hernández[8], C.J. Ross[2,3,4], B. Carleton[2,3,4].* 1) Laboratorio de Investigacion en Nefrologia, Hospital Infantil de México Federico Gomez, Mexico, Mexico City, Mexico; 2) Pharmaceutical Outcomes Programme, BC Children's Hospital, Vancouver, Canada; 3) Division of Translational Therapeutics, Department of Paediatrics, Faculty of Medicine, University of British Columbia, Vancouver, Canada; 4) Child&Family Research Institute, Vancouver, Canada; 5) Coordinación de Investigación en Salud, Instituto Mexicano del Seguro Social , México D.F; 6) Departamento de Oncología, Hospital Infantil de México Federico Gómez; 7) Unidad de Investigación en Epidemiología Clínica, Hospital Infantil de México Federico Gómez, México D.F; 8) Departamento de Farmacología, CINVESTAV IPN, México D.F.

Objective: To perform pharmacogenetic associations with nephrotoxicity (NTX) in Mexican patients treated with cisplatin for childhood cancer. Methods: Retrospective study of children treated with cisplatin for solid tumors that were part of a cohort studied for adverse reactions to chemotherapy, approved by the Hospital IRB and Ethics Committee. NTX was graded as follows: normal renal function (Grade 0); asymptomatic electrolyte disorders, including an increase in serum creatinine, up to 1.5 times baseline value (Grade 1); need for electrolyte supplementation < 3 months and/or increase in serum creatinine 1.5-1.9 times from baseline (Grade 2) grade 3: increase in serum creatinine 2-2.9 times from baseline or need for electrolyte supplementation for more than 3 months after treatment completion, grade 4: increase in serum creatinine ≥ 3 times from baseline or renal replacement therapy. DNA was obtained from saliva. A 4608 SNPs ADME panel were assessed by Illumina iScan SNP genotyping platform (Illumina Inc., USA). Results: 73 patients were included, with a minimum follow up of one year after treatment completion. 53 developed NTX (72.6%), No nNTX (grade 0) was observed in 20 patients (27.3%). Grade 1 NTX was observed in 20 patients (27.3 %), grade 2 in 8 patients (10.9%) and grade 3 in 25 patients (34.2 %). Patients with NTX were younger than patients with non-nephrotoxicity, median age 5.9 years vs. 13.4 years respectively (p=0.006). The following polymorphisms were associated to NTX: *MHTFR* rs1801133 (p=0.011, OR 3.3, 95%CI 1.22, 8.98*), EPHX1* rs1051740 (p=0.035, OR 0.34, 95%IC 0.12-0.98), *SLC22A2* rs316019 (p=0.037), no association was found with *ERCC2* rs13181, *ERCC1* rs11615 y *CD3EAP* rs3212986. Conclusion: 72.6% of cisplatin treated children presented NTX. This study replicates the importance of *MHTFR* rs1801133, *EPHX1* rs1051740 and *SLC22A2* rs316019 in NTX, previously reported in adult population.

Expression of *miR-124* **and** *SPHK1* **in human breast cancer.** *M. Minouei[1], M.A. HosseinPour Feizi[2], S.A. Rahmani[1], V. Montazeri[3], R. Ravanbakhsh Gavgani[2], M. Kazem Zadeh[2], Sh. AzarBarzin[2], A. Fateh[2].* 1) Biology Department, Faculty of Basic Sciences, Islamic Azad University, Ahar Branch, East-Azerbaijan, Islamic Republic of Iran; 2) Animal Biology Department, Faculty of natural Sciences, Tabriz University, Tabriz, Islamic Republic of Iran; 3) Department of Thorax Surgery, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran.

   Background: Breast cancer is still one of the most leading causes of cancer mortality in the women worldwide. MicroRNAs(miRNAs), are a class of small non-coding RNAs, that post transcriptionally regulate gene expression. *MiR-124* is a brain-enriched miRNA, related to the regulation of growth, carcinogenesis and metastasis. *SPHK1*, a highly conserved lipid kinase, which phosphorylates sphingosine to the formation of sphingosine-1-phosphate (S1P). Evidence show that *SPHK1*, via the production of S1P, is an important signal molecules in the regulation of a wide range of cellular functions including cell proliferation, differentiation, as well as prevention of apoptosis. This study aims to determine and comparison of the *SPHK1* and *miR-124* expression level in tumoral and adjacent normal tissues in Breast Cancer tissues. **Methods:** Total RNA was isolated from 40 breast cancer and adjacent normal fresh tissues. Following the confirmation of the quality and quantity of extracted RNA, Complementary DNA (cDNA) was synthesized. Afterward, the expression of *miR-124* and *SPHK1* was evaluated by Real-Time PCR in 40 paired breast cancer and normal tissues. Variability in the initial quantities of mRNA was normalized to the internal control for both *miR-124* and *SPHK1*; the relative expression levels were evaluated using the $2^{-\Delta\Delta Ct}$ method. **Results:** Our study indicates that the expression level of *miR-124* was significantly reduced and the mean expression level of *SPHK1* was increased in breast cancer tissues compared with the matched normal tissues. Furthermore, correlation between *SPHK1* upregulation and reduced expression level of *miR-124* in tumoral tissues compared with those of adjacent healty tissues was evaluated in the present study. **Conclusion:** In current study increase of *SPHK1* expression was seen in the advanced stage of breast cancer, also this study confirm *SPHK1* oncogenic role. We also, showed that the expression level of *miR-124* was significantly lower in human breast cancer tissues than that of adjacent normal tissues. The decreased expression level suggests an inhibitory effect of *miR-124* on metastasis of breast cancer. In conclusion, according to our findings, *miR-124* and *SPHK1* may be probably used as a new potential therapeutic targets for the treatment of breast cancer patients.

Effects of AlCl₃ in the lipid profile of a breast cancer cell line detected by Desorption Electrospray Ionization Mass Spectrometry (DESI-MS). *R.M. Rodrigues-Peres[1], A.M. Porcari[2], J.K.R. Heinrich-Muçouçah[1], M.N. Eberlin[2], L.O.Z. Sarian[1].* 1) CAISM – Women´s Hospital, State University of Campinas - UNICAMP, Campinas, SP, Brazil; 2) ThoMSon Mass Spectrometry Laboratory, Institute of Chemistry, State University of Campinas - UNICAMP, Campinas, SP, Brazil.

   Introduction: Aluminum is used in many different chemical presentations and in a wide range of products such as food, paper, dyes, pigments, paints, glass, fuels, textiles, cosmetics and pharmaceuticals, as well as in water purification and oil refining processes. Aluminum compounds are known for biological effects on human health and its linkage to breast cancer has been hypothesized. In vitro and in vivo studies show that this metal might bind estrogen receptors, interfering with cell pathways and phenotype characteristics, as in protein expression, exhibiting neuronal effects in humans and also showing influence in hormone responses. We used the Desorption Electrospray Ionization Mass Spectrometry (DESI-MS) technique to verify the differential expression of lipids in a breast cancer cell line cultivated with and without aluminum chloride. Methods: Breast cancer cell line T47D was grown in HAM F-10 medium containing 10% FBS (control), 10, 15 and 25% of AlCl₃. Pellets were extracted (Bligh & Dyer) and analyzed using a DESI source connected to a Q-Exactive (Thermo) at a resolution of 70,000. The sprayed solvent was MeOH (2 uLmin⁻¹) and the negative ion mode was used in 100 – 1500 *m/z* range. Metaboanalyst 3.0 was used for chemometrics. Results: Mass spectra were mainly composed of ions up to *m/z* 700. Fat acids molecules and dimmers, as well as other small lipids formed the predominant ions. When partial least square discriminant analysis (PLS-DA) was applied for the *m/z* 290 - 470 range, full differentiation of the control and treated groups was achieved. Such discrimination was mainly attributed to the ions of *m/z* 350.246, 364.226, 346.215, 367.215. Based on their exact mass values, these ions were assigned as [M + Cl]⁻ adducts of acylcarnitines, sphingosines, prostaglandins and steroidal compounds. Conclusion: We observed a differential profile for ions that are mainly associated with hormones, in the control group in contrast to the treated group, independently on the AlCl₃ concentration used. These findings endorse the assumption that aluminum might be altering some pathways within the cell, in this case, affecting the lipid profile in breast cancer cells. Further studies are needed to elucidate the possible effects of aluminum in human breast cells, whether it is influencing cell pathways or the tissue microenvironment.

A flexible single-cell RNA-seq system for the accurate processing of 1,000s of single-cells. *M. Srinivasan.* WaferGen BioSystems, Fremont, CA.

   Genomics measurements on genetically identical single cells have significantly advanced our understanding of deterministic variability in gene expression and how those differences impact the formation and maintenance of cellular communities. Understanding these complex events with enough statistical rigor require the rapid sampling and processing of thousands of individual cells in a high throughput manner. To fulfill this growing need, we have engineered ICELL8, a novel single cell analysis system that can process thousands of cells from several samples for RNA-seq applications. The system consists of: ICELL8 chip - a micro-fabricated metal-alloy scaffold with 5,184 nanowells. MultiSample NanoDispenser - an automation system to dispense nanoliters of reagents into the nanowells of the ICELL8 chip Imaging Station - a microscope fitted with a fast stage to quickly image Hoechst 33324 and propidium iodide stained cells in all 5,184 wells and CellSelect™ - software used to identify single cell containing wells (or wells of researcher's choice) and dispense reagents to make cDNA ONLY to wells either automatically called by the software and/or selected by user. To showcase the ability of ICELL8 system in translational research, 1000s of mesothelioma cells were processed. RNA sequencing and analysis of the mesothelioma cells at the single cell level revealed the heterogeneity and also the genes that are expressed in common between the cells. Principal component analysis of the single cell RNA-seq data showed that mesothelioma cells formed a distinct cluster compared to other tumor types and normal cell. Overall this study significantly expands on previous genomic studies on mesothelioma and identifies several previously unknown alterations and biological pathways that are potential targets for drug discovery and treatment. Incorporating genomic analysis for detection of actionable alterations as part of mesothelioma patient care will help in developing rational individualized therapy.

Analysis of structural integrity of genomic DNA in tissue sample prep using Bulk Lateral Ultrasonic™ Energy. *V. Vivek[1], P. Sansanwal[1], D. Holley[1,2].* 1) Microsonic Systems Inc., San Jose, CA; 2) Department of Biological Sciences, San Jose State University, San Jose, CA.

   As Next-Gen sequencing throughput continues to accelerate, a serious tissue sample preparation bottleneck is emerging, calling for an automated higher throughput tissue processing technique. The solution must be quick, efficient, and should not affect DNA quality. Microsonics has pioneered the use of a novel ultrasonic technology called "Bulk Lateral Ultrasonic™ Energy." This "Microprocessor for Life Sciences" is the core technology that makes possible a multi-channel front-end tissue sample prep device that is scalable to any number of simultaneous channels, and processes (lyses) tissue samples in less than 10 minutes resulting in high DNA yield and quality. This work reveals how this new form of energy is utilized to quickly and efficiently process tissue samples, and analyzes the effect of BLU energy on the structural integrity of DNA, including: 1) the influence of ultrasound sonication on the structural integrity of pre-purified genomic DNA, 2) the results of tissue lysis with ultrasound sonication, 3) the influence of ultrasound sonication on the structural integrity of genomic DNA during lysis of animal tissue, and 4) the efficacy of BLU energy for complete elution of DNA bound to magnetic beads. Careful optimization of these parameters has led to a successful implementation of Bulk Lateral Ultrasonic energy for automated high throughput and efficient front-end tissue sample prep sufficient to meet the needs of current and emerging Next-Gen sequencing throughput demands.

Mutation signatures and intratumor heterogeneity of esophageal squamous cell carcinoma in a Chinese cohort. *Y. Wang[1], W.Q. Yuan[2], M.F. Liu[2], J. Bai[3], Q.X. Song[1], A. Abliz[2], Z. Liu[2], J.J. Li[2], C.Q. Zeng[3], H. Cai[2], Y. Ke[2], J. Li[1].* 1) Department of Human Genetics, 4909, Buhl, Medical School of Michigan University, Ann Arbor, MI; 2) Laboratory of Genetics, Key laboratory of Carcinogenesis and Translational Research, Peking University, Cancer Hospital & Institute, Beijing, China; 3) Laboratory of Disease Genomics and Individualized Medicine, Beijing Institute of Genomics, Chinese Academy of Sciences, Beijing, China.

Esophageal squamous cell carcinoma (ESCC) is one of the most common and most aggressive cancers. Epidemiological features of ESCC are extremely complex, with strong geographic differentiation among world's populations. Rural Anyang in the Henan Province of China is a well-known high-incidence area, however the causal factors in this population remain elusive. We performed exome sequencing of 81 tumor-normal pairs, identified TP53, ZNF750 and NOTCH1 as significantly mutated genes, and observed highly recurrent aberrations in several other genes previously reported for ESCC (PIK3CA, KMT2D, FAT2 and FAT1). The total set of ~7,000 SNVs revealed two main signatures: C>T transitions at NpCpG due to spontaneous deamination of 5-methyl-cytosine, and C>T and C>G mutations at TpCpW attributed to the APOBEC family of cytidine deaminases. The latter signature points to HPV infection as one of the potential mutagenic sources, even a possible etiological factor. To characterize intratumor heterogeneity we applied our newly developed method, CHAT, to estimate the clonal frequencies of copy number alternations and single nucleotide mutations in each tumor. Many tumors show a wide, sometimes multi-modal distribution of clonal frequencies, suggesting extensive within- tumor diversity due to coexistence of multiple clones. Survival analysis suggests that patients with complex multi-clonal tumor structure tend to have poorer prognosis. To better understand the patterns of growth, migration and metastatic potential among different cells within a tumor we performing exome sequencing to compare multiple regions in 10 ESCC as well as 2 esophageal neuroendocrine carcinoma tumors. In many ESCC's, each local-region sample still contains multiple clones, which are often shared with a distant region, suggesting extensive dispersal of the clonal populations and relatively slow sweep by the most dominant clone. We constructed "clone trees" to depict the most likely lineage relationship of the clones and the likely driver genes or pathways for each branch. Metastatic samples at lymph node often contain multiple clones, including those appearing in the early portions of the evolutionary tree, suggesting polyclonal seeding to the lymph nodes as well as invasion of early-stage tumor cells. Our analysis of spatial heterogeneity of molecular lesions in ESCC revealed likely temporal progression of tumorigenic events that may have driven the initiation, outgrowth, and metastasis.

Pro-Seq: A rapid and low cost method for obtaining duplex sequencing data for liquid biopsy applications. *J. Pel[1], W. Choi[1], M. Despotovic[1], L. Gelinas[1], A. Leung[1], G. Shibahara[1], A. Marziali[1,2].* 1) Boreal Genomics, Vancouver, BC, Canada; 2) Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada.

A considerable challenge to the widespread clinical adoption of sensitive sequencing-based liquid biopsy for cancer is the high assay cost compared to potential reimbursement. Assay cost is currently dominated by the large amount of DNA sequencing required to achieve coverage of a broad gene panel, and by the high read depth required for high clinical sensitivity. Attaching unique molecular barcodes to each ctDNA fragment for the purpose of error reduction further increases sequencing requirements, making liquid biopsy commercialization in many clinical applications impractical. We present a novel library construction process for NGS that increases the accuracy of the combined library construction and sequencing process by at least an order of magnitude. Named Proximity-Sequencing (Pro-Seq), the method duplicates the sequence information in each original DNA strand prior to the bulk of library construction in such a way as to provide redundant, linked templates to the sequencer that contain copies of both senses of the starting template (duplex sequencing). The redundant templates remain linked through the library construction process, allowing detection of PCR errors as sequence disagreement between multiple strands. The linked templates are amplified in a single sequencing reaction, such that base quality and incorporation information can be used to determine which bases of the sequence were corrupted during PCR amplification steps. Since multiple strands are sequenced as part of the same sequencing read, sequencing accuracy is improved without requiring use of additional redundant reads used in molecular barcoding techniques. The method is expected to have significant utility in any applications that require detection of rare sequence variants, including analysis of cell free DNA for liquid biopsy. Additionally, the workflow is entirely based on novel reagents and can be implemented without additional instrumentation beyond standard NGS equipment. We present the detailed method on an Illumina platform, and data from sequencing of bacterial and human cell free DNA that demonstrate error rates that are improved by an order of magnitude over the current state of the art NGS chemistries. Plasma-derived mutation detection is also demonstrated.

Deep learning models of cell type-specific chromatin accessibility profiles elucidate genome-wide tissue-of-origin signatures in cell-free DNA.
C. Probert, C.S. Foo, N. Sinnott-Armstrong, J. Israeli, D. Kim, C. Curtis, A. Kundaje. Stanford University, Stanford, CA, CA.

Cell-free DNA (cfDNA) has recently been shown to contain a nucleosome footprint tissue-of-origin signature; however, current methods for deconvolving tissue-of-origin from this signal use only reads mapping to specific promoter regions and measure correlation to gene expression. Here, we improve tissue-of-origin inference from cfDNA by leveraging large, publicly available DNA accessibility datasets to train a deep latent factorization model to deconvolve tissue-of-origin mixture from genome-wide cfDNA read positioning profiles. We have uniformly processed DNase accessibility data for > 300 human tissues and cell types to create a comprehensive tissue-specific atlas of chromatin accessibility. We use this dataset as the basis for a deep latent factor embedding to infer a mixture of cell types and tissues present in a given cfDNA sample. We apply read positioning profile 'V-plots' to cfDNA, and show that they can be used to learn more discriminative representations of cfDNA profiles that improve tissue signature deconvolution. We demonstrate the concordance of this model with both the tissue-of-origin composition of simulated cfDNA mixtures and also with clinical pathology assessments for both healthy and diseased individuals with high-coverage cfDNA sequencing data. We believe these models of tissue and disease signatures in cfDNA datasets are potentially informative for earlier cancer detection and diagnosis..

NanoChannel based next-generation mapping for the "dark matter" in the genome- comprehensive genome wide large structural variation detection in population. *H. Cao[1], A. Hastie[1], A.W. Pang[1], E.T. Lam[1], W. Andrews[1], T. Anantharaman[1], T. Liang[1], J. Lee[1], K. Pham[1], T. Chan[1], W. Stedman[1], M. Saghbini[1], X. Zhou[1], J. Wang[1], Z.Y. Zhu[1], M. Austin[1], M. Borodkin[1], P. Kwok[2], M. Xiao[3].* 1) BioNano Genomics Inc, San Diego, CA; 2) UCSF, San Francisco CA; 3) Drexel University.

Association of genome structural variations (SV) with complex diseases and traits has been well established; however, large SV (> 1 kb) analysis of human genomes has been limited to date by technical shortcomings of Microarrays (limited to imbalanced copy number variation (CNV) with a narrow dynamic range, low resolution, and relative readouts), next-generation sequencing (NGS) (primarily CNV, some balanced events but too short to span most repeats), karyotyping and fluorescence *in situ* hybridization (FISH) (both low resolution). Using a single-molecule-based genome analysis system, BioNano Genomics next-generation Irys® mapping (NGM) technology, it is now possible to comprehensively analyze whole genomes for SVs > 1 kilobase pairs (kbp), including balanced events such as translocations and inversions in a cost-effective and high-throughput manner. This technology allows for the *de novo* discovery or confirmation of large SVs in patient cohorts and population studies, which is needed to potentially uncover genomic structural causes of Mendelian and complex diseases such as cancer and neurobehavioral disorders. We demonstrate the robustness of NGM for genome-wide discovery of SVs in the CEPH trio from the 1000 Genomes Project with a 96% Mendelian concordance rate. We uncovered 100s of insertions, deletions, and inversions greater than 5 kbp, 7 times more than the large SV events detected by NGS, a large portion of which was novel, and some are located in the regions likely leading to disruption of gene function or regulation. We have also begun analysis of a trio of Ashkenazi Jewish descent from the NIST GIAB project, where we have found hundreds of inversions, insertions, and deletions, including large deletions in a clinically relevant UGT2B17 gene loci in the mother and son. We have also demonstrated the direct detection of translocation events in clinically validated leukemia and multiple myeloma samples as well as large inversion events frequently occurred in DUF1220-domain repeat region of NBPF gene loci related to brain size development and mental disorders. We show that NGM is a robust and effective method for structural variation detection in the human genome. Systematic whole genome structural variation within healthy and disease population cohorts is needed, in addition to the conventional SNP analysis, to study the effects of a full spectrum of genomic variations in human disease and to decipher complex traits in the era of precision medicine.

2886F

Detecting a novel subset of large genomic rearrangements in primary prostate cancer using next generation mapping. *V.M. Hayes[1,2], W. Jaratlerdsiri[1], C. Yang[3], P. Sheth[3], D.C. Petersen[1], E.K.F. Chan[1].* 1) Human Comparative & Prostate Cancer Genomics, Garvan Institute of Medical Research, Darlinghurst, Sydney, NSW, Australia; 2) Central Clinical School, University of Sydney, Camperdown, Sydney, NSW, Australia; 3) Bionano Genomics Inc., San Diego, CA, USA.

   Whole genome sequencing has recently revealed complex genomic rearrangements to be common molecular events driving prostate carcinogenesis, with clinical significance yet to be fully elucidated. Detecting the full range and subtypes of large structural variants (SVs), greater than one kilobase (kb) in length, is however challenging using clinically feasible short-read next generation sequencing (NGS) technologies alone. Unlike NGS, with single base resolution, next generation mapping (NGM) allows for the interrogation of megabase length DNA molecules outside the detection range of short-read NGS. To the best of our knowledge, this is the first study to use a nanochannel NGM technology, namely the Irys system from BioNano Genomics Inc., to generate a complete tumour-normal genome map from a clinically derived primary prostate cancer. Achieving an effective mapped coverage of 35X for a Gleason score 7 (4+3), ETS-negative prostate tumour, at an estimated 43% tumour purity, we identifying 85 large somatic deletion and insertion rearrangements. Only one-tenth of these large SVs were detectable using high-coverage short-read NGS and automated five-tooled bioinformatic analyses. Armed with our NGM-derived target regions, we performed manual inspection of corresponding NGS reads and *de novo* assembled scaffolds, allowing for a dramatic 94% of the total NGM-called SVs to be verified. Furthermore, while less than 0.5% of SNVs show oncogenic potential, over 50% of the SVs directly impact a gene or gene region. From this single-patient study, we hypothesize that a novel spectrum of large genomic rearrangements largely undetectable using standard short-read NGS may be driving primary in prostate cancer, with additional clinically relevant potential to enhance subtype classification.

2887W

Enabling low input samples for low frequency mutation detection. *J. RoseFigura[1], S. Sandhu[1], C. Schumacher[1], L. Kurihara[1], G. Durin[2], T. Harkins[1], V. Marakov[1].* 1) Swift Biosciences, Ann Arbor, MI; 2) Covaris Inc., Woburn, MA.

   A major goal in the field of next generation sequencing is to increase the number of clinical samples that can be analyzed, particularly at low input. Often, detection of low frequency somatic mutations is needed, which additionally requires higher complexity library construction, demanding deep sequencing. To determine the workflow that supports these requirements best, we compared two library preparation methods coupled to either mechanical DNA shearing or enzymatic fragmentation, by comparing the Covaris Focused-ultrasonicator coupled with the Swift Accel-NGS 2S Kit to the KAPA HyperPlus kit that includes enzymatic fragmentation. Inputs of 100, 10, and 1 ng of high quality DNA were tested with both Swift-Covaris and KAPA. There were notable differences between these two methods in both the workflow set-up and performance. For the Swift-Covaris method, no modifications in set-up were required for either DNA shearing or library prep, spanning a six-order range from 100 ng to 1 ng. This method produced consistent insert size distribution and proportional library complexity across the sample input range of 1 ng to 100 ng, without loss of efficiency at low input. The KAPA HyperPlus workflow was sensitive to DNA quality and varying inputs, requiring optimization of fragmentation time and adapter concentration for each sample change. The insert size distribution had a higher standard deviation compared to Swift/Covaris and library complexity was disproportionally reduced at 1 ng inputs. Some libraries were subjected to hybridization capture using the IDT xGEN lockdown Pan Cancer panel. When comparing sequence data using high quality genomic DNA at 1 ng, duplication rates were > 2 fold higher for KAPA compared to Swift/Covaris. At 1 ng input, the mean target coverage was also reduced approximately 2 fold for KAPA. In addition, KAPA libraries consistently displayed a broader insert size distribution than Swift/Covaris libraries. These results demonstrate that, while the Swift Accel-NGS 2S kit using Covaris DNA shearing can maintain coverage metrics at low inputs, KAPA HyperPlus can not. The benefits of both higher quality and the more robust workflow of the Swift/Covaris process enable successful sequencing of low input clinical samples.

2888T

Enrichment based NGS is superior to amplicon based protocols for hereditary cancer gene analyses in somatic tumor samples of patients at risk for tumor predisposition syndromes. *E. Schrock[1,2], F. Zakrzewski[2], K. Hackmann[1], K. Grueztmann[2], L. Gieldon[1], J. Porrmann[1], S. Zeugner[3], A. Kruger[2], K. Kast[4], P. Wimberger[4], D. Aust[2,3], G. Baretton[2,3], A. Rump[1], B. Klink[1,2].* 1) Institut fuer Klinische Genetik, Medizinische Fakultaet Carl Gustav Carus, Technische Universitaet Dresden, Fetscherstraße 74, 01307 Dresden, Germany; 2) Deutsches Konsortium für Translationale Krebsforschung (DKTK), Dresden; Deutsches Krebsforschungszentrum (DKFZ), Heidelberg; Nationales Centrum für Tumorerkrankungen (NCT), Dresden, Germany; 3) Institut für Pathologie, Universitaetsklinikum Carl Gustav Carus, Technische Universitaet Dresden, 01307 Dresden, Fetscherstraße 74, Germany; 4) Klinik und Poliklinik für Gynaekologie und Geburtshilfe, Universitaetsklinikum Carl Gustav Carus, Technische Universitaet Dresden, Fetscherstr. 74, 01307 Dresden, Germany.

Introduction: Pedigree analysis of families at risk for tumor predisposition syndromes often reveals that the index patient is not available for genetic diagnostics. In a substantial number of cases, however, DNA of formalin-fixed paraffin-embedded (FFPE) tumor blocks could be provided from pathology. Since the analysis performed in the index patient is of particular importance, we compared the overall performance between a novel enrichment-based NGS protocol and amplicon-based NGS protocols with regards to the detection of mutations in 94 hereditary cancer genes, including BRCA1, BRCA2, and TP53, in numerous FFPE tumor samples. **Method:** The detection of mutations (SNVs, InDels, and CNVs) was done using fragmented DNA of poor to very poor quality from more than 50 routine FFPE tumor samples. The Illumina TruSeq Nano DNA Library Prep Kit was used in combination with the TruSight Cancer 94 gene panel and compared to the amplicon-based TruSight Tumor 26 and BRCA1/2 gene panels. The overall performance and the detection rate of SNV- and CNV-mutations were compared between enrichment- and amplicon-based NGS-strategies. **Results:** The enrichment-based panel generated results of much higher quality and higher reproducibility. In particular, distribution of sequencing reads along target regions is very homogeneous and comparable within a sample and between different samples. The detection of CNVs, which is mandatory for analyzing hereditary cancer genes with suspected deleterious mutations, could only be performed robustly using the enrichment-based strategy, since amplicon-based protocols show huge coverage changes within and between samples and drop-out of amplicons. Furthermore, amplicon-based methods caused PCR- artifacts. Consequently, the enrichment-based panel was applied to FFPE tumor samples in families with suspicion of hereditary cancer syndromes were no living index patient was available. We were able to detect the underlying pathogenic mutations, for example in the CDH1 gene in a family with hereditary diffuse gastric cancer. We also could confirm germline mosaic mutations in TP53 identified in peripheral blood to be present in the majority of cells in corresponding FFPE tumor tissues. **Conclusions:** Using our enrichment-based strategy on fragmented DNA from FFPE samples leads to an increased NGS performance and to robust mutation detection even in large tumor suppressor genes (e.g. BRCA1/2) and is therefore recommended rather than amplicon-based strategies.

2889F

Resolving the functional significance of *BRCA1* RING missense substitutions. *A.M. Paquette[1], K. Tao[1], A.W. Stark[1], R. Bell[1], A. Thomas[2], W.D. Foulkes[3,4], D.E. Goldgar[5], S.V. Tavtigian[1].* 1) Department of Oncological Sciences, Huntsman Cancer Institute, University of Utah School of Medicine, Salt Lake City, UT; 2) Division of Genetic Epidemiology, Department of Medicine, University of Utah School of Medicine, Salt Lake City, UT; 3) Program in Cancer Genetics, Departments of Oncology and Human Genetics, Montreal, Quebec, Canada; 4) Department of Medical Genetics, Jewish General Hospital and McGill University Health Centre, McGill University, Montreal, Quebec, Canada; 5) Department of Dermatology, Huntsman Cancer Institute, University of Utah School of Medicine, Salt Lake City, UT.

Interpreting variants of uncertain significance (VUS) is a central challenge to clinical geneticists. Two well documented functions of the *BRCA1* (MIM 113705) RING domain are its interaction with *BARD1* (MIM 601593) and subsequent E3 ubiquitin ligase activity of the heterodimer. Although several substrates have been identified as *BRCA1* ubiquitination targets, mice homozygous for the *BRCA1* p.I26A RING mutation are no more tumor prone than their wild type littermates. This missense substitution abrogates the heterodimer's E3 ubiquitin ligase activity without affecting heterodimer formation. In contrast, *BRCA1* variants that disrupt heterodimer formation result in DNA repair defects and loss of tumor suppression. Interestingly, a recent report provided evidence that measurement of *BRCA1*: *BARD1* interaction by itself poorly predicts the pathogenicity of RING missense substitutions. Here we combine these recently published high-throughput functional assay data with data from 68,000 full sequence tests of *BRCA1* to estimate genetic risk attributed to these two functional classes of missense substitutions. Our analyses find minimal evidence of pathogenicity for missense substitutions that are damaging to E3 ligase activity (from phage display assay data), but not the *BARD1* interaction (from yeast 2-hybrid assay data). In contrast, RING variants that disrupt heterodimer formation had strong evidence of pathogenicity. While these results are consistent with the functional activity of the only two known neutral missense substitutions in the *BRCA1* RING domain, multiple RING variants that have already been classified as pathogenic appear to have wild type *BARD1*-binding scores in the yeast 2-hybrid assay data. Mindful of the limitations of yeast two-hybrid screens, we moved this assay into mammalian cells, and found that a system that is more sensitive to the abundance and stability of each protein eliminates this discord. To facilitate clinical classification via the Bayesian Integrated Evaluation, we calibrated this assay by regressing % WT activity for all of the known pathogenic and neutral *BRCA1* RING missense substitutions (plus several cross-species likely neutral substitutions) against their observational data odds of pathogenicity. Moving forward, we envision a high-throughput assay to accelerate the clinical classification of all possible *BRCA1* RING missense substitutions that are the result of a single-nucleotide substitution.

2890W

Using Irys next-generation mapping to identify medically-relevant genomic variation. *A.W.C. Pang, J. Lee, S. Chan, W. Andrews, T. Anantharaman, A. Hastie, E. Holmlin, H. Cao.* Research and Development, BioNano Genomics, San Diego, CA.

Structural variation (SV) detection is fundamental to understand the genetic basis of diseases. While karyotyping, cytogenetic, and conventional molecular detection approaches are robust, they can be manually intensive, biased towards targeted loci, and cannot elucidate the copy number of long repeats. The BioNano Genomics Irys® System offers an unbiased and sensitive method to detect large variants. Based on next-generation mapping (NGM), it uses NanoChannel arrays to linearize DNA hundreds of kilobases in size, high resolution imaging, and haplotype-aware *de novo* assembly to construct genome maps megabases in length. To complement the *de novo* assembly method, the long molecules can be aligned to the *in silico* digested human reference to identify aneuploidy and copy number alterations by depth counts. The combined methods can capture over 4,000 insertions, deletions (>one kilobases), translocations and inversions in a human sample, about 2.5 times more than sequencing alone. We present a novel software that examines genome map calls to identify disease-associated SVs. To search for high-confidence calls, it searches for genomic elements such as centromeres and segmental duplications that may confound SV-calling, and evaluates quality scores of the assembly, alignments, and SVs detected. To further ascertain medically-relevant candidates, it filters the remaining calls with over 36,400 SVs collected from 32 mapping experiments from phenotypically "normal" individuals, and compares with calls from disease-specific databases. Using this pipeline, whose total runtime is only a few hours, we can efficiently focus on several dozens of significant candidates for further analysis. We ran the Irys System on 10 samples with hematological malignancy, applied the candidate-finding software, and identified known rearrangements such as the t(9;11)(q21.3;q23.3) in acute myeloid leukemia AML and t(9;22)(q34.12;q11.23) in CML. Moreover, we uncovered novel mutations ranging in size from a small 4.2 kb insertion disrupting an ALL gene *CNOT3* to a large 9.6 Mb deletion at 17q25. In conclusion, Irys technology may replace conventional detection approaches with one standardized and comprehensive platform, aid the discovery of functional SV, and improve our understanding of the mechanisms of diseases.

2891T

From FFPE tissue to targeted multiplex panel sequencing in less than 60 minutes using Hyb & Seq™ chemistry. *D. Kim, M. Walsh, E. Piazza, R. Khafizov, E. Manrao, J. Beechem.* NanoString Technologies, Inc., Seattle, WA.

Hyb & Seq is a single molecule sequencing method that uses cyclic nucleic acid hybridization of fluorescent molecular barcodes to sequence native single molecule targets. The ability to directly sequence native molecules affords the opportunity for a simple, very rapid and automatable sample preparation workflow for targeted sequencing, even with challenging sample types such as formalin-fixed paraffin embedded (FFPE) tissue. Here, we demonstrate proof-of-principle Hyb & Seq sample preparation by targeting 100 different gene targets, and quantifying the efficiency of the sample preparation on various FFPE tissue types (lung, colon, skin and tonsil). In the Hyb & Seq sample preparation, FFPE tissue is first 'liquefied' (one-pot deparaffinization and tissue lysis) using an aqueous reagent mixture containing lysis buffer with Proteinase K and with heat. Following incubation for 30 minutes at 56°C and for 5 minutes at 98°C, the liquefied FFPE tissue slurry is passed through a syringe filter to separate and collect the supernatant, which contains the genomic DNA released from the tissue. Fragmented genomic DNA is captured directly in a 15 minute hybridization reaction using multiplexed target specific capture probe panel to both enrich for gene targets of interest and to create 'gapped' single-stranded regions in the captured native DNA molecules. These 'gapped' single stranded gene targets are purified, captured onto a flow-cell, and then quantified using Hyb & Seq* to identify and digitally count, yielding both the unique sequence and qualitative copy number of each target gene. Experimental results showed that more than 95% of the 100 targets were successfully captured onto the flow-cell using just one to three FFPE slices of 10 microns each, with no PCR amplification (success criteria of ≥1,500 copies captured per target). The total counts from each target were within one log range, demonstrating good capture uniformity. The total processing time from FFPE curls to start of sequencing was under 60 minutes, with the total hands-on time of less than 15 minutes. Based on these results, Hyb & Seq's simple workflow demonstrates the possibility of a rapid sample-to-answer sequencing instrument well suited for clinical applications. *Detailed description of Hyb & Seq chemistry is available on-line: https://www.youtube.com/watch?v=LUc5Yf9Dlgg.

miRNA as liquid biopsy biomarkers in breast cancer. *B.M. Dugan, J.M. Shaffer, E. Lader.* Qiagen Sciences, Frederick, MD.

miRNA are small, 21 nucleotide RNA that play in important role in normal and abnormal gene regulation. Changes in miRNA expression have been observed in an assortment of cancers including breast cancer. Recently, increased interest in noninvasive surveillance and detection of biomarkers associated with cancer are driving the discovery of miRNA expression profiles that can be used to detect disease without the need for tissue biopsy. To demonstrate the effectiveness of miRNA as a potential early biomarker for breast cancer, small RNA-sequencing was conducted on matched breast cancer samples, tissue biopsy from a breast malignancy as well as serum/plasma. By comparing non-invasive techniques to standard tissue biopsies will determine if specific miRNA profiles are reliable biomarkers for early detection of breast cancer.

2893W

Differential expression of miRNA in 2D and 3D human colon cancer cell cultures after therapeutic compound treatment. *B. Hook, S. Lewis, T. Schagat.* Scientific Applications Support, Promega Corporation, Fitchburg, WI.

MicroRNAs (miRNAs) are small-noncoding RNA molecules that regulate gene expression post-transcriptionally. Amplification and overexpression of individual oncomiRs (miRNAs associated with cancer) or genetic loss of tumor suppressor miRNAs are associated with human cancer and are sufficient to drive tumorigenesis in mouse models. A global decrease in miRNA levels has been observed in human cancers and linked to genetic and epigenetic alterations in components of the miRNA biogenesis machinery. Fluorouracil is an anti-cancer chemotherapy drug that acts as an antimetabolite in cells and has been previously shown to modify the expression profiles of miRNAs in human cancer cells. In this study, we developed a workflow to enable testing of viability, cytotoxicity and apoptosis in the same cells in multiple culture formats, with downstream analysis of miRNA effects. Two colon cancer cell lines (HCT116 and HT-29) were grown as monolayers in standard 2D culture plates, as Matrigel-embedded 3D cultures, and as large 3D spheroids generated using ultra-low attachment plates followed by treatment with 5-Fluorouracil. Viability and cytotoxicity were monitored in real-time for 48 hours followed by measurement of apoptosis and subsequent extraction and quantification of miRNA expression changes.   We determined that 5-Fluoruracil had differential potency between 2D and 3D culture models for both of the two colon cancer cells lines tested. From the same assay wells that were used to determine potency, total RNA including miRNAs was extracted and three miRNAs were analyzed for expression using RT-qPCR. The impact on miRNA expression was dependent on cell culture format and was lower in the 3D culture models. This complete workflow solution enables assessment of cell health and gene expression from the same samples.

Multiplex detection of driver mutations in lung cancer: Simultaneous assay of single nucleotide variants (SNV) and fusion-transcripts from small amounts of FFPE samples on the nCounter® analysis system. *G. Meredith[1], J. Kargl[2], J. McKay-Fleisch[1], M. Ross[1], J. Garber[1], G. Ong[1], C. Ngouenet[1], J. Phan[1], M. Krouse[1], M. Pansalawatta[1], L. Dennis[1], A. Kharkia[1], E. Piazza[1], R. Boykin[1], A.M. Houghton[2], D. Kim[1], J. Beechem[1].* 1) R&D, NanoString Technologies, Seattle, WA; 2) Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA.

Worldwide, lung cancer is the most diagnosed form of cancer with a survival rate that is among the lowest. Combined, mutations (in the form of SNVs and InDels) and gene fusions account for the majority of clinically interpretable and actionable genomic alterations seen in the disease's most common form, non-small cell lung cancer (NSCLC). Thus, tools and methods for rapid and robust multiplexed detection of these genomic alterations from formalin-fixed, paraffin-embedded (FFPE) tissue samples are critically needed. NanoString's optical barcoding technology now enables detection of small genomic sequence changes such as SNVs and InDels. A test-panel that targets dozens of clinically relevant variants has been developed that permits multiplex detection of SNVs and InDels. Detailed technical performance of this test panel is described in a companion presentation. Importantly, this panel can be used in a 3D Biology™ workflow when combined with the nCounter Vantage™ Lung Gene Fusion panel to permit simultaneous detection of fusion transcripts from RNA. The SNV assay workflow begins with pre-amplification of 5 ng of FFPE-extracted gDNA via multiplex PCR. Resulting amplicons are then hybridized to nCounter probes. The fusion assay uses 150 ng of total FFPE-extracted RNA which is directly probed in a separate hybridization. These low input requirements support minimal use of precious samples that may obviate the need for microdissection. After hybridization, the two reactions are pooled for quantification within a single cartridge lane on an nCounter system. Each panel has specific controls that ensure QC checks and proper statistical data analysis. Here, we first demonstrate simultaneous assay of both classes of driver mutation using cell line and commercial control samples to verify the analytical performance. Next a cohort of 50 patients was assayed for the presence of SNVs and/or gene fusions and the results compared to matched whole-exome sequencing data. SNV detection via the nCounter assay was highly concordant (>95% cross-validation) with sequencing results. Further, SNVs were accurately detected from FFPE samples with as little as 5-10% tumor cellularity. Likewise, positive gene fusion calls were validated by follow-up clinical assays. Significantly, we show that SNVs and fusion transcripts that are clinically relevant in lung cancer can be assayed together using a single 10 micron FFPE slice.

Multiplex profiling of cancer driver mutations: Detection of single nucleotide variants (SNV) and small InDels from small amounts of FFPE samples on the nCounter® analysis system. *M. Ross[1], J. Lee[2], J. McKay-Fleisch[1], C.P. Vellano[2], J. Garber[1], A.K. Eterovic[2], E. Manrao[1], M. Krouse[1], J. Phan[1], M. Pansalawatta[1], E. Piazza[1], L. Dennis[1], A. Kharkia[1], D. Kim[1], G.B. Mills[2], G. Meredith[1], J. Beechem[1].* 1) R&D, NanoString Technologies, Seattle, WA; 2) Dept. of Systems Biology, The University of Texas MD Anderson Cancer Center, Houston, TX.

Tools and methods to perform rapid and robust multiplexed molecular profiling of formalin-fixed, paraffin-embedded (FFPE) tissue samples are critical for basic and translational cancer research. NanoString's optical barcoding technology has been adapted to enable detection of small genomic sequence changes such as SNVs, multiple base substitutions, and insertions and/or deletions of less than 20 bases through development of a novel class of variant-specific hybridization probes*. A test panel of variant-specific probes that targets 26 clinically relevant variants has been developed that permits multiplex detection of SNVs from gDNA. This assay can be combined with other NanoString Vantage™ panels for 3D Biology™ to enable, for example, simultaneous detection of gene expression from RNA. The workflow begins with a pre-amplification of gDNA (fresh or FFPE-extracted) via multiplex PCR to enrich targets of interest. Resulting amplicons are then hybridized with the SNV panel of variant-specific nCounter probes. After hybridization, pooling with any other 3D Biology panel can be done for simultaneous quantification within a single cartridge lane on an nCounter system. SNV panel specific controls have been implemented for both thorough QC measures and proper statistical analysis. All variant-specific hybridization probes in the panel were verified to have accurate detection down to 5% variant allele fraction, with many able to go below 1%. As little as 5 ng of FFPE-extracted gDNA is sufficient for the assay, supporting minimal use of precious samples, such as patient-derived FFPE tissues and obviating the need for microdissection. Using 5 ng, simultaneous detection of 15 variants, each present at either 2.4% or 4.8% allele fraction, was demonstrated using a blend of genomic DNA from engineered cell-lines. Most importantly, SNV mutations were detectable from a range of patient-derived FFPE samples that were known to harbor mutations (as low as 5% tumor) or were subsequently verified as such by sequencing. Significantly, we show that the SNV detection chemistry can be combined with gene expression analysis by using an nCounter Vantage RNA Panel in a 3D Biology workflow to provide simultaneous assay of these two important classes of analytes, DNA and RNA, from limited amounts of nucleic acid. *Kim, D. et al. 3D Biology™: Simultaneous single-molecule quantification of DNA (SNVs), mRNA, & proteins. Poster presented at AGBT; February 2016; Orlando, FL.

Comprehensive identification of piwi-interacting RNAs binding sites associated with hypoxia-inducible genes downregulation. *B.C. Minatel, N. Firmino, E.A. Marshall, K.L. Bennewith, W.L. Lam, V.D. Martinez.* Department of Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, Canada.

   Background: The expression of hypoxia-induced genes is tightly regulated and involves a variety of regulatory mechanisms. Piwi-interacting RNAs (piRNAs) are small (24-32 bp) RNA species able to recognize complementary DNA sequences throughout the genome, inducing epigenetic silencing nearby to target regions. Since the expression of specific piRNAs is responsive to changes in oxygen tension, we investigated if piRNAs play a role in the regulation of hypoxia-induced genes, by predicting their binding pattern to regulatory DNA regions (upstream transcript start site, TSS) of genes downregulated under hypoxic conditions. **Methods:** We determine gene expression profiles, as well as piRNA expression profiles from small-RNA sequencing libraries, derived from hypoxic (n=932) and normoxic (n=894) tumors from 7 human organs, and for normoxic/hypoxic (16h at 1% O_2) cell lines from the same sites. For prediction analyses, we considered a 3.5 kb DNA sequence window upstream of the TSS of previously described hypoxia downregulated genes (n=51). piRNA/DNA binding prediction was performed using two different algorithms (miRanda and ThermoBLAST), with specific parameters defined by piRNA features. **Results:** Our analysis identified that a total of 36 piRNAs were consistently upregulated under hypoxia in tumor samples and cell lines from different organs. Twenty seven (75%) of these piRNAs are predicted to bind the upstream region of genes known to be downregulated by hypoxia. We further determined the concordance of piRNA upregulation with corresponding mRNA downregulation. To identify which of these 27 piRNAs are predominantly interacting with hypoxia related genes, we compared their binding preference between the 3.5 kb window upstream TSS of hypoxia downregulated genes and those of all human protein-coding genes. Five piRNAs were found to have binding sites significantly enriched in upstream regions of hypoxia-downregulated genes. These piRNAs had predicted upstream binding sites in 0.9-1.6% of the hypoxia-repressed genes compared to only 0.1-0.3% of all genes in the human transcriptome (p value $X^2 <= 0.005$). **Conclusion:** Our results indicate that a set of piRNAs may have a role in the regulation of hypoxia induced gene expression. Although further mechanistic validation is needed, the enriched presence of piRNA binding sites in regulatory regions of hypoxia-regulated genes suggests the involvement of piRNA mediated epigenetics mechanisms in hypoxia-induced gene silencing.

Impact of the cell cycle on mRNA-Seq gene expression profiling for single cancer cells using BD™ Precise assays. *C. Lomas[1], K. Dembski[1], J. Goglio[1], K. Yaccato[2], C. Betts[2], S. Weaver[2], X. Wang[1].* 1) BD Life Sciences, San Jose, CA; 2) BD Life Sciences, Menlo Park, CA.

   Single cell mRNA sequencing has been developed as a powerful tool to examine the heterogeneity of a cell population. However, confounding factors, such as the cell cycle state of the cell, might obscure the observation at the single cell level. In a biological sample, each cell is at an unknown phase of the cell cycle. Cell cycle-dependent gene expression can bias assessment of differential gene expression or even drive cluster analysis when trying to cluster cells by gene expression patterns. In this study, we analyzed the influence of the cell cycle states on gene expression profiles by sequencing mRNAs from single cells sorted by BD's fluorescence-activated cell sorting (BD FACS™ technology). Three different methods of cell preparation were used to study the relationship between known cancer-related genes and cell cycle genes using the T47D breast cancer cell line. For the first method, cells were treated with cell cycle inhibitors to arrest cells in G0/G1, S, and G2/M phases of the cell cycle before sorting. For the second method, cells in culture were sorted based on G0/S1, S, G2/M phases, without cell cycle inhibitors. Finally, a third method was used to sort the cells irrespective of the cell cycle phase and track the cell cycle phase information by using a BD FACS index sorting feature. The cell cycle phase was determined by intracellular staining using Hoechst 34580, a DNA dye that is excited by a violet laser, to estimate the DNA content. 96 cells prepared by each method were sorted into individual wells of a BD™ Precise encoding plate using a BD FACSseq™ cell sorter and assayed using a gene panel containing common cell cycle- and cancer-specific markers. Principle component analysis of mRNA expression of the cell cycle genes was used to cluster the cells, and cancer gene expression profiles were determined. The cell cycle phase of each cell deduced from the targeted gene panel gene expression clustering matched the index sorting data generated by the BD FACSseq cell sorter. In this study, we present a BD Precise assay to study BD FACSseq sorted single cells at different phases of the cell cycle, which allowed us a better understanding of the effects of cell cycle phases on gene expression profiles at the single cell level. The panel and algorithm generated could be applied in cancer tissue samples and other biological tissue sample types to separate the potential confounding effect of cell cycle on single cell gene expression studies.

Massively parallel functional analysis of missense mutations in *BRCA1*.
L. Starita[1], M. Islam[2], S. Fields[1,3], J. Parvin[2], J. Shendure[1,3]. 1) Genome Sciences, University of Washington, Seattle, WA; 2) Department of Biomedical Informatics and The Ohio State University Comprehensive Cancer Center, The Ohio State University, Columbus, OH; 3) Howard Hughes Medical Institute.

Interpreting the effects of genetic variation is the central challenge for the progress and prospects of precision medicine. Variant-effect prediction algorithms can classify any possible genetic variation but despite substantial efforts, they do not have the accuracy to support their use in a clinical setting. On the other hand, experimentally testing the effect of each individual variant on protein function or gene expression yields high-quality information, but is low-throughput. To resolve this, we are developing massively parallel functional assays to determine the effects of thousands of genetic variants on protein function and/or gene expression in a single experiment. Using such an assays, we comprehensively evaluated the effects of >1,300 amino acid substitutions on the biochemical functions of the RING domain of BRCA1 as well as the effects of all possible nucleotide substitutions in exon 18 of *BRCA1* on mRNA splicing. We have now successfully parallelized a cellular assay to test the effects of large numbers of missense variants on the tumor suppressive functions of the full-length BRCA1 protein, the best proxy for its *in vivo* function in relation to breast and ovarian cancer risk. The sum of our results-to-date show that predictions based on massively parallel experimental analysis markedly outperform commonly used computational tools in predicting the effects of missense variants on BRCA1 function. We envision that for *BRCA1* and other clinically relevant genes, massively parallel functional assays will facilitate the prospective interpretation of variants observed in clinical sequencing.

Guiding platinum-based chemotherapy with a somatic mutation signature of *BRCA1/2* **impairment.** *E.Y. Zhao[1], Y. Shen[1], E. Pleasance[1], K. Kasaian[1], M. Jones[1], C. Ch'ng[1], C. Reisle[1], P. Eirew[2], K.L. Mungall[1], N. Thiessen[1], Y. Ma[1], A. Fok[1], A.J. Mungall[1], Y. Zhao[1], R.A. Moore[1], D. Villa[4], T. Shenkier[4], C. Lohrisch[4], S. Chia[4], S. Yip[3], K. Gelmon[4], H. Lim[4], S. Sun[4], K.A. Schrader[2,6], S. Young[5], A. Karsan[1,5], R. Roscoe[1], J. Laskin[4], M.A. Marra[1,6], S.J.M. Jones[1,6,7].* 1) Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada; 2) Department of Molecular Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada; 3) Department of Pathology & Laboratory Medicine, The University of British Columbia; 4) Department of Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada; 5) Cancer Genetics Laboratory, British Columbia Cancer Agency, Vancouver, BC, Canada; 6) Department of Medical Genetics, University of British Columbia, Vancouver BC, Canada; 7) Department of Molecular Biology and Biochemistry, Simon Fraser University, Vancouver BC, Canada.

Background: *BRCA1* and *BRCA2* are centrally involved in homologous recombination. Mutations in these genes account for 5-10% of breast cancers and have been associated with sensitivity to platinum-based chemotherapies. Whole genome sequencing has revealed somatic mutation signatures which are molecular phenotypes of genomic instability. A signature associated with *BRCA1* or *BRCA2* deficiency (BRCAd) has been found to predict cisplatin response in pancreatic cancer xenografts. Here, we investigate whether this signature can direct platinum-based therapy in breast cancer patients and quantify the associated clinical benefit. **Methods**: 47 advanced breast cancers underwent whole genome and transcriptome sequencing on an Illumina HiSeq sequencer. Comprehensive genomic characterization involved alignment, *de novo* assembly, and comparison to matched blood sequence to characterize somatic mutations and gene expression. Mutation signatures were deciphered using non-negative matrix factorization. A retrospective chart review was performed to obtain the timing and outcomes of cisplatin and carboplatin regimens. Of 29 platinum treated patients, 24 underwent radiological investigation. 11 were treated exclusively before sequencing, 14 after, one both before and after, and 3 during. **Results**: Six mutation signatures were deciphered, of which four have been previously observed in breast cancer. The BRCAd signature accounted for a range of 12 to 10,246 somatic mutations per cancer. Logistic regression demonstrated 59% increased odds (odds ratio 1.16-2.50) of radiological clinical improvement (CI) on platinum-based therapy for every 1000 mutations attributed to the BRCAd signature (p = 0.01). All patients with CI fell within the top BRCAd quartile. One patient with CI and high BRCAd signature possessed no detectable abnormalities in *BRCA1* or *BRCA2*. Another carried a *BRCA1* missense variant of unknown significance (H1390R). Patients with above-median BRCAd signature also experienced a 69 day extension of time to treatment failure on platinum-based therapy compared to patients with below-median BRCAd signature (p = 0.005). Cox analysis demonstrated 18% decreased daily odds of treatment failure per 1000 BRCAd-attributed mutations (hazard ratio 0.71-0.95, p = 0.007). **Conclusion**: A BRCAd-associated mutation signature predicts clinical improvement on platinum-based therapy in breast cancer and extends time to treatment failure, even in the absence of detected *BRCA1*/*BRCA2* mutations.

Somatic mutations of a specific type (<u>C</u> to T or G substitutions in the T<u>C</u>A or T<u>C</u>T motifs) have been described in many tumors as APOBEC-signature mutations. This mutation pattern has been correlated with expression of two members of the *APOBEC3* subfamily - *APOBEC3B* and *APOBEC3A*. However, factors affecting APOBEC mutagenesis are largely unknown. Here, we explored the contribution to cancer risk and APOBEC mutagenesis of the two common germline variants in the *APOBEC3* region - a single nucleotide polymorphism (SNP), rs1014971, and a 30 Kb deletion that eliminates *APOBEC3B* and creates *APOBEC3AB* chimera. Imputation and association analyses were performed in 3,732 bladder cancer cases and 10,721 controls. Expression analysis of all genes and their isoforms in 1 Mb region centered at rs1014971 was performed in the Cancer Genome Atlas (TCGA) bladder cancer dataset (N=412) and breast cancer dataset (N=520). Expression was analyzed by linear regression in relation to rs1014971 genotypes adjusting for age, sex, race, DNA CpG methylation status and copy number variation (CNV). APOBEC-signature mutation analysis was performed with genotypes of rs1014971. Functional annotation of rs1014971 and two correlated SNPs ($r^2 \geq 0.8$) was performed *in silico* using ENCODE data, and experimentally, using electrophoretic mobility shift assays (EMSA). Three bladder and three breast cancer cell lines were treated with bleomycin, a DNA-damaging drug or Sendai virus, that induces robust antiviral interferon response, and mRNA expression of *APOBEC3s* was evaluated by qRT-PCR. We found that SNP rs1014971 was associated with bladder cancer risk, increased *APOBEC3B* expression, and enrichment with APOBEC-signature mutations in bladder tumors. In contrast, the deletion was not important in bladder cancer, while being associated with breast cancer risk and enrichment with APOBEC-signature mutations in breast tumors. Experimental analysis showed allele-specific DNA-protein interactions for rs1014971, which is located within a putative enhancer region of *APOBEC3B*. *In vitro, APOBEC3B* was predominantly induced by treatment with a DNA-damaging drug in bladder cancer cell lines and *APOBEC3A* was induced as part of antiviral interferon-stimulated response in breast cancer cell lines. These findings demonstrate contribution of germline variants to APOBEC mutagenesis and suggest tissue-specific role of environmental oncogenic triggers, particularly in individuals with germline *APOBEC3* risk variants.

Next generation sequencing analysis of *CDH1* gene in Mexican patients with diffuse gastric cancer. *A.R. Bustos-Carpinteyro[1,2], M.G Flores-Miramontes[3,4], V. Ramírez-Rodríguez[5], S.A. Romero-Martínez[5], A. Aguilar-Lemarroy[4], L.F. Jave-Suarez[4], J.Y. Sánchez- López[2].* 1) Instituto de Genética Humana, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico; 2) División de Genética, Centro de Investigación Biomédica de Occidente, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, México; 3) Doctorado en Ciencias Biomédicas. Universidad de Guadalajara, Guadalajara, Jalisco, México; 4) División de Inmunología, Centro de Investigación Biomédica de Occidente, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, México; 5) División Diagnóstica, Roche México, México, Distrito Federal.

Introduction. Gastric cancer (GC) constitutes the third cause of cancer death worldwide; histologically, GC can be classified as diffuse and intestinal. Diffuse GC has a reduced expression of the E-Cadherin cell adhesion protein, which is encoded by the *CDH1* gene; mutations in this gene are one of the main causes for gene inactivation and has been considered as an important factor in cancer progression and metastasis. To date, have been reported a total of 155 *CDH1* germline mutations, of which 126 are pathogenic and 29 are unclassified variants. **Materials and Methods.** We studied 22 DNA tumoral tissues of Mexican patients with diffuse GC. Mutation analysis of the promoter region and exome of the *CDH1* gene was performed by NGS throw the GS Junior 454 platform by Roche® and the GS Amplicon Variant Analyzer software (Roche®). **Results.** We found a total of44 mutations of which 18 are point mutations, 18 deletions and 8 insertions; these mutations were located mainly in the promoter region and introns (47.7% and 36.4%, respectively), whereas only 13.6% were in exons and the remaining (2.3%) was in the 3'UTR. 11 of the 44 variants have been previously reported as SNPs or mutations. The most important variants found were: two polymorphisms in the promoter region (rs5030625 and rs16260), which have been previously reported and associated with gastric cancer. Two intronic variants, IVS1 48+3delA and IVS4 531+10 G>C, that could have pathologic potential due to their localization. Three variants in codifying region: c.202delT (rs786202151) reported as pathogenic for be associated with hereditary cancer-predisposing syndrome; c.360delG (COSM1684458); and c.367insC (not previously reported); these variants alter the reading frame leading to a truncated polypeptide (at 82, 142 and 136 residues, respectively), affecting the precursor protein. **Conclusions.** Most of the mutations identified in this study are located in the gene promoter region; these variants could be relevant for the expression regulation of *CDH1* (mainly down-regulated in GC); for this reason, a complementary study of gene expression (mRNA and protein) would be appropriate. Additionally, further bioinformatics analyses are needed in order to understand the biological meaning of the variants found, and to identify those with potential pathogenicity.

The genomic landscape of never smoker lung adenocarcinomas. *T. de Silva[1], V. Martinez[1], K. Thu[1], S. Lam[2], W. Lam[2], H. Varmus[3], W. Lockwood[1].* 1) Department of Integrative Oncology, British Columbia Cancer Research Centre, Vancouver, Canada; 2) National Intramural Sequencing Center, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 3) NISC Sequencing Program, Sandra and Edward Meyer Cancer Center, Weil Cornell Medical College, New York, NY.

   Although the majority of lung cancers can be attributed to tobacco exposure, approximately 15 to 25% arise in individuals who report smoking fewer than 100 cigarettes during their lifetimes ("never smokers"). Lung cancer may develop in never smokers through mechanisms distinct from those that affect smokers and is strongly associated with female gender, East Asian ethnicity, adenocarcinoma histology, and a significantly higher frequency of EGFR mutations and ALK translocations--- findings that are useful biomarkers for administration of targeted drugs. Our studies build on two important observations. First, a significant fraction of lung adenocarcinomas in never smokers have not been found to have mutations in known oncogenic driver genes. Second, mutations in oncogenic driver genes appear to be insufficient for tumorigenesis, suggesting that additional alterations are required. To address these issues, we have comprehensively studied the genomes of 15 lung adenocarcinoma from never smokers - seven "triple negative" tumors (with normal EGFR, ALK, and KRAS genes) and eight EGFR mutant tumors - with the goal of identifying novel mutant genes in these subsets. Whole exome sequencing revealed a median of 46 coding mutations per tumor with a median mutation density of 2.69 mutations/Mb. To identify mutated genes that confer a selective growth advantage we used a multistep approach, filtering variants based on gene expression level, background mutation rate and gene size. 32 unique genes demonstrated significant evidence of conferring a selective advantage. These included known oncogenes (EGFR, ERBB2 and MET) and tumor suppressor genes (p53, RB1 and ATM). In addition, sequencing of tumor RNA revealed fusions involving RET or ROS1, one fusion in each of two tumors. The variations in MET consisted of truncating and splice-site mutations and have not been previously characterized in this context. We also observed mutation, hemizygous and homozygous loss of multiple genes from the chromosome arm 6q. Pathway analysis indicated frequent mutation in genes implicated in PI3 kinase signaling, RNA splicing and histone modification. Expanded genomic analyses of captured exons from over 180 genes from the initial 15 tumors and an extended panel of 85 tumor/normal pairs have revealed a shared signature, which indicates prevalence in such lung adenocarcinomas. Together, this work will expand our understanding of lung adenocarcinomas arising in never smokers. .

Identification of functional candidate variants at two ovarian cancer outcome loci. *D. Glubb, S.E. Jonatty, M. Quinn, S. MacGregor, G. Chenevix-Trench.* QIMR Berghofer Medical Research Institute, Brisbane, QLD, Australia.

   Recently, we identified associations between five SNPs and either progression free or overall survival ($p < 1 \times 10^{-5}$) in a genome-wide association analysis of over 4,000 European epithelial ovarian cancer patients. All five SNPs and other candidate outcome variants correlated by linkage disequilibrium ($r^2 > 0.4$) are located in non-coding regions. To identify genes targeted by these SNPs, we have analysed candidate outcome variants using bioinformatic, chromatin conformation capture (3C) and reporter gene approaches.   eQTL data from the Genotype-Tissue Expression Project indicate that candidate variants at the 19p12 outcome locus significantly associate ($q < 0.05$) with *ZNF100* expression in normal ovarian tissue. Through 3C analyses of the 19p12 outcome locus in two ovarian cancer cell lines (OVCAR8 and COV362), we identified two putative regulatory elements (PREs) that physically interact with the *ZNF100* promoter. Allele-specific 3C analysis indicated that the major alleles of two candidate variants (rs10421113 and rs10421342) correlated with the interaction of the *ZNF100* promoter and one of the PREs. Since this PRE was found to increase *ZNF100* promoter activity in ovarian cancer cells, these alleles may associate with greater *ZNF100* expression in ovarian tumors. At the 1q22 outcome locus, candidate variants were located in a super-enhancer that was predicted to regulate *MEF2D* in ovarian tissue. The *MEF2D* promoter was too close to candidate variants for 3C analysis but the super-enhancer and eQTL data from normal ovarian tissue suggested that *MEF2D* is a regulatory target. A PRE coincident with the super-enhancer and containing the major alleles of four candidate variants (rs11264488, rs10159180, rs11264489 and rs942964) acted as an enhancer and increased *MEF2D* promoter activity by 117% ($p < 0.0001$) and 61% ($p = 0.03$) in OVCAR8 and COV362 cells, respectively. In OVCAR8 cells, a haplotypic variant of the PRE, carrying minor alleles of the candidate variants, increased promoter activity by a further 21% ($p = 0.03$ after multiple comparison correction).   In summary, we have found functional evidence that candidate variants at two loci associated with ovarian cancer survival may mediate effects on outcome through regulation of *ZNF100* and *MEF2D*.

Rapid CNV characterization of clinical cancer samples on the Oxford Nanopore MinION. *S. Goodwin[1], F. Sedlazeck[2], T. Baslan[3], R. Levine[3], W.R. McCombie[1], M.C. Schatz[1,2].* 1) Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; 2) John Hopkins University, Baltimore, MD; 3) Memorial Sloan Kettering Cancer Center, New York, NY.

Acute myeloid leukemia (AML) is a complex, devastating cancer of the myeloid blood cells where the cells lose the ability to differentiate normally. While this rare disease only accounts for ~1% of cancer deaths annually, the mortality rate exceeds 50% and left untreated can lead to death within just a few weeks. Approximately 30% of patients present with complex karyotypes upon conventional cytogenetic examination, and these patients have a poor prognosis. Copy number variations are widely recognized as contributing to cancer pathogenesis, patient prognosis and therapeutic response. DNA sequencing can provide molecular cytogenetic information, which in turn provides improved patient classification and can direct sub-type specific therapies. Despite recent advancements in Next-Generation Sequencing (NGS) approaches, clinical genetic sequencing often takes weeks before actionable results are generated due to the substantial investment in infrastructure required for most sequencing pipelines. This time to actionable results is time which AML patients may not have. The Oxford Nanopore MinION device could theoretically provide clinicians with a tool to generate rapid low-coverage copy number profiles, equivalent to cytogenetic examination in a point-of-care setting. We have developed a pipeline for generating copy number profiles from clinical cancer samples in three days from sample collection to analysis. Using the widely rearranged SKBR3 cancer cell line as a model we have been able to generate >300k short reads on during a single MinION run followed by CNV analysis by Ginkgo, software capable of profiling CNV in low-coverage samples. These profiles have been able to identify nearly all CNVs called by Ginkgo from MiSeq libraries. This approach can be used by clinicians to accurately and rapidly to characterize the CNV profile from clinical samples and may help in informing patient treatment. With upcoming improvements to the Oxford Nanopore platform and software we are optimistic that the time from sample collection to results can be decreased even further.

Genetic revolution or evolution: Will complex single gene variance within breast cancer tumors challenge the long standing genetic principles that assume that universal laws govern genotype to phenotype relationships. *B. Gottlieb[1,2,3], F. Babrzadeh[7], K. Klein Oros[1,6], C. Alvarado[1], C. Wang[7], B. Gharizadeh[7], M. Basik[1,2,4,5], C.M.T. Greenwood[1,5,6], L.K. Beitel[1,2,3,4], M. Trifiro[1,2,3,4].* 1) Cell Genetics, Lady Davis Institute for Medical Research, Montreal, Quebec, Canada; 2) Segal Cancer Center, Jewish General Hospital, Montreal, Quebec, Canada; 3) Human Genetics, McGill University, Montreal, Quebec, Canada; 4) Medicine, McGill University, Montreal, Quebec, Canada; 5) Oncology, McGill University, Montreal, Quebec, Canada; 6) Epidemiology, McGill University, Montreal, Quebec, Canada; 7) Stanford Genome Technology Center, Stanford University, Palo Alto, California, USA.

An additional level of diversity in breast tumors has been revealed by sequencing at much greater than usual depths and by using sequencing analysis tools that have identified for the first time a degree of genetic heterogeneity within individual genes, a condition that we have termed, complex single gene variance (CSGV). An analysis of six breast tumors revealed the presence of CSVG within the androgen receptor gene. A total of 53 mutations were identified, although always only in a minority of cells within each tumor. The presence of different single gene mutations in a minority of cells within a tumor has never been considered a possibility and therefore when identified usually ignored by being assumed to be the result of sequencing or sequence analysis errors. This assumption will be discussed in light of new developments in sequence analysis. Hopefully, the ability to identify CSGV in cancer tissues will further contribute to our understanding of both carcinogenesis as well as resistance to chemotherapy by being able to more closely follow putative mutations in cancer-associated genes through cancer ontogeny and treatment. Although the idea that breast tumors even within individuals may have unique and highly complex genetic profiles could be seen as a daunting obstacle in the fight to cure cancer. In the "age of personalized medicine" we believe that identifying CSGV when and where it occurs in breast tumor development is an important step to understanding breast cancer ontogeny. Finally, CSVG challenges the traditional scientific philosophy of "parsimony" that underlies our desire to find the common gene mutations that contribute to breast cancer, in the belief that doing so is essential if we are to make progress in understanding the role of genomics in breast cancer.

2906T

Genomic survey of microsatellite instability reveals cancer-specific signatures and driver mutations. *R.J. Hause[1], C.C. Pritchard[2], J. Shendure[1], S.J. Salipante[2].* 1) Department of Genome Sciences, University of Washington, Seattle, WA; 2) Department of Laboratory Medicine, University of Washington, Seattle, WA.

Microsatellites, 1-5 base pair repetitive sequences present throughout the human genome, can abnormally shorten or lengthen because of defects in the DNA mismatch repair (MMR) system, resulting in a "microsatellite instability" (MSI) phenotype. MSI is a key prognostic and diagnostic tumor phenotype that has been well studied by conventional methods. However, both the genomic landscape of MSI events and differences in MSI among cancer types remain poorly illuminated. To address this, we analyzed over 200,000 incidentally sequenced microsatellite loci across 4,224 cancer exomes spanning 18 different cancer types from The Cancer Genome Atlas, to our knowledge the first comprehensive investigation of the landscape of microsatellite instability in cancer exomes. We constructed a highly accurate global classifier for MSI (MOSAIC) that achieved 95.0% sensitivity and 97.8% specificity compared with gold-standard MSI calls based on the revised Bethesda guidelines. We observed that MSI-low (MSI-L) samples did not display significant differences from MS-stable (MSS) samples in the number of MSI events and support discontinuation of the use of MSI-L as a distinct classification. Comparative examination of MSI revealed both cancer-specific and general loci associated with global MSI, such as a frameshift mutation in an 8-bp polyadenine tract in exon 10 of the tumor suppressor *ACVR2A* which was observed in 56.6% of MSI-high (MSI-H) cancers. Lastly, we observed a correlation between survival outcomes and the overall burden of unstable microsatellites, suggesting that MSI may be a continuous, rather than discrete, phenotype that is informative across many cancer types. Our results provide a comprehensive view of MSI in cancer exomes, highlighting both conserved and cancer-specific MSI properties reflecting selective pressures and identifying candidate cancer drivers. Future work will extend these analyses to whole genomes and attempt to functionally validate unstable microsatellite candidates as causally influencing cancer phenotypes.

Effects of G6PD activity inhibition on the mechanical properties and cytoskeletons of cervical cancer cells. *W. Jiang, Z. Fang, C. Jiang, Y. Feng, R. Chen, X. Lin, Z. Zhang, L. Han, X. Chen, H. Li, Y. Guo.* Medical genetics, Sun Yat-sen Univeristy, Guangzhou, China.

Glucose-6-phosphate dehydrogenase (G6PD) deficiency has been revealed to be involved in the efficacy to anti-cancer therapy but the mechanism remains unclear. In our previous study, we have observed increased ROS generation caused by the inhibition of G6PD activity using Dehydroepiandrosterone (DHEA) and shRNA technology. We aimed to investigate the further anti-cancer mechanism of G6PD deficiency. In the present study, Peak Force QNM Atomic Force Microscopy was used to assess the changes of topography and biomechanical properties of cells and detect the effects on living cells in a natural aqueous environment. Moreover, Laser Scanning Confocal Microscope was used to observe the alterations in cytoskeleton to explore the involved mechanism. When G6PD was inhibited by DHEA or shRNA interference, the abnormal Young's modulus and increased roughness of cell membrane were observed in HeLa cells. Simultaneously, the inhibition of G6PD activity caused the disorganization of microfilaments and microtubules of cytoskeletons. Our results indicated the anti-cervix cancer mechanism of G6PD deficiency may be involved with the abnormal reorganization of cell cytoskeleton and abnormal biomechanical properties caused by the increased ROS due to the inhibition of G6PD activity. The results suggested suppression of G6PD may be a promising strategy in developing novel therapeutic methods for cervical cancer.

   Known gene mutations account for approximately 50% of the risk for breast cancer. However, over half of the heritable risk remains unexplained. Fifteen percent of the heritable risk is accounted for by rare variants, while SNPs explain another 14% of the heritable risk. Many moderate risk variants, being discovered by next generation sequencing, account for an as yet unknown proportion of the remaining heritability. A truncating mutation c.325C>T:p.Arg109* in the ATP dependent helicase ERCC3 was observed recurrently among exomes sequenced in BRCA negative, breast cancer-affected individuals of Ashkenazi Jewish ancestry. Modeling of the mutation in ERCC3 deficient or CRISPR/Cas9 edited cell lines showed a consistent pattern of reduced expression of the protein and concomitant hypomorphic functionality when challenged with UVC exposure or treatment with the DNA alkylating agent IlludinS. DNA damage repair capability and overall survival of cells was compared for the mutant and wild type, demonstrating a significantly reduced survival following DNA damage. Overexpressing the mutant protein in ERCC3 deficient cells only partially rescued their DNA repair-deficient phenotype. Comparison of frequency of this recurrent mutation in over 6500 chromosomes of breast cancer cases and 6800 Ashkenazi controls showed significant association with breast cancer risk (OR_{BC}=1.53, OR_{ER+}=1.73) particularly for the estrogen receptor positive (ER+) subset (P<0.007). Significance: A functionally significant recurrent ERCC3 mutation increased the risk for breast cancer in a genetic isolate. Mutated cell lines showed lower survival after in vitro exposure to DNA damaging agents. Thus, similar to tumors arising in the background of homologous repair defects, mutations in nucleotide excision repair genes such as ERCC3 could constitute potential therapeutic targets in a subset of hereditary breast cancers.

Evolution of multiple cell clones over a 29 year period of a chronic lymphocytic leukemia patient.

S. Liu[1,2], Z. Zhao[1,3], L. Wu[1], Y. Hou[1,4], M. Dean[5,1]. 1) BGI, Shenzhen, Guangdong, China; 2) School of Life Sciences, Sun Yat-sen University, Guangzhou, China; 3) School of Biological Science and Medical Engineering, Southeast University, Nanjing, China; 4) Department of Biology, University of Copenhagen, Copenhagen, Denmark; 5) Division of Cancer Epidemiology and Genetics, National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, Maryland, USA.

   Chronic lymphocytic leukemia (CLL) a frequent B-cell malignancy characterized by recurrent somatic chromosome alterations and a low level of point mutations. We performed SNP microarray analyses of a single chronic lymphocytic leukemia (CLL) patient over 29 years of observation and treatment, and transcriptome and whole genome sequencing at selected timepoints. We identified the chromosome alterations 13q14-, and 6q- and 12q+ in early cell clones, elimination of clonal populations following therapy, followed by the appearance of a clone containing trisomy 12 and a chromosome 10 copy neutral LOH that marks a major population dominant at death. Serial single cell RNA sequencing revealed an expression pattern with high *FOS*, *JUN* and *KLF4* at presentation, which resolved following therapy, but reoccurred following relapse and death. The pseudo-temporal analysis further characterized the cancer initiation, proliferation and extinction, and relapse, indicating that complex changes in expression occur over time. Several signalings, including B cell receptor signaling, EGFR signaling, ERKs signaling and NF-kappa B signaling, showed expression changes along evolution. In conclusion, we performed a very detailed and extensive analysis of a single CLL patient across the evolutionary lifespan. And we provided the evidence that CLL can evolve gradually during indolent phases, and undergo rapid changes following therapy.

2910F

Splice-site mutations in MET as a potential driver of lung adenocarcinoma. *D.C.H. Lu[1], V. Martinez[1], K. Thu[1], S. Lam[2], W. Lam[2], H. Varmus[3], W. Lockwood[1], NISC Sequencing Program.* 1) Department of Integrative Oncology, British Columbia Cancer Research Centre, Vancouver, British Columbia, Canada; 2) NIH Intramural Sequencing Center, NHGRI, NIH, Bethesda MD; 3) Sandra and Edward Meyer Cancer Center, Weil Cornell Medical College, New York, NY.

Lung cancer is a complex genetic disease, suffering from a lack of curative therapies available for treating advanced tumours that often present upon diagnosis. Despite their high mutational load, many malignancies are driven and sustained by a single oncogenic mutation affecting key cellular pathways. This concept is known as "oncogene addiction", and forms the basis behind the use of targeted therapies to combat the molecular mechanisms driving cancer development. However, many lung cancers do not contain mutations in currently known oncogenic drivers. To uncover new targetable mutations, we performed whole exome sequencing of lung adenocarcinoma (LAC) samples from 15 patients. By stratifying patient samples based on known oncogenic drivers, we discovered that mutations in the hepatocyte growth factor receptor (MET [OMIM 164860]) were exclusive of other known oncogenic drivers. These findings were subsequently confirmed in an expanded panel of 83 LACs and by cross-referencing with recently published LAC sequencing studies including The Cancer Genome Atlas. Our expanded analysis and assessment of paired RNA-seq data revealed that MET is most commonly mutated through a splice site deletion that leads to skipping of exon 14. This exon contains the CBL binding site that is necessary for receptor degradation following activation by HGF, suggesting that splice site mutations affecting MET could act as the driver of tumourigenesis in LACs. To explore this possibility, we performed siRNA knockdowns of MET in LAC cell lines containing either wild-type MET, amplified MET, or the MET splice mutant. We observed cell death only in MET amplified lines, suggesting that cells are not dependent on splice mutant MET for survival. To further explore whether MET splice site mutations can act as an oncogenic driver, we have generated mice which conditionally overexpress MET and its splice mutant counterpart in lung epithelial cells. These mouse models are being used to understand whether the MET splice mutant is hyperactive and capable of driving as well as sustaining lung tumourigenesis, comparing its effects with the overexpression of wild type MET. To supplement our in vivo work, we have also generated human cell lines overexpressing the MET splice mutant. Our in vitro work will serve to help uncover genetic interactions with the MET receptor, and facilitate the testing of drugs to determine whether therapeutic inhibition of MET is capable of inducing tumour regression. .

Identification of copy number variations in high-risk lung cancer families from Louisiana. *D. Mandal[1], K. Wood[1], K. Broussard[1], A. Bencaz[1], M. Baddoo[2], J. Chambliss[1], R. Govindan[3], S.M. Pinney[4], M. deAndrade[5], C. Gaba[6], P. Yang[5], M. You[7], A.G. Schwartz[8], C.I. Amos[9], M.W. Anderson[4], J.E. Bailey-Wilson[10].* 1) Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) Tulane Cancer Center, New Orleans, LA; 3) Washington University School of Medicine, St. Louis, MO; 4) University of Cincinnati College of Medicine, Cincinnati, OH; 5) Mayo Clinic, Rochester, MN; 6) University of Toledo Dana Cancer Center, Toledo, OH; 7) Medical College of Wisconsin, Milwaukee, WI; 8) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 9) Geisel School of Medicine, Dartmouth College, Lebanon, NH; 10) National Human Genome Research Institute, National Institutes of Health, Baltimore, MD.

Lung cancer is the leading cause of cancer death among both men and women, and according to the estimates of the American Cancer Society, about 14% of all new cancers are lung cancers. About 10% of lung cancer cases (22,000 cases per year in the U.S.) have at least one first-degree relative affected with lung cancer, and 25% of cases have at least one first- or second-degree affected relative, indicating that family history is a significant risk factor. To identify germline genetic variants we have performed whole exome sequencing (WES) on high-risk lung cancer families (≥7 LC cases/family) from Louisiana. Identification of copy number variations (CNVs) has been reported on lung cancer cell lines and somatic samples; however, no germline specific CNVs have been reported in high-risk lung cancer cases. Studies on CNVs are becoming essential in understanding the genomic variation that might enable prevention and early detection of lung cancer in family members. The objective of the present study is to detect germline CNVs that might be responsible for increased lung cancer susceptibility in high-risk families. Whole exome sequencing (WES) of three selected high-risk families (≥7 LC cases/family) from Louisiana, including affected and unaffected family members, was performed. Phenotype, genotype, and smoking data are available on all family members. CNV specific algorithm incorporated in CANOES is used in order to successfully call and identify CNVs. Identified variants are visualized using Integrative Genomics Viewer (IGV). In addition to identifying CNVs, we will also be able to detect the transmission of any CNVs in multiple generations in these families. Once confirmed by IGV, these CNVs will be further validated in other families with hereditary lung cancer. In the long run, identification and hereditary transmission of CNVs might be useful in conjunction with the identification of other genomic variants in the detection of high-risk individuals with multiple cases of lung cancer in the families.

2912T

Molecular-genetic evaluation of squamous cell carcinoma of the larynx. *C.O.A. Melo[1,4], T.C. Vieira[1,2,3], A.D. Da Cruz[1,2,3], C.C Da Silva[1,2,3].* 1) Departament of Biology, Pontifical Catholic University of Goias, Replicon Research Group, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 2) Human Cytogenetics and Molecular Genetics Laboratory, Secretary of Goias State for Public Health, Goiânia, GO, Brazil; 3) Pontifical Catholic University of Goias, Genetics Master's Program, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 4) Genetics and Molecular Biology Graduate Program, Federal University of Goias, Campus Samambaia, Goiânia, GO, Brazil.

The larynx is a tubular structure of the upper aero digestive tract. Any pathology that affects the larynx can cause several problems in their normal physiological function, with full and direct influence on the decrease in quality of life of the individual. Among different diseases that affect the larynx, the cancer is one of the most serious. The squamous cell carcinoma of the larynx is a multifactorial disease, influenced by environmental factors, behavioral and inherent to the individual. The aim of this study was to describe the polymorphism of *TP53* gene in 20 individuals with the squamous cell carcinoma of the larynx, and investigate the microsatellite instability (MIS) and loss of heterozygosity (LOH). Samples from peripheral blood and tumor tissue biopsies from 20 patients diagnosed with laryngeal squamous cell carcinoma (SCC) were used. The investigation of the chromosome imbalances was performed by comparative genomic hybridization (a-CGH) using the commercial kit CGH/Nick Translation® (Vysis, USA), following the manufacturer's recommendations. The DNA samples were submitted to LOH and MIS analysis using a bank with eight polymorphic microsatellite markers: D17S1678; STS-M955a85; D8S135; RH68036; WI-20580; RH17792; HR 92600 and 027856. The STS-AA microsatellite DNA fragments were amplified using GeneAmp® Thermal Cycler 9700 (Perkin Elmer, USA). Regarding polymorphism *TP53* gene, the results were 65% of homozygous (p53AA) and 35% of heterozygous (p53PA). The genomic instability in the regions 8p21 and 8p22 were found 20% of MIS in both, and 5% of LOH for 8p21. For regions 17q22 and 11p15 has been identified the same frequency of MIS 30%. Found also 20% of LOH and 5% of MIS at 3p13 and 30% of LOH corresponding region 9p21. For the region 17p13.1 was observed that 20% of the samples had LOH and 35% MIS. The high frequency of MIS found in the study suggests that the process of tumorigenesis of the larynx following the mechanism of mutant phenotype. The imbalances in the regions of chromosomal gains were observed in 1q21→qter. The losses occurred in chromosome 3p21→p28, 11q23, 16p16, 16q12, 17p13→pter and 22q13. The techniques of comparative genomic hybridization have improved the understanding of genetic alterations in squamous cell carcinoma of the larynx, especially to characterize the relationship among the early precursors of laryngeal cancer, as well as to identify genomic regions that may contain oncogenes and tumor suppressor genes.

2913F

Analysis of genetic variability and mutational spectrum of ABCG2 transporter in Mexican patients with prostate cancer. *G.M. Mimendi Aguilar[1], E. Sierra[2], M. Villanueva[3], M. Dean[4], S. Sanchez[5], J. Sanchez[6], S. Flores[6], M. Rosales[6], M. Romero[7], M.C. Moran Moguel[1].* 1) Doctorado en Genética Humana, CUCS, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico; 2) Servicio de Urología, UMAE Hospital de Especialidades, IMSS, Guadalajara, Jalisco, Mexico; 3) Unidad de Anatomía Patológica, UMAE, Hospital de Especialidades, IMSS, Guadalajara, Jalisco, Mexico; 4) Laboratory of Translational Genomics, Division of cancer Epidemiology and Genetics, NCI, NIH Advanced Technology Center, Gaithersburg, MD; 5) Servicio de Urología UMF No 45, IMSS, Guadalajara, Jalisco, Mexico; 6) División de Medicina Molecular, CIBO, IMSS, Guadalajara, Jalisco, Mexico; 7) Facultad de Medicina, UAG, Guadalajara, Jalisco, Mexico.

Background. Prostate cancer is the most common cancer diagnosed in men and the sixth leading cause of cancer-related death in men worldwide. Most cancers arise from tissue specific stem cells. Several characteristic markers identify cancerous prostate stem cells like CD44, CD133, integrin α and β and ABCG2 transporter protein involved in efflux dihydroxy-androgens such as testosterone, which has been proposed as a mechanism for maintaining phenotype of prostate stem cells (cancer). The Objective of this study was to identify gene variability in *ABCG2* in genomic DNA (gDNA) tumor tissue from Mexican patients with prostate cancer. **Methods.** gDNA was obtained from 32 patients attending at the Urology Service at Unidad Médica de Alta Especialidad, Hospital de Especialidades CMNO with confirmed diagnosis of prostate cancer. 16 exons of *ABCG2* gene were amplified by polymerase chain reaction (PCR). PCR products were analyzed on agarose gels stained with ethidium bromide and purified before sequencing using equipment Life Technlogy®3730 DNA analyzer. The electropherograms were analyzed using the "Surveyor DNA mutation analysis software variant" (Softgenetics®). **Results.** The sequence analysis of 1,024 *ABCG2* gene fragments of 32 mexican patients with prostate cancer (64 chromosomes) revealed the presence of 15 variants located in coding region (exons) and 8 in intronic regions. In exon 9 six different variants were identified. The frequency of the different alleles varies between 3.12% and 68.75%. **Conclusion.** This study is the first in which are identified and described variants of *ABCG2* gene in patients with prostate cancer in Mexican population, most of them have been previously described and variability is similar to that described in other populations, except Asian population. The transition (G/A) is the most frequent substitution found between variants of *ABCG2* gene and exon 9 is likely a hot spot mutation in patients with prostate cancer of the Mexican population.

2914W

Second-hit" genes in lung adenocarcinoma. *M. Oh, W. Lockwood, B. Harbourne.* University of British Columbia, Vancouver, Canada.

   Lung cancer is the leading cause of cancer death worldwide. Despite the continuing efforts to better understand its molecular origins and to develop an effective therapeutic agent, the 5-year survival rate remains poor at 18% for lung cancer patients. Recent studies have uncovered several key genes, like the Epidermal Growth Factor Receptor (EGFR) gene, that are frequently activated in lung adenocarcinoma (LAC) and drive lung tumorigenesis. the advent of small molecule tyrosine-kinase inhibitors (TKI), such as Erlotinib, that target EGFR and interfere with its activation. Despite new targeted therapies being introduced, the long-term prognosis still remains low largely due to the acquired resistance to TKIs in patients.   Our project aims to find secondary mutations in LAC that cooperate with EGFR to help accelerate lung tumorigenesis. To find candidate genes, we have analyzed tissue specimens from LAC patients through integrative genomic analysis. Our studies revealed a copy number gain in chromosome 16p in mutant-EGFR tumors, which corresponded with increased expression in Golgi-localized, gamma-ear-containing, ARF-binding proteins 2 (GGA2). Functionally, GGA2 has been implicated in protein trafficking and sorting. We hypothesize that GGA2 interacts with internalized EGFR and traffics the receptors to the cell surface. Consequently, overexpression of GGA2 in LAC tumors will result in the accumulation of mutant EGFR in cells and increased EGFR signalling, which will help drive tumor progression To determine whether GGA2 interacts with EGFR, we performed co-immunoprecitation assays on cells that overexpress EGFR and GGA2. We also generated GGA2 knockdown and overexpression lines to observe whether GGA2 induces a phenotypic change in EGFR-mutant lung cancer cells. Different techniques like Western blot and flow cytometry were performed to elucidate detailed interaction mechanisms.   Our project aims to demonstrate whether GGA2, a candidate "second-hit gene", helps increase EGFR signalling by trafficking the receptors to the cell surface. GGA2 can further be implicated in acquired resistance in EGFR LAC as GGA2 acts to help EGFR maintain its oncogenic activities. Ultimately, GGA2 can become a potential therapeutic target in LAC and lead to advancements in chemotherapeutic strategies for lung cancer.

Microsatellite instability in chronic myeloid leukemia using D17S261 and D3S643 markers - A pilot study in Western India. *T.N. Patel[1], M. Chakraborty[2], P. Bhattacharya[2].* 1) Department of Medical Biotechnology, VIT University, Vellore, India; 2) Department of Biomedical Sciences, VIT University, vellore, India.

   Tumor progress through a series of genetic alterations that involve proto-oncogenes and tumor suppressor genes. Microsatellite, the short tandem repeat sequences, present over the span of human genome, can show instability at multiple loci due to error in DNA mismatch repair machinery. The study was aimed to evaluate the association between microsatellite instability (MSI) and evolution of CML.The markers chosen for this study were D17S261 (Mfd41) and D3S643 (CI3-9). Five patient and three control DNA samples were provided by Genexplore Diagnostics and Research Centre Pvt. Ltd. in MoU with VIT University as per ethical guidelines. The DNA was used to polymerase chain reaction (PCR) with normal and fluorescent primers and the PCR products were subjected to bioanalyzer and fragment analysis. Bioanalysis and fragment analysis results on comparison showed deviated results. Bio-analysis did not show any significant variation in (AC) repeats but fragment analysis indicated presence of MSI in most of the patients as compared to normal individuals for both the markers. Although bioanalysis was performed to check the presence of altered peak for the marker chosen, fragment analysis helped in confirmation of MSI. These findings suggest that MSI is an event tat may also contribute towards CML progression and may induce resistance to various drugs.

2916F

Comparative genomic analysis of NF1-associated atypical neurofibromas (ANF) and malignant peripheral nerve sheath tumors (MPNST). *A. Pemov[1], N.F. Hansen[2], R. Patidar[3], J.F. Boland[4], S.C. Chandrasekharappa[2], J.C. Mullikin[2,5], NISC corporate author[5], CGRL corporate author[6], M. Wallace[7], J. Khan[3], E. Legius[8], B. Widemann[9], D.R. Stewart[1].* 1) Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Rockville, MD; 2) Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, Rockville, MD; 3) Genetics Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD; 4) CGRL, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 5) NIH Intramural Sequencing Center, National Human Genome Research Institute, Rockville, MD; 6) Cancer Genomics Research Laboratory, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 7) Department of Molecular Genetics and Microbiology, UF Genetics Institute, UF Health Cancer Center, University of Florida, Gainesville, FL; 8) Department of Human Genetics, Catholic University Leuven, Leuven, Belgium; 9) Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD.

   BACKGROUND. NF1-associated ANF are tumors characterized by atypical pathological features that often arise within plexiform neurofibromas (PNF) in NF1 and can transform into MPNST. Currently, it is not clear what causes PNF transformation into ANF and further into MPNST, however several studies identified deletion of the *CDKN2A/2B* locus as the most frequent genetic event distinctive from PNF in ANF. In this study, we performed genomic analysis of 16 ANF and 4 MPNST matched with germline DNA obtained from 14 and 4 unrelated patients, respectively. All tumors but 2 MPNST (cell lines) were primary ones. **METHODS.** We performed Whole Exome Sequencing (WES) on Illumina Hi-Seq 2500 platform (96 Mb SeqCap EZ Exome + UTR Library), copy-number analyses by Illumina HumanOmniExpressExome SNP-arrays, and deep sequencing of *NF1* and validation of select mutations on ThermoFisher IonTorrent PGM platform. **RESULTS. ANF.** We identified *NF1* germline mutations in 94% and somatic mutations in 81% of samples, and heterozygous *CDKN2A/2B* deletion in 75% of samples. In addition, there were 13 other somatic mutations in 9 tumors (median 1, range 0-4; 7 samples could not be validated due to lack of DNA). *NF1* and *CDKN2A/2B* were the only genes having inactivating mutations in multiple samples. We observed an elevated level of genomic instability in the tumors. **MPNST.** We identified *NF1* germline and somatic mutations in 100% of samples, somatic *CDKN2A/2B* locus deletion in 100% of samples (in 3/4 samples the deletion was homozygous) and inactivating mutations in PRC2 genes *EED* and *SUZ12* (both were accompanied by loss of heterozygosity (LOH) thus becoming homozygous). There were no PRC2 mutations in the remaining MPNST, however we observed two deleterious mutations in a histone H4-specific acetyltransferase gene. In addition, there were 69 somatic mutations in 3 tumors (23 mean, 18-31 range). *NF1*, *CDKN2A/2B* and PRC2 complex genes were the only ones inactivated in multiple samples. We observed highly re-arranged chromosomal architecture in all tumors. **CONCLUSIONS.** It appears that PNF-ANF transition is predominantly driven by heterozygous deletion of the *CDKN2A/2B* locus. Further progression to MPNST likely involves an additional inactivation of one of the components of the PRC2 complex or possibly other chromatin modifying genes. In our data, large deletions result in LOH of PRC2 mutations and *CDKN2A/2B* locus deletions and are necessary for malignant transformation of these tumors.

2917W

Insecticide exposure induces gene rearrangements associated with hematological malignancies. *P. Perez-Vera, M.P. Navarrete-Meneses, C. Salas-Labadia, M.A. Sanabrais-Jimenez, J. Santana-Hernandez, A. Serrano-Cuevas, A. Olaya-Vargas.* Genética Humana, Instituto Nacional de Pediatría, MEXICO, Mexico.

   Insecticides are used to control insect pests worldwide, and general population is commonly exposed to these agents. Epidemiological studies have shown that exposure to insecticides is associated with an increased risk of hematological cancer in adults and children. In addition, it was demonstrated that these agents damage DNA. However, there is a lack of biological evidence showing if insecticides can induce genetic aberrations associated with hematological cancer. The aim of this study was to assess if *in vitro* exposure to insecticides induces gene rearrangements associated with hematological malignancies. Mononuclear cells from two healthy volunteers were cultured and exposed to 200μM of permethrin or malathion for 24h. *MLL*, *ETV6-RUNX1* and *IGH*, leukemia/lymphoma associated genes, were analyzed independently with FISH. Aneuploidy was assessed with centromeric probes for chromosomes 12, 18 and 14/22. *MLL-AF4*, *ETV6-RUNX1* and *IGH-BCL2* oncogenic fusions were detected by RT-PCR in mononuclear cells from GMCSF-stimulated peripheral blood (5μM, 96h), bone marrow (0.1μM 72h), peripheral blood (200μM 24h), as well as in K562 cell line (0.1 μM, 24h). Insecticide exposure increased the frequency of cells with *MLL* structural aberrations (p<0.05). A high diversity of abnormal patterns were observed, the most frequent aberration was the rupture at the specific leukemia breakpoint. Permethrin also induced *IGH* breakage at J segment and deviations in the number of gene signals as a consequence of aneuploidy (p<0.05). Malathion induced *MLL-AF4* and *ETV6-RUNX1* gene fusions, and permethrin induced *IGH-BCL2* gene fusion in K562 cells. Moreover, permethrin exposure induced *ETV6-RUNX1* in peripheral blood, bone marrow and GMCSF-stimulated peripheral blood. Permethrin and malathion exposure can affect leukemia/lymphoma-related genes in structure and number. This study provides biological evidence showing that insecticide exposure is implicated in the generation of leukemia/lymphoma associated gene aberrations, which could drive the development of these malignancies, as epidemiological studies have suggested. Public resources from the NIH's Genotype-Tissue Expression (GTEx) program: Biospecimens, data, SOPs and more. *A.K. Rao[1], P. Guan[1], S. Koester[2], S. Volpi[3], H.M. Moore[1], The GTEx Consortium.* 1) National Cancer Institute, Bethesda, MD; 2) National Institute of Mental Health, Bethesda, MD; 3) National Human Genome Research Institute, Bethesda, MD.

The Genotype-Tissue Expression (GTEx) project, a National Institutes of Health (NIH) Common Fund program, aims to better understand how genetic variation influences gene expression in normal human tissues. Non-diseased tissues were collected from nearly 1000 postmortem donors for genomic analyses with the resulting data deposited into the database of Genotypes and Phenotypes (dbGaP) at NIH. Additional information imported into dbGaP for each donor includes clinical, genotype, and gene expression data, pathology review, and data from expression quantitative trait loci (eQTLs). Biospecimens were obtained with the consent of donor families through partnerships with Organ Procurement Organizations. Researchers are encouraged to request access to utilize residual GTEx biospecimens. A new, open access GTEx histological image library where images can be viewed with zooming capability is available. The GTEx program developed and has made publicly available the Standard Operating Procedures (SOPs) detailing collection procedures. Public resources from GTEx include: 1. GTEx Portal: an open access database of GTEx expression data and analysis results: http://www.gtexportal.org 2. Access to residual GTEx biospecimens: http://www.gtexportal.org/home/samplesPage and https://specimens.cancer.gov/ 3. dbGaP: controlled access of comprehensive GTEx clinical and raw sequencing data: http://www.ncbi.nlm.nih.gov/gap 4. SOPs from GTEx biospecimen collections: http://biospecimens.cancer.gov/resources/sops/library.asp 5. GTEx histological image viewer: http://biospecimens.cancer.gov/resources/tissue_image_library.asp 6. Training videos for consenting personnel: http://gtextraining.org/ 7. Various manuscripts detailing the GTEx program available through PubMed   Data from GTEx is already being used in numerous projects to better understand predisposition to disease, with several high profile studies already published. The breadth of the program has afforded multiple, varied public resources from biospecimens to molecular analyses datasets. Furthermore, an embedded ELSI study continues to study the factors affecting consent for research tissue donation. The full potential of GTEx resources has yet to be fulfilled; however, it is likely that these resources will be useful tools for medical research immediately and in future years.

Genetic interaction networks in *S. cerevisiae* identify cancer relevant Synthetic Cytotoxicity (SC) interactions with cohesin mutations. *S. Reytan[1,2], H. Li[2], M. Kofoed[2], N. O'Neil[2], P. Hieter[2].* 1) Medical Genetics, The University of British Columbia, Vancouver, BC, Canada; 2) Michael Smith laboratories, The University of British Columbia, Vancouver, BC, Canada.

Whole genome sequencing technologies are advancing at an unprecedented pace, opening new opportunities for the genotype-driven personalized treatment of cancer. Synthetic Lethality (SL) based therapeutics have emerged as promising approaches to target cancer specific somatic mutations. SL exploits the genetic distinctness of the malignant cell by targeting a second gene that is required for viability in the presence of a tumour specific mutation, resulting in its specific killing while the normal cells remain viable. We are expanding the list of SL partner genes by screening for conditional SL interactions, in which loss of function of 2 genes results in sensitivity to low doses of a DNA damaging agent, a concept we have called Synthetic Cytotoxicity (SC). SC has the potential to extend the number of genotypes that can be treated with existing chemotherapeutics and to improve the efficacy of these therapeutics.   We have focused our efforts by screening for SC interactions with cohesin-mutated genes. The cohesin complex is highly mutated across a wide range of tumours, including acute myeloid leukemia (12%), bladder cancer (20%), colorectal cancer (~13%), glioblastoma (~6%), Ewing's sarcoma and melanoma (~17%). We used Synthetic Genetic Array (SGA) technology, a high-throughput genetic method in yeast, to screen cohesin-mutated strains against an array of 310 deletions affecting DNA damage response genes. The screens were done in the presence and absence of four distinct genotoxic agents: benomyl (microtubule inhibitor), bleomycin (radiomimetic), camptothecin (TOP1 inhibitor), and methyl methanesulfonate (alkylating agent). We screened and analyzed ~12,400 potential genetic interactions, identifying hundreds of SL and SC interactions. The corresponding genes, when knocked-out, lead to specific killing of cohesin-mutated yeast cells in the presence of sublethal concentrations of a genotoxic agent. Many of these genes belong to conserved biological pathways such as DNA damage-response and chromatin modification, which are known to have effects on genome instability. We created a map of these interactions that can further expand our knowledge about the biological importance of these genes and their potential role in cancer.   These SC genetic interactions can inform and improve individual cancer therapies as personalized medicine treatments, and lead to discovery of new pathways or candidates for anti-cancer treatments.

Evaluation of mtDNA alterations and *BCL-2* **prompter polymorphism in involvement of metastasis on Iranian breast cancer patients.** *E. San-jari[1], M. Ghaffarpour[1,3], S. Esalamizadeh[2,4], M. Arabzadeh[2,4], B. Motahari[2,5], M. Houshmand[1,2].* 1) National Institute of Genetic Engineering and Biotechnology, Tehran, Iran; 2) Special Medical Center, Tehran, Iran; 3) Iranian Research Organization for Science and Technology; 4) Islamic Azad University,Tabriz,Iran; 5) Islamic Azad University and Research Complex, Tehran, Iran.

Breast cancer is the first most common cancer among the females in Iranian cancer patients. The role of mtDNA alterations is recognized as being in carcinogenesis, tumor progression and prognosis in breast cancer. MtDNA alterations G13397A(ND6),G8993T(ATP6) and alteration of 12308 in tRNA Leu gene have been reported in involvement in metastasis in vivo but to date there was not shown on clinical breast cancer samples as a prognosis factors. It has been also shown that BCL-2 prompter (-938C>A) polymorphism, mtDNA alterationA15326G and G10398A (ND3) correlated with increased breast cancer risks and metastasis respectively. The aim of this study was to address the question if mtDNA alterations of G13397A, G8993T, 12308G, G10398Aand BCL-2 prompter (-938C>A) polymorphism can play a role in promoting of tumor and leading to metastasis. 69 paired fresh tumor and adjacent normal samples were obtained from patients with Breast Cancer (31 of 69 who are experienced metastasis and 38 of 69 non metastasis) .Fresh tumors and their adjacent were extracted for genomic DNA. Whole mtDNA sequencing was used for investigation of mtDNA alterations. The G13397A and G8993T mutations were not seen for all patient including metastasis and non-metastasis. There was an association between 12308 G alteration and metastasis patients. It was also a role for mtDNA alterations G10398A and A15326G and an increase Breast Cancer risk. There was no association between BCL-2 prompter (-938C>A) polymorphism and Breast Cancer risk and metastasis.

2921T

Genome wide copy number profiling detects significant deletion (4q35.1) and amplifications (20p12.1, 12q14.2 and 12q14.3) in gallbladder carcinoma. *A. Sharma, A. Kumar, N. Kumari, N. Krishnani, B. Mittal.* SGPGIMS, Lucknow, Uttar Pradesh, India.

Gall bladder cancer (GBC) is a malignancy of biliary tract having an unusual geographic distribution. Late diagnosis and poor prognosis are typical features of this disease. Recent studies have shown that molecularly targeted therapies are critically dependent on genetic profile of tumour which can lead to refinement of prognostic information. Available molecular profiling data in GBC is limited due to lack of enough high-throughput screening regarding its genetic information. So understanding molecular features of GBC is critical towards improving treatment paradigm for this disease. Present study was aimed to determine mutations, copy number variations (CNVs) in 890 major cancer related genes in GBC patients. 13 histopathologically confirmed GBC cases were included in this study. GBC cells were micro-dissected from formalin fixed paraffin embedded tissue blocks having >80% of tumour cells. DNA extraction was done by standard protocols. Copy number/mutation profiling was done by "OncoScan™ FFPE Assay Kit" (Affymetrix, CA). Data analysis was done by SNPFASST2 algorithm using the Nexus Express for Oncoscan software version 3.0 and 7.5 (Biodiscovery, Inc., CA USA). A substantial number of CNVs detected were recurrent. Recurrent gains were at chromosome 12q (53%), 20p (69%) and recurrent losses were at 4q (46%). The common genes affected in CN loss process were *NPP6, IRF2, CASP3, PRIMPOL, MLF1IP, CENPU, ACSL1, SLED1* in chromosome 4, whereas genes involved in copy number gain process are *HMGA2*, *RPSAP52* on 12q14.3, *RASSF3* gene on 12q14.2 and *MACROD2* on 20p12.1. Present study provides data of copy number profiling in GBC. Significant copy number abrasions were detected in genes involved in tumor suppressing and apoptosis functions. Presence of loss of hetrozygosity was also found to be a significant character in Gallbladder cancer. More studies with greater sample size are required for validation of findings.

2922F

High-throughput functional classification of *BRCA2* **variants of uncertain significance (VUS).** *H. Shimelis, S. Andreas, H. Chunling, F.J. Couch.* Mayo Clinc, Rochester, Rochester, MN.

  Genetic testing of individuals with a family history of breast and/or ovarian cancer has led to the identification of many unique BRCA2 and BRCA1 missense variants of uncertain significance (VUS). Considering that the majority of missense changes in cancer predisposition genes lack sufficient genetic information, cancer risks conferred by many germline missense variants have not been established. Classification of these variants using quantitative models such as the established BRCA1 and BRCA2 multifactorial Likelihood Model has proved challenging due to limited availability of family data for each VUS. In contrast functional analysis of VUS using validated Functional assay may be useful for classifying VUS in the absence of case-control or family data. We have used a homology directed repair (HDR) cell-based assay to characterize missense variants in the DNA binding domain (DBD) of BRCA2. The method has been validated using known pathogenic and known non-pathogenic BRCA2 missense variants and has been associated with 100% sensitivity (95% confidence interval (CI): 75.3%–100%) and 100% specificity (95% CI: 81.5%–100%) for pathogenic BRCA2 variants. We have recently established high-throughput methods for characterization of BRCA2 variants using this HDR assay. Over 300 BRCA2 missense variants within the DBD have been evaluated, of which 80 variants are deleterious and 19 have intermediate activity. When combined with sequence-based in silico prediction models in a probability model, these variants can be classified as pathogenic and moderate risk, respectively. The HDR assay is being applied to all known missense variants in the DNA binding domain in order to provide information on the pathogenicity of all variants identified in this region of the BRCA2 tumor suppressor. In addition, the HDR assay has been used to characterize the influence of missense variants on the activity of proteins encoded by other cancer predisposition genes.

Integrated genomic characterization of tumors with somatic *NF1* **driver mutation.** *T. Zhang, M. Xu, K.M. Brown.* National Cancer Institute, Bethesda, MD.

  The *NF1* gene encodes a RAS GTPase-activating protein called neurofibromin that influences RAS-MAPK signaling. Somatic loss-of-function driver mutations in *NF1* have bene found in numerous tumor sequencing studies; however, genetic and genomic commonalities between tumor types for which *NF1* is a driver, which may provide mechanistic clues about the role of *NF1* mutations in the development of these tumors, remain unclear. We systematically analyzed and compared all available expression, mutation, CNV, and methylation data for 15 tumor types from TCGA (3,131 sequenced samples). We first used MutSig2CV to identify tumor types for which *NF1* was among the most significantly mutated (driver) genes: cutaneous melanoma (SKCM), lung adenocarcinoma (LUAD), glioblastoma multiforme (GBM), pheochromocytoma and paraganglioma (PCPG), brain lower grade glioma (LGG), and ovarian serous cystadenocarcinoma (OV). Driver mutations in several genes were found only in *NF1*-mutant tumor types (*BRAF*, *EGFR*, *IDH1*, *ARID2*, *EMG1* and *STK19*), while mutations in others (*FBXW7* and *MLL2*) were only found in non-*NF1* tumor types. mRNA expression of *NF1* was significantly lower in *NF1*-mutated samples compared to wild-type samples across all six *NF1*-mutant tumor types. Expression enrichment analysis identified multiple genes whose correlation with *NF1* differed between *NF1* and non-*NF1* tumors, including multiple Ras family genes. Pathway enrichment analysis for these genes further suggested activation of the MAPK-ERK-Rho signaling pathway in *NF1* driver tumors, consistent with the known role of *NF1* as a negative regulator of Ras. While mutation enrichment analysis identified multiple genes with mutations that co-occurred with *NF1* mutations, this co-occurrence was observed in only tumor types with a high mutation burden (SKCM, LUAD and UCEC). Hotspot mutations in four genes were found to be mutually exclusive with the *NF1* mutation in *NF1* tumors (*IDH1* in LGG, *KRAS* in LUAD, *BRAF* in SKCM, and *EGFR* in GBM). However, co-occurrence between less-frequent (non-hospot) mutations of these genes and NF1 was observed, suggesting that *NF1* mutations can amplify the effects of other driver gene mutations. Finally, methylation-based enrichment analysis determined that hypermethylation contributed to *NF1* inactivation in SKCM and LGG. In conclusion, these data suggest that *NF1* inactivation is a common genomic alteration in six different human cancer types, cooperating with other non-hotspot driver gene mutations.

2924T

Detecting cancer-associated structural variants by using megabase-scaled DNA molecules and whole-genome sequencing. *J. Xu[1], D. Bann[2], R. Clark[3], Y. Wang[1], J.R. Broach[1,2], F. Yue[1,2].* 1) Biochemistry Dept, Penn State Univeristy; 2) Institute of Personalized Medicine, Penn State Univeristy; 3) Computer and Info System Dept, Penn State University.

A typical cancer cell manifests abundant genomic structure variants (SV), including copy number alteration (CNA) such as insertions and deletions, and positional rearrangement such as inversions and translocation. It has been shown that a single SV can drive oncogenic transformation, through CNA, gene fusion, or disrupting the linkage between enhancers and their target genes. To assess the global effect of the overall SVs from a cell on its cancerous phenotype, we profiled and characterized all types of SVs in three cancer cell lines Caki2, T47D and K562, by incorporating whole-genome sequencing (WGS) and genome maps generated by Bionano Irys platform, a new technology that uses megabase-scaled DNA molecules and can capture large-scale SVs. Our approach identified genome aneuploidy, hundreds of insertions and deletions, and tens of inversions and translocations from each cell line. We also identified several hundred genes deleted in each cell line, and stratified them by copy numbers retained. Some deleted genes are known to canonically associate with cancer, such as ATM from breast cancer cell T47D and CDH1 from kidney carcinoma cell Caki2. Moreover, the T47D deleted regions are enriched of genes involved in the regulation of mammary gland epithelium proliferation. We further examined SV's impact on gene expression by comparing transcriptomes of T47D and normal breast cell HMEC, and found that expression of many partially deleted genes are gene-dose dependent. Finally, we interrogated its clinical significance by examining the TCGA breast tumor samples and reported luminal and basal-specific copy number loss of genes deleted in T47D cells, coupled with reduced gene expression.   Overall, we have shown that incorporating WGS and Bionano Irys can accurately capture SVs in cancer cells. Our results identified a spectrum of deleted essential genes in cancer cells that are representative for patient cohorts, and we believe that efficient detection of SVs encompassing those marker genes might be critical to cancer diagnosis and subtyping.

2925F

Reclassifying duplication variants in high risk cancer genes by identifying tandem duplication breakpoints. *H. Chong[1], W. Mu[2], S. Willett[1], S. Lam[1], R. Huether[2], A. Elliott[1].* 1) R&D, Ambry Genetics, Aliso Viejo, CA; 2) Bioinformatics, Ambry Genetics, Aliso Viejo, CA.

Alterations in genomic copy numbers may lead to changes in gene expression and function and are known to cause various disease states including congenital anomalies, developmental disorders and numerous cancer syndromes. Most gross deletions in high risk cancer genes, usually larger than 3~5 megabases, fall within microarray reporting guidelines and are reported as pathogenic. However, gross duplications are generally reported as variants of unknown significance (VUSs), which can then subsequently be reclassified as likely deleterious or likely benign as more information becomes available. To determine whether a copy number duplication variant can be reclassified as likely pathogenic, we utilized paired-end Next Generation sequencing (NGS) method that can detect the breakpoints of tandem duplications in high risk cancer genes, including *BRCA1, BRCA2, ATM, CHEK2, CDH1*, and *TP53*. DNA was available for NGS on 103 consenting cancer patients with a variety of gross duplications who had a personal or family history of breast and/or ovarian cancers. We designed probe sets to capture the target regions with the suggested breakpoints identified by array comparative genomic hybridization (aCGH) for 32 different gross duplication variants. The captured DNA was then sequenced by paired-end NGS and mapped to the genome. Our custom pipeline identified a tandem duplication in 79% of samples we tested (81/102). Most tandem duplications in these high risk cancer genes caused a frameshift or structural change, which may result in novel function of the genes (loss-of-function or gain-of-function) and is predicted to be damaging by most *in silico* algorithms examined. Therefore, this study suggests that 32 previously classified VUSs detected as tandem duplications can be re-classified as likely pathogenic. Proper classification of variants detected for these high risk cancer genes will help guide physicians in selecting the best course of treatments for their patients and improve the overall recovery and health of the patient.

2926W

Single-cell whole genome sequencing reveals clonal diversity and evolution in small-cell lung cancer. *D.C.J. Spierings[1], H. van den Bos[1], P. Ferronika[2], A. Saber[3], T.J.N. Hiltermann[4], K. Kok[2], A. Taudt[1,5], D. Porubsky[1], F. Foijer[1], M. Colomé-Tatché[1,5], H.J.M. Groen[4], A. van den Berg[3], P.M. Lansdorp[1,6].* 1) ERIBA, UMCG, Groningen, the Netherlands; 2) Genetics Dept, UMCG, Groningen, the Netherlands; 3) Pathology and Medical Biology Dept, UMCG, Groningen, the Netherlands; 4) Pulmonary Diseases Dept, UMCG, Groningen, the Netherlands; 5) Institute for Computational Biology, Helmholtz Zentrum München, Neuherberg, Germany; 6) Terry Fox Laboratory, BC Cancer Research Centre and UBC, Vancouver, Canada.

Small-cell lung cancer (SCLC) is characterized by aggressive growth and high metastatic potential. Intra-tumor genomic heterogeneity can facilitate tumor evolution and has been thought to be relevant to cancer resistance towards chemotherapy. Unfortunately, classic genomic profiling by comparative genomic hybridization (CGH) or whole-exome sequencing (WES) of bulk material can only identify global genomic alterations of a cell population. In the present study, we assessed intra-tumor heterogeneity in genomic copy number variations (CNVs) in a primary SCLC tumor and its metastases at the single cell level using low coverage single-cell whole genome sequencing (scWGS). Single nuclei isolated from frozen tissue sections were flow sorted and scWGS libraries were prepared without upfront whole genome amplification to reduce PCR amplification biases and maintain a direct correlation between sequence reads and genome content. The distribution of reads across the chromosomes was found to faithfully represent the chromosome copy number. An in-house developed algorithm, called AneuFinder, was used to determine the copy number state for each chromosome. Merged scWGS data of all individual cells within a sample resulted in CNV patterns similar to CGH-based CNV patterns obtained from genomic DNA of the same samples. However, at single cell level, a high degree of intra-tumor CNV heterogeneity was observed. The highest level of heterogeneity was observed in the primary tumor and in the lymph node metastasis and the lowest heterogeneity in the liver metastasis. Interestingly, within the heterogeneous population of the primary tumor, one cell displayed a CNV pattern identical to that of the merged lymph node metastasis, whereas two cells resembled the liver metastasis. These rare cells in the primary tumor would not be detected when assessing CNVs using CGH or WES on bulk material. In conclusion, scWGS is a powerful technique to assess intra-tumor CNV heterogeneity providing insight into tumor cell evolution and metastasis.

2927T

Robust whole genome sequencing technology enables structural variant detection from 100ng to 1ng. *S.K. Sandhu, J. Laliberte, C. Schumacher, S. Chupreta, V. Kelchner, L. Kurihara, T. Harkins, V. Makarov.* Swift Biosciences, Ann Arbor, MI.

Detection of structural variants (SV) from whole genome sequencing (WGS), whole exome sequencing (WES), targeted capture and amplicon sequencing data enables access to the 1.2% of the human genome, variations in which, forms the basis of human evolution, genetic diversity among individuals, and genomic disorders/syndromes. Some technical challenges exist owing to the nature of these genomic regions which are often characterized by low complexity and lack sufficient coverage, especially in cases with limiting input material. These problems are further accentuated by PCR bias and a higher frequency of misalignments in these regions. Unbiased, comprehensive, uniform coverage of whole genome ensures even representation of these low complexity regions. We describe a robust, PCR-free method which enables high quality sequencing from 100ng DNA input using Swift Accel NGS 2S technology compared to ten times more input DNA (1000ng) required for an Illumina kit. 100ng PCR-free WGS libraries were compared to 10ng and 1ng plus-PCR generated from the Coriell NA12878 DNA using Swift Accel NGS 2S kit, sequenced on HiSeq 2500 and HiSeq X to 35x coverage for all inputs and 1000ng Truseq PCR-free. Preliminary data from PCR-free sequencing of patient samples from these low inputs was also investigated. A set of curated deletions, insertions, inversions, copy number variants, and translocations reported by the 1000 Genomes Project and confirmed with PacBio and/or Illumina sequencing was evaluated from the data obtained from above libraries using multiple tools including Lumpy, Pindel, Delly, CNVnator and Breakdancer. We found a similar number of total SVs detected across all inputs even from the low input samples with PCR. However, a higher number of insertions and inversions, were detected in the 100ng PCR-free input with high level concordance to the truth list. Further analysis of these SVs is underway.

2928F

Identification of a novel alternative splicing of *PCDH17* **gene: Whole exon-2 skipping.** *T.N.U. Le[1], K. Sakashita[2,3], T.M.T. Ha[1], V.N. Nguyen[1], K. Koike[2].* 1) Medical Genetics, Hue University of Pharmacy and Medicine, Hue, Thua Thien Hue, Viet Nam; 2) Pediatrics, School of Medicine, Shinshu University, Nagano, Japan; 3) Pediatric Hematology and Oncology, Nagano Children's Hospital, Azumino, Japan.

    Introduction *Protocadherin* (*PCDH*) 17 gene is a member of cadherin superfamily, a group of cell membrane proteins that mediates Ca^{2+}-dependent cell-cell adhesion. Recently, *PCDH17* has been reported as a tumor suppressor gene in a number of solid cancers. However, little is known about this gene. Here we report a novel alternative splicing of *PCDH17* gene in peripheral blood cells. **Methods:** DNA and total RNA were extracted from peripheral blood cells. Conventional PCR was used to amplify a *PCDH17* fragment from downstream region of intron 1 to downstream region of exon 3. RT-PCR was used to examine *PCDH17* gene expression. PCR products were extracted and subjected to subcloning for sequencing. **Summary results:** We identified a present of an alternative mRNA isoform of *PCDH17* gene that skipping whole 58-bp exon 2. We also detected an existence of alternative splicing variants mediated by the tandem splice acceptor motif NAGNAG at intron 1-exon 2 boundary. There was no mutation in *PCDH17* examined sequence at DNA level.

2929W

Chromosomal instability and XRCC1 Arg399Gln and XRCC2 Arg188His polymorphism in esophageal cancer patients. *J. Kaur[1], V. Sambyal[1], K. Guleria[1], N. Singh[2], M. Uppal[2], M. Manjari[3], M. Sudan[4].* 1) Department of Human Genetics, Guru Nanak Dev University, Amritsar, Punjab, India; 2) Department of Surgery; 3) Department of Pathology; 4) Department of Radiotherapy, Sri Guru Ram Das Institute of Medical Sciences and Research Vallah, Amritsar, Punjab, India.

    Background: DNA repair genes continuously monitor chromosomes to correct injuries caused by exogenous agents such as cigarette smoking, a potent risk factor for esophageal cancer. Among various DNA repair genes, XRCC1, located on chromosome 19q13.2, plays a predominant role in both single strand break repair and base excision repair. A genetic polymorphism (rs25487) in codon 399 in XRCC1 gene results into a non-conserved amino acid substitution. Another DNA repair gene, XRCC2, located at 7q36.1, is a member of a family of genes related to RAD51 and is necessary homologous recombination (HR) repair. A relatively rare G to A polymorphism (rs3218536), located in exon 3 of this gene results in substitution of Arginine by Histidine (Arg188His). METHODS: In the present study, approved by institutional ethical committee, comparison of cytogenetic profile and genotype frequencies of the Arg399Gln polymorphism of XRCC1 and Arg188His polymorphism of XRCC2 gene was done in esophageal cancer patients. Genomic DNA was extracted from blood samples of 100 esophageal cancer patients and 100 controls by standard phenol chloroform method. Standard in-vitro cell culturing technique of 72 hours in RPMI-1640 medium was used for cytogenetic analysis. DNA samples were screened for above polymorphisms by PCR-RFLP method. RESULTS: A large number of cytogenetic abnormalities including loss of chromosomes [2,3,4,5,7,9,11,16,17,19,21,22], gain of chromosomes (4,5,20), polyploidy, translocations (rob(13;21), rob(14;22), rob(13;15)), ring chromosomes [46,XY,r?], dicentric chromosomes, breaks [46,XY,chtb(2q),tas(14:21)], acrocentric associations were found in esophageal cancer patients and these aberrations were found to be increased in patients with advanced stages. In addition, the number of terminal associations and triradials were much more in number in patients as compared to controls.However, no significant association was found between Arg399Gln polymorphism of XRCC1 and Arg188His polymorphism of XRCC2 with the advancement of the esophageal cancer. CONCLUSION: The findings demonstrated the potential utility of combining chromosomal instability and gene expression data to determine if these changes are associated with genetic susceptibility to esophageal cancer or might serve as early detection of cancers. Moreover, the study can provide a platform to evaluate the radiotherapy response and survival rate of the esophageal cancer patients in context of the studied polymorphisms.

2930T

Elucidation of a conserved role for *DIS3* in genome stability maintenance. *K. Milbury[1,2], P. Stirling[1,2,3].* 1) Terry Fox Laboratory, BC Cancer Research Centre, Vancouver, British Columbia, Canada; 2) Genome Science & Technology, University of British Columbia, Vancouver, British Columbia, Canada; 3) Department of Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada.

Chromosome instability (CIN) is characterized by an increased rate of the unequal distribution of DNA between daughter cells. These large changes in chromosome structure or number can occur due to both mitotic defects leading to aneuploidy and DNA damage-induced chromosome rearrangements. Previous large-scale screens for CIN genes in the model organism *Saccharomyces cerevisiae* identified *DIS3*, which codes for a catalytic component of the core RNA exosome complex, as a novel CIN gene. Presumed reduction-of-function mutations in human *DIS3* have been identified in roughly 11% of multiple myeloma (MM) cases. We sought to determine the mechanism of CIN in *DIS3* mutants, and to recapitulate MM-associated point mutations at conserved sites in yeast cells, in order to understand potential connections of emergent CIN to MM. We have found that MM-associated *DIS3* mutations induce DNA:RNA hybrid accumulation and increased rate of CIN, although analysis of DNA damage foci by microscopy revealed no increase in double-strand breaks. Yeast *DIS3* mutants experience growth retardation, and cell cycle analyses indicate that these mutants suffer from delayed progress through mitosis. Microarray analysis of one MM mutant has additionally demonstrated downregulation of cell cycle components, consistent with the potential for mitotic defects, in addition of upregulation of a host of metabolic pathways. Further, genetic interaction profiling by synthetic genetic array indicates MM-associated *DIS3* mutations synthetically interact with rRNA processing proteins, as well as a host of mitotic regulators, particularly those involved in the spindle assembly checkpoint. Together, these results demonstrate extensive phenotypic consequences of MM-associated point mutations in *DIS3*, and support a model for CIN in *DIS3* mutants involving defects in cell cycle processes.

Loss of KMT2D results in PRC2-mediated transcriptional deregulation. *J.T. Topham, A. Gagliardi, D. Trinh, R.D. Huff, A.J. Mungall, J. Schein, M.A. Marra.* Canada's Michael Smith Genome Sciences Centre, BC Cancer Agency, Vancouver BC.

Lysine (K)-Specific Methyltransferase 2D (*KMT2D*) encodes a methyltransferase responsible for mono-methylation of the fourth lysine of histone 3 (H3K4me1), marking active enhancers. Although *KMT2D* is one of the most frequent targets of all types of somatic mutation in human cancers, the cellular consequences of *KMT2D* mutations and their role in cancers are not fully understood. To understand the effects of *KMT2D* mutation on the transcriptional landscapes of cells, we performed differential expression analysis (DEA) using RNA-sequencing data from isogenic *KMT2D*-knockout and wildtype HEK293A cell lines. To investigate whether these effects recapitulate what occurs in *KMT2D*-mutant tumors, we performed subsequent DEA using RNA-sequencing data from 11 different cancer types in which *KMT2D* loss-of-function mutations were frequent (data from The Cancer Genome Atlas (TCGA)). Through integrative analysis, we identified a distinct subset of genes that are consistently altered upon KMT2D loss across both isogenic cell lines and 11 primary tumor contexts. Moreover, we found that these genes are enriched for targets of polycomb repressive complex 2 (PRC2) and are often involved in regulation of extracellular matrix components and cell adhesion/migration. Thus, our results indicate PRC2-mediated deregulation of genes as a consequence of *KMT2D* mutation relevant to oncogenesis.

2932W

Epigenome-wide reprogramming of enhancer elements during *in vivo* **melanoma progression to brain metastasis.** *D.M. Marzese[1], M.P. Salomon[1], J.I.J. Orozco[1], M.A. Bustos[1], S.K. Huang[1], L. Takeshima[1], N. Nellie[2], S.C. Hsu[2], S. Izraely[3], O. Sagi-Assif[3], D.F. Kelly[4], I.P. Witz[3], D.S.B. Hoon[1,2].* 1) Department of Molecular Oncology, John Wayne Cancer Institute (JWCI), Santa Monica, CA, USA; 2) Sequencing Core Center, John Wayne Cancer Institute, Santa Monica, CA, USA; 3) Department of Cell Research and Immunology, George S. Wise Faculty of Life Sciences, Tel Aviv University, Tel Aviv, Israel; 4) Brain Tumor Center, Providence Saint John's Health Center, Santa Monica, CA, USA.

The tendency of melanoma cells to metastasize to the brain represents an important unsolved clinical complication. This high affinity has been postulated to be a consequence of a homing effect since both melanocytes and neural cells derive from the neuroectoderm and thrive in similar tissue microenvironments. To better understand the molecular events driving melanoma progression to brain metastasis (MBM), we performed genomic (Exome-Seq), epigenomic (MethEPIC BeadChip and ChIP-Seq for H3K4me1 and H3K27ac) and transcriptomic (RNA-Seq) analyses on three independent human-to-mouse MBM xenograft models with paired cutaneous and MBM variants. Exome-Seq data revealed a negligible number of mutations (mean SNV=15±4) in MBM compared to the paired cutaneous variants. However, integration of epigenomics data revealed a significant redistribution of both, chromatin modifications and DNA methylation patterns. Subsequently, this data was used to train a Hidden Markov Model to systematically annotate regulatory elements and genomic segments enriched for H3K4me1, H3K27ac, and low regional DNA methylation level were annotated as enhancer elements (EEs). When comparing cutaneous and MBM variants, we observed that 427 EEs were lost and 2,938 EEs were gain during melanoma progression to MBM. To identify active EEs, we evaluated changes on the expression of genes encoded ±1Mb of the annotated EE. Active EEs in MBM variants but absent in cutaneous variants were named 'MBM-specific EEs' (n=604; mean size=1,340±53bp). The regional DNA methylation level was significantly lower at MBM-specific EEs compared with non-EEs. To identify putative target gene promoters for MBM-specific EEs, we used long-range chromatin interaction data (ChIA-PET) of human cell lines generated by the ENCODE project. Gene ontology analyses of coding and non-coding genes potentially associated with MBM-specific EEs revealed enrichment in neurological disorders and brain developmental processes. Regional DNA methylation patterns of MBM-specific EEs were further evaluated by generating DNA methylomes of 56 MBM and 90 non-MBM clinical FFPE specimens. Interestingly, we identified a set of EEs significantly hypomethylated in a large proportion of MBM specimens. Together, our data suggest that melanoma progression to MBM is largely influenced by epigenome-wide remodeling specifically affecting enhancer regions and offer a new alternative to understand the complexity of this clinical complication.

2933T

The impact of *PRDM9* **expression among different cancers and cancer patients.** *A. Ang Houle[1,2], H. Gibling[1,2], M. Agbessi[3], V. Bruat[3], L. Stein[1,2], P. Awadalla[1,2,3,4], Pan-Cancer Whole Genome Consortium.* 1) Molecular Genetics, University of Toronto, Toronto, Ontario, Canada; 2) Genome Informatics, Ontario Institute of Cancer Research, Ontario, Canada; 3) Research Center of the Sainte-Justine Mother and University Hospital Center, Montreal, Quebec, Canada; 4) Department of Pediatrics, Universite de Montreal, Montreal, Quebec, Canada.

Homologous recombination is a process allowing for exchange of genetic information between homologous chromosomes, and, when impaired, has been linked to multiple genomic failings, ranging from indels to larger scale aneuploidies. In meiosis, PRDM9 binding sites determine positions of double strand breaks by recruiting SPO11, a topoisomerase-like protein that catalyzes double strand breaks. This initiates meiotic recombination, a process essential to proper chromatid segregation. Allelic variation at PRDM9 has been associated with pediatric acute lymphoblastic leukaemia, suggesting the role of PRDM9 in some cancers. In mitotic cells, homologous recombination is a conservative repair mechanism following genetic damage from double strand breaks introduced by either endogenous or exogenous factors. Cancer genomes often show deficiencies in homologous recombination processes. For this study, we exploit more than 2000 samples available in the Pan-Cancer Whole Genome (PCAWG) program of the International Cancer Genome Consortium (ICGC), which generates and hosts whole genome and transcriptome sequencing of tumoral and matching healthy tissue. PRDM9 is a meiosis-specific gene, yet we observed a significant proportion of samples showing PRDM9 expression. Remarkably, PRDM9 expression is found at significant levels in over 260 tumor samples across multiple cancer subtypes, even after applying stringent filtering corrections to ensure its bona fide expression by minimizing signatures from other gene family members. Expression of PRDM9 appears to have an effect on genomic architecture, specifically regarding somatic structural variations and single nucleotide variants. We observed differences in the distributions of somatic genomic alterations, suggesting an association between PRDM9 expression, genomic breakpoints and somatic deregulation. We also identified variations in transcriptome-wide patterns of expression in tumors that are dependent on PRDM9 expression. This study highlights the role of meiosis-related genes, in particular PRDM9, on the transcriptomic and genomic landscapes of tumors, and provides alternative mechanisms explaining homologous recombination deficiencies in cancers.

Down-regulation of metastasis-associated genes *MTA1* and *MTA2* by resveratrol leads to alteration of epigenetic repression on tumor suppressor genes in chronic myeloid leukemia cells. *C. Biray Avci, Z. Mutlu, C. Caliskan Kurt, B. Göker Bagca, O. Ozalp, Z. Abbaszade, C. Gündüz.* Medical School Department of Medical Biology, Ege University, Izmir, Turkey.

   Chronic myeloid leukemia (CML) is a hematological disease resulting from generation of BCR/ABL oncogene by philadelphia chromosome. Resveratrol is an important phytoalexin in many plants, has cytotoxic and antileukemic effects. Metastasis-associated gene (MTA1) is a member of cancer progression-related gene family. Also, MTA2 gene belongs to metastasis associated family, MTA1 and MTA2 are highly expressed in tumors. In this study we aimed to evaluate the effects of resveratrol on epigenetic alterations in chronic myeloid leukemia cell line and explore a novel therapeutic target of CML. K562 cells were treated with resveratrol time and dose dependent manner and cytotoxicity was evaluated by using WST-1 assay. The RT-qPCR is used for gene expression analysis. Gene expression levels were evaluated by using RT2 Profiler PCR Array. Significant decreases in MTA1 and MTA2 gene expressions were observed in K562 treated with resveratrol. Resveratrol downregulated MTA1 and MTA2 gene expression levels 2.62 and 3.54 folds according to the control cells, respectively. Our findings showed that Resveratrol down-regulated MTA1 and MTA2 gene expression levels. MTA1 and MTA2 modulate the response of several tumor suppressor genes as p53 and oncogenes like c-myc. Therefore, down-regulation of MTA1 and MTA2 gene expression levels by resveratrol could lead to alteration of epigenetic repression on tumor suppressor genes. Thus they could activate themselves. MTA genes could use as a marker for cancer progression and potential target and Resveratrol might be a new target for CML therapy.

2935W

Epigenome dynamics of cultured breast cancer cells after transient treatment with magnetic nanoparticles. *R.S. Bonadio[1], E.C.O. Lima[2], R.C. Silva[1], F.H. Horst[1], M.J.P. Fonseca[1], J.P.F. Longo[1], R.B. Azevedo[1].* 1) Universidade de Brasilia, Brasilia, Brazil; 2) Universidade Federal de Goiás, Goiânia, Brazil.

   Introduction: Several studies have reported changes in gene expression of cells exposed to nanomaterials, but to date there is no toxicity study at epigenetic level that describes the effects of the 'epigenotoxicity' through successive cell generations induced by nanoparticles. Therefore, it becomes necessary to study these phenomena in order to contribute to the development of more appropriate nanoparticles for biological applications. **Objective:** To evaluate the global DNA methylation profile in MCF-7 cells in culture during and after the treatment with maghemite nanoparticles (MNP). **Methods:** The MNP were synthesized by Fe (II) and Fe (III) coprecipitation method and direct addition of citric acid to stabilize the particles. To identify the IC-20 sub-lethal concentration, the MCF-7 cells were treated with MNP during 24h and it was performed the Trypan Blue and the lactate dehydrogenase (Cytotox 96® Non-Radioactive Cytotoxicity Assay, Promega) assays. In order to investigate the real time cell proliferation through 96h after treatment it was performed an assay in the xCELLigence™ system (Roche / ACEA). The global DNA methylation was performed by colorimetric assay with the MethylFlash™ kit (Epigentek) and Whole Genome Bisulfite Sequencing in the HiSeq 2500 platform (Illumina). **Results:** MNP caused a cytostatic effect on MCF-7 cells treated with 60µgFe/ml during 24h. However, after the 24h treatment it was found that the proliferation rate of treated cells was higher than untreated cells. This phenotype could be associated with the DNA methylation pattern that we observed. During the treatment, cells undergo hipomethylation and after the treatment cells restore their DNA methylation status. The whole genome bisulfite sequencing is still being analysed, but the preliminary data indicates that the differentially methylated regions (DMR) among treated and control samples occur mostly on the intergenic regions, introns and CpG islands. **Discussion:** The influence of nanomaterials in the epigenetic status of a biological system is still poorly understood. Thus, nanomaterials have a risk in biological applications, even when administered in non-toxic concentrations considered by conventional techniques. This is because their effects can be extended to multiple generations, even during transient exposure. **Conclusion:** The MNP promote significant changes in global DNA methylation in MCF-7 cells and this event can be exploited for future biomedical applications.

2936T

Resistance to BET inhibitors in lung adenocarcinoma is mediated through a MYC independent mechanism. *J. Calder, W. Lockwood.* Department of Pathology, BC Cancer Research Center, Vancouver, BC, Canada.

JQ1 is an inhibitor of the bromodomain and extraterminal (BET) family proteins, which function as important reader molecules of acetylated histones and recruit transcriptional activators to specific promoter sites. The down-regulation of c-MYC has been linked to JQ1 inhibition in many sensitive cancer cell lines, while reactivation of c-MYC expression has been shown to induce JQ1 resistance. Our lab has shown that lung adenocarcima (LAC) cells are inhibited by JQ1 through a mechanism independent of c-MYC down-regulation, identifying FOSL1 as a possible target in LAC cells. This suggests that the epigenetic landscape of cells from different origins and differentiation states influences response to JQ1. This study aims to identify potential mechanisms regulating resistance to JQ1 in LAC in order to determine if the epigenome affects different processes in different cancer types. LAC cell lines sensitive to JQ1 treatment, H23 and H1975, were passaged with increasing concentrations of JQ1 until the cells were resistant to high doses of the drug. Expression profiles were generated for parental and resistant cells and genes differentially expressed between the states for each cell line were identified and compared across both H23 and H1975 to identify candidate genes. Gene Set Enrichment Analysis (GSEA) was used to identify potential cell pathways and programs driving JQ1 resistance in LAC. Protein expression was evaluated through Western Blot analysis to confirm gene changes associated with resistance. Initial morphological and western blot analysis showed resistant H1975 cells underwent EMT transition with significant decrease in E-cadherin and increase in Vimentin. Initial analysis of differentially expressed genes between the parental and resistant pairs identified 101 significantly differentially expressed genes (corrected p-value <0.005) common between the H1975 and H23 lines; however, MYC was not significantly altered. Preliminary GSEA results identified a few enriched pathways including Wnt signaling pathway and ERK/MAPK targets. The discovery and optimization of small-molecule inhibitors of epigenetic targets is a major focus of current biomedical research. We determined that LAC cells, unlike those from other cancers, develop JQ1 resistance through mechanisms independent of c-MYC, suggesting the epigenomic landscape of a cell can influence both sensitivity and resistance to BET inhibitors.

2937F

The role of the immune system in field cancerization: Progressive inactivation of immune related pathways in esophageal cancer. *L. Cordeiro, L. Pinto.* INCA, Rio de Janeiro, RJ, Brazil.

The concept of field cancerization was introduced over 60 years ago and its presence has been described in many cancer types. It is believed that progressive molecular changes affect cellular functioning spatially, giving rise to an expanding field of heterogeneously altered cells. Unhindered, such progression may lead to cancer. We present *in silico* evidence that field cancerization occurs in the most prevalent subtype of esophageal cancer. Esophageal cancer is the 8th most incident cancer globally and the 6th leading cancer in mortality (5% of all cancer deaths). Esophageal adenocarcinoma (EAC) and esophageal squamous cell carcinoma (ESCC) are the main histological types of esophageal cancer, the latter responsible for over 85% of cases. Prognosis is grim: the 5-year survival rate ranges from 5% to 15%. Despite being one of the most lethal cancers, little is known about its carcinogenic mechanisms. We systematically mined public gene expression data and built a unique dataset of over 400 samples of ESCC, tumor-adjacent tissue and esophageal cells from healthy individuals. We analyzed the progression of changes in global gene expression from healthy to tumor-adjacent to ESCC samples and found 17 consistently differentially expressed genes from "healthy" to "tumor" state. Five genes were consistently overexpressed and four of them – *RIPK4*, *FGFR3*, *IRF6*, *EPCAM* – are directly associated with deregulation of epithelial proliferation pathways. Twelve genes were consistently underexpressed and nine of them – *HLA-DPA1*, *IGHM*, *ATP6V1A*, *FAS*, *HLA-G*, *HLA-DRA*, *IGLC1*, *HLA-B*, *POU2AF1* – code for crucial elements in both humoral and cell-mediated immune responses. Network and pathway enrichment analysis on differentially expressed genes in each state transition show a distinctive pattern of changes in global expression. In the first transition, from "healthy" to "tumor-adjacent", several immune-related pathways are inhibited causing grave deregulation in antigen processing and presentation processes as well as decreased immune-related signaling. In the second transition, from "tumor-adjacent" to "tumor", the inhibition of these immune-related pathways is sustained, with respect to the "healthy" state, and epithelial–mesenchymal transition pathways became deregulated. Taken together, these findings suggest the existence of field cancerization in esophageal squamous cell carcinoma and highlight a possible role of global immune system inhibition on its carcinogenic mechanism.

2938W

Integrated gene-level analysis of molecular features in high-grade serous ovarian cancer. *J.M. Cunningham[1], M.A. Earp[2], S.M. Armasu[2], B.L. Fridley[3], K. Kalli[2], M.C. Larson[2], R.A. Vierkant[2], C. Wang[2], S.J. Winham[2], E.L. Goode[2].* 1) Dept Lab Med & Pathology, Mayo Clinic & Fndn, Rochester, MN; 2) Dept. Health Sciences Res., Mayo Clinic & Fndn, Rochester, MN; 3) Biostatistics and Informatics Shared Resource, University of Kansas Medical Center, Kansas City, KS.

High grade serous ovarian cancer (HGSOC) is a complex disease in which initiation and progression have been associated with gene mutation, DNA methylation changes, genetic variation, and environmental processes. To reveal novel genomic mechanisms underlying HGSOC development, we conducted an integrated analysis of 54 HGSOC tumors to determine how tumor gene expression (RNA-seq) may be influenced by germline genetic variation (Illumina platforms imputed to 15.5M variants using 1000 Genomes) and tumor DNA methylation (Illumina Meth 450K) while adjusting for somatic copy number (Illumina OncoArray). Elastic net (ENET) penalized regression methods were used for model fit, and a permutation-based step-down multiple testing procedure (MaxT) was used to derive adjusted *p*-values. Each of the ~20,000 Ensembl IDs (hg19:GTF75) corresponding to protein-coding genes was analyzed using a window 500kb up- and downstream of the gene start and stop. Three nested models were compared: a) genotype and DNA methylation (full model), b) genotype only, and c) DNA methylation only. No model for gene expression was significantly different from the null after adjustment for multiple testing (MT). Based on a p<0.01 (unadjusted for MT) for the full, genotype only, and methylation only models: 161, 135, and 537 genes, respectively, were found to have a model for expression significantly different from the null. No genes were overlapping in all three lists, 13 overlapped in the full vs genotype-only comparison, 22 overlapped in the full vs methylation only comparison, and 6 overlapped in the methylation only vs genotype only comparison. Gene set enrichment analysis (GSEA) of these gene-lists reveals expected and novel signatures. For example, as expected, the gene list derived from the tumor DNA methylation only model analyses is most enriched for genes known to be altered in cancer (false discovery rate [FDR] q-value=1.4×10^{-28}), and involved immune and inflammatory responses (FDR q-value=1.4×10^{-43}), suggesting this method is capable of detecting true biological signals. Genes identified by the full and genotype only model were most enriched for genes involved in signal transduction (FDR q-value= 6.7×10^{-7}) and with promoter regions containing the binding motif (~2kb from transcription start site) for SP1 (FDR q-value=9.2×10^{-7}), respectively. All genes with an ENET model for expression significant at p<0.05 (unadjusted for MT) will be tested for replication using TCGA HGSOC tumor data.

2939T

The effects of malign breast tissue stromal cells in proliferating of MDA-MB-231 cancer cells and miRNA relation. *I. Değirmenci[1], O. Saglam[1,2], Z.S. Unal[2], G. Posteki[3], E. Karaoz[2], H.V. Gunes[1], Z. Utkan[3].* 1) Eskisehir Osmangazi University, Medical Faculty, Department of Medical Biology, Eskisehir/Turkey; 2) Kocaeli University, Center for Stem Cell and Gene Therapies Research and Practice, Department of Stem Cell, Kocaeli/Turkey; 3) Kocaeli University, Medical Faculty, Department of General Surgery, Kocaeli/Turkey.

Purpose: MicroRNAs (miRNAs) are endogenous non-coding RNAs which regulate gene and protein expression through the RNA interference (RNAi) mechanism. Oncogene or tumor suppressor miRNAs play an important role in tumorigenesis. It has been reported that stromal cells in tumor microenvironment gained similar features of tumor-associated cells. Detailed analysis of miRNA functions should be investigated to discover novel markers and to determine the prognosis through better understanding of molecular basis of cancer concept, and to develop new treatment approach consequently. Thus in the current study, we aimed to investigate the effects of co-culture of cancer cells and stromal cells, isolated from normal and malign breast tissues, on each others, and the possible effects of miRNAs in these cross-effects. **Methods:** Subsequently after isolation of stromal cells from healty and malign breast tissue, appropriate culture condition will be maintained. Characterized stromal cells that are derived from normal and malign breast tissue will co-cultured with MDA-MB-231 cancer cell line in the presence of semi-permeable membranes. After the co-culture, proliferation capacity of the experimental groups were evaluated with WST-1 assay. Expression levels of breast cancer specific miRNAs and related genes will be evaluated by real-time PCR. After the co-culture, ELISA test will be performed to determine some of cytokine and chemokine levels. **Results:** As a result of experiments we found that increased proliferation capacity of the cancer cells after co-culture with malignant stromal cells. Also we found that microenvironment is important in the formation of cancer in support of the changes in the expression levels of oncogenic and tumor suppressor miRNA and their targeted genes after the co-culture with malignant stromal cells. As a conclusion, the possible roles of miRNAs on the alterations in cancer cells by paracrine mechanisms of both normal and malign breast tissues stromal cells are attempt to reveal. In the result of the performed studies with this aim, specific gene expressions of related pathways are going to be detected correlated with miRNA changes, and the effects of the tumor microenvironment in tumorogenesis will be revealed in detail.

2940F

Identification of 102 new candidate target genes for prostate cancer risk-SNPs utilizing a normal prostate tissue eQTL dataset. *M.S. DeRycke[1], M.C. Larson[1], Z.C. Fogarty[1], S.M. Riska[1], S. Baheti[1], L.S. Tillmans[2], S.K. McDonnell[1], D.J. Schaid[1], S.N. Thibodeau[2].* 1) Health Sciences Research, Mayo Clinic, Rochester, MN; 2) Dept Lab Med & Pathology, Mayo Clinic, Rochester, MN.

Multiple risk SNPs for prostate cancer have been identified, however determining which genes the SNPs influence is difficult. Previously we analyzed 146 risk SNPs in 100 regions and identified 51 regions with significant eQTL signals associated with 88 genes for prostate cancer risk while creating a normal prostate tissue eQTL database. Expanding on our earlier work, we have reanalyzed the data increasing the number of risk SNPs analyzed to 202 in 107 regions and using ENSEMBL gene annotation. All risk SNPs, and those SNPs within +/-100Kb and in LD (r^2>0.5) (n=8,073 SNPs) with the PC-risk SNP, were tested against all genes located within +/-1.1Mb from the SNPs (n=3,225 genes). Of the genes tested, 187 demonstrated a gene-level false discovery rate (FDR) <=0.01 (p<1.69e-4). 102 genes not previously reported were identified. Additionally, 85 of the original 88 genes were also reconfirmed; the three genes not reconfirmed included TUBA1B; (FDR=0.0026) and two uncharacterized genes not found in the ENSEMBL gene annotation (LOC284578 and LOC284581). Further studies, including utilizing public datasets to map the significant SNPs to prostate-specific known and predicted regulatory elements, including promoters, enhancers, transcription factor binding sites, transcription start and stop sites, are currently in progress.

Secreted miRNA: A dual role in promoting oral carcinogenesis. *C.T.D. Dickman[1,2], J. Lawson[1], K. Bennewith[1], C. Garnis[1,3].* 1) BC Cancer Research Center, Vancouver, British Columbia, Canada; 2) Department of Medicine, University of British Columbia, Vancouver, British Columbia, Canada; 3) Department of Surgery, University of British Columbia, Vancouver, British Columbia, Canada.

There has become a growing interest in the role of exosomes in cancer biology, particularly due to their involvement in communication between cancer and stromal cells. Exosomes are small membrane bound vesicles that are known to contain a wide variety of proteins and nucleotides such as miRNAs. Exosomal contents can be a source of biomarkers and their transfer system could be exploited for drug delivery. As the miRNA content of exosomes is non-randomly packaged we hypothesize that miRNAs are selectively retained or excreted into exosomes in oral cancer cells to promote growth within the cell and to create a favorable microenvironment for tumor growth. By examining a panel of oral cancer and dysplasia cell lines we identified several miRNAs under selection for exosomal packaging and release. When exosome release is inhibited by the knockdown of the protein Rab27A (a protein involved in exosomal trafficking) we were able to increase the intracellular concentration of excreted miRNAs and we were able to determine that increased intracellular miR-142-3p targeting TGFBR1 and thereby decreasing cancer cell growth. Over-expression of miR-142-3p in exosomes was shown to increase the tumor supporting effects of endothelial cells with a subsequent decrease in TGFBR1. Mouse tumor injections showed that cells over-expressing miR-142 grew at a slower rate but were more vascular and as a result less hypoxic. Together these data suggest that miR-142-3p excretion plays a dual role in tumorigenesis: the removal of a tumor suppressive effect within the cell and the creation of a pro-carcinogenic niche in the stromal cells.

2942T

Alterations to the *ELF3* oncogene circumvent upstream regulation in lung cancer. *K.S.S. Enfield[1], D.A. Rowbotham[1], S. Rahmati[2], C. Anderson[1], J.Y. Kennett[1], E.A. Marshall[1], R. Chari[3], D.D. Becker-Santos[1], K. Ng[1], C.E. MacAulay[1], S. Lam[1], W.W. Lockwood[1], I. Jurisica[2], W.L. Lam[1].* 1) Integrative Oncology, British Columbia Cancer Research Centre, Vancouver, British Columbia, Canada; 2) Princess Margaret Hospital, Toronto, Ontario, Canada; 3) Harvard Medical School, Boston, MA, USA.

   Introduction: The transcription factor ELF3 has been implicated as both an oncogene and a tumour suppressor. In lung cancer its overexpression is in part due to SMAD4 inactivation and upregulation of ERBB2 and PI3K signaling. Here we perform a large scale multi-omics investigation to determine the genetic mechanisms underlying ELF3 overexpression in lung adenocarcinoma (LUAD) as well as the tissue-specific interactions that may explain its divergent functions. **Methods:** Multi-omic data was analyzed from the BCCRC (n=83), TGCA (n=420), and four transgeneic murine models of LUAD tumourigenesis. Associations of *ELF3* with patient survival were assessed by log-rank method. Lentiviral delivery of shRNA knock-down and overexpression vectors was performed in cell lines; cell proliferation, cell viability and anchorage independent growth was assessed. Physical protein-protein interaction (PPI) networks of 65 cancer and normal expression datasets across 16 tissues were interrogated to investigate tissue-specificity of ELF3 interactions. Pathway analysis was performed using pathDIP. **Results:** *ELF3* overexpression was most frequently associated with DNA copy number gain, focal amplification, and hypomethylation at the *ELF3* locus observed in 82% of LUAD, rather than mutation of upstream regulators. LUAD with *ELF3* DNA-level alteration also harbored known driver mutations, with a statistical enrichment of *KRAS* and exclusion of *MET*. High *ELF3* expression was observed in all transgenic models and associated with poor survival. ELF3 regulated cell proliferation, viability, and the ability to form colonies in soft agar. PPI networks indicated highly tissue and disease-specific interactions. Lung tumour-specific ELF3 networks included gain of NOTCH and TGFβ, and loss of TNFα and MAPK signaling. **Conclusions:** While ELF3 is downstream of several key lung cancer signalling pathways, upstream regulation is often bypassed due to frequent alteration to the *ELF3* locus. Our cell models show ELF3 regulates cancer phenotypes and provide biological evidence for its associations with survival. The biological significance of *ELF3* alteration in LUAD driven by different mutations remains to be deciphered. The tissue-specific PPI networks observed suggest distinct roles of ELF3 across cancers from diverse tissue origins. Lung cancer specific PPI networks reveal ELF3 function in this deadly disease. Due to the nearly ubiquitous overexpression, ELF3 represents a promising therapeutic target in LUAD.

2943F

A combined miRNA-piRNA signature derived from the DLK1-DIO3 imprinted locus predicts lung adenocarcinoma patient outcome. *J.R. Enterina, K.S.S. Enfield, V.D. Martinez, W.L. Lam.* Integrative Oncology, BC Cancer Agency, Vancouver, BC, Canada.

   Introduction: Deregulation of small RNAs at the imprinted DLK1-DIO3 locus has been linked to lung adenocarcinoma (LUAD) patient outcome. While the contribution of microRNAs (miRNA) is established, the role of Piwi-interacting RNAs (piRNA), small RNAs involved in epigenetic regulation, is unknown. In this study, we quantified expression of piRNAs and miRNAs mapping to this locus in two independent cohorts of LUAD and assessed the ability of a combined miRNA/piRNA signature to improve patient outcome stratification. **Methods:** Expression levels (RPKM) for miRNA and piRNA were determined from small RNA sequencing experiments from two cohorts (TCGA n=156; BCCA n=75). Associations with patient overall survival were calculated by inputting miRNA and piRNA expression combinations into a Cox proportional hazard model. Risk scores were calculated by multiplying the expression value for a given gene by its hazard coefficient, and then summing the transformed gene expression values per model. Risk scores were ranked and divided into tertiles of high, medium, and low risk. Risk group survival curves were compared by the log-rank (LR) method. **Results:** A total of 138 piRNAs mapped to the imprinted locus; only 7 were expressed. The survival model was improved in TCGA cohort following the addition of four of the seven piRNAs (p=1.725e-04) to the original miRNA-based model (p=6.053e-04). By LR analysis of risk groups, the miRNA/piRNA model better predicted outcome (p=0.0038) than the miRNA model (p=0.0506). In the long-term follow up (>8 years) BCCA cohort, the miRNA/piRNA model (p=0.04915) out-performed the miRNA model (p=0.4493). Strikingly, LR survival analysis showed only the combined miRNA/piRNA signature effectively separated high and low risk groups (p=0.0019). The median survival for the low risk group was undefined up to 100 months, vs. 45.3 months in the high risk group. **Conclusions:** We find the combination of miRNA and piRNA expression derived from the DLK1-DIO3 locus produces a superior stratification of patient outcome than either metric alone. While the contribution of miRNAs to patient risk stratification is established, the improved model performance derived from the addition of piRNAs indicates another level of gene regulation (piRNAs mainly target DNA sequences). Model performance is optimal when these two small RNA species are considered simultaneously; suggesting coordinated biological effects as a result of locus deregulation. JRE & KSSE contributed equally.

2944W

Hypoxia-regulates piwi-interacting RNAs in human tumor. *N. Firmino, E.A. Marshall, B.C. Minatel, W.L. Lam, K.L. Bennewith, V.D. Martinez.* Department of Integrative Oncology, BC Cancer Research Center, Vancouver, Canada.

   Background: Tumor hypoxia promotes cancer aggression by inducing the expression of genes related to angiogenesis, metastasis, and cell survival. MicroRNA expression patterns have been shown to change under hypoxic conditions suggesting potential involvement in post-transcriptional regulation of hypoxia-inducible genes. PIWI-interacting RNAs (piRNAs) is another class of small non-coding RNAs. piRNAs facilitate gene silencing by recruitment of protein complex components to sequence specific gene targets. piRNAs are primarily expressed in germ cells. However, we recently showed that a subset of piRNAs are expressed in somatic tissues, and might be linked with epigenetic mechanisms in cancer development. In this study, we determine if hypoxia-regulates piRNA expression in human tumors. **Methods:** We classified human tumors from The Cancer Genome Atlas (TCGA) Research Network according to their oxygenation state using expression signatures derived from established hypoxia-associated gene expression changes. We analyzed 3,020 human tumors derived from cervix (N=306), esophagus (N=196), head and neck (N=522), kidney (N=534), lung (N=1,018), ovaries (N=265) and pancreas (N=179). We extracted piRNA sequences from miRNA sequencing libraries using a custom pipeline and quantified high-quality reads that mapped to the piRNA annotation database derived from piRNABank (http://pirnabank.ibab.ac.in/). **Results:** Our analysis revealed that piRNA expression is selectively deregulated by hypoxia in human tumors. We deduced expression levels from 32,237 human piRNAs on a per tumor basis, and identified the most robust changes in piRNA expression between hypoxic and non-hypoxic groups. We included piRNAs in our analysis that: 1) have a median expression ≥ 10 RPKM in at least one of the groups (hypoxic and/or normoxic), and 2) a minimum of 2-fold variation in median RPKM expression values. Considering piRNAs meeting these requirements, we performed the comparison using the non-parametric Mann-Whitney U test. We found that 40 piRNA were consistently deregulated across human tissues. Of those, 36 were upregulated, while 4 were downregulated. In-vitro tumor cell models recapitulated hypoxia-regulated piRNA expression patterns. **Conclusion:** Our data provide the first indication that piRNAs can be up-regulated by hypoxia in patient samples and in cell cultures, and suggest that hypoxia-induced piRNAs may represent an undiscovered mechanism of gene repression in hypoxic tumor cells.

Methylome-wide profiling of DNA from paired diagnostic prostate tumour and adjacent benign tissue. *L.M. FitzGerald[1,2], E.M. Wong[3], C. Jung[4], J. Joo[3], J. Pedersen[5], G. Severi[6], G.G. Giles[1], M.C. Southey[3].* 1) Cancer Epidemiology Centre, Cancer Council Victoria, Melbourne, VIC, Australia; 2) Cancer, Genetics and Immunology, Menzies Institute for Medical Research, University of Tasmania, Hobart, TAS, Australia; 3) Genetic Epidemiology Laboratory, University of Melbourne, Melbourne, VIC, Australia; 4) Victorian Life Sciences Computation Initiative, University of Melbourne, Melbourne, VIC, Australia; 5) TissuPath, Mount Waverley, VIC, Australia; 6) Human Genetics Foundation Torino, Turin, Italy.

   A number of studies have compared genome-wide DNA methylation profiles in prostate tumor and adjacent benign tissue with the aim of identifying diagnostic biomarkers or therapeutic targets. Several differentially methylated CpG (dmCpG) sites have been shown to differentiate tumor from benign tissue but these studies have been conducted using radical prostatectomy (RP) samples, thus their relevance at the time of diagnosis is not known. Here, we aimed to investigate differential methylation in diagnostic tumor and benign prostate tissue samples to identify biomarkers relevant at the time of diagnosis. Our study included 138 DNA samples from FFPE diagnostic trans-rectal ultra sound or trans-urethral resections of the prostate, including 33 paired prostate tumor and adjacent histologically benign tissue samples. DNA methylation was measured using the Illumina Infinium HM450K BeadChip. Linear models to account for the paired study design and an adjusted Bonferroni p-value of 0.01 were used to evaluate differential methylation. After quality control measures and ComBat normalisation, analysis of 31 tumor-benign pairs identified 32,104 significantly dmCpG sites, 2,146 of which had a mean methylation difference (delta-beta) of >0.4. The majority (74.7%) of dmCpG sites were hypermethylated in tumor samples, including 98.1% of dmCpG sites with strong methylation changes (delta-beta >0.4). Using methylation patterns at the dmCpG sites, tumor samples were distinguished from benign samples, including 67 unpaired tumor and benign samples. In addition to confirming several previously identified dmCpG sites from RP studies, our study of diagnostic tissue identified dmCpG sites that had not been previously described in this context. Preliminary gene expression data from the same diagnostic tissues demonstrates that 337 of 550 differentially expressed genes (FDR<0.01) are associated with dmCpGs, the majority of which (78%) are down-regulated in tumor. Our study used diagnostic FFPE samples and applied a genome-wide strategy to identify dmCpG sites that distinguish prostate tumor from adjacent benign tissue. In addition to confirming previously identified dmCpGs from RP studies, we report additional dmCpG sites that appear to be specific to diagnostic tumor tissue. This study provides insight into some of the DNA methylation changes that occur in the early stages of this disease and could potentially lead to improved diagnostic biomarkers and novel therapeutic targets.

Repair DNA pattern expression and ribosomal genes are associated with adult medulloblastoma subtype. *A.M. Fontes[1], F.B. Barbosa[1], A.L. Simoes[1], C.E.V. Wiezel[1], F.S. Ramalho[2], H.R. Machado[3], S.L. Gerson[4], K.J. Abraham[5].* 1) Genetics, University of Sao Paulo, Ribeirao Preto, SP, Ribeirao Preto, Brazil; 2) Department of Pathology and Legal Medicine, FMRP-USP, Brazil; 3) .Department of Surgery and Anatomy, FMRP-USP, Brazil; 4) Case Comprehensive Cancer Center, School of Medicine, CWRU, USA; 5) Estácio- Uniseb, Ribeirao Preto, Brazil.

   Introduction: Medulloblastoma (MB) represents a genetic and epigenetic heterogeneous group of neuroepithelial primary tumors arising from the cerebellum. MB can be classified in four major subtypes: WNT, SHH, Group C and Group D. With current treatment, some MB patients still do not respond to treatment suggesting heterogeneity whithin these subtypes. To better understand these tumors we investigated five groups of genes associated with cancer and other phenotypes. **Methodology:** In this study we analyzed 4 frozen tumor samples from 4 adult MB patients and 3 control cerebellum tissues. Two color microarray-based gene expression profiling and human comparative genomic hybridization (CGH) (2x 400K) were performed. Bioconductor and Agilent Cytogenomics were used for the analysis. **Results:** We performed hierarchical clustering with 22 transcripts and observed the existence of three subtypes among the specimens analyzed (WNT, SHH and Group D). Next, we analyzed 294 genes, which were categorized in five groups (1. Classic oncogenes, classic tumor suppressor and apoptosis related genes; 2. Repair DNA genes (including POLB and XRCC5); 3. Epigenetic regulator genes; 4. Hox genes including long noncoding associated-Hox and 5. Lysosomal and Ribosomal-genes). We found these tumors have altered expression in 46-62% of these genes with upregulation much more frequent than downregulation. Compared with control samples, *POLB* mRNA is up to 164 times more expressed in MB-SHH, and 44 times less expressed in Group D. *XRCC5* mRNA is 143 times lower regulated in MB-SHH and 126 times up-regulated in MB-WNT. *RPL15* mRNA is up-regulated 140-390 times in all MB-tissues compared with control tissues and *RPS20* mRNA is downregulated 61-156 times. We also observed the DNA CNVs in these tumors and found 3-26 CNVs among these 294 genes. The MB-SHH sample has 22 CNVs, mostly copy number loss, in DNA repair or epigenetic regulator genes. The MB-Group D sample has 26 CNVs mostly copy number gain, in HOX genes or epigenetic regulator genes. The epigenetic genes and long non-coding RNAs show both copy number gain and loss. In some repair genes downregulation and copy number loss were jointly observed while in oncogenes upregulation was observed along with copy number gain. **Conclusion:** This study analyzed the correlation between copy number variation and up or down expression in several cancer-associated genes which can provide useful insights for biomarkers and therapeutic intervention. .

2947W

ETV6/TEL plays a key role in KAP1/TRIM28-dependent DNA damage response in acute lymphoblastic leukemia. *R. Gioia[1], C. Drullion[1], S. Drouin[1], S. Langlois[1], J. Larose[1], C. Jimenez-Cortez[1], D. Sinnett[1,2].* 1) Division of Hematology-Oncology, CHU Sainte-Justine Research Center, 3125 chemin de la Côte-Sainte-Catherine, Montréal, Québec, H3T 1C4, Canada; 2) Department of Pediatry, University of Montreal, 2900 Édouard-Montpetit, Montreal, QC, H3T 1J4, Canada.

   Pre-B acute lymphoblastic leukemia (ALL) represents ~25% of all pediatric cancer cases, which makes it the most common hematological malignancy and the leading cause of disease-related death in children. The most frequent genetic alteration associated with pre-B ALL is the t(12;21) translocation, which results in the formation of the ETV6-AML1 (TEL/RUNX1) chimera and the frequent deletion of the residual ETV6 allele, which leads to complete ETV6 inactivation. ETV6 had been previously described only as a ubiquitously expressed transcriptional repressor. We showed here that ETV6 plays an important role in genotoxic stress cytoprotection by repressing DNA damage response (DDR). Moreover, mass spectrometry and co-immunoprecipitation data indicated that KAP1/TRIM28 is an ETV6 physical interaction partner implicated in this novel function. Indeed, we have characterized through gain- and loss-of function assays ETV6 as a negative regulator of apoptosis and DDR and KAP1 as a critical regulator of ETV6 activity. Finally, we have shown that ATM-dependant phosphorylation of KAP1-S824 modulates ETV6's DDR activity. This study describes a novel role for the ETV6 transcriptional repressor in DNA damage response and apoptosis regulation and suggests new leads as to its role in childhood leukemogenesis..

Genome-wide differential methylation profiles in circulating cell free DNA for pancreatic cancer early detection and prognosis. *R.J. Hung[1], G. Fehringer[1], R. Singhania[2], S.Y. Shen[2], P. Zuzarte[3], D. Chadwick[2], A. Borgida[1], S. Gallinger[1], D.D. De Carvalho[2].* 1) Lunenfeld-Tanenbaum Research Institute of Mount Sinai Hospital, Toronto, Ontario, Canada; 2) Princess Margaret Cancer Centre, University Health Network, Toronto, Canada; 3) Genome Technologies, Ontario Institute for Cancer Research, Toronto, Canada.

   Background: Around 90% of pancreatic cancer patients die within the first year, underlining the importance of early detection and the need for prognostic marker. Methylation aberrations have substantial impact on tumorigenesis and disease progression, but biomarkers that require tumor tissues have limited clinical value for early detection and unresectable cases. On the other hand, circulating cell free DNA (cfDNA) is ideal for biomarker discovery as it was shown to reflect genetic alterations in tumor tissue and can be obtained minimally invasively. Thus we investigate whether aberrant methylation related to pancreatic tumors can be detected in cfDNA, and if so, the clinical utility for early detection and prognosis. **Methods**: To overcome the low input and fragmented nature of cfDNA, we developed a new method specifically for cfDNA genome-wide methylation sequencing with ultra-low input . Based on tumor-normal pairs and cfDNA from a total of 157 individuals (71 cases and 86 controls), we identified differential methylated regions (DMRs) and linked back to epigenetic changes in the tumors. We conducted motif analysis to identify tissues of origin. We assessed the predictive performance of the DMRs based on cross-validation and penalized regression with Lasso penalty. We applied multivariate Cox regression to identify prognostic markers, and network analysis to identify core survival gene networks. **Results:** We identified 12085 DMRs that distinguish pancreatic cancer patients from healthy individuals. The cfDNA methylation profile in patients significantly resembled that of matched resected tumors from the same patients (p= 3.12^{-15} for hypermethylation; p=2.67^{-109} for hypomethylation). Based on 2485pancreatic cancer-specific DMRs (qFDR<0.05) detectable in cfDNA, we observed an increase of area under receiver operating characteristic curve (AUC) of additional 0.39 when comparing to a model with only personal health history and clinical variables, from AUC of 0.59 to 0.98 in the *validation set*. In addition, 59 DMRs were found to be associated with pancreatic cancer survival (qFDR<0.05), and they were located mainly in genes related to apoptosis and tumorigenesis network. **Conclusions**: We demonstrated that differential methylation patterns specific to pancreatic tumors can indeed be detected in the cfDNA, and further identified potential DMRs for pancreatic cancer early detection and prognosis. These results will be further validated in a larger cohort of patients.

2949F

Molecular characterization of the role of RUNX1 in Notch signaling in T-cell Acute Lymphoblastic Leukemia (T-ALL). *R. Islam[1,2], C. Jenkins[3], M. Bilenky[5], A. Carles[2,4], L. Li[2], A. Lorzadeh[2], V. Giambra[3], S. Lam[3], C. Hoofd[3], M. Belmonte[3], X. Wang[3], A. Weng[3,6], M. Hirst[2,4,5].* 1) Bioinformatics, University of British Columbia, Vancouver, BC, Canada; 2) Michael Smith Laboratories, University of British Columbia, Vancouver, BC, Canada; 3) Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada; 4) Department of Microbiology & Immunology, University of British Columbia, Vancouver, BC, Canada; 5) Canada's Michael Smith Genome Sciences Centre, BC Cancer Agency, Vancouver, BC, Canada; 6) Department of Pathology & Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada.

   T-cell acute lymphoblastic leukemia (T-ALL) is a hematopoietic malignancy driven by oncogenic activation of Notch signaling. Runt-related transcription factor 1 (RUNX1) is hypothesized to participate in supporting Notch signaling, which is well characterized as an oncogenic pathway in T-cell leukemia. In support of this hypothesis we find that human T-ALL patient-derived samples and cell lines (e.g., KOPT-K1) are sensitive to RUNX1 depletion mediated by lentiviral shRNAs and pharmacologic Notch pathway inhibition. In order to dissect the molecular mechanism(s) underlying these phenotypes, we have performed mRNA-seq and ChIP-seq against a panel of histone modifications (H3K4me1, H3K4me3, H3K27ac, H3K36me3, H3K27me3 and H3K9me3) for samples that have either been depleted of RUNX1 (shRNA) or NOTCH1 (pharmacologic inhibition). RNA-seq analysis revealed that 14 genes (e.g., CR2, DTX1, EGR1, FGR, HES4, MYC, NOTCH3 etc.) with NOTCH1 and RUNX1 binding site at proximal region (+-5Kb of TSS) are down regulated in absence of either NOTCH1 or, RUNX1. We found NOTCH1 and RUNX1 sites localized to H3K27ac and H3K4me3 enriched promoters of those 14 genes, whereas these regions lose enrichment when NOTCH1 or, RUNX1 is turned off. These NOTCH1 and RUNX1 co-regulated sites also intersect with other co-activators e.g., P300, ETS1, BRD4, MED1, GABPA, RBPJ (source: Hongfang W. et al. PNAS,2014;111(2):705-10). Kitabayashi I. et al. EMBO Journal, 1998,17,2994-3004, showed that RUNX1 interacts with p300 and overexpression of p300 stimulates RUNX☐dependent transcription to induce myeloid cell differentiation. We observed a global loss of H3K27ac upon RUNX1 silencing which is possibly the absence of RUNX1 halts the recruitment acetylation through P300. This result suggests the potential role of RUNX1 in recruitment of histone acetyl transferases in T-ALL. Simultaneously, there is gain of H3K27me3 in proximal regions and ~30% active enhancers become poised in absence of RUNX1. The loss of H3K27ac and gain of H3K27me3 indicates a broad chromatin re-structuring in absence of RUNX1. KEGG pathway enrichment analysis shows RUNX1 target genes are involved in cell cycle, receptor sinaling and metabolic pathways. Consequently, using BrdU incorporation assay we observed a proportion of cells stopped replication and blocked cell cycle. Together these results we suggest an essential role for RUNX1 in regulating the expression of genes involved in maintaining T-ALL through recruiting H3K27ac.

2950W

Epigenetic regulation of *SMPD3* **alters cell stress response in human oral cancer cells.** *J. Jabalee, R. Towle, C. Garnis.* Dept of Integrative Oncology, University of British Columbia, Vancouver, Canada.

Oral squamous cell carcinoma (OSCC) displays a dismal five-year survival rate of ~50%, one of the worst for all cancer types. To significantly improve survival rates we must better understand the molecular events driving the disease. To identify genes involved in OSCC progression, we performed genome-wide DNA methylation profiling of patient-derived normal, pre-malignant, and tumor tissue and identified the *SMPD3* promoter as a site of frequent hypermethylation in pre-malignant (6/10 patients) and tumor (10/10 patients) tissues. Hypermethylation correlates with a decrease in *SMPD3* expression in 4/6 pre-malignant samples and 6/10 tumor samples. In cancer, gene silencing via promoter hypermethylation is a common feature of tumor suppressors. The product of the *SMPD3* gene, neutral sphingomyelinase 2 (NSMASE2), degrades sphingomyelin to ceramide, a key lipid second messenger involved in diverse processes such as apoptosis, growth arrest, and cell signaling via exosomes. Tumor-derived exosomes contain various signaling molecules, including microRNAs, which can influence recipient cells and promote tumorigenesis. We find that *SMPD3* is methylated and not expressed in 5/6 oral cancer cell lines examined; however, the role of *SMPD3* in cancer is not well understood. In order to determine its functional role, we overexpressed *SMPD3* using lentiviral vectors in the oral carcinoma cell lines SCC-25 and Cal27. Our preliminary results suggest that overexpression decreases growth rate compared to control cells. This effect has been observed in other cancer types, including breast, bone, and liver. *SMPD3* is thought to mediate the response to various stress conditions, including serum starvation and radiation, via the generation of proapoptotic ceramide. Interestingly, *SMPD3* overexpression protected Cal27's against serum starvation, in contrast to recent results in mouse fibroblasts. Furthermore, *SMPD3* appears to sensitize Cal27 cells to radiation treatment, in agreement with previous studies. We are currently repeating these experiments in other cell lines. In addition, we are investigating the role of *SMPD3* in regulating microRNA packaging into exosomes under stress conditions Our results suggest that *SMPD3* acts as a tumor suppressor and alters cancer cells' response to stress. Further research is required to determine the effectiveness of *SMPD3* expression level in guiding clinical decision making, particularly with respect to radiation therapy.

Analysis of long-range gene regulation by the lncRNA MALAT1 genomic locus using enhanced chromosome conformation capture & sequencing (e4C) in lung cancer cells. *J. Kim[1], R. Myers[2], D. Dorset[2], E. Ahn[1].* 1) University of South Alabama, Mitchell Cancer Institute, Mobile, AL; 2) HudsonAlpha Institute for Biotechnology, Huntsville, AL.

Diverse oncogenic promoters create aberrant DNA loop structures and chromatin interaction with other genomic loci which play a key role in long-range regulation of histone modification and co-expression of gene pairs. Despite technical advances in chromatin structure analysis, only a limited number of long-range chromatin interactions have been identified related to oncogenic potential in cancers. During our analysis of ChIP-seq data of genome-wide binding sites of SON, a nuclear protein that interacts with both DNA and RNA, we identified a strong peak in a putative enhancer region downstream of the *MALAT1* (metastasis-associated lung adenocarcinoma transcript 1) gene. MALAT1 is a long non-coding RNA (lncRNA) originally described as abundantly expressed in lung cancer. While the function of MALAT1 has been extensively studied in metastasis of diverse cancers, any role of the *MALAT1* genomic region in long-range chromatin regulation has not been explored. To examine detailed features of the sequence downstream of the *MALAT1* gene, we analyzed several ChIP-seq and ChIA PET-seq results from the ENCODE (Encyclopedia of DNA Elements) database. Interestingly, the data revealed that the genomic region downstream of the *MALAT1* gene represents high levels of H3K4me1 and H3K27Ac, numerous transcription factor binding sites, and potential interactions with other genomic loci. Since these features strongly suggest a potential enhancer function of this DNA region, we identified genome-wide chromatin interaction partners of the *MALAT1* downstream sequence using enhanced chromosome conformation capture and sequencing (e4C) method in A549 lung cancer cell line. Interestingly, our e4C revealed specific interactions between the *MALAT1* locus and many target genes which are closely associated with ion transport and GTPase regulation, such as *CACNA2D1* and *HVCN1*. Furthermore, among the interacting genes, we also found *VAV2* and *SMAD6*, well known metastatic genes, as potential co-expression gene pairs with *MALAT1* in lung cancer cells. Taken together, our study demonstrated that the DNA sequence located downstream of the *MALAT1* gene forms long-range chromatin interactions with several genetic loci which are critical for tumorigenesis and co-regulated by transcription factors and SON. Furthermore, our findings strongly suggest a potential role of the *MALAT1* genomic locus as a long-range regulatory *cis*-element that facilitates aberrant transcriptional regulation in lung cancer.

2952F

Frequent silencing of the candidate tumor suppressor *TSLAC1* **by promoter methylation in early stage lung adenocarcinoma.** *T. Kohmoto, K. Kajiura, T. Narut, K. Masuda, K. Kondo, A. Tangoku, I. Imoto.* Tokushima University, Tokushima, Tokushima, Japan.

Transcriptional repression through aberrant DNA methylation of promoter of specific tumor suppressor genes (TSGs) play an important role in carcinogenesis. In order to identify novel TSG candidates implicated in the early development of lung adenocarcinoma (LAC) regardless of smoking status, we performed a genome-wide screening of aberrantly methylated CpG-islands in 12 stage I LAC (6 smokers and 6 non-smokers) with paired non-cancerous tissues using the Illumina Human Methylation 450K BeadChips. A series of criteria targeting novel genes frequently silenced in LADC primary tumors and cell lines possibly through hypermethylation were applied to prioritize the selection of top candidates for validation. As the result, we identified TSLAC1 (Lab. name) for further detailed analyses of methylation and expression status using a larger panel of LADC tumors and cell lines. Frequent hypermethylation and silencing of TSLAC1 were observed in LAC tumors compared with paired non-tumorous lung tissues from early stage. Our results were also validated by a dataset obtained from the Cancer Genome Atlas (TCGA). Methylation-dependent silencing of TSLAC1 was confirmed by the 5-aza-2-deoxycytidine treatment-induced restoration of gene expression and promoter assay of the methylated region using LAC cell lines. In addition, a series of *in vitro* and *in vivo* functional analyses using LAC cell lines demonstrated that TSLAC1 suppresses anchorage-independent and dependent cell growth, suggesting that inactivation of this gene is a crucial early event for the development of LAC. Our results suggest that TSLAC1 is a novel TSG for LAC, which is inactivated by DNA hypermethylation regardless of smoking status from early stage of this disease.

2953W

Concerted transcriptional response to cancer drug treatment among genes involved in DNA methylation, demethylation, and folate-mediated one-carbon metabolism. *J. Krushkal[1], Y. Zhao[1], C. Hose[2], A. Monks[2], J.H. Doroshow[3], R. Simon[1].* 1) Biometric Research Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Rockville, MD; 2) Molecular Pharmacology Laboratory, Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD; 3) Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD.

Dysregulation of DNA methylation and demethylation is abundant in cancer, and epigenetic pathways are increasingly being targeted in cancer treatment. Genetic components of the folate-mediated one-carbon metabolism pathway can affect DNA methylation and other vital cell functions, including DNA synthesis, amino acid biosynthesis, and cell growth. We examined how cancer drug treatment affects temporal changes in gene expression among epigenetic regulators of DNA methylation and demethylation, and one-carbon metabolism genes. We utilized data from the NCI-60 cell line panel, a popular resource from the U.S. National Cancer Institute, which includes 59 human cancer cell lines representing 9 cancer tissue types. We analyzed changes in gene expression after treatment with five antitumor agents, 5-azacytidine, doxorubicin, vorinostat, paclitaxel, and cisplatin. Each antitumor agent elicited concerted changes in gene expression of multiple pathway components across the cell lines. Expression changes of *FOLR2, SMUG1, GART, GADD45A, MBD1, MTR, MTHFD1,* and *CTH* were significantly correlated with chemosensitivity to some of the agents. The genes encoding DNA methyltransferases *DNMT1, DNMT3A,* and *DNMT3B,* epigenetic and DNA repair factors *MGMT, GADD45A,* and *MBD1,* and one-carbon metabolism pathway members *MTHFD1, TYMS, DHFR, MTR, MAT2A, SLC19A1, ATIC,* and *GART,* and a number of other important genes demonstrated concerted transcriptional response to individual antitumor agents. These transcriptional changes are likely to influence vital cellular functions of DNA methylation and demethylation, cellular growth, DNA biosynthesis, and DNA repair, and some of them may contribute to cytotoxic and apoptotic action of the cancer drugs. This concerted molecular response was observed in a time-dependent manner, which may provide future guidelines for temporal selection of genetic drug targets for combination drug therapy treatment regimens of cancer. Funded by NCI Contract No. HHSN261200800001E.

2954T

Characterization of microRNAs upregulated in metastatic lung adeno-carcinoma. *S.H.Y. Kung[1], K.S.S. Enfield[1], D.A. Rowbotham[1], C. Pastrello[2], B. de Carvalho Minatel[1], I. Jurisica[2], C. MacAulay[1], S. Lam[1], W.L. Lam[1].* 1) British Columbia Cancer Research Centre, Vancouver BC; 2) Princess Margaret Cancer Centre, Toronto ON.

   Introduction: Lung cancer is the leading cause of cancer-related death worldwide, where poor survival is attributed to late stage at diagnosis and lack of effective treatment options. Improved understanding of advanced stage lung cancer biology could lead to new therapeutic developments. MicroRNAs (miR-NAs) are known regulators of tumor cell invasion and migration. We identify *miR-106a* and *miR-106b* to be associated with metastasis in a clinical cohort of lung adenocarcinoma (AC) and assess their ability to regulate growth and metastasis. **Methods:** MiRNA expression was deduced from small RNA sequencing data derived from clinical lung AC specimens (60 localized, 27 with lymph node invasion) and paired non-malignant tissues. *MiR-106a* and *miR-106b* overexpression vectors and controls were stably transfected into stage I AC cell lines with low endogenous *miR-106* levels with an epithelial phenotype by lentiviral delivery. Migration and invasion was assessed by Boyden chamber assay, while cell proliferation was assessed by BrdU incorporation assay. Expression of epithelial-to-mesenchymal transition (EMT) markers and cell cycle proteins were assessed by Western Blot. DNA copy number, methylation, and Gene Set Enrichment Analysis were queried to identify putative mechanisms of *mir-106a/b* overexpression. Clinical associations in an external cohort were derived using publically available TCGA data. **Results:** *MiR-106a* and *miR-106b* were significantly overexpressed in lung AC with lymph node invasion. Overexpression of *miR-106a* and *miR-106b* significantly increased proliferation of lung AC cell lines, and was associated with decreased levels of predicted target, p21. AC cell lines displayed enhanced metastatic phenotypes *in vitro*, and were associated with increased mesenchymal and decreased epithelial markers, characteristic of EMT. Copy number and methylation status did not correlate with miRNA expression; however, upstream regulation by E2F is likely. In an external cohort, miR-106a/b and vimentin were associated with poor outcome. **Conclusions:** *MiR-106a* and *miR-106b* are overexpressed in metastatic lung AC and regulate the metastatic potential of cells by influencing EMT and cell proliferation. A deeper characterization of this observation may reveal therapeutic intervention points, or, with the development of miRNA therapeutics, *miR-106a/b* may be promising targets to prevent or treat metastatic disease. SHYK and KSSE contributed equally.

2955F

The Y-located TSPY and its X-homologue are co-activator and co-repressor respectively for androgen receptor functions in human cancers and diseases. *Y.-F.C. Lau, Y. Li, T. Kido.* Dept Medicine/ VAMC-111C5, Univ California, San Francisco, San Francisco, CA.

   Sexual dimorphisms are prevalent in human diseases and cancers. The male sex hormone, androgen, and its receptor, AR, could contribute to male-specific, e.g. prostate cancer, and sexually dimorphic cancers, e.g. liver cancer, and diseases, e.g. autism and Hirschsprung disease, in male-biased manners. Significantly, actions of Y chromosome genes could potentiate such hormonal effects on the oncogenic and pathogenic processes. The testis-specific protein Y-encoded (*TSPY*) is the gene for the gonadoblastoma locus on the Y chromosome (GBY). It has an X-located homologue, *TSPX*, which functions as a tumor suppressor in human cancers. *TSPY* and *TSPX* originated from the same ancestral gene and code for homologous proteins with a conserved protein-binding SET/NAP domain, but diverged significantly at their C-termini, in which TSPX harbors a large acidic domain, absent in TSPY. We show that both proteins interact with AR and its constitutively active variants (AR-Vs) lacking the ligand-binding domain. TSPY co-activates and TSPX co-represses AR/AR-V transactivation of target genes in ligand-dependent and independent manner respectively. ChIP analysis shows that TSPY and TSPX could co-localize with AR on the promoters and modulate the expression of endogenous AR target genes in prostate cancer cells. Domain mapping identifies the SET/NAP domain as their interactive domain with AR/AR-V, and the acidic tail of TSPX as the repressor domain. Transcriptome analysis shows that *TSPY* and *TSPX* exert contrasting properties on various canonical pathways, functions and diseases and upstream regulators, associated with onco-genesis and physiology. Hence, due to their evolutionary divergence, *TSPY* and *TSPX* function respectively as an oncogene and a tumor suppressor in androgen-responsive human cancers. Importantly, AR and AR-V bind to the *TSPY* promoter and up regulate its expression. Hence, *TSPY* and *AR/AR-V* form male-specific positive feedback loops that could amplify the male-biases in human oncogenesis. Further, *TSPX* also serves critical functions in neuro-evelopment and its mutations have been associated with various neural and cognitive diseases. The contrasting properties of *TSPY* suggest that, when expressed in somatic tissues, this Y-located gene could compete/disrupt *TSPX* functions and exert male-specific and/or androgen-sensitive effects in human development, physiology and disease processes, thereby contributing to the sexual dimorphisms in human development and diseases.

Investigating the role of *CIC* mutations in malignancy. *V.G. LeBlanc[1,2], S. Chittaranjan[1], M. Firme[1], S.Y. Chan[1], J. Song[1], M.H. Lee[1], S. Yip[3], M.A. Marra[1,4].* 1) Canada's Michael Smith Genome Sciences Centre, British Columbia Cancer Agency, Vancouver, British Columbia, Canada; 2) Genome Science + Technology graduate program, University of British Columbia, Vancouver, BC, Canada; 3) Department of Pathology & Laboratory Medicine, UBC, Vancouver, BC, Canada; 4) Department of Medical Genetics, UBC, Vancouver, BC, Canada.

Type I low-grade gliomas (LGGs), characterized by 1p/19q co-deletions and *IDH1/2* mutations and mostly composed of oligodendrogliomas, show superior overall survival compared to other infiltrating gliomas; however, the molecular mechanisms underlying their characteristic slow growth and chemosensitivity remain poorly understood. Approximately 70% of Type I LGGs also harbour mutations in the *Capicua* (*CIC*) gene. CIC was originally identified as a tissue-specific transcriptional repressor in *Drosophila melanogaster*, functioning as an effector of the mitogen-activated protein kinase (MAPK) signalling pathway. These functions seem to be evolutionarily conserved and CIC appears to be involved in mammalian development, possibly playing a role in central nervous system development. CIC dysfunction has also been implicated in other cancer types, such as *CIC*-rearranged Ewing-like sarcomas, prostate cancer, and stomach adenocarcinomas (STADs), where *CIC* was recently found to be significantly mutated within the microsatellite instability (MSI) subtype. Nevertheless, CIC's role in human development and malignancy remains unclear. To address this discrepancy and to further elucidate CIC function, we developed *CIC* knockout cell line models and used transcriptome and proteome analyses to investigate the consequences of CIC loss. We also made use of publicly available data from The Cancer Genome Atlas (TCGA) and the Canadian Epigenetics, Environment and Health Research Consortium (CEEHRC) for Type I LGGs and MSI subtype STADs to detect and explore transcriptomic and epigenomic differences between *CIC* wild type and *CIC* mutant tumour samples. We were able to identify known and novel high-confidence candidate targets of CIC transcriptional regulation. We found that, while CIC targets appear to be partially context-specific, the effects of CIC deficiency converge on the dysregulation of similar biological processes and pathways in different cancer types. In particular, we showed that CIC deficiency is associated with upregulated expression of up- and downstream members of the RAS/RAF/MEK/ERK signalling pathway. This suggests that loss of CIC may present a novel mechanism for activation of this oncogenic signalling pathway, which is affected in many cancer types. Overall, our results indicate an oncogenic role for *CIC* mutations and help uncover the mechanisms underlying their function in malignancy.

Elucidating the function of neomorphic *IDH* mutations in acute myeloid leukemia. *A. Lorzadeh[1], J. Parker[2], D. Knapp[3,4], M. Bilenky[1,2], M. Moksa[1], G. Paliouras[2], D. Hogge[4,5], M. Marra[2,3], C. Eaves[3,4,5], A. Karsan[2,5], M. Hirst[1,2].* 1) Microbiology and Immunology, University of British Columbia, Vancouver, BC, Canada; 2) Canada's Michael Smith Genome Science Centre, BCCA, Vancouver, BC, Canada; 3) 3Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 4) Terry Fox Laboratory, BCCA, University of British Columbia, Vancouver, BC, Canada; 5) Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada.

Introduction: Neomorphic isocitrate dehydrogenase (IDH) mutations are recurrent genetic lesions observed in Acute Myeloid Leukemia (AML) that drive the accumulation of the metabolite D-2-hydroxyglutarate (D2-HG). D2-HG is an inhibitor of 2-oxoglutarate-dependent dioxygenases (2-OGDD), a family of enzymes that include a class of epigenetic modifiers that are responsible for histone and DNA demethylation. In mouse models neomorphic IDH mutations have been shown to reversibly transform progenitor hematopoietic populations harboring FMS-like tyrosine kinase 3 internal tandem duplications (FLT3[ITD]). To investigate the role D2-HG might play in remodelling the epigenome of primary FLT3[ITD] AML blast cells we performed native ChIP-seq on cord blood derived CD34+ cells and primary AML cells harboring FLT3[ITD] in the presence and absence of neomorphic IDH mutations. **Methods:** We applied an optimized native ChIP-seq protocol to profile five histone modifications (histone3 lysine 4 tri-methylation (H3K4me3), H3K4me1, H3K27me3, H3K36me3, and H3K9me3). ChIP-seq was conducted on aliquots of ~10,000 CD34+ cells purified from cord blood by a 2-step Rosette-Sep-EasySep procedure to ≥95% purity and ~10,000 AML cells harboring the FLT3[ITD] allele and IDH2[R140Q] or IDH2[WT] alleles. The resulting libraries prepared from these cells were sequenced on an Illumina HiSeq platform in paired-end mode, analyzed using our ChIP-seq analysis tool FindER and integrated with existing matched RNA-seq datasets. **Results:** Pair-wise comparisons between AML-IDH2[WT]-FLT3[ITD] and AML-IDH2[R140Q]-FLT3[WT] revealed a global increase in H3K27me3 (a repressive histone modification) in AML-IDH2[R140Q]- FLT3[WT] compared to that of AML-IDH2[WT]-FLT3[ITD]. Among genomic regions with differentially modified nucleosomes were the HOXA and HOXB clusters that include the key AML driver HOXA9. Matched RNA-seq datasets confirmed transcriptional repression of genes with H3K27me3 gains in their promoter. Overall our results are consistent with a model where inhibition of 2-OGDD histone demethylases, such as the UTX (H3K27me3 demethylase) by 2D- HG lead localized gains of H3K27me3 and gene repression. **Conclusions:** Our results support a model where IDH neomorphic mutations lead to localized reprogramming of the epigenetic landscape of primary AML through the inhibition 2-OGDD histone demethylases.

2958F

Integrative genomics analysis identifies SIRPA as a key regulator of the EGFR pathway with both tumor suppressive and oncogenic properties. *E.A Marshall[1], R. Chari[2], J.Y. Kennett[1], S. Lam[1], W.L. Lam[1], L.A. Pikor[1].* 1) Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, Canada; 2) Genetics, Harvard Medical School, Boston, USA.

   Background: The *Epidermal Growth Factor Receptor* (*EGFR*) signaling pathway is frequently deregulated in non-small cell lung cancer (NSCLC). Targeted therapies against EGFR effectively prolong survival. However, targeted therapies only benefit a subset of patients harboring EGFR alterations. Resistance inevitably develops, and additional genes downstream of *EGFR* are often abrogated in NSCLC. **Methods:** To investigate the complement of genetic alterations affecting the EGFR pathway in lung adenocarcinoma (AC), we performed a multi-dimensional integrative analysis of copy number, DNA methylation and gene expression profiles on 77 tumor and matched non-malignant tissues. Novel candidate genes were validated in external datasets and tissue microarray IHC was used to relate protein levels with clinical features. Signal-Regulatory Protein Alpha (SIRPA) functions were assessed by stable knockdown (KD) and overexpression (OE) in a panel of lung cancer cell lines *in vitro* and *in vivo*. **Results:** Our analysis revealed *SIRPA* to be underexpressed in 70% of tumors due to both copy loss and hypermethylation, ranking it in the 95th percentile of altered genes within the EGFR pathway. *SIRPA* negatively regulates receptor tyrosine kinsase activity and we observed frequent downregulation at both the mRNA and protein level in NSCLC tumors and cell lines which was correlated with EGFR mutations and an AC subtype. KD of SIRPA enhanced colony formation and wound healing while also simultaneously inducing a dramatic senescent phenotype, suggesting SIRPA may act as a barrier to tumorigenesis. We show this phenotype is dependent on upregulation of the CDK inhibitor p27 which hypophosphorylates RB leading to cell cycle blockade and reduced tumor growth in vivo. SIRPA OE abrogated senescence, promoting cell growth however it also promoted migration, suggesting SIRPA may also possess oncogenic properties. Western blotting and immunofluorescence confirmed that OE of SHP2 upon ectopic expression of SIRPA promotes migration through the inhibition of focal adhesions and that this phenotype is abrogated upon siRNA KD of SHP2. **Conclusion:** Our integrative analysis of the EGFR pathway revealed SIRPA to be frequently downregulated in lung AC. Through its regulation of multiple signalling pathways, SIRPA possesses both oncogenic and tumor suppressive properties, underscoring its importance in lung AC. To our knowledge, this is the first study to report a role for SIRPA in lung tumorigenesis.

2959W

The combined effect of methylation and copy number on gene expression across cancer types. *E.K. Moeller[1], O.C. Lingjaerde[1,2], A.L. Borresen-Dale[1], S. Nord[1].* 1) Department of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway; 2) Department of Computer Science, University of Oslo, Oslo, Norway.

   Regulation of gene expression is key to determine cell type and fate. An extra copy or loss of a gene or an entire chromosome will disrupt the normal DNA burden. Copy number alterations (CNAs) are frequently seen in many cancer types and it has been estimated that CNAs influence expression of ~40% of the genes in the breast cancer (BC) genome. Multiple regulatory factors of gene dosage are known, such as DNA methylation, histone modification, as well as post-transcriptional and translational regulation. In order to better understand what drives the variation in gene expression and the underlying biology of tumor cells, we propose to integrate the two most prominent features: CNAs and methylation. CNAs are a key driver of BC and differences in degree of methylation within BC subtypes have been reported. Therefore BC is a good model system for studying the integrative effect of methylation and/or CNAs on gene dosage in cancer. We have developed a novel method that captures methylation patterns per-gene rather than per-probe, which is the approach that has typically been applied in previous studies. The model was trained on all BC samples from TCGA (n=648) and results were validated in two independent cohorts. Our results show that CNAs have a greater impact on gene expression than methylation, both with respect to the number of genes they influence and their total effect. Overall, we found that methylation, CNAs or both, significantly influenced expression of 39%, 62.2% and 78% of all genes, respectively. Typically, focal aberrations showed the largest impact on expression, and interestingly, they harbored reduced methylation levels. This included hallmark alterations of BC, such as 8p11.23 and 17q12. To assess whether gene dosage regulation is uniform across cancer types, we applied the model to eight different cancers, including BC. Pan Cancer analysis revealed similar patterns with significant associations for a large number of genes, but their total impact on gene expression was limited. For most cancer types, CNAs rather than methylation showed a stronger influence on gene expression, and it was correlated to the genomic instability index (GII). However, the key regulator of gene dosage is cancer type dependent. For known focal aberrations in BC, an inverse correlation was observed between CNAs and methylation, enhancing the oncogenic effect of genes such as *HER2*.

2960T

Piwi-interacting RNAs display cancer-specific expression patterns that hold prognostic value in lung cancer. *K. Ng, B.C. Minatel, E.A. Marshall, K.S.S. Enfield, S. Lam, W.L. Lam, V.D. Martinez.* Integrative Oncology, BC Cancer Agency Research Centre, Vancouver, BC, Canada.

   Background: PIWI-interacting RNAs (piRNAs) are small (24-32bp) non-coding RNAs with a key role in epigenetic regulation of gene expression and maintenance of genomic stability in germ cells. Recent evidence suggests they are also expressed and functionally active in somatic tissues and cancer. Aberrant expression of individual piRNAs has been associated with clinical features in some cancer types; however, their involvement in lung cancer remains to be deciphered. Towards this end, we analyzed piRNA transcriptomes from human tumors and adjacent non-malignant tissues, and identify lung cancer specific expression patterns associated with clinical features and prognosis. **Methods:** We developed a custom small-RNA analysis pipeline to deduce expression of approximately 32K human piRNAs. As a baseline, we generated 6,378 piRNA transcriptomes (non-malignant/tumor tissue) from 11 organ sites. In lungs, we analyzed 1,082 tumors and 209 non-malignant samples from two different cohorts (The Cancer Genome Atlas/BC Cancer Agency). Using a network-based approach, weighted gene co-expression network (WGCNA), we evaluated clinical parameters of tumor aggressiveness (stage, number of mutations, nodal/distant metastasis) and outcome (overall/disease-free survival). Multi-piRNA survival signatures were identified using a Cox Proportional Hazard model. **Results:** Only a small proportion of piRNAs is somatically expressed, and displays highly organ-specific expression. Tumor piRNA expression profiles are markedly different from their non-malignant counterparts, and are correlated with clinical features. Specifically in lung cancer, we find piRNA expression differs between the subtypes adenocarcinoma and squamous cell carcinoma, and we identify piRNA expression networks associated with features of tumor aggressiveness and patient survival. **Conclusions:** We provide evidence of somatic, tissue-specific human piRNA expression. Aberrant expression patterns contribute to lung cancer subtype-specific biology. We discover piRNA-based signatures that identify aggressive lung tumors and have prognostic value. The unique expression patterns of piRNAs offer an opportunity to better understand cancer-specific biology as well as develop novel prognostic markers for clinical application.

2961F

Cell of origin shapes the molecular profile of tumors across cancer types. *S.H. Nordgard[1], L. Silwal-Pandit[1], E.K. Møller[1], O.C. Lingjærde[2], A. Langerød[1], A-L. Børresen-Dale[1], T. Sørlie[1].* 1) Department of Cancer Genetics, Oslo University Hospital, Oslo, Norway; 2) Department of Informatics and Centre for Cancer Biomedicine, Biomedical Informatics, University of Oslo, Oslo, Norway.

   Cell of origin of many different tumor subtypes remains unknown. Basal-like tumors represent a unique molecular entity within breast cancer. Here we hypothesize that the distinctiveness of basal-like tumors may represent features that go beyond organ of origin to include squamous tumor of the cervix, head and neck, lung, bladder and esophagus. The commonality arises from similar cell of origin, and this may be reflected by shared methylation pattern. Taking advantage of the universality of the PAM50 breast cancer classifier, we clustered all 23 solid tumor types available through TCGA by their PAM50 expression profiles. This exercise was subsequently repeated using multiple other intrinsic gene-lists, ensuring robustness to our observations. Two supra clusters were produced; one with tumors clustering in an organ-specific manner including low proliferative and differentiated prostate, non basal-like breast, thyroid, kidney and pancreatic cancers, and a fraction of lung adenocarcinomas and brain tumors. The other supra cluster was composed of highly proliferative tumors where organ specificity was less prominent. The basal-like breast cancers formed, together with squamous carcinomas of the lung, head and neck, cervix, esophagus and bladder, a distinct cluster within this supra cluster (referred to as Pan Cancer basal-like), characterized by an epithelial signature and elevated expression of certain oncogenes and tumor suppressor genes such as *CDKN2A*. The remaining tumors included adenocarcinomas of the lung and digestive system and a subcluster of stem cell like tumors including amongst others, testicular germ cell cancers. Interestingly, clustering the same tumors by their corresponding PAM50 methylation profiles recapitulated the grouping seen by gene expression. The Pan Cancer Basal-like tumors continued to form a distinct entity, and this was amongst other characteristics, driven by the hypomethylation of keratins and the *PTTG1* oncogene. Our results support a "cell-of-origin" dominance on the molecular portraits of the tumors, and that the hypomethylation patterns of certain tumors may have limited influence on tumor progression, and instead, reflect the differentiation level of the cell of origin.

2962W

Lung cancer: One disease or many? *T. O'Brien[1,2], P. Jia[3], Z. Zhao[2,3].* 1) Vanderbilt Genetics Institute, Vanderbilt University School of Medicine, Nashville, TN 37232, USA; 2) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN 37203, USA; 3) Center for Precision Health, School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX 77030, USA.

　　Molecular subtyping of cancers may facilitate the development of targeted therapies that treat each subtype like a single disease rather than one cancer type. However, many cancers are still only characterized by their specific tissue of origin. Lung cancer, for example, is classified into two main types: small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC). NSCLC has several subtypes, the two most common being lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC). These classifications are mostly based on lung physiological and clinical characteristics, although there is increasing evidence of genetic and molecular differences as well. Previous work has identified unique somatic driver genes for each subtype and suggests more than one distinct disease. However, little work has been done to characterize unique germline susceptibility genes. We hypothesize that non-coding common variants act in a regulatory manner to control expression of genes associated with each lung cancer subtype. Thus, we explored the regulatory roles for SNPs associated with each subtype from genome-wide association studies (GWAS) of Europeans. We obtained SNPs associated with each subtype by $p < 10^{-4}$ including SNPs in linkage disequilibrium (LD) with $r^2 > 0.8$ from the 1000 Genomes Project. This expansion resulted in 1427, 1700, and 1059 SNPs for LUAD, LUSC, and SCLC, respectively. We identified SNPs within regulatory regions and their target genes using several lung tissue-specific expression quantitative trait loci (eQTL) and enhancer datasets. We found a total of 27, 60, and 19 germline regulated genes for LUAD, LUSC, and SCLC, respectively. Interestingly, only three genes (*CHRNA5*, *IDH3A*, and *RP11-650L12.2*) overlapped among all three subtypes. *CHRNA5* and *IDH3A* have prior associations with lung cancer, while the function of *RP11-650L12.2* has not been characterized. We found biological pathways enriched with genes from each subtype, such as regulation of actin cytoskeleton and focal adhesion that are both involved in the epithelial-mesenchymal transition (EMT), important in cancer metastasis, only in the most aggressive subtype, SCLC. These results, along with somatic profile differences, suggest these subtypes are unique diseases that only share a small set of germline regulated genes and the difference in the biological basis of each subtype may partially be explained by common variants altering expression of genes that are unique to each subtype.

2963T

Deregulation of long non-coding RNAs in lung adenocarcinoma highlight alternative regulatory mechanisms. *A. Sage, G. Stewart, K. Enfield, D. Rowbotham, R. Hubaux, S. Lam, W. Lam.* Integrative Oncology, BC Cancer Agency Research Centre, Vancouver, BC, Canada.

　　Background: Lung cancer remains the cause of the most cancer-related deaths each year, with a 5 year survival rate of less than 17%. The poor therapeutic outcome is largely due to a complex molecular background as well as late stage diagnosis, with most patients presenting unresectable local tumors, or metastatic disease. Targeted therapeutics have been developed against well-defined drivers of the lung adenocarcinoma (AC) subtype, but such treatment regimens are relevant only to the proportion of patients harbouring these genetic aberrations, emphasizing the need to explore alternative mechanisms of AC development. Natural antisense transcripts (NATs) are long non-coding RNA products expressed from the opposite strand of coding mRNAs. NATs can function in *cis* or *trans* to regulate the transcriptional activity of their cognate gene partner in either a positive or negative fashion. Here we take an unbiased approach to identify NATs deregulated in lung AC, and explore function of these genes with regards to their protein coding partner genes. Methods: We performed RNA-sequencing on a set of 36 lung AC and matched non-malignant lung tissues. A sign-rank test was used to identify NATs and partner genes with significantly altered expression between tumor and matched normal tissues. These findings were validated in an external dataset of lung AC tumors from The Cancer Genome Atlas (TCGA). Survival analysis was performed using a Cox Proportional hazard model, as well as the log-rank method. Results: Analysis of Illumina Hi-seq data from TCGA revealed the majority (79%) of deregulated sense-antisense partnerships observed in AC displayed concordant regulation. However, several cis-NAT pairs were identified including an antisense to *OIP5*, a lung cancer oncogene required for chromatin segregation. *OIP5 Anti Sense 1* (*OIP5-AS1*) was significantly underexpressed in AC, while in the same tumors we find the overlapping partner gene, *OIP5* mRNA, to be significantly overexpressed, suggesting that *OIP5-AS1* may negatively regulate its sense counterpart. In addition, we find that expression of both OIP5 and *OIP5-AS1* are significantly associated with 5-year survival. Conclusions: These findings suggest that deregulation of cancer associated genes through NATs may represent a novel mechanism regulating tumor phenotypes in lung AC.

2964F

Lemur Tyrosine Kinase-2, a potential novel target for prostate cancer therapy. *K. Shah, N. Bradbury.* Physiology & Biophysics, Rosalind Franklin University of Medicine & Science, North Chicago, IL.

Progression from early forms of prostate cancer to castration-resistant disease is associated with an increase in signal transduction activity. The majority of castration-resistance cancers persist in the expression of the androgen receptor (*AR*), as well as androgen-dependent genes. The *AR* is regulated not only by it associated steroid hormone but also by manifold regulatory and signaling molecules, including several kinases. We undertook an evaluation of the role of Lemur Tyrosine Kinase 2 (*LMTK2*) in modulating *AR* activity, as several Genome Wide Association Studies (GWAS) have shown a marked association of *LMTK2, TET2* and *FAM84B* gene expression with the prostate cancer risk. We confirm that not only is *LMTK2* mRNA reduced in prostate cancer tissue, but also *LMTK2* protein levels are markedly diminished. Furthermore, knockdown of *LMTK2* protein in prostate cancer cell lines significantly increased the transcription of androgen-responsive genes. Interestingly, loss of *LMTK2* led to an increase in populations of prostate cancer stem cell, indicative of increased tumourigenicity. Using multiple approaches, we also demonstrate that *LMTK2* interacts with the *AR* and that a loss of *LMTK2* in castrate resistant prostate cancer cell leads to an increase in total *AR* expression. Thus, indicating that a loss of *LMTK2* most probably stabilizes *AR* protein, increases *AR* phosphorylation and results in an increase in castrate-resistant prostate cancer cell proliferation and tumorigenicity. Takayama et al. recently showed that *AR* activity can mediate the expression of a *TET* family, *TET2*, which is correlated with prostate cancer progression. Hence, based on our data, there is a strong possibility that a loss of *LMTK2* can modulate *TET2* expression via androgen-AR axis. As such, our study identifies *LMTK2* as a novel regulator of *AR* and potentially as a novel therapeutic target.

Integrated analysis of genome-wide miRNAs and targeted gene expression in esophageal squamous cell carcinoma (ESCC). *H. Su[1,2], H. Yang[3], N. Hu[2], C. Wang[2], L. Wang[1,2], D. Ti[4], C. Giffen[5], A.M. Goldstein[2], M.P. Lee[3], P.R. Taylor[2].* 1) Leidos Biomedical Research, Inc. MD 21702, USA; 2) Genetic Epidemiology Branch, DCEG, NCI, MD 20892, USA; 3) Laboratory of Population Genetics, CCR, NCI, MD, 20892, USA; 4) Shanxi Cancer Hospital, Taiyuan, Shanxi 030013, P. R. China; 5) Information Management Services, Inc, Silver Spring, MD 20904, USA.

Esophageal squamous cell carcinoma (ESCC) occurs worldwide as the sixth leading cause of cancer mortality and the fourth most common new cancer in China. ESCC is an aggressive tumor with about less than 20% 5-year survival rate, which is fourth worst among all cancers in the USA. Studies have demonstrated that miRNAs modulate gene expression by binding to the 3' untranslated region (UTR) of target mRNA, causing either mRNA degradation or translation inhibition. DNA microarray and next-generation sequencing provide genome-wide scale techniques to identify miRNA signatures which can be potentially applied into cancer diagnosis, prognosis and even personalized medicine. Up to date, no genome-wide analysis of miRNA and mRNA expression in the same set of paired ESCC samples has been studied. Here, we conducted a study of miRNA and mRNA by using same 113 paired ESCC frozen samples to find that a) novel differential expressed miRNAs and mRNA involved in the pathogenesis of ESCC in the same sample set; b) miRNA significantly correlates with mRNA expressed within the same ESCC set; c) significant miRNA expressions associate with patients' clinical parameters including patient's survival as a potential prognostic biomarker.

2966T

Genome-wide DNA methylation assessment of "*BRCA1*-like" early-onset breast cancer: Data from the Australian Breast Cancer Family Registry. *E.M. Wong[1], C.M. Scott[1], J.H.E. Joo[1], N. O'Callaghan[1], J. Dowty[2], G.G. Giles[2,3], J.L. Hopper[2], M.C. Southey[1].* 1) Dept of Pathology, Univ Melbourne, Parkville, VIC, Australia; 2) Centre for Epidemiology and Biostatistics, Univ Melbourne, Parkville, VIC, Australia; 3) Cancer Epidemiology Centre, Cancer Council Victoria, VIC, Australia.

   Introduction: Breast cancers arising in women carrying a germline mutation in *BRCA1* are typically high-grade, early-onset, and have distinct morphological features. Approximately 75% of early-onset breast cancer cases of this subtype (often referred to as "*BRCA1*-like") have the same features but do not carry an identifiable germline *BRCA1* mutation. DNA methylation can mimic the effect of genetic mutation and result in gene silencing. **Methods:** In this study, we examined the role of methylation in "*BRCA1*-like" breast cancer by measuring genome-wide methylation in blood-derived DNA from women under the age of 40 years, participating in the Australian Breast Cancer Family Registry diagnosed with: i) "*BRCA1*-like" breast cancer ("*BRCA1*-like"; n=30); and ii) breast cancer without "*BRCA1*-like" morphological features (non "*BRCA1*-like"; n=30), and age-matched unaffected women (n=30) (controls). Corresponding tumor-derived DNA from 43 of the affected women was also assessed. **Results:** Methylation in blood-derived DNA was elevated across 17 consecutive marks in the *BRCA1* promoter region and decreased at several other genomic regions (including *TWIST2* and *CTBP1*) for seven (23%) women diagnosed with "*BRCA1*-like" breast cancer compared with women in the other groups. Corresponding tumor-derived DNA from these seven women had elevated methylation within the *BRCA1* and *SPHK2* promoter regions and as well as decreased methylation within *MYO10* and *HLA-E*. **Conclusion:** These methylation marks could be biomarkers of "*BRCA1*-like" breast cancer, and responsible in part for their distinctive morphological features, biology, and even risk of breast cancer. This could assist with prevention and targeted therapies for this cancer subtype.

2967F

Tracing Enhancer Networks using Epigenetic Traits (TENET) characterizes enhancer networks from heterogeneous methylomes. *S.K. Rhie[1], G. Yu[1], Y.G. Tak[1], L. Yao[1], H. Shen[2], G.A. Coetzee[2], P.W. Laird[2], P.J. Farnham[1].* 1) Department of Biochemistry and Molecular Biology and the Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA; 2) Van Andel Research Institute, Grand Rapids, MI.

   A single genome can give rise to several hundred distinct cell types that are genetically identical but display different epigenetic marks at regulatory elements, leading to altered gene expression. There are two main types of regulatory elements involved in transcriptional activation, promoters and enhancers. Promoters are defined as a relatively small region surrounding a transcription start site of a gene, and are critical for basal transcription of that gene. Enhancers are regulatory elements, containing multiple transcription factors binding sites, which can be far upstream or downstream of the gene they regulate. In fact, the state most consistently linked to cellular identity is the 'active enhancer' state. Recent studies from the Encyclopedia of DNA Elements (ENCODE) and the Roadmap Epigenome Mapping Consortium (REMC) have shown that more than ten thousand enhancers can be identified using epigenomic marks in a given cell line or tissue. However, it's not clear whether all of these enhancers are functional and which gene is connected to which enhancer. To facilitate understanding of enhancer networks, we have developed a method called Tracing Enhancer Networks using Epigenetic Traits (TENET), which identifies enhancers and genome-wide links between enhancers and genes using DNA methylation and gene expression data. Using profiles of tumor tissues from The Cancer Genome Atlas (TCGA) and next generation sequencing data in cell lines, we identified more than eighty thousand enhancers and further linked a subset of these enhancers to gene expression in prostate, breast and kidney tissues. Our studies revealed epigenetically regulated genes including key transcription factors that are involved in enhancer networks for specific cancer types. For example, we identified key transcription factors (e.g. *GATA3* in breast cancer and *HOXC6* in prostate cancer) linked to many tumor-specific enhancers, and further validated binding of these transcription factors to the enhancers using ChIP-seq data. Additionally, we detected a subset of prostate tumors mutated for *FOXA1* that has more tumor-specific enhancers, more enhancer to gene links, and higher Gleason scores. Thus, TENET can be used to characterize tumor-specific enhancer networks and mechanisms leading to the development of different cancer subgroups. TENET can also be applied to studies beyond cancer and can characterize enhancer networks for different types of case vs. control datasets.

Epigenome-wide tumor DNA methylation profiling identifies novel prognostic biomarkers of metastatic-lethal progression in men with clinically localized prostate cancer. *J.L. Stanford[1,2], S. Zhao[3], M.S. Geybels[1,4], A. Leonardson[1], R. Rubicz[1], S. Kolb[1], Q. Yan[5], B. Klotzle[6], M. Bibikova[6], A. Hurtado-Coll[7], D. Troyer[8], R. Lance[9], D.W. Lin[1,10], J.L. Wright[1,10], E.A. Ostrander[11], J. Fan[6], Z. Feng[5].* 1) Division of Public Health Sciences, Fred Hutchison Cancer Research Center, Seattle, Washington; 2) Department of Epidemiology, University of Washington School of Public Health, Seattle, Washington; 3) National Institute of Environmental Health Sciences, Biostatistics & Computational Biology Branch, Research Triangle Park, North Carolina; 4) Department of Epidemiology, GROW School for Oncology and Developmental Biology, Maastricht University, Maastricht, the Netherlands; 5) MD Anderson Cancer Center, Houston, Texas; 6) Illumina, Inc., San Diego, California; 7) Department of Urologic Sciences, University of British Columbia, and the Prostate Center, Vancouver General Hospital, Vancouver, Canada; 8) Departments of Pathology, Microbiology, and Molecular Cell Biology, Eastern Virginia Medical School, Norfolk, Virginia; 9) Department of Urology, Eastern Virginia Medical School, Norfolk, Virginia; 10) Department of Urology, University of Washington School of Medicine, Seattle, Washington; 11) Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, NIH, Bethesda, Maryland.

Purpose: Aside from Gleason sum few factors accurately identify the subset of prostate cancer (PCa) patients at high risk for metastatic progression. We hypothesized that epigenetic alterations could distinguish prostate tumors with life-threatening potential. **Experimental Design:** Epigenome-wide DNA methylation profiling was performed in surgically resected primary tumor tissues from a population-based (n = 430) and a replication (n = 80) cohort of PCa patients followed prospectively for at least five years. Metastasis was confirmed by positive bone scan, MRI, CT or biopsy, and death certificates confirmed cause of death. AUC, partial AUC (pAUC, 95% specificity), and P-value criteria were used to select differentially methylated CpG sites that robustly stratify patients with metastatic-lethal from non-recurrent tumors, and which were complementary to Gleason sum. **Results:** Forty-two biomarkers stratified patients with metastatic-lethal versus non-recurrent PCa in the discovery cohort, and eight of these CpGs replicated in the validation cohort based on a significant (P <0.05) AUC (range: 0.66-0.75) or pAUC (range: 0.007-0.009). The biomarkers that improved discrimination of patients with metastatic-lethal PCa include CpGs in five genes (*ALKBH5*, *ATP11A*, *FHAD1*, *KLHL8*, and *PI15)* and three intergenic regions. In the validation dataset the AUC for Gleason sum alone (0.82) significantly increased with the addition of four individual CpGs (range: 0.86-0.89; all P <0.05). **Conclusions:** Eight differentially methylated CpGs that distinguish patients with metastatic-lethal from non-recurrent tumors were validated. These novel epigenetic biomarkers warrant further investigation as they may improve prognostic classification of patients with clinically localized PCa and provide new insights on tumor aggressiveness.

2969T

TET2 loss modifies androgen signaling in prostate cancer. *M.L. Nickerson.* Laboratory of Translational Genomics, National Cancer Institute, Bethesda, MD.

We recently characterized the exomes of multiple tumors from a patient with metastatic prostate cancer (PCa) to identify alterations associated with disease. We detected a somatic alteration of the methylcytosine dioxygenase *ten-eleven translocation 2* (*TET2*), which is altered in 5-15% of myeloid, kidney, colon and prostate cancers. We show *TET2* is expressed in normal prostate tissue and reduced in a subset of tumors from the Cancer Genome Atlas (TCGA). Small interfering RNA (siRNA)-mediated *TET2* knockdown (KD) increases LNCaP and DU145 prostate cell proliferation, and LNCaP migration and wound healing, verifying *TET2* loss drives a cancer phenotype. By affinity chromatography and immunoprecipitation, endogenous TET2 bound the androgen receptor (AR) and AR-coactivator proteins in LNCaP cell extracts, and *TET2* KD increases prostate-specific antigen (*KLK3*/PSA) expression. Published data reveal TET2 binding sites and hydroxymethylcytosine proximal to *KLK3*. A gene co-expression network identified using TCGA prostate adenocarcinoma tumor RNA-sequencing data shows *TET2* expression is co-regulated with cancer genes associated with 2-oxoglutarate (2-OG) metabolism, including the lysine demethylase *KDM6A*, BRCA1-associated *BAP1*, and the citric acid cycle enzymes *IDH1/2*, *SDHA/*B, and *FH*. This suggests a role for TET2 as an energy sensor of 2-OG that may modify androgen-AR signaling based on the metabolic state of the cell. Decreased *TET2* mRNA expression in TCGA PCa tumors is strongly associated with reduced patient survival indicating reduced *TET2* expression in tumors maybe an informative biomarker of disease progression.

RNA polymerase II pausing regulates human gene expression including EGF signaling pathway. *J.M. Boden[1], V.G. Cheung[2,3,4].* 1) Cancer Biology Graduate Program; 2) Life Sciences Institute; 3) Howard Hughes Medical Institute; 4) Departments of Pediatrics and Human Genetics, University of Michigan, Ann Arbor, MI.

This project focuses on promoter-proximal RNA Polymerase II (RNA Pol II) pausing and its effects on global transcription and cellular functions. Pausing of RNA Pol II occurs 20-60 nucleotides downstream of transcription start sites through interactions with the pausing factors negative elongation factor (NELF) and DRB sensitivity-inducing factor (DSIF). In human cells, the expression levels of a few genes such as *MYC* and *JUNB* are known to be regulated through RNA Pol II pausing; however, little is known about the global effects of RNA Pol II pausing on human gene expression and cellular functions (Krumm, A. et al. 1992, Aida, M. et al. 2006). Here, we show that RNA Pol II pausing regulates thousands of human genes, including those in the epidermal growth factor (EGF) signaling pathway. First, we generated a genome-wide profile of paused RNA Pol II by PRO-seq (Kwak, H. et al. 2013) which identified proximal promoter pausing at over 7,800 human genes. We then confirmed the presence of RNA Pol II and the pausing factors NELF and DSIF at the promoter regions of these genes by ChIP-seq. To identify genes whose expression levels are regulated by the pausing factors, we knocked-down NELF and examined changes in pausing and gene expression. Following loss of NELF, we found that over 1,200 genes show a decrease in pausing as well as altered expression. Many of these genes are members of the EGF signaling pathway, including the EGF receptor (EGFR). Because EGFR is a driver of many human cancers, it has been the target of a number of successful therapies. However, patients commonly develop resistance to these treatments. A detailed understanding of transcriptional regulation of EGFR may enable development of strategies to overcome this resistance. To this end, we explored how EGF signaling is regulated by RNA Pol II pausing. We validated that EGFR transcript and protein levels increase upon loss of pausing. We then found that the increased EGFR expression results in an increased response to EGF stimulation as measured by the expression of *CDKN1A* and *CCND1*. In this presentation, we will show that pausing regulates EGFR expression and subsequently its function. We will present data on the effect of pausing on ERK kinase phosphorylation, its target gene expression and cell cycle progression.

2971W

Integrated multi'omics analysis identifies pathogenetic molecular phenotypes of lung cancer and COPD. *V.D Martinez[1], E.A. Vucic[1], K.L. Thu[1], E.A Marshall[1], K.S.S Enfield[1], B.C Minatel[1], S. Rahmati[2], M. Abovsky[2], I. Jurisica[2], C.E. MacAulay[1], S. Lam[1], R.T. Ng[3], W.L. Lam[1].* 1) Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, Canada; 2) Princess Margaret Cancer Centre, Toronto, ON, Canada; 3) PROOF Centre of Excellence, St. Paul's Hospital, Vancouver, BC, Canada.

Background: Inflammatory processes are associated with an increased cancer risk in multiple organs. Chronic obstructive pulmonary disease (COPD) is an inflammatory lung disease associated with a 10-fold increased risk of lung cancer (LC), independent of smoking habits. We hypothesized that lung tumors arising from COPD and non-COPD patients exhibit molecular phenotypes reflective of distinct and specific biology underlying tumorigenesis in COPD patients. Here, we aim to identify disrupted functional gene networks associated with COPD, that contribute to the biology of COPD-related lung cancer. **Methods:** Genome-wide multi-omics profiling (copy number, DNA methylation, mRNA) was performed on tumor and normal lung tissues (n=146). Additionally, mRNA expression levels from non-cancerous, small (<2 mm) airways from COPD and non-COPD patients (n=267) were also analyzed. Integrated gene scores were generated based on magnitude and disruption of DNA and mRNA level change, on a per sample pair basis. Cluster analysis was carried out using the non-negative matrix factorization method. Module-based functional analyses were performed using the weighted gene co-expression network analysis (WGCNA) algorithm. Functional analyses were done using IPA and pathDIP algorithms. **Results:** Globally, COPD and non-COPD lung tumors cluster separately based on their gene integrated scores. COPD-related lung tumors are differentially enriched for gene sets associated with senescence (PITX2), lung malignancies (NR2F2, SP1, PPARG) and inflammation-associated fibrosis and cancer of the liver (HNF4A). A module-based co-expression network analysis identified XBP1/SEC31A/COG3 as the most significantly enriched gene regulatory network in non-cancerous COPD tissues (p = 9.01E-08), as well as highly altered at DNA and mRNA levels COPD-tumors. Interestingly, these networks have been associated with inflammatory liver disease, cirrhosis, proliferation of hepatocytes and liver cancer. **Conclusions:** COPD and non-COPD lung tumors harbor distinct biological processes. The identification of common regulatory network between non-cancerous COPD tissue and COPD-related lung cancer reflects the interplay of both diseases and reveals involvement of tumor-inducing mechanisms related to chronic inflammation in other organs. These and other gene networks altered in non-cancerous airway cells associated with LC in COPD patients may represent ideal targets for LC risk stratification or therapy.

Epigenetic signature of Gleason score and prostate cancer recurrence after radical prostatectomy. *M.S. Geybels[1,2], J.L. Wright[1,3], M. Bibikova[4], B. Klotze[4], J. Fan[4], S. Zhao[5], Z. Feng[6], E.A. Ostrander[7], D.W. Lin[1,3], P.S. Nelson[8,9,10], J.L. Stanford[1,11].* 1) Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Department of Epidemiology, GROW School for Oncology and Developmental biology, Maastricht University, Maastricht, The Netherlands; 3) Department of Urology, University of Washington School of Medicine, Seattle, Washington; 4) Illumina, Inc., San Diego, California; 5) National Institute of Environmental Health Sciences, Biostatistics & Computational Biology Branch, Research Triangle Park, North Carolina; 6) Department of Biostatistics, MD Anderson Cancer Center, Houston, Texas; 7) Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, NIH, Bethesda, Maryland; 8) Division of Human Biology, Fred Hutchinson Cancer Research Center, Seattle, Washington; 9) Division of Clinical Research, Fred Hutchinson Cancer Research Center, Seattle, Washington; 10) Department of Medicine, University of Washington School of Medicine, Seattle, Washington; 11) Department of Epidemiology, University of Washington School of Public Health, Seattle, Washington.

Background Identifying the subset of patients with localized prostate cancer at the highest risk of recurrence remains challenging and better prognostic markers are needed. DNA methylation patterns in tumors cells may predict prostate tumors' aggressiveness potential. The aim of this study was to identify an epigenetic signature of Gleason score (or tumor grade), the best predictor of prostate cancer prognosis, and evaluate its ability to predict prostate cancer recurrence after radical prostatectomy. **Methods** Genome-wide DNA methylation data from The Cancer Genome Atlas (TCGA; No. prostate cancer patients = 333) and the Elastic Net method were used to generate the tumor epigenetic signature. The signature was created by contrasting patients with high (8–10) versus low (≤6) Gleason score tumors. The signature was then tested for its ability to predict prostate cancer recurrence in another cohort of 431 patients with localized prostate cancer who had radical prostatectomy as primary treatment and were prospectively followed for recurrence (mean follow-up time = 8 years). Samples taken from the primary tumor were used for DNA methylation profiling. **Results** The epigenetic signature of Gleason score includes 52 differentially methylated CpG sites. In the validation cohort, the signature was associated with poorer recurrence-free survival (hazard ratio per 25 percent increase = 1.78; 95% confidence interval: 1.48, 2.16), which remained significant after adjusting for standard clinical-pathological parameters. Among patients with Gleason 7 tumors, which are heterogeneous and have a variable prognosis, the signature significantly improved the Area Under the Curve (AUC) for prostate cancer recurrence compared to clinical-pathological parameters alone (0.64 vs. 0.76, P = 1.34E-4). Results were similar for patients with Gleason 3+4 and those with 4+3 tumors. The signature includes CpGs in different genes, which are enriched for genes encoding cell cycle-related targets of E2F transcription factors (e.g., *PLK1*, *CDC25B*, *MKI67*, and *RRM2*). **Conclusions** This study shows evidence that DNA methylation patterns measured in prostate tumor cells are predictive of prostate cancer aggressiveness. The epigenetic signature may have clinical utility to improve prognostication particularly in patients with intermediate grade tumors that have a Gleason score of 7.

2973F

Internal smoking dose is associated with specific blood DNA methylation patterns and with different magnitude across race/ethnicity. *S.L. Park[1], Y.M. Patel[1], M. Tiirikainen[2], D.O. Stram[1], K. Siegmund[1], S.E. Murphy[3], L. Le Marchand[2].* 1) University of Southern California, Los Angeles, CA; 2) University of Hawaii Cancer Center, Honolulu, HI; 3) University of Minnesota, Minneapolis, MN.

Lung cancer is the most common cancer in the U.S. and leading cause of cancer-related death. While, cigarette smoking is the primary cause of this malignancy, risk differs across racial/ethnic groups. For the same number of cigarettes smoked, Native Hawaiians (NH) compared to whites, are at greater risk of lung cancer, while Japanese Americans (JA) are at lower risk of disease. DNA methylation of CpG sites as a result of cigarette smoking is one of the most common epigenetic modifications. Prior methylation studies have found that current smoking status was associated with differential methylation patterns from leukocytes in 26 genetic regions. However, the influence of internal smoking dose on the epigenome has not been investigated, nor has a study evaluated whether for the same smoking dose, peripheral blood DNA methylation patterns differ by race. Here, we have conducted an epigenome-wide association study for urinary nicotine equivalents (NE), which is an optimal marker of internal smoking dose, as opposed to smoking history or cotinine, since NE is not biased by self-report and reflects inter-individual variation in nicotine metabolism. This study includes 612 current smokers at time of specimen collection, from three racial/ethnic groups: whites, NH and JA. Genome-wide DNA methylation in blood leukocytes was measured using the Illumina 450K BeadChip array. Distribution of leukocyte cell-types (based on methylation data) were estimated for each sample (https://labs.genetics. ucla.edu/horvath/dnamage/). Average beta-values or the ratio of methylated probe intensities (i.e. intensity of the Methylated allele [M] / (intensity of the Unmethylated allele [U] + M)) was the dependent variable in linear regression models adjusting for age, sex, race (for pan-ethnic analysis) and cell-type distribution. We found that NE was associated with six differentially methylated probes (Bonferoni corrected $p < 1.48 \times 10^{-7}$) in or near the *FOXK2*, *PBX1*, *FNDC7*, *FUBP3*, and *BSND* genes, where higher levels of NE were associated with increasing beta-values in all six probes. These six probes also had statistically significant interactions by race, where the strongest associations were found in NH, suggesting that NH have greater differential DNA methylation patterns, compared to whites and JA (p-interaction$<8.8 \times 10^{-8}$), in relation to smoking dose. In conclusion, NE is associated with specific DNA methylation of leukocytes and these patterns differ in magnitude by race/ethnicity.

Microvesicular miRNAs regulate gene expression in local lung adenocarcinoma stromal cells. *J. Lawson[1,2], C. Dickman[1,2], S. MacLellan[1,2], R. Towle[1,2], C. Garnis[1,2].* 1) University of British Columbia, Vancouver, British Columbia, Canada; 2) BC Cancer Research Center, Department of Integrative Oncology, Vancouver, British Columbia, Canada.

   Introduction: Microvesicles are small vesicles released from all cell types which can be used as a form of cell to cell communication. Recently tumor derived microvesicles have been shown to play a key role in cancer development, growth, progression and angiogenesis. These microvesicles can be loaded with functional mRNAs, miRNAs and proteins which can be transferred from one cell to another. miRNAs within microvesicles differ in disease states compared to those derived from normal cells resulting in cancer microvesicles containing altered miRNA profiles. Tumor derived microvesicles have been known to enter neighboring cells including the surrounding stroma, and have been detected in virtually all types of biofluids. Our research shows that miRNAs transferred from lung adenocarcinoma cells through microvesicles can influence gene expression in endothelial cells and increase their ability to form new blood vessels. **Materials and Methods:** Using 5 lung adenocarcinoma cell lines H1395, H1437, H2073, H2228 and H2347 we isolated microvesicles using differential ultracentrifugation. RNA was extracted from the microvesicles as well as the cells from which they were derived. RNA was profiled for 742 miRNAs using the miRCURY LNA™ Universal RT miRNA PCR system to identify miRNAs that were enriched in the microvesicles. Isolated microvesicles were also co-cultured with endothelial cells (HMEC-1) to assess the ability of the cells to form capillary like structures. **Results:** An enrichment of a select set of miRNAs within the lung adenocarcinoma microvesicles were identifed. These miRNAs have previously been identified as tumor suppressors: miR-142-3p, miR-143-3p, miR-144-3p, miR-145-5p, miR-150-5p, miR-223-3p, miR-451a, miR-486-5p, miR-605-5p. When exosomes from miRNA over expressing adenocarcinoma lines were incubated with HMEC-1 cells an increase in their ability to form new blood vessels was observed. Several of these miRNAs were also found to be enriched in serum samples draining directly from lung adenocarcinoma tumors compared to arterial serum. **Significance:** Identifying key miRNAs in cancer-stromal signaling will allow for us to better understand this interaction, and potentially identify targets for novel therapeutics in order to better combat this disease. .

Parent of origin effect of hypomorphic mutations explains low penetrance in retinoblastoma not due to mosaicism of full mutations. *V. Imperatore[1], A.M. Pinto[1,2], S. Amitrano[2], S. Somma[1,2], M. Bruttini[1,2], E. Trevisson[6], T. Hadjistilianou[3], S. de Francesco[3], P. Toti[4], E. Gusson[5], M.A. Mencarelli[1,2], F. Mari[1,2], A. Renieri[1,2], F. Ariani[1,2].* 1) Medical Genetics, Department of Medical Biotechnology, University of Siena, Policlinico 'Santa Maria alle Scotte', SIENA, Italy; 2) Medical Genetics, Azienda Ospedaliera Universitaria Senese, Siena, Italy; 3) Unit of Ophthalmology. And Retinoblastoma Referral Center, Department of Surgery, University of Siena, Policlinico 'Santa Maria alle Scotte', Siena, Italy; 4) Department of Human Pathology and Oncology, Section of Pathology, University of Siena, Policlinico 'Santa Maria alle Scotte', Siena, Italy; 5) Unit of Ophthalmology, Azienda Ospedaliera Universitaria Integrata, Verona, Italy; 6) Departement of Woman and Child Health, University of Padova Istituto di Ricerca Pediatrica, IRP, Città della Speranza, Padova, Italy.

   Incomplete penetrance in retinoblastoma (RB), one of the more extensively studied pediatric cancer, is still an unsolved question. In 2009, it has been demonstrated a ~ 3 fold excess of the *RB1* maternal canonical transcript due to an imprinting mechanism. As a consequence, maternally inherited hypomorphic mutations may retain sufficient suppressor activity to prevent tumor development. Here, we change the perspective of retinoblastoma field demonstrating a differential allelic expression of hypomorphic variants that significantly influence the phenotypic outcome in families at risk for RB onset. In one family, the father who presented with retinoma and the two children who developed retinoblastoma were all identified harboring an hypomorphic splicing variant (c.2663+2T>C). RT-PCR quantitative analysis showed a higher expression of the abnormally spliced product in the father along with an inversion of the ratio between the two differentially spliced isoforms. A parent-of-origin-effect was demonstrated for another hypomorphic mutation (p.Arg661Trp) able to induce RB in a child of a male carrier with an anamnestic history positive for osteosarcoma. For the first time, here we also identified somatic mosaicism as important factor that can impact the phenotype expression. Indeed, segregation analysis performed by high-depth NGS assay in other families, showed a ~ 50% of mutated molecules in the proband with retinoblastoma in comparison with a 25% in one parent with retinoma, accordingly with a somatic mosaicism. These findings underline the importance of performing high-sensitivity NGS for RB diagnosis and completely change the genetic and prenatal counselling and the clinical management of the families.

2976F

Mapping of differential allelic protein binding in eQTL SNPs associated with prostate cancer. *L. Tillmans[1], S. McDonnell[1], P. Zhang[2], M. Larson[1], S. Riska[1], Z. Fogarty[1], N. Larson[1], S. Baheti[1], D. Schaid[1], L. Wang[2], S. Thibodeau[1]. 1) Mayo Clinic, Rochester, MN; 2) Medical College of Wisconsin, Milwaukee, WI.*

In a previous study, we created a normal prostate tissue eQTL database using 471 tissue samples from patients with low Gleason grade prostate cancer, from which we identified 88 genes from 51 risk regions with eQTL signals. To identify possible functional SNPs for each of the risk-regions, we utilized a novel assay to test differential allele binding of each selected SNP to proteins in LnCap cells with and without androgen treatment. We chose 28 of our 51 eQTL positive risk regions for further study. For 24 of these regions, all significant eQTL SNPs that had r2 >0.5 with the risk SNP were examined along with a few from the remaining 4 regions (total number of SNPs tested was 1274). After quantifying the oligos that were bound to proteins by DNA sequencing, the ratio of oligo counts was determined and normalized with input ratios from a library of oligo mix. After excluding SNPs with low confidence, there were 683 high quality SNP sites (53%) representing 27 regions for further analysis. We found that low confidence SNP sites were correlated with low GC% (<40%). Significant allelic ratios were defined as less than 0.65 or greater than 1.5 (range 0.11-10.9). For androgen treated LnCap cell lines, 37% of the SNPs showed a significant ratio difference and untreated cell lines had 43%. We also compared the allelic ratio between the treated and untreated nuclear extracts and found 9% had significant ratio differences indicating a functional change under androgen stimulation. Finally, we looked at the oligos containing the SNP in programs such as MATCH ™ to find specific transcription binding proteins at these motifs. For example, the SNP rs113082846 on chromosome 10 shows a strong eQTL signal with the gene *NCOA4* [MIM: 601984] (p value 5.32 E-52). NCOA4 is an androgen receptor coactivator. In our binding analysis, the ratio of alternate allele C to reference G allele was 8.25 in androgen treated cell line nuclear extract and 10.09 in untreated extract. When the experimental oligo sequence with the C allele was entered in MATCH™, a binding site for ELK-1 (transcription activator) was reported with a core match of 1.000 and a matrix match of .988. No binding sites were reported for the G allele. Utilizing our experimental data along with bioinformatics tools provides a strategy for identifying candidate functional elements for prostate cancer susceptibility loci to help guide subsequent laboratory studies.

2977W

Onco-exaptation: Endogenous retroviral LTRs as promoters of oncogenic transcripts in cancer. *A. Babaian[1,2], Y. Zhang[1,2], L. Gagnier[1,2], M.T. Romanish[1,2], D.L. Mager[1,2]. 1) Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada; 2) Medical Genetics, University of British Columbia, Vancouver, BC, Canada.*

Exaptation is the incorporation of transposable elements (TEs) into functional, and in some cases necessary, genes or regulatory units over evolutionary time. We postulate that an analogous process occurs in oncogenesis, where TE-derived promoters generate "noisy" transcription and novel transcripts, which can be exploited and selected for to drive cancer transcriptome evolution. Such "onco-exaptation" of TE promoters occurs in Hodgkin Lymphoma (HL), resulting in expression of the oncogenes *CSF1R* and *IRF5*, but it is unclear how widespread this mechanism is. We hypothesize that epigenomic dysregulation in cancer leads to a genome-wide derepression of TE-initiated transcripts, some of which can play an oncogenic role. To begin to test this hypothesis, we developed a computational tool called 'LIONS' to analyze RNA-sequencing data for TE-initiated transcripts, specifically those driving the expression of coding genes or long non-coding RNAs. *LIONS* detects and quantifies TE-initiated transcripts through transcriptome assembly, applies a novel artificial neural network classifier to identify TE promoter events, and compares biological sets of data. Using this tool, we determined that the HL transcriptome has an overall increase in TE-initiated transcripts relative to non-cancerous B-cell controls. This increase is specifically driven by an increase in endogenous retroviral long terminal repeat (LTR) initiated transcripts in the HL transcriptome relative to the B-cell control (148.3 N =12 vs. 90.2 N=9 respectively, t-test P = 0.0024). The sets of TE-initiated transcripts across HL samples are more diverse compared to B-cells. However, certain TE-initiated transcripts are exceptionally recurrent and specific to HL, including the known LTR-driven oncogene transcripts of *CSF1R* and *IRF5,* as well as the enticing cases of *RALB* and *IL1R2* (reported to be greatly overexpressed in HL). A similar phenomenon of LTR derepression was observed in cells treated with the DNA demethylating agent 5-azacytidine, in cells in replicative senescence and in other cancers such as diffuse large-B-cell lymphoma and colorectal carcinoma, relative to their respective controls. We propose that this process of onco-exaptation is a distinct mechanism for oncogene activation and a model for studying exaptation and transcriptome evolution.

2978T

A novel isoform of IL-33 revealed by screening for retroelement activated genes in colorectal cancer. *F.E. Lock[1,2], Y. Zhang[1,2], L. Gagnier[1,2], A. Babaian[1,2], S. Kuah[1,2], D.L. Mager[1,2].* 1) Terry Fox Laboratory, British Columbia Cancer Agency, 675 West 10th Avenue, Vancouver, BC, V5Z1L3, Canada; 2) Department of Medical Genetics, University of British Columbia, 675 West 10th Avenue, Vancouver, BC, V5Z1L3, Canada.

Remnants of transposable elements (TEs) are abundant in the human genome. TEs, particularly long terminal repeats (LTRs) of endogenous retroviruses, contain enhancers and promoters and are capable of influencing genes. TEs can be released from epigenetic repression and become transcriptionally active in cancer, which can lead to activation of oncogenes, as described in two types of lymphoma. However, there are no reports of this mechanism in solid cancers. Here, we analyzed RNA-Seq data from 66 patients with colorectal cancer (CRC), compared to matched normal colon, to detect genes expressed through activation of TE promoters. We found an overall increase in LTR-initiated chimeric transcripts in CRC. Among these, we identified six such transcripts, where the gene has some known role in cancer, that are expressed in CRC but not normal colon, including an LTR-driven form of the ion transporter *SLCO1B3*, previously reported as cancer-specific. We confirmed expression of the six transcripts in CRC cell lines and further characterized one involving Interleukin 33 (LTR-*IL-33*) that is expressed in a subset of CRC samples through use of an ancient LTR promoter in an intron. The LTR promoter is silent in normal colon but its usage in CRC, combined with the native promoter, leads to an overall increase in *IL-33*. IL-33 is thought to play a role in solid tumors, including CRC, where it promotes polyposis and a tumorigenic microenvironment. IL-33 functions as a cell-free cytokine and also in the nucleus, where it acts as a transcriptional repressor through its N-terminal homeodomain-like region (amino acids 1-65). The LTR-*IL-33* transcript encodes a novel chimeric isoform of the protein, which is N-terminally truncated, missing the first 41aa, including highly conserved motifs. LTR-IL-33 is expressed in 3 out of 12 CRC cell lines tested, where its activity is linked to DNA hypomethylation. Transient LTR-IL-33 depletion using siRNA in these lines did not result in detectable changes in cell morphology or proliferation. LTR-IL-33 expression is regulated by cell confluence and is found in the nucleus of expressing cells, similar to native IL-33. Future studies will evaluate LTR-IL-33 function as a transcriptional regulator of the known native IL-33 target NF-κB p65, and assess LTR-IL-33 extracellular release and tumorigenicity of expressing cells. Taken together, these data demonstrate the significance of TEs as regulators of aberrant gene expression in colon cancer.

2979F

Polymorphisms of the *XRCC3* and *XPD* genes and risk of head and neck squamous cell carcinoma. *K. Chukka[1], Z. Vishnuvardhan[2], U. Radhakrishna[3].* 1) Biotechnology, Acharya Nagarjuna University, Guntur, Andhra Pradesh, India; 2) Department of Botany and Microbiology, Acharya Nagarjuna University, Nagarjuna Nagar, Guntur, India; 3) Department of Obstetrics and Gynecology, Oakland University- William Beaumont School of Medicine, Royal Oak, MI, USA.

The actual burden of Head and Neck Cancer (HNC) in India is much greater than previous literature suggested, as evidenced by the recent reports of *'Net-based Atlas of Cancer in India'*. Southeast Asia is likely to face a sharp increase of over 75% in the number of cancer deaths by 2020 as compared to 2000. DNA-repair genes play an important role in protecting individuals from cancer-causing agents. Single-Nucleotide Polymorphisms (SNPs) are the most common form of genetic variation found in the human population. The aim of this study was to evaluate the association between polymorphisms in *XPD* (Lys757Gln) and *XRCC3* (Thr245Met) with cases with head and neck squamous cell carcinoma (HNSCC). Sixty cases with HNSCC were selected from the Department of Radiotherapy, Government General Hospital, Guntur, AP, India. An age and sex-matched control group of healthy subjects (n=60) was used to compare the frequency of polymorphic variants. We studied the risk of HNSCC in relation to common non-synonymous SNPs in two DNA repair genes: *XPD* (Lys757Gln) and *XRCC3* (Thr245Met). DNA was extracted from peripheral blood. SNPs were genotyped by direct sequencing. Results: No differences were observed among the studied groups with regard to the genotype distribution of *XPD* (Lys757Gln), and *XRCC3* (Thr245Met). 79 % of the HNSCC cases were heterozygous and only 21% of the cases were homozygous. All the controls were heterozygous. Conclusion: *XPD* (Lys757Gln), and *XRCC3* (Thr245Met) may not be useful as biomarkers for HNSCC. The analysis of other genetic factors along with this parameter may provide the gateway for personal risk assessment and an opportunity for individualized therapy. We suggest that large and well-designed studies of common polymorphisms in DNA repair genes are needed. Such studies may benefit from analysis of polymorphisms as well as from the consideration of relevant exposures that may influence the likelihood of HNSCC when DNA repair capacity is reduced.

2980W

Autism linked to increased oncogene mutations but decreased cancer rate. *B. Darbro[1,2,3,4], R. Singh[1,5], M. Zimmerman[6], V. Mahajan[7,8], A. Bassuk[1,2,3,9,10,11,12]*. 1) Department of Pediatrics, Division of Medical Genetics, University of Iowa, Iowa City, Iowa, United States of America; 2) Interdisciplinary Program in Genetics, University of Iowa, Iowa City, Iowa, United States of America; 3) Roy J. and Lucille A. Autism spectrum disorder (ASD) is one phenotypic aspect of many monogenic, hereditary cancer syndromes. Pleiotropic effects of cancer genes on the autism phenotype could lead to repurposing of oncology medications to treat this increasingly prevalent neurodevelopmental condition for which there is currently no treatment. To explore this hypothesis we sought to discover whether autistic patients more often have rare coding, single-nucleotide variants within tumor suppressor and oncogenes and whether autistic patients are more often diagnosed with neoplasms. Exome-sequencing data from the ARRA Autism Sequencing Collaboration was compared to that of a control cohort from the Exome Variant Server database revealing that rare, coding variants within oncogenes were enriched for in the ARRA ASD cohort ($p < 1.0 \times 10^{-8}$). In contrast, variants were not significantly enriched in tumor suppressor genes. Phenotypically, children and adults with ASD exhibited a protective effect against cancer, with a frequency of 1.3% vs. 3.9% ($p < 0.001$), but the protective effect decreased with age. The odds ratio of neoplasm for those with ASD relative to controls was 0.06 (95% CI: 0.02, 0.19; $p < 0.0001$) in the 0 to 14 age group; 0.35 (95% CI: 0.14, 0.87; $p = 0.024$) in the 15 to 29 age group; 0.41 (95% CI: 0.15, 1.17; $p = 0.095$) in the 30 to 54 age group; and 0.49 (95% CI: 0.14, 1.74; $p = 0.267$) in those 55 and older. Both males and females demonstrated the protective effect. These findings suggest that defects in cellular proliferation, and potentially senescence, might influence both autism and neoplasm, and already approved drugs targeting oncogenic pathways might also have therapeutic value for treating autism.

2981T

RNA-seq analysis of Tmed2[99J/WT] mice with NAFLD and liver tumor. *A. Djedid[1], J. Majewski[1], L. Majewska[2]*. 1) McGill University and Genome Quebec Innovation Center, Montreal, Quebec, Canada; 2) Department of Human Genetics, McGill University, Montreal, Quebec, Canada.

Non-Alcoholic Fatty Liver Disease (NAFLD) is characterized by the accumulation of extra fat in liver cells not caused by alcohol. This disease can evolve in cancer and is becoming a major cause of hepatocellular carcinoma in the US. Recently, Dr. Majewska research laboratory identified a null allele of Transmembrane emp24 domain-containing protein or p24 (TMED2/p24) in an N-ethyl-N-nitrosourea (ENU) mutagenesis screen for recessive developmental abnormalities, in which 99J homozygous mice embryos present developmental delay, abnormal rostral-caudal elongation, randomized heart looping, absence of the labyrinth layer of the placenta, and death at mid-gestation. It has been reported that TMED2/p24 regulates protein-cargo selection and vesicle budding. TMED2/p24 is also required for liver homeostasis and liver development. In the current study, we investigate mechanisms underlying NAFLD and liver tumor pathogenesis in 99J heterozygous mice. We performed an integrated analysis on liver samples from four C3H/HeJ mice and four Tmed2[99J/WT] mice with NAFLD and tumor in order to identify genes that are differentially expressed between our controls and NAFLD/liver tumor samples, as well as fusions and splicing events. To achieve this, we built an in-house pipeline that uses latest efficient (open-source) RNASeq tools: STAR, HTSeq and DESeq for expression analysis, STAR-Fusion and GMAP-Fusion for fusion detections, then rMATS, MISO and Cufflinks for splicing event detections. David Pathway Analysis was used to determine dysregulated pathways in Tmed2[99J/WT] mice. In tumor samples, more than 750 genes were dysregulated. David analysis on these samples showed an up-regulation of genes implicated in cancer pathways. The Splicing analysis demonstrated a difference in RNA isoform expression between control and tumor samples of genes implicated in processes related to cancer such as cell death, immune system processes, protein metabolic processes, cell proliferation.

Generation of PCS (MVA) syndrome mutation knock-in mice using CRISPR/Cas9-mediated genome editing technology. *K. Hosoba, T. Miyamoto, S. Matsuura. Department of Genetics and Cell Biology, Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan.*

Germline mutations of *BUB1B* gene encoding BUBR1, a central molecule of mitotic spindle assembly checkpoint, cause an autosomal recessive disorder PCS (MVA) syndrome ([MIM:176430]), which is characterized by constitutional aneuploidy, a high risk of childhood cancer and ciliopathy disease spectrum, including polycystic kidney and Dandy Walker anomaly. We previously reported that seven Japanese patients were compound heterozygotes for an exonic null mutation and an intergenic mutation located 44 kb upstream of the *BUB1B* transcription start site. It was reported that *BUB1B* knockout mice (*BUB1B-/-*) were embryonic lethal (Baker et al, 2004), while *BUB1B* hypomorphic mice (*BUB1B$^{H/H}$*) with 90% reduction in BUBR1 protein expression showed cellular senescence in most organs to induce accelerated aging and did not show cancer susceptibility. To validate the phenotypic difference between PCS (MVA) syndrome patients and *BUB1B$^{H/H}$* hypomorphic mice, here we generated PCS ;(;MVA); syndrome mutation knock-in mice. Co-microinjection of Cas9 mRNA, guide RNA for exon15 of *BUB1B*, and single stranded oligodeoxynucleotides (ssODN) with c.1833delT (F611fsX625) *BUB1B* mutation as a targeting donor into mouse fertilized eggs enabled to introduce the human mutation into mouse genome quickly. During this process, we also obtained a mouse carrying a 12-bp deletion (Δ608-611 LAST) in exon 15 of *BUB1B,* which was likely a hypomorphic mutation. These mutations were transmitted into germline. Currently we are crossing these mice to generate PCS (MVA) syndrome model mice.

2983W

Analysis of NF-kB activation compared to seric levels and genic expression of TNF-alfa in patients with sporadic colorectal cancer. *U. Santana[1,4], E. Torres-Anguiano[1,4], L. Bobadilla-Morales[1,2], B. González-Quezada[1], V. Maciel Gutiérrez[3], M. Centeno Flores[3], J. Corona Rivera[1], H. Pimentel Gutiérrez[2], C. Ortega de la Torre[2], A. Corona Rivera[1,2]. 1) Laboratorio de Citogenética, Genotoxicidad y Biomonitoreo", Instituto Dr. Enrique Corona Rivera", CUCS, U de G; 2) Unidad de Citogenética y Servicio de Colon y Recto, Nuevo Hospital Civil de Guadalajara, "Juan I. Menchaca; 3) Servicio de Colon y Recto, Hospital Civil de Guadalajara "Dr. Juan I. Menchaca; 4) Doctorado en Ciencias en Biología Molecular en Medicina, CUCS, UdeG.*

The transcription factor NF-kB regulates several genes associated with cancer development, constitutive activation in colorectal cancer (CRC) patients has been reported. TNF- α is the main molecule associated with NF-kB activation. The aim of this study was to determine NF-kB activation status compared with *TNF-α* protein and mRNA levels in tumor tissue and normal adjacent tissue from the same patient with sporadic CRC, and analyze the mRNA levels of genes regulated by NFkB (*BIRC5, Bcl-2, c-Myc, TNF, PTGS1, NFKBIA, LOX, NFkB1, VEGF y CTNNB1*). Patients were classified into 2 groups: CRC advanced stages (CAS= III and IV, n = 11) and CRC early stages (CES= I and II, n = 9). Tumor and normal tissue were collected during surgery; we obtained cells for the NF-kB activation analysis, evaluating the p65 subunit phosphorylation by flow cytometry. The samples also underwent to RNA extraction for later cDNA synthesis. qRT-PCR were performed for *TNF-α, BIRC5, Bcl-2, c-Myc, TNF, PTGS1, NFKBIA, LOX, NFkB1, VEGF* and *CTNNB1* genes, we use the *GUS, ABL* and *ACTB* constitutive genes for assay validation. Comparative Ct method (ΔCt) was used to analyze the mRNA levels.Venous blood samples (5–10 mL) were collected in vacutainer tubes from CRC patients (CP) and controls (CTRL), serum was obtained and stored at −70°C until processed using ELISA. p65 imunostaining showed greater activation of NF-kB in tumor than in normal tissue, this were increased during CRC progression. *GUS* and *ACTB* were validated for CRC expression assays, we showed that *ABL* can be used in similar studies. All analyzed genes presented mRNA overexpression in tumor compared to normal tissue, although significant differences were observed just in *BIRC, PTGS. ALOX, TNF* and *NFKBI* genes, it was gradually increased during CRC progression. TNF- α serum levels were higher in CP compared to CTRL (11.18; 1.85 pg/ml), and CES presents elevated levels compared to CAS (15.3; 7.05 pg/ml). Our findings suggest that NF-kB is greatly activated in CRC tissue compared to normal tissue and it correlates with tumor progression. Simultaneously, NF-kB regulated genes exhibit overexpression in tumor compared to normal tissue;could be due to their activity in CRC processes. TNF-α serum levels were elevated in CRC patients, showing higher levels in CES, possibly due to inflammation.

2984T

Animal models support *TNS1* gene involvement in wild type GIST development. *N. Settas[1], F. Faucz[1], T. Silva[1], E. Rapizzi[2], M. Mannelli[2], S. Reincke[1], A. Sen[3], R. Cox[3], M. Miettienen[4], S. Lo[5], J.A. Carney[6], C.A. Stratakis[1].* 1) Section on Endocrinology & Genetics (SEGEN), NICHD, NIH, Bethesda, MD, USA; 2) Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; 3) Department of Biochemistry and Molecular Biology, Uniformed Services University, Bethesda, MD, USA; 4) Department of Diagnostic Pathology, National Cancer Institute (NCI), NIH, Bethesda, MD, USA; 5) epartment of Biochemistry and Molecular Medicine University of California - Davis Sacramento, CA, USA; 6) Laboratory of Pathology, Mayo Clinic, Rochester, MN, USA.

Tensin 1 (*TNS1*) is a cytoplasmic protein that is located on the integrin-mediated cell-basement membrane junctions and is implicated in cytoskeletal organization, cell migration, and proliferation. It is known that *tns1* knockout (KO) mice develop polycystic kidney disease, while the female mice also exhibit reduced fertility. *Drosophila Melanogaster Tns1* KO ("blistery" fly) develop defective wing unfolding and subsequent blister formation. Genome-wide association studies have linked *TNS1* to lung disease, asthma and colorectal cancer, and TNS1 expression is reduced or absent in several prostate and breast cancer cell lines. Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal neoplasms of the gastrointestinal tract. Most GISTs carry activating mutations in the *KIT* and/or *PDGFRA* genes; some cases are attributed to germline mutations in succinate dehydrogenase subunit genes (SDHx). However, up to 10% of GISTs do not have mutations in the above genes and are known as wild type (WT). Patients with WT GISTs show an epigenetic down-regulation of *SDHC* gene and abnormal mitochondrial structure. In this study, we screened 24 patients with WT GISTs for *TNS1* gene mutations and we identified 12 variants predicted to be damaging after *in silico* analysis. Fifty percent (12/24) of the patients exhibited at least one *TNS1* variant. Six variants were novel, 4 of which were missense (p.Y327C, p.G1306R, p.G1227D, and p.R984W); in addition, we found an insertion (c.1978insCAGCAG) and a somatic frameshift mutation (p.P890Qfs*96). We also found 6 previously described variants (one aminoacid deletion, one splice site mutation and 4 missense variants) with low frequency in the general population. We studied the blistery flies and the *tns1* KO mice: we identified in both structural mitochondrial defects, which are consistent with those described in patients with WT GISTs. Additionally, as observed in patients, we noted significantly lower levels of SDHB expression in the blistery flies. The KO flies had also significantly delayed SDH activity. We conclude that *TNS1* genetic variants are frequent in WT GISTs; both mouse and fly models of *tns1* inactivation indicate that *TNS1* gene may be important in regulating mitochondrial SDH function.

2985F

Influence of *CYPA4*1B*, *CYP3A5*3*, *GSTT1* and *GSTM1* polymorphims with treatment-related chronic myeloid leukemia. *E.P. Silveira-Lacerda[1], K.A. Delmond[1], D.C. Abreu[1], T.M. Pinto[1], R.M. Golveia[1], A.P. Barbosa[2], R.S. Tavares[2].* 1) Genetics Department, Federal University of Goias, Goiânia, Goiás, Brazil; 2) Hematology Department. Federal University of Goias, Goiânia, Goiás, Brazil.

Imatinib Mesylate (IM) (Gleevec™ [STI571]; Novartis Pharmaceutical Corporation, East Hanover, NJ), is used in Brazil as a first- line drug for Chronic Myeloid Leukemia (CML) treatment. The IM act as potent and selective inhibitor of BCR–ABL tyrosine kinase activity, however cases of treatment failure or of suboptimal response are sometimes seen. The cytochrome-P450 (CYP) system is involved in the oxidative metabolism of IM and the major pathway is catalyzed by CYP3A4/5. Further, phase II enzymes Glutathione S-transferases (GSTs) are involved in the metabolism of a wide range of xenobiotics, including chemotherapeutic drugs. *CYP3A4*, *CYP3A5* and *GST*s are polymorphic genes, thus genetic variations these genes could influence the treatment response to IM. This is the first study of CML patients Goias (Brazil) residents in order to associate the genotype of patients for polymorphims in metabolic genes with cytogenetic and molecular responses during treatment with IM. The study was conducted in accordance with the Declaration of Helsinki and was approved by a recognized ethics committee (*Comitê de Ética em Pesquisa do Hospital das Clínicas da Universidade Federal de Goiás*). A total of 114 CML patients in use of IM from Hospital das Clínicas-UFG, Goiânia, Goiás, Brazil, were enrolled in this study. Response criteria were based on European Leukemia Net recommendations. Genotyping was carried out for *CYP3A4*1B* (-392A>G (rs2740574)), *CYP3A5*3* (6986A>G (rs776746)), *GSTT1*0* (null allele) and *GSTM1*0* (null allele) polymorphisms by q-PCR. Statistical analysis was carried out using GraphPad Prism5® software. The X_2-test or Fisher's exact test was used to compare response and specific genotypes (α=0,05). The results revealed no statistical difference between evaluated polymorphisms *CYP3A4*1B, CYP3A5*3, GSTT1*0* and *GSTM1*0* and responses to treatment with IM (*P*>0,05). The same result was seen when comparison was performed with polymorphisms grouped for each patient (*P*>0,05). These findings have shown that in the studied population the polymorphisms *CYP3A4*1B, CYP3A5*3, GSTT1*0* and *GSTM1*0* do not influence the performance efficiency of the drug (IM). Subsequent investigations to other genes involved in IM metabolizing pathway should be performed.   .

Effects of G6PD activity inhibition on the viability, migration and morphology of cervical cancer cells. *F. Zishui, J. Chengrui, F. Yi, C. RiXin, L. XiaoYing, Z. ZhiQiang, H. LuHao, C. XiaoDan, Li. HongYi, G. YiBin, J. WeiYing.* Department of Medical Genetics, Zhongshan School of Medicine, Sun Yat-sen Univer, GuangZhou, China.

Glucose-6-phosphate dehydrogenase (G6PD) deficiency has been revealed to be involved in the efficacy to anti-cancer therapy but the mechanism remains unclear. We aimed to investigate the anti-cancer mechanism of G6PD deficiency. In our study, Dehydroepiandrosterone (DHEA) and shRNA technology were used for inhibiting the activity of G6PD of cervical cancer cells. Flow cytometry was used to detect the apoptosis and reactive oxygen species (ROS) generation. Scanning electron microscopy was used to observe cell morphology. And the migration rate of cell was also observed using the imaging system of inverted living cell microscope. When G6PD was inhibited by DHEA or RNA interference, idioblasts were observed in HeLa cells. Simultaneously, G6PD deficiency resulted in decreased HeLa cells migration and proliferation ability but increased ROS generation inducing apoptosis. What's more, the inhibition of G6PD activity caused filopodia and reticulopodium of cells shorten and reduce as well as cells shrinkage. Our results indicated the anti-cervix cancer mechanism of G6PD deficiency may be involved with the decreased cancer cells proliferation caused by the increased ROS and decreased migration ability as a result of abnormal filopodia and reticulopodium of cells. Suppression of G6PD may be a promising strategy in developing novel therapeutic methods for cervical cancer.

Role of a p53 polymorphism in the development of nonfunctional pituitary adenomas. *G. Yagnik, A. Jahangiri, R. Chen, J. Wagner, M. Aghi.* Dept of Neurosurgery, University of California San Francisco, San Francisco, CA.

Non-secreting pituitary adenomas are typically benign, non-familial tumors with estimated prevalence of 17%, making them the most common primary brain tumor. Their evolution varies from indolent slowly growing tumors to tumors that, while histologically benign, often reach sufficient size to limit their therapeutic options and destroy patients' quality of life. Investigations of the molecular etiology of adenomas have failed to identify prevalent genetic changes and, while a role for p53 has been suggested, to date no study on pituitary adenomas has performed a comprehensive search for genetic aberrations in the TP53 gene. We therefore performed the first complete exonic sequencing on a cohort of 35 non-functioning pituitary adenomas with paired lymphocytes obtained from blood. While no somatic mutations were discovered between the blood and adenoma tissue, we did note a significant frequency of a previously reported polymorphism associated with other cancers, rs1042522, in our cohort. The functional effect of this variant, however, has thus far been conflicting and cell-type specific. Population analysis showed most ethnic groups had a C allele in codon 72 leading to a proline residue (P72). In contrast, our pituitary adenoma cohort showed a higher prevalence of the G nucleotide in the same location, leading to an arginine residue (R72). The allelic frequency of R72 in our cohort (75.7%) showed a statistically significant difference as compared to control populations matched to the self-reported ethnicity of our pituitary patients (34.6%) ($p<1.09 \times 10^{-9}$), a far greater association than demonstrated for this polymorphism in other cancers. To understand the potential implications of the P72 and R72 residues in pituitary adenoma, we performed functional analyses examining the downstream effects of both variants, including transcription, proliferation and migration assays, as well as a pulse-chase assay to determine changes in protein half-life. The results show that the R72 variant reduces expression of cell arrest gene p21 and increases adenoma cell proliferation with increased protein survival as compared to P72. Taken together, these data suggest that the R72 variant survives longer and can drive an increased level of proliferation through reduced expression of p21, which normally modulates cell growth. This increased proliferation in pituitary cells may be responsible for the growth of the adenoma to surgical proportions.

2988F

Mitochondrial matrix HtrA Proteases plays key role in tumorogenesis and regulates mitochondrial gene expression in colorectal and prostate cancer cell lines. *N. Fatima[1], M.W. Hameed[1,2].* 1) Panjwani Centre for Molecular Medicine And Drug Research, International Centre For Chemical And Biological Sciences, University Of Karachi, Karachi, Sindh, Pakistan; 2) Molecular Biology Lab, MaxPlank, Germany.

The High Temperature Requirement A (HtrA) proteins are serine proteases that plays a significant role in quality control of cellular proteins in variety of organisms. They are mitochondrial chaperones, has role in oncogenesis, neurodenerative disorders, and apoptosis. Loss of HtrA function accumulates unfolded proteins, disrupts mitochondrial respiration, generates reactive oxygen species and leads to the proliferation of tumor cells while over expression of this family of proteases triggers cell death. Human HtrA proteases are of four types, HtrA1, HtrA2, HtrA3 and HtrA4. HtrA2/Omi resides in the mitochondrial intermembrane space (IMS), its paralogs HtrA1, 3 and 4 are most likely targeted to the secretory pathway. In the current study, we have used colorectal cancer cell lines (HCT-116) and prostate cancer cell lines (PC3) to analyze if this ATP depended protease family (HtrA and other proteases of the interacting pathway) effects mitochondrial genome expression and its regulation in this cancer. Prostate cancer is the most common non-dermatologic cancer of males and is a leading cause of death in Pakistani males. The incidence rate of colorectal cancer is also increasing worldwide, having relatively high incidence in western countries than in Asia and Africa. It's the seventh most common cancer in women and ninth most common cancer in men of Pakistan. We have induced the expression of these proteases in these cell lines through heat mediated stress and drug induced ER stress and then monitored the transcription level of these proteases through Real Time PCR. Protein level of these proteases are observed through western blotting. Reactive oxygen levels were also observed after induction of these proteases. Moreover, the effect of these proteases on mitochondrial gene expression was studied and interesting results were obtained. Overexpression of these proteases correlates with increase in transcription of mitochondrial genome and therefore, we can regulate the mitochondrial genetic machinery by targeting these proteases.

2989W

Dissecting TRIM8 role in the pathogenesis of glioma. *S. Venuto[1], M. Monti[2], I. Appolloni[3], T. Mazza[5], P. Pucci[2], P. Malatesta[3,4], G. Merla[1], L. Micale[1].* 1) IRCCS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, FG, Italy; 2) CEINGE Advanced Biotechnology and Department of Organic Chemistry and Biochemistry, Federico II University, Napoli, Italy; 3) U.O. Trasferimento Genico, IRCCS-AOU San Martino-IST, Genoa, Italy; 4) IRCCS AOU San Martino – IST, University of Genova, Italy; 5) Bioinformatics Unit, IRCCS Casa Sollievo della Sofferenza, Istituto Mendel, Italy.

Gliomas are among the most lethal brain tumors with a still unclear molecular pathogenesis. This study investigates the role of E3 ubiquitin ligase TRIM8, a member of tripartite motif (TRIM) protein family, in the pathophysiology of glioma. Our preliminary data corroborate mounting evidence showing a down regulation of TRIM8 in glioma and its role in controlling cell growth. Many experimental evidences showed that some TRIMs through their E3 ubiquitin ligase activity are involved in oncogenic processes by proteolytic degradation of regulatory proteins, including those involved in cell proliferation and apoptosis. We reasoned that defects in TRIM8 E3 ligase activity might promote carcinogenesis and cancerous growth in glioma cells by contributing to oncogenes stabilization, oncosuppressors degradation, and tumor-related pathway deregulation. To assess this hypothesis we profiled Trim8-related protein and transcript signatures in Neural Stem Cells overexpressing Trim8 (NSC-Trim8), by Mass Spectrometry and RNAseq. Proteomic analysis identified 57 Trim8-related interactors and/or substrates including four members of the kinesin-like protein family, known to be involved in various kinds of mitotic spindle dynamics and drivers of invasion, proliferation and self-renewal in glioblastoma. Co-immunoprecipation confirmed Trim8-kinesin interaction. Global gene expression profile revealed the most enriched pathways as involved in axonal guidance signaling, synaptic long-term potentiation, Stat3 signaling and immune cell trafficking. Interestingly, a transcriptional deregulation of genes involved in mitotic spindle assembly and chromosome segregation was detected by RNASeq and validated by qPCR, in line with the proteomic data. Validation of transcriptomic data was carried out by PCR arrays kits that profile the expression of a panel of genes central to the Stat3 pathway and inflammation process. Several receptors, nuclear co-factors and co-activators of Stat proteins, Stat-inducibile genes and negative regulators of the pathway were found deregulated in NSC-Trim8 compared to the NSC control. A similar approach confirmed the deregulation of key secreted proteins central to the immune response in NSC–Trim8. Our expression and proteomics data give preliminary evidences that TRIM8 may participate in the carcinogenesis and progression of glioma through an aberrant regulation of biological pathways and protein networks known to be correlated with glioma pathogenesis.

2990T

Utilization and patient reported outcomes of clinical multi-gene panel testing for cancer susceptibility in the multi-center COGENT study. *A.R. Bradbury[1,2], L. Patrick-Miller[4], B.L. Egleston[6], S.M. Domchek[1,3], O.I. Olopade[4,5], M.J. Hall[7], M.B. Daly[7], L. Fleisher[10], G. Grana[9], P. Ganschow[8], D. Fetzer[7], The COGENT Research Team.* 1) Department of Medicine, Division of Hematology-Oncology, University of Pennsylvania, Philadelphia, PA; 2) Department of Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, PA; 3) Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA; 4) Division of Hematology-Oncology, Department of Medicine, The University of Chicago, Chicago, IL; 5) Center for Clinical Cancer Genetics and Global Health, The University of Chicago, Chicago, IL; 6) Fox Chase Cancer Center, Temple University Health System, Biostatistics and Bioinformatics Facility, Philadelphia, PA; 7) Fox Chase Cancer Center, Temple University Health System, Department of Medical Genetics, Philadelphia, PA; 8) Department of Internal Medicine, The John H Stroger Jr Hospital of Cook County, Chicago, IL; 9) Division of Hematology-Oncology, MD Anderson Cancer Center at Cooper, Camden, NJ; 10) The Children's Hospital of Philadelphia Research Institute, Center for Injury and Research Prevention, Philadelphia, PA.

    Background: Multi-gene panels (MGP), including both high and moderate penetrance cancer susceptibility genes are currently being used despite questions regarding their clinical utility and no standard approach to genetic counseling. We have shown no difference in outcomes between telephone (TD) and in-person disclosure (IPD) of MGP results, but how frequent providers use MGP testing and how patient reported outcomes (PROS) differ from targeted testing has not been reported. **Methods:** We evaluated use of MGP testing and PROS in participants undergoing cancer genetic testing in the multi-center COGENT study (NCT01736345), a randomized study of TD versus IPD of genetic test results. In this "real world" study, genetic counselors offered targeted (i.e. *BRCA1/2*) or MGP considering clinical indication and insurance coverage. Participants completed PROS at enrollment (after pre-test counseling) and after result disclosure. **Results**: Since the inclusion of MGP testing in 2014, 600 participants with no prior genetic testing enrolled; 395 (66%) patients were offered MGP, 205 were offered *BRCA1/2* testing only. Offering MGP testing increased from 57% of patients in 2014 to 66% in 2015 (p=0.02), and varied by site (46-78%, p<0.01). In a regression, the most salient factors associated with being offered MGP testing were study site (p<0.01), not being of Ashkenazi heritage (OR 5.2, p<0.001), not having a known mutation in the family (OR 26.5, p<0.001), and patient request for IPD (OR 2.7, p=0.01). Patients offered MGP testing had lower genetic knowledge after pre-test counseling than those offered *BRCA1/2* testing (22.7 v. 23.6, p=0.001). 376 (95%) of patients proceeded with MGP testing. After adjusting for arm, patients receiving MGP had less increase in cancer worry (-0.07 v. +2.7, p=0.01), lower state (33.0 v. 36.1, p=0.01) and general anxiety (5.9 v. 6.6, p=0.04), higher satisfaction (40.2 v. 39.0, p=0.02) and lower post-test genetic knowledge (22.7 v. 23.7, p=0.001) than patients who received *BRCA1/2* results only. **Conclusions:** Use of MGP has increased over time. Affective outcomes are not worse after MGP, although genetic knowledge may be lower compared to *BRCA1/2* testing and some patients undergoing MGP testing express a preference for in-person disclosure. Longitudinal cognitive and behavioral outcomes are needed to better understand the clinical risks and benefits of using multi-gene cancer panels and guidelines for use of MGP testing in clinical cancer genetics.

2991F

Interest in web-based education and informed consent for return of individual genetic research results. *J.B. Gaieski[1], L. Patrick-Miller[4], B. Egleston[5], D. Fetzer[1], W.K. Chung[10,11], K. Bradbury[1,2].* 1) Department of Medicine, Division of Hematology-Oncology, University of Pennsylvania, Philadelphia, Pennsylvania, USA; 2) Department of Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, Pennsylvania, USA; 3) Abramson Cancer Center, University of Pennsylvania, Philadelphia, Pennsylvania, USA; 4) Division of Hematology-Oncology, Department of Medicine, The University of Chicago, Chicago, Illinois, USA; 5) Fox Chase Cancer Center, Temple University Health System, Biostatistics and Bioinformatics Facility, Philadelphia, Pennsylvania, USA; 6) Center for Clinical Cancer Genetics and Global Health, The University of Chicago, Chicago, Illinois, USA; 7) Biological Sciences Division, Section of Hematology/Oncology, Center for Clinical Cancer Genetics, University of Chicago, Chicago, Illinois, USA; 8) Department of Medicine, Division of Translational Medicine and Human Genetics, University of Pennsylvania, Philadelphia, Pennsylvania, USA; 9) Section of Hematology/Oncology, Department of Medicine, Comprehensive Cancer Research Center, University of Chicago, Chicago, Illinois, USA; 10) Department of Pediatrics, Columbia University Medical Center, New York, New York, USA; 11) Department of Medicine, Columbia University Medical Center, New York, New York, USA; 12) Department of Clinical Genetics, Columbia University Medical Center, New York, New York, USA; 13) Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, New York, USA.

    Background: Genetic counselors (GC) are frequently employed to conduct pre-disclosure education and return of individual research results (IRR). Given high costs and a limited GC workforce, alternative informed consent and delivery models are needed. **Methods**: In the multi-center RESPECT study, women with a personal or family history of breast cancer are offered the opportunity to learn multi-gene cancer susceptibility IRR. Participants have the choice to complete pre-disclosure education and informed consent with a genetic counselor or through a web-based intervention (WebEd). Descriptive statistics and logistic regressions were used to describe uptake of WebEd, website use characteristics, patient reported outcomes (PROS) and associated participant factors. **Results**: To date, 104 participants have completed pre-disclosure education and informed consent. 92 (88%) chose WebEd, 12 (12%) chose to speak with a GC because they did not have web access. Mean time to WebEd access was 10.3 days (SD 18, range 0-94). 35 (38%) completed required WebEd content and made a decision about receiving IRR on their first visit. Mean time to decision was 33.8 minutes (SD 22.5, range 4.3-111.8). 52 (57%) participants visited WebEd multiple times before making a decision. Mean number of visits was 3 (SD 2, range 2-12); mean total viewing time prior to making a decision was 63 minutes (SD 52, range 5-249). 7 (8%) participants asked to speak with a GC after using WedEd before making a decision. Being younger (OR 0.92, p=0.003) and having higher cancer specific distress at baseline (OR 1.05, p=0.05) were associated with making a decision on the first WebEd visit. Overall, 92 (88%) participants elected to receive IRR, 35 (100%) of those deciding at their first WebEd visit, 45 (79%) of those who visited WebEd multiple times and 12 (100%) among those who spoke with a GC. There were no significant differences in change in knowledge or distress from baseline to post WebEd between those who completed WebEd in one versus multiple visits. **Conclusions:** Web-based alternatives for genetic education and informed consent for return of IRR may be an acceptable and scalable alternative for many research participants. Further recruitment and collection of PROS after receipt of results is expected to inform the risks and benefits of using web-based alternatives for pre-disclosure education and informed consent for return of IRR.

2992W

Patient interest and risk communication preferences regarding a novel *BRCA1/2* **genetic modifier test.** *J.G. Hamilton[1], J.S. Westerman[1], M.C. Genoff[1], E. Shuk[1], J.L. Hay[1], K. Offit[2], M.E. Robson[2].* 1) Behavioral Sciences Service, Department of Psychiatry & Behavioral Sciences, Memorial Sloan Kettering Cancer Center, New York, NY; 2) Clinical Genetics Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Recent research has identified a set of genetic variants that modify breast cancer risks among female *BRCA1/2* mutation carriers. By incorporating these genetic modifiers into a clinical genetic testing panel, healthcare providers may be able to more accurately predict *BRCA1/2* carriers' likelihood of developing breast cancer. This specificity would represent a substantial improvement in disease risk prediction for these patients, as currently breast cancer risk estimates by age 70 range from 44-78% for *BRCA1* carriers and from 31-56% for *BRCA2* carriers. To prepare for the future availability of genetic modifier testing, it is critical to understand the opinions of *BRCA1/2* mutation carriers about both the test and the ways that test results can be communicated. Method: We conducted in-person interviews with 30 female *BRCA1/2* mutation carriers about their perceptions, comprehension, and preferences regarding sample genetic modifier risk communication materials. Participants (aged 25-80 years; 87% Caucasian; mean numeracy score = 4.8 on a scale ranging from 1-6) were randomized to receive one of three sample genetic modifier test results (indicating low, moderate, or high breast cancer risk). Participants were shown results in four different formats (panel of genes, icon array providing social comparison information, verbal risk estimate, and graphical risk estimate) and asked to provide qualitative feedback based on a semi-structured interview guide. Results: Interest in obtaining genetic modifier testing was high, with 77% of participants indicating that they would be willing to pay out of pocket for the test. Many believed that genetic modifier test results would make their cancer risk management decisions easier, whereas a few were unsure and one indicated that it would make her decisions harder. The preferred format across the three breast cancer risk levels was the graphical estimate, alone or in combination (often with the verbal estimate). The least popular format was the icon array, which many participants deemed confusing. Conclusion: These results suggest that patients would be highly receptive to genetic modifier testing, and that the minimal amount of necessary information to include in genetic modifier test results would be graphical and verbal estimates of risk. These findings will inform future efforts to translate genetic modifier testing into care in a manner consistent with patients' preferences.

Systematic assessment and reporting of secondary findings in whole exome sequencing: The project of HOPE. *Y. Horiuchi[1,2], Y. Kiyozumi[1,4], H. Matsubayashi[2], S. Nishimura[2], K. Urakami[3], S. Oonami[3], M. Arai[1], M. Kusuhara[3], K. Yamaguchi[2,3].* 1) Dept of Psychiatry and Behavioral Sci., Tokyo Metropolitan Institute of Med. Sci., Tokyo, Japan; 2) Dept. of Genetic Counseling, Shizuoka Cancer Center, Shizuoka, Japan; 3) Research institute of Shizuoka Cancer Center, Shizuoka, Japan; 4) Graduate school of Ochanomizu University, Tokyo, Japan.

Recent advantage of whole genome sequencing (WGS) and whole exome sequencing (WES) techniques are increasingly used in both clinical and research contexts. On the other hand, new ethical issues regarding the disclosure of incidental or secondary findings, i.e., results that are unrelated to the original aims of the study may be expected to arise in the genome studies. In 2013, the American College of Medical Genetics (ACMG) announced recommendations for handling incidental findings in genome sequencing. However, the guidelines for the secondary findings and a system of the return of results for patients have not been well established yet in Japan. In this study, we systematically constructed the genetic counseling system from clinical genome study "Shizuoka Cancer Center (SCC) the Project HOPE (High-tech Omics-based Patient Evaluation)", as a basis for initial trials in Japan. The aim of Project HOPE is to evaluate biological characteristics of cancer and diathesis of each patient by multi-omics based analyses, which integrate genomics, transcriptomics, proteomics and metabolomics. We here report the prevalence of secondary findings and the system of the return of results to patient from the HOPE study. The disclosure of secondary findings for the patients were conducted carefully and systematically in SCC. To date, 1500 cases have been analyzed and approximately 3% of the total cases were reported to be associated with hereditary cancer syndromes and approximately 1% of the total cases were reported as based on the guidelines of the ACMG. Our systematic approach will contribute to a cancer genomic medicine and serve as a useful basis for genetic counseling system in Japan.

2994F

FamilyTalk: Developing a tool to help families communicate about colorectal cancer risk. *T. Hyams, D. Bowen.* University of Washington, SEATTLE, WA.

   Purpose: Relatives of people with colorectal cancer (CRC) are about twice as likely to also develop the disease. It is essential to educate both CRC patients and their families about their increased risk in order to increase screening behavior and reduce disease burden. The purpose of this poster is to present on the development of an innovative web-based tool kit called FamilyTalk with the purpose of increasing family communication about risk for developing CRC. The overarching goal is to increasing screening behavior through increasing communication in families with CRC. This poster will present on the development of FamilyTalk, findings from paper and electronic usability testing, and plans for future testing. Methods: FamilyTalk presents users with educational content about colorectal cancer and its genetic components including genetic screening, family history and treatment information. Family and provider communications sections help users navigate potentially complicated conversations about risk, and actions to be taken to reduce risk. FamilyTalk uses existing tools, such as the NCI colorectal cancer risk assessment tool (http://www.cancer.gov/colorectalcancerrisk/tool.aspx) which allows users to calculate their own risk for colorectal, and an interactive family history tool, built by this group, which allows participants to build on both familial and social relationships and create a family health history. Users can also invite members of their family and greater social network to utilize website features including allowing them to view and edit the family tree tool. We employed an 8-step process used previously in our website development research to translate our print intervention, included conceptual design, drafting web-appropriate informational and motivational content, prototyping materials, acceptability review with community members, detailed medical and genetics review, usability testing, system testing, and final modifications. Results: Colorectal families liked the paper version, but had multiple suggestions, including adding a better introduction, sections on genetics and family history, and clearer communication assistance. The web-based tool improved upon the linear book format with links and better section instructions. The processes outlined produced materials that satisfied diverse families and individuals with support. Results also include screenshots of the electronic version of FamilyTalk.

2995W

Beliefs and attitudes of Egyptian parents influencing participation in a pediatric biorepository. *R.M. Labib, O. Hassanian, M. Alaa, S. Ahmed, S. AbouEl-Naga.* Research, Children's Cancer Hospital, Cairo, Egypt.

   Background: Biobanks have become a powerful tool that can foster many types of research. The success of biobanks depends upon people's perception and willingness to donate their samples for future research. This is the first pediatric biorepository in the middle-east, hence, little is known about the beliefs and attitudes of parents towards their children participation in a research biorepository. **Aim:** To investigate the level of willingness to donate samples for research in an Egyptian Children's cancer hospital and understand factors influencing enrollment. **Materials and Methods:** A Standardized questionnaire was designed covering multiple items expected to affect the enrollment. This was conducted in-person and data collected included, demographics data, socioeconomic level, educational and religious constraints. Additionally, in the case of refusal, participants were asked about reasons for nonparticipation. **Results:** We succeeded to enroll 7,000 pediatric participants from November 2012 till March 2016. Yet, approximately 3.1% of patients have refused to participate and 0.3% have withdrawn. Three demographic factors were found having disparate trends in the parents decision making process to participate or not: father's education (p-value = 0.0001), mother's education (p-value = 0.0001) and father's age (p-value = 0.034). **Conclusion:** More intense awareness programs need to be designed specifically for parents with a higher level of education and who are of older age, as they tend to be more unwilling to participate in a research biorepository.

2996T

Pre-test genetic counseling as a requirement for germline hereditary cancer testing: What do patients do? *G.A. Lazarin, K. Sedgwick, D. Doyle, I.S. Haque, K. Ready.* Counsyl, South San Francisco, CA.

Background: To ensure informed consent and appropriate test utilization, some health insurers require individuals seeking certain hereditary cancer (HC) genetic testing to undergo pre-test genetic counseling (GC). The effect of this requirement on patient access to HC testing has not been fully studied.**Methods:** We evaluated BRCA1/2 or Lynch syndrome test orders to Counsyl for 327 members of two national health insurers to evaluate their risk status with respect to National Comprehensive Cancer Network (NCCN) guidelines for identification of individuals at high risk of an HC syndrome. NCCN was used as a proxy for insurance coverage criteria given similarities. Counsyl holds contract agreements with these payors. Patients are referred to a third-party fee-based GC service per the plan requirements. Patients were provided an estimated cost based on plan benefits and predicted risk category (high/low). All patients were offered a discounted self-pay option, regardless of insurance status. We examined patient decision making with respect to payment action, risk status, and GC action.**Results:** 262 patients (80%) met NCCN high-risk criteria based on information provided on the test requisition. In total, 29 patients (11%) canceled their tests after being informed of estimated test cost and the requirement for pre-test GC; 19 of these 29 were high-risk (7.3% of all high-risk patients). Of those continuing with testing, 110/230 (49%) high-risk and 44/65 (68%) low-risk individuals elected self-pay. 104/110 (95%) high-risk and 10/44 (77%) low-risk self payers did not seek pretest genetic counseling.**Conclusion:** 56% of patients meeting NCCN guidelines did not complete the pre-test GC requirement for insurance coverage, instead choosing to avoid the requirement through self-pay or canceling the test altogether. 7.3% of all high-risk patients canceled their testing. These data suggest the requirement for pre-test GC may not accomplish the stated goal of improving patient education, and may be seen as an impediment or unnecessary expense by patients.

2997F

Do patients receive recommended care following a diagnosis of Lynch Syndrome in an integrated health care system? *A.F. Rope[1], J.M. Zepp[1], K.R. Muessig[1], J.L. Schneider[1], K.M. Bergen[1], J.V. Davis[1], J.E. Hunter[1], S.K. Peterson[2], S. Syngal[3], L.S. Acheson[4], G.L. Wiesner[5], J.A. Reiss[1], K.A.B. Goddard[1].* 1) Center for Health Research, Kaiser Permanente Northwest, Portland, OR; 2) Department of Behavioral Science, University of Texas MD Anderson Cancer Center, Houston, TX; 3) Dana-Farber Cancer Institute, Boston, MA; 4) Departments of Family Medicine and Community Health, Reproductive Biology, and Oncology, Case Western Reserve University, Cleveland, OH; 5) Vanderbilt Hereditary Cancer Program, Department of Medicine, Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN.

Individuals with Lynch Syndrome (LS) are at increased risk of developing cancer, primarily colorectal cancer (CRC) and endometrial cancer (EC). Because of the risk, patients with LS are recommended to receive screening for CRC via colonoscopy starting at an earlier age and at more frequent intervals. Women with LS may have risk reducing surgery to prevent EC, and additional screening and interventions may be recommended for other associated cancer risks. We investigated the use of recommended interventions for LS in a real-world integrated health care system. We also conducted interviews with 12 patients and 10 primary care providers (PCPs) with at least one patient with LS to better understand how care is managed, and barriers and facilitators to receiving recommended care. We identified 73 patients with LS via chart review at Kaiser Permanente Northwest (KPNW), representing only 6% of the expected number of cases based on the population prevalence of the condition. We used chart review to extract information on family history, LS diagnosis, cancer history, and related healthcare utilization. Most patients (83%) received their diagnosis of LS at KPNW, and 67% had a diagnosis of ≥1 cancer prior to their diagnosis of LS. Patients accumulated an average of 3.2 years (range, 0 – 14) of electronic medical record history since their diagnosis of LS. Patients received colonoscopy during 87% of the observed follow-up intervals; 42% of at-risk women had a hysterectomy, and 38% had an oophorectomy following diagnosis of LS. While most had an initial visit with the Genetics department, 70% of patients with sufficient follow-up never contacted Genetics again. In interviews, patients had good recall of their recommended care, and 1/3 reported it was primarily their responsibility to manage their care, while 2/3 reported it was a joint responsibility with their PCP. PCPs reported limited awareness of LS guidelines, and most often provided care for £2 patients with LS. PCPs often reported that it was primarily another specialty's responsibility to manage LS care or that they rely on joint responsibility with the patient. Both patients and PCPs desire greater support in managing patient care for LS patients. In this setting, patients are often able to obtain recommended care to reduce their cancer risks. The Genetics department has an important role in supporting coordination of care, and needs to find ways to communicate their useful roles to PCPs and patients.

"A change in perspective": Exploring the experiences of adolescents with hereditary tumor predisposition. *E. Weber[1,2], C. Shuman[1,2,3], J.D. Wasserman[4], M. Barrera[5,6], A.F. Patenaude[7], K. Fung[8], D. Chitayat[1,2,9], D. Malkin[6], H. Druker[1,3,6].* 1) Department of Molecular Genetics, University of Toronto, Toronto, Quebec, Canada; 2) Division of Clinical and Metabolic Genetics, Department of Pediatrics, The Hospital for Sick Children, Toronto, ON, Canada; 3) Department of Genetic Counselling, The Hospital for Sick Children, Toronto, ON Canada; 4) Division of Endocrinology, Department of Pediatrics, The Hospital for Sick Children, Toronto, ON, Canada; 5) Department of Psychology, The Hospital for Sick Children, Toronto, ON, Canada; 6) Division of Hematology/Oncology, Department of Pediatrics, The Hospital for Sick Children, Toronto, ON, Canada; 7) Department of Psychosocial Oncology and Palliative Care, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA; 8) Department of Social Work, The Hospital for Sick Children, Toronto, ON, Canada; 9) Prenatal Diagnosis and Medical Genetics Program, Department of Obstetrics and Gynecology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada.

   Introduction: Hereditary tumor predisposition syndromes are being more frequently recognized in the context of pediatric neoplasms. As more adolescents are identified with hereditary tumor predisposition, insight from their experiences can guide the provision of health care including genetic counseling. Previous research indicates that disclosure of tumor susceptibility is a significant event in adolescents' lives. However, no previous research has explored the experiences and perceptions of adolescents following the identification of a hereditary tumor predisposition syndrome. Purpose: We explored the lived experiences of adolescents with hereditary tumor predisposition syndromes and their perceptions of living at risk. Methods: Participants were sampled purposively from the Cancer Genetics Program at the Hospital for Sick Children, and included adolescents with pediatric-onset hereditary tumor predisposition syndromes, irrespective of personal or family history of tumors. Seven adolescents (ages 14-17) with five different syndromes were interviewed by telephone or in person using a semi-structured interview guide. We explored the disclosure process, support systems, and the benefits and harms of knowledge of tumor susceptibility. Interviews were transcribed verbatim and analyzed via interpretive description. Results: Four major themes emerged from the data: 1) The benefits of knowing about tumor susceptibility outweigh the harms; 2) Tumor susceptibility leads to a change in life perspective and choices made with respect to the future; 3) Perceptions are shaped by the disclosure process within one's health and family contexts; 4) Self-concept is not defined by tumor risk. Conclusions: Adolescents recognize the challenges associated with awareness of tumor predisposition, but also identify positive aspects in their life experiences. Results of this study can guide pre- and post-test genetic counseling of adolescents for hereditary tumor predisposition syndromes, facilitating the incorporation of this genetic information into an adolescent's self-concept in an adaptive manner.

2999T

The cost and cost-trajectory of whole-genome analysis to guide treatment of patients with advanced cancers. *D. Weymann[1], J. Laskin[2], R. Roscoe[3], M. Marra[3,4], K. Schrader[4,5], S. Chia[2,6], S. Yip[7], W. Cheung[2,6], K. Gelmon[2,6], A. Karsan[2,3,7], D. Renouf[2,6], D.A. Regier[1,8].* 1) Canadian Centre for Applied Research in Cancer Control (ARCC), Cancer Control Research, BC Cancer Agency, Vancouver, British Columbia, Canada; 2) Division of Medical Oncology, BC Cancer Agency, Vancouver, British Columbia, Canada; 3) Canada's Michael Smith Genome Sciences Centre, BC Cancer Agency, Vancouver, British Columbia, Canada; 4) Department of Medical Genetics, Faculty of Medicine, University of British Columbia, Vancouver, British Columbia, Canada; 5) Department of Molecular Oncology, BC Cancer Agency, Vancouver, British Columbia, Canada; 6) Department of Medicine, Faculty of Medicine, University of British Columbia, Vancouver, British Columbia, Canada; 7) Department of Pathology & Laboratory Medicine, Faculty of Medicine, University of British Columbia, Vancouver, British Columbia, Canada; 8) School of Population and Public Health, Faculty of Medicine, University of British Columbia, Vancouver, British Columbia, Canada.

   PURPOSE: Precision medicine is gaining momentum in oncology. While the costs of whole genome sequencing (WGS) have decreased over time, the feasibility of the widely hyped $1,000 per genome is uncertain. Few data on the real-world costs of applying WGS and analysis (WGA) have been published. This study estimated the costs of applying WGA to guide treatments for patients with advanced cancers and characterized how the costs of applying these next generation genetic technologies are expected to evolve over time. **METHODS:** The setting for this study is the BC Personalized OncoGenomics (POG) program at the BC Cancer Agency Genome Sciences Centre in Vancouver, Canada. Individual-level cost data was obtained for 301 patients who underwent POG-initiated WGA from July 2012 to December 2015. We estimated mean sequencing costs across patients using bootstrapping methods and applied time series analysis to determine whether sequencing costs changed over time. We specified autoregressive integrated moving average models with explanatory variables (ARIMAX) for WGA costs and WGS and transcriptome sequencing costs. We produced ten-year forecasts to determine when costs are expected to reach thresholds, such as $1,000 per patient. **RESULTS:** The mean cost of POG-initiated WGA was $34,991 per patient (95% CI: $34,153, $35,828). WGS and transcriptome sequencing drove the majority of expenditures, with a mean cost per patient of $19,400 (95% CI: $18,404, $20,395). Targeted gene panels cost an average of $1,530 per patient (95% CI: $1,443, $1,617). Over time, mean WGA costs decreased, driven mainly by decreases in the cost of WGS and transcriptome sequencing. However, mean costs of bioinformatics and validation increased over time. Forecasting models showed that WGS and transcriptome sequencing costs could reach $1,000 per patient in the next 6 years. Reaching significant thresholds for WGA costs could take longer. **CONCLUSION:** The cost of WGA decreased over the studied time horizon, but mean per patient expenditures needed to realize WGA remain significant. Despite these elevated costs, WGA will identify a greater number of clinically actionable findings than lower cost alternatives, such as gene panels. Future research exploring the trade-offs between costs and benefits of WGA-guided cancer care will be crucial to guide health policy.

3000F

The Angelina Effect: An ongoing impact on cancer referrals in Northwest London. *S.K. Best, M. Tsakok, A. Melville, M. Kosicka-Slawinska, A. Brady, B. Bernhard.* North West Thames Regional Genetics Service, Northwick Park Hospital, London North West Healthcare NHS Trust.

   Background: The North West Thames Regional Genetics Service (NWTRGS) serves a population of 3.6 million people in North West London and adjacent counties. Following the publicity of Angelina Jolie's *BRCA1* diagnosis and risk-reducing mastectomy in May 2013, the NWTRGS experienced an unprecedented increase in cancer referrals. NICE guidelines recommend referral to specialist genetic services for patients with moderate or high-risk of a genetic basis for cancer. Managing the sudden increase in referrals was challenging and required initiative to continue to provide adequate care. **Methods: Initial Audit** A retrospective study was conducted on all genetic cancer referrals in January and June 2013; before and after the Angelina Jolie *BRCA1* announcement. Data collected: referral date, cancer type, appointment date, risk category, diagnostic tests. Microsoft Excel analysis was performed. Findings were compared with NICE guidelines for referral to specialist services (2013).   **Intervention** The following changes were implemented following initial audit: Only high risk patients to be offered clinic appointments – lower risk patients to receive standardised letters explaining risk and screening advice. Increased triage workforce employed.   **Reaudit** A reaudit was performed on January and June 2014 cancer referrals as per initial audit methods to evaluate change in practice.   **Results: Referral patterns: Initial audit:** cancer referrals more than doubled (129 to 271) between January and June 2013. 82% of total cancer genetic referrals were for breast or ovarian cancer. **Reaudit:** The number of referrals reduced but remained higher than pre-announcement levels. Referrals for breast and ovarian cancer increased compared to 2013, representing 93% of total genetic cancer referrals.   **Consultations: Initial audit:** 85.5% of patients (moderate and high cancer risk) receiving clinic appointments. 40% of patients seen subsequently had genetic testing. **Reaudit:** Only high risk patients (53.5%) were offered clinic appointments. The remainder of referred patients received standardised letters. 89.5% of patients seen subsequently had genetic testing.   **Conclusions:** There has been a sustained surge in genetic cancer referrals following the Angelina Jolie *BRCA1* announcement in 2013. Increasing demands on genetic services has driven implementation of new triage systems and re-allocation of resources. Ongoing adjustment will be needed to manage high numbers of referrals associated with increasing public awareness.

3001W

Screening new diagnoses of endometrial cancer for Lynch syndrome to reduce morbidity and mortality: A systematic review. *H.C. Groom[1], M.A. Piper[1,2], J.L. Kuntz[1], C.S. Bennette[3], D.L. Veenstra[3], K.A.B. Goddard[1].* 1) Center for Health Research, Kaiser Permanente Northwest, Portland, OR; 2) Hayes, Inc., Lansdale, PA; 3) Pharmaceutical Outcomes Research and Policy Program, University of Washington, Seattle, WA.

   Statement of purpose: We conducted a systematic review to assess the evidence for whether screening for Lynch syndrome (LS) among women newly diagnosed with endometrial cancer (EC) improves cancer morbidity and mortality outcomes for the patient or her family members, as the over-arching research question. **Methods**: An indirect evidence chain composed of 4 major questions was constructed to address the over-arching question. We conducted a systematic literature search from 2008 to 2016 for the over-arching question and to 2015 for all other questions. Two investigators independently reviewed 1086 abstracts and quality-rated 140 full-text articles against pre-specified inclusion criteria. Data was abstracted from included studies and randomly checked for accuracy. We also developed an economic evaluation. **Results**: No direct evidence addressed the overarching research question was identified. Studies in the indirect evidence chain indicate microsatellite instability and immunohistochemistry screening tests have diagnostic accuracy for LS in EC similar to LS in colorectal cancer (CRC). Sensitivities of 100 percent were reported for next generation sequencing to detect LS variants. Results of the economic model indicate that screening and followup Sanger sequencing of LS-related genes in screen-positive samples, compared to genome/exome sequencing, remains the cost-effective method for detecting LS even when considering the benefits of cascade testing among relatives. The distribution of EC versus CRC as the first cancer in LS patients who were diagnosed with both did not favor CRC, suggesting that EC is an important sentinel cancer in LS families. EC also appears to be the defining cancer in a small number of LS families. **Conclusions**: Screening new EC diagnoses could identify LS families in addition to those found by CRC screening alone. Indirect evidence suggests that screening new EC diagnoses can reduce CRC incidence and mortality, and EC (among female relatives) but not ovarian cancer incidence and burden. Improvements in uptake of genetic counseling are needed for screening to achieve full benefits; uptake of genetic testing and surveillance for cancer in LS-confirmed individuals could also be improved. Rare, serious harms are associated with CRC surveillance and with certain risk-reducing surgical options. This study was supported by funding from Leidos Biomedical Research, Inc. Prime Contract HHSN261200800001E issued by The National Cancer Institute.

3002T

Implementing a clinical partnership to provide telegenetics services at community sites without access to genetic counselors. *N.K. Reddy[1], E.M. Wood[1], D. Harris[1], S. Jideama[1], P. Higgins[1], R. Sawhney[2], P. Singh[2], K. Vidrine[2], H. Pinkston[2], J. Shevock[2], J. Jaeger[1], A. Bradbury[1]. 1) University of Pennsylvania, Philadelphia, PA 19104; 2) Bayhealth Medical Center, Dover, DE 19901.*

  Background: Many patients in community practices do not have access to cancer genetic services, creating potential disparities in care. Remote two-way video-conferencing (RVC) is a feasible alternative but scalability of this model remains unclear. **Methods:** The Penn Telegenetics Program provides cancer genetic counseling services using RVC to community hospitals without access to genetic providers. This program originated from an NIH-funded pilot-study investigating the feasibility of using RVC cancer genetic services at 3 community practices. Bayhealth Medical Center, one of the participating community sites, established a clinical contract to maintain continuity of telegenetic services. We present the data from the first 18 months of our clinical partnership. **Results:** 191 patients have been referred to the program by on-site physicians (n=105, 55%) and local community doctors (n=86, 45%). The majority of referrals are from oncologists (52%) and surgeons (32%). Genetic counselors obtained licensure in the site state, collaborating with the site physician who is the ordering provider. To date, 84 patients have been seen for pre-test (V1) RVC counseling; of the remaining 107 referrals not seen for V1, reasons include patient refusal of services, lost to follow-up or pending decision to receive services. 60 (71%) patients elected to have genetic testing and completed disclosure sessions (V2) by RVC (n=56) or phone (n=4). 5 (8%) had a positive result, 10 (17%) had a variant of unknown significance and 45 (75%) had negative results. 131 RVC sessions (including V1 and V2) were conducted. 109 (83%) sessions were completed successfully without disconnections, 19 (15%) were completed with difficulty (e. g. screen freezing, prolonged reduced audio/video quality) and 3 (2%) had technology failures prompting completion by phone. An online family history tool was added to increase efficiency, but some patients (25%) did not use the tool due to discomfort with computers or no internet access. The clinical contract covers the cost of the genetic counseling but testing is covered by patient insurance, consistent with usual care. **Conclusion:** Remote two-way video-conferencing services can be implemented through clinical contracts to provide access to genetic services at community sites without genetic counselors, providing a novel delivery model to enhance the dissemination of and reduce disparities in access to cancer genetic services.

3003F

Patient safety in genomic medicine: Learning from the experiences of cancer genetics professionals. *S.M. Fullerton[1], D.M. Korngiebel[2], J. Zech[3], A.M. Chapelle[3], D. Davies[1], J.D. Carline[2], W. Burke[1], T.H. Gallagher[3]. 1) Dept Bioethics & Humanities, University of Washington, Seattle, WA; 2) Dept Biomedical Informatics & Medical Education, University of Washington, Seattle, WA; 3) Dept Medicine, Div General Internal Medicine, University of Washington, Seattle, WA.*

  Introduction: Genetic and genomic testing poses a variety of concerns for patient safety, related to clinician training, practice variation, and rapidly evolving technologies and test standards. As genomic tests are increasingly integrated into medical care, anticipating and addressing such potential concerns will be crucial. Here, we report a qualitative investigation of the views of cancer genetics professionals aimed at identifying challenges to the use of cancer predisposition-related genetic testing in oncology, an area in which genomic medicine is already established and growing in significance. **Methods**: First, we conducted semi-structured interviews with 22 key informants (medical geneticists, genetic counselors, and medical oncologists) affiliated with diverse cancer practice settings in the US. Interviews were designed to explore informants' experiences with the use of genetic testing and to identify examples of testing-related care breakdowns. Next, we used the interview findings to develop case vignettes, which formed the basis for focus group discussions with 18 additional cancer genetics providers drawn from three different healthcare institutions in the Pacific Northwest. **Results**: Key informants offered numerous examples of challenges they and their patients had encountered in the course of pursuing cancer-related genetic testing. These rich first-person accounts informed the development of 8 vignettes, encompassing errors in genetics referral, test ordering, interpretation, and follow-up, as well as team-based communication about test results. Two of the vignettes, one focused on surgical referral for a patient with a Variant of Uncertain Significance (VUS), and one focused on clinical trial-related *BRCA1/2* testing in the absence of pre-test counseling, were brought to the focus groups for detailed consideration and discussion. Together, these results informed the development of a national survey, currently in the field, which aims to quantify the degree to which oncologists in academic and community settings grapple with the concerns identified by our preliminary sample of cancer genetics professionals. **Conclusions**: Our study has provided a description of recent practice challenges associated with cancer-related genetic and genomic testing. Additional research will be needed to identify and test suitable interventions aimed at promoting the safe incorporation of genetic and genomic tests into existing systems of healthcare.

3004W

Personal utility and economic benefit of returning incidental findings in patients with colorectal cancer/polyposis syndromes. *D. Regier[1,2], G. Jarvik[3], D. Veenstra[3].* 1) BC Cancer Agency, Vancouver, British Columbia, Canada; 2) School of Population and Public Health, University of British Columbia, Canada; 3) University of Washington, Seattle, WA.

   Background: A challenge with the application of next generation DNA sequencing technology is the possibility of uncovering incidental genomic findings. A paucity of evidence on patients' preferences and economic value for money has hindered health policy outlining the return of incidental findings. The study objective was to estimate the personal utility and net economic benefit for returning complex information derived from genomic incidental findings. **Methods:** A discrete-choice experiment evaluated preference-based personal utility and willingness to pay for incidental findings information. Study subjects were drawn from randomized controlled trial of exome sequencing versus usual care in patients with colorectal cancer/polyposis syndromes conducted in Seattle, Washington. Preference data were analyzed with a random parameters hurdle model. Decision analytic modeling was used to estimate the net-benefit of returning incidental findings information. **Results:** 130 respondents completed the preference questionnaire. Respondents valued receiving information on high-penetrance disorders, but expressed disutility for receiving information on low-penetrance disorders. Respondents indicated an average willingness to pay of $483 (95% CI, 359,695) to receive incidental findings information in a scenario where clinicians return high-penetrance, medically actionable disorders, but 6% of respondents were predicted to opt-out of receiving incidental findings information under these conditions. In terms of cost-effectiveness, incorporating WTP for genomic knowledge resulted in a net-benefit of $281 per patient. **Conclusions:** Most patients valued receiving incidental findings, but preferences depend on the type of finding and not all individuals want to receive incidental results. Our results indicate that returning incidental findings information may provide net economic value, but individual-level patient preference should be elicited in order to maximize societal benefit.

Personalizing cancer care: A policy perspective. *J. Zhang[1,2], G. Bertier[3,4], Y. Joly[3,4].* 1) Cancer Program, Broad Institute of Harvard and MIT, Cambridge, Massachusetts, USA; 2) Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, Massachusetts, USA; 3) Centre of Genomics and Policy, Montreal, Quebec,Canada; 4) Department of Human Genetics, McGill University, Montreal, Quebec, Canada.

   Context: Precision medicine can be defined as a predictive, preventive, personalized and participative healthcare service delivery. Although it seemed like a futuristic ideal only a decade ago, recent developments in molecular biology and information technology make it possible for precision medicine to take place today, through the use of massive amounts of genetic, omics, clinical, environmental and lifestyle data. Cancer being one of the most prominent public health threat in developed countries, both the research community and governments have been investing significant time, money and efforts to make cancer precision medicine a reality. Cancer precision medicine (CPM) research is extremely promising. Indeed, genomic research results are providing us with a more thorough understanding of cancer. It is a complex, multifaceted disease, which challenges our established way to classify, counsel and treat patients. A number of these results are already actionable, and highly publicized examples demonstrate significant improvements of prevention, survival and patients quality of life in certain cancers. But a number of hurdles are still on the road to an optimal integration of standardized and evidence based use of CPM in healthcare systems. **Objective:** In this perspective, we describe key issues that public health policymakers will need to consider in the near future for CPM's promises to be fully realized. **Conclusions:** Policy makers have a duty to optimally integrate CPM research results to the clinic. Genomic medicine is one of the most promising avenues for cancer prevention, survival and treatment. Focusing on translating cancer genomic research results does not mean to disregard all other (non-genetic) aspects of cancer. Many areas still need research efforts, but these have to be made simultaneously with clinical applications.

3006F

A molecular autopsy program for sudden unexpected death: San Diego County study. *M. Rueda[1], E.G. Spencer[1], E.D. Muse[1], J.R. Lucas[2], E.J. Topol[1], A. Torkamani[1].* 1) Scripps Translational Science Institute, La Jolla, CA; 2) Medical Examiner Department, San Diego County, California, 92123, USA.

Many thousands of <45 year old individuals die suddenly and unexpectedly (SXD) in the USA. Depending on the underlying cause, SXD is divided into sudden cardiac death (SCD) including sudden infant death, or sudden death caused by non-cardiac failure such as pulmonary embolism, ruptured aortic aneurysm or infectious disease. Post-mortem examination of these cases yields negative results for ~10% of them, leaving relatives (often asymptomatic yet still at risk) with an inaccurate or ambiguous family health history. Genetic diagnosis is getting momentum in helping solving SXD mysteries. Analysis of literature shows that post-mortem genetic testing (a.k.a. molecular autopsy), even limited to gene panels of cardiac channelopathies, produced positive diagnosis in ~30% of the cases analyzed. According to our studies in the San Diego county, exome analysis of 25 cases referred by the Medical Examiner provided a likely cause of death (where a previously reported or expected pathogenic mutation was observed in a SCD-related gene) in 17% of them, a plausible cause in 25% of them (where a rare mutation of unknown significance was observed in a SCD gene), and a speculative cause in 25% of the cases (where a known pathogenic mutation was identified for a condition that potentially led to SXD). Despite the abundance of functional studies, in silico predictors of pathogenicity, and a plethora of databases of allele frequencies for variants, many of resulting variants remain of unknown significance (VUS). On top of that, most putative pathogenic mutations were inherited from living relatives and at population frequencies incompatible with full disease penetrance. These observations suggest that SXD risk may be influenced by incomplete penetrance, variable expressivity, and gene-environment interactions. We believe that a comprehensive molecular autopsy program would provide more accurate family health information to a wider spectrum of families. Consequently, we initiated a systematic and prospective, family-based, molecular autopsy study, jointly organized by a medical examiner office and an academic center. Our objective is to create a worldwide catalog of genetic variants associated to SXD to allow for large-scale genetic studies and empower the unrealized potential of prevention for SXD conditions.

3007W

Reaction to risk, decisional regret, and perception of locus control in central hubs of information exchange following disclosure of disclosing genetic risk for coronary heart disease: The MI-GENES study. *S. Brown, I. Kullo.* Department of Cardiovascular Diseases, Mayo Clinic, Rochester, MN.

In the myocardial infarction genes study, participants (n=203) aged 45-65 years at intermediate CHD risk based on conventional risk factors and not on statins were randomized to receive their conventional risk score (CRS) or also a genetic risk score (GRS) based on 28 variants, in meetings with a genetic counselor and then a physician. Individuals exhibiting high levels of information exchange via the internet and interpersonal communication were identified as central hubs. Whether disclosing genetic risk for coronary heart disease (CHD) to individuals identified as central hubs of information exchange in social networks influences their reaction to risk, decisional regret, and perception of locus control is unknown. Surveys to assess information exchange, as well as reaction to risk, decisional regret, and locus control were completed prior to, at, or following risk disclosure. We assessed whether reaction to risk, decisional regret, and locus control differed by GRS disclosure. Data were reported as mean with standard error or odds ratio with confidence interval; significance was determined by regression analysis. Upon risk disclosure, central nodes in the GRS group were more likely than GRS peripheral nodes to feel hopeful (OR 4.36, CI 1.46-15.52, p=0.01) and determined (OR 0.17, CI 0.03-0.67, p=0.01). Three months later, central nodes in the GRS group were less likely than GRS peripheral nodes to believe their CHD risk was primarily determined by chance (11.22±0.83 vs. 13.63±0.59, p=0.02). Central nodes in the GRS group (15.21±0.46 vs. 14.05±0.33, p=0.03) and the CRS group (15.3±0.59 vs. 13.74±0.31, p=0.02) were more likely than GRS and CRS peripheral nodes, respectively, to believe that their CHD risk was influenced by taking actions in response to doctors' recommendations. Among GRS participants, central nodes were less likely than peripheral nodes to regret their decision to undergo CHD genetic risk testing at six months after risk disclosure (5%±2 versus 14%±2, p=0.0016). There was no difference in reaction to risk or decisional regret between central and peripheral nodes in the CRS group. Individuals identified as central hubs reported higher locus of control, positive reactions to risk, and less decisional regret than their peers in the GRS group, and higher locus of control in the CRS group. These parameters may serve as psychosocial markers of successful health promotion in central hubs of social networks following disclosure of a GRS for CHD.

3008T

Motivation, perception, and treatment beliefs in the Myocardial Infarction Genes (MI-GENES) randomized clinical trial. *S. Kattel[1], T. Onyekwelu[2], S.A. Brown[1], H. Jouni[1], E. Austin[1], I.J. Kullo[1].* 1) Mayo Clinic, Rochester, MN; 2) Medical University of South Carolina, Charleston, SC.

   Background: Current risk estimation equations for coronary heart diseases (CHD) are based on conventional risk factors. Incorporating newly identified genetic markers for CHD may improve risk estimation and individualization of therapy. Little is known about individuals' motivation, perception, or treatment beliefs related to the use of genetic information in risk estimates for CHD. Methods: Participants age 40-65 years, not on statin therapy and at intermediate 10-year risk for CHD were randomized to receive their estimated 10-year risk for CHD as a conventional risk score (CRS) based on conventional risk factors alone, or a CRS and a genetic risk score (GRS) based on 28 CHD genetic risk variants. CHD risk was disclosed during a 30-min scripted session by a genetic counselor, followed by a physician visit for shared decision-making to determine the need for statin therapy initiation. After 6 months, participants who initially received only their CRS also received their GRS. Surveys on motivation and perception were completed at 3 months and treatment beliefs at 6 months following risk disclosure. Survey data were analyzed using Wilcoxon Signed-Rank, Chi-square, or Fischer's exact tests, or linear or logistic regression, as appropriate. Results: Overall, motivation to participate in the study was favorable and did not differ between the CRS and GRS groups (16.95 ± 0.82 vs. 17.58 ± 0.83, p=0.091), but participants who initially received their GRS indicated a greater desire to find ways to improve health as a reason for participation (OR: 0.53 (95%CI: 0.29,0.94), p=0.028). Correct perception about genetic testing did not vary between the two groups (15.29 ± 0.39 vs. 15.12 ± 0.40, p=0.835). However, participants who initially received their GRS were more inclined to recommend genetic testing to family and friends (9.95 ± 1.88 vs. 10.52 ± 2.17, p=0.023). Conclusions: In this study, motivation to participate and perception towards genetic testing were overall favorable. Genetic risk disclosure was associated with increased motivation to recommend genetic testing to family and friends. Perceptions about genetic testing were not affected by genetic risk disclosure.

3009F

A novel approach to screening for familial hypercholesterolemia. *H. Zierhut, M. Campbell, J. Humanski.* Genetics, Cell Biology, & Development, University of Minnesota Twin Cities, Minneapolis, MN.

   Heterozygous familial hypercholesterolemia (FH) is a common genetic condition affecting ~1 in 300 to 1 in 500 individuals worldwide. Yet FH is highly underdiagnosed with as few as 1% of individuals identified with the condition in the United States. The primary aim of this study was to test the feasibility of a public health screening program to identify individuals at high risk of FH through a novel screening approach at the Minnesota State Fair. A finger-prick, non-fasting lipid panel was obtained and a survey which consisted of 44 open and close ended questions divided into four sections: medical and family history of FH, opinions of cascade genetic testing, patient activation, and demographics was completed. A total of 971 participants met criteria and completed a cholesterol screen. In total, five individuals met either the Simon Broome Register or Dutch Lipid Clinic Network criteria for possible FH. Overall participants held positive opinions of genetic testing for FH and most participants responded that they would like to know if they had a genetic form of high cholesterol. The vast majority listed they had no barriers to communication of genetic testing information. However, the most common barrier listed was lack of communication skills. Participants' preferred mode of communication with the highest comfort with communicating in-person (n=591, 64%), followed by telephone (n=468, 51%), email (n=460, 50%), letter (n=230, 25%), link to website (n=220, 24%), or conversation through a physician or genetic counselor (n=209, 23%). Our results suggest that a public health screening program for FH is viable at the State Fair. Cascade screening for FH is acceptable by the public, but barriers to communication and faciliation of genetic testing will likely exist. We argue that further research is needed to expand this study to test the outcomes of a fully operational screening program for FH at the State Fair.

3010W

Cascade family screening following molecular autopsy for sudden cardiac death using targetted gene panels. *J.C.S. Dean[1], F. Cann[1], M. Corbett[2], D. O'Sullivan[1], S. Tennant[1], H. Hailey[1], P. Broadhurst[3], R. Rankin[4], J.H.K. Grieve[2].* 1) Medical Genetics, Aberdeen Royal Infirmary, Aberdeen, United Kingdom; 2) Forensic Medicine Unit, University of Aberdeen; 3) Department of Cardiology, Aberdeen Royal Infirmary; 4) Department of Pathology, Raigmore Hospital, Inverness.

Inherited cardiac conditions are thought to underlie between 27 and 44% of sudden arrhythmic death syndrome (SADS - sudden unexpected death with negative pathology and toxicology). This has led to a recommendation that a molecular autopsy should become part of the standard of care in such cases. Interpretation of genetic variants may be difficult where the phenotype is limited, although variant frequency data and family segregation studies may be helpful. 96 cases of sudden cardiac death were assessed through a multidisciplinary approach (46 with normal hearts, 50 with pathological evidence of cardiomyopathy) and DNA samples were screened using small gene panels comprising 6 channelopathy genes (KCNQ1, KCNH2, SCN5A, KCNE1, KCNE2 and RYR2), 4 Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) genes (PKP2, DSC2, DSP and DSG), 6 sarcomere genes (MYBPC3, MYH7, TPM1, MYL2, TNNI3, TNNT2) with or without LMNA, SCN5A and TTN depending on the phenotype (SADS, ARVC, dilated and hypertrophic cardiomyopathy respectively). 15% of SADS cases and 18% of cardiomyopathy cases had pathogenic variants in the genes tested. 3 families had variants previously reported as pathogenic which had no clinical phenotype in relatives, and were relatively common in the ExAC population – these cases were counted as negative. Amongst those with a positive molecular autopsy, 94% of families sought cascade screening, while only 41% of those with a negative molecular autopsy sought cardiological screening. In families who had a full evaluation, an inherited cardiac condition was identified in 33% of SADS families, and 56% of cardiomyopathy families. Molecular autopsy is useful in reaching a diagnosis after a sudden unexpected death, but variants must be interpreted in the context of family clinical investigations and population variant frequency data. A positive molecular autopsy encourages family cascade screening and may help prevent further morbidity and mortality.

3011T

Barriers and facilitators to optimal visit frequency in management of hypertension among African American and Latino patients in a safety-net clinic. *J. Lee[1,2], V. Fontil[2].* 1) San Francisco State University, 1600 Holloway ave. San Francisco, CA 94132; 2) University of California, 1001 Potrero Ave, San Francisco, CA 94110.

Despite improvements in management of hypertension (HTN) at the national level, rates of uncontrolled hypertension remain disproportionally high among African American and Latino patients. Visit frequency is a key process in HTN management that leads to improved blood pressure (BP) control. However, African Americans and Latino patients have the highest no-show rates in clinic, which may contribute to the racial disparity in BP control. We seek to examine cognitive and socioeconomic barriers to more frequent clinic visits in African American and Latino patients that contribute to higher no-show rates. We will conduct focus groups of African American, Latino, and White patients with uncontrolled HTN at the Zuckerberg San Francisco General Hospital's Richard Fine People's Clinic (RFPC) – a large safety-net clinic associated with an academic institution. Qualitative analysis will examine racial differences in patient barriers and facilitators to improving visit frequency for management of HTN at RFPC. We anticipate that patient identified challenges and preferences will vary between African Americans, Latinos and White patients at RFPC. A clearer understanding of patient identified facilitators and barriers will inform interventions and best practices to optimize visit frequency and ultimately improve hypertension control in safety-net clinics and in high-risk populations that are vulnerable to health disparities.

3012F

Cardiologists' responses to whole genome sequencing: Preliminary findings from the MedSeq Project. *K. Christensen[1], J.L. Vassy[1,2], A.L. Cirino[1], M.F. Murray[3], A.L. McGuire[4], R.C. Green[1,5,6] for the MedSeq Project.* 1) Brigham & Women's Hospital and Harvard Medical School, Boston, MA; 2) VA Boston Healthcare System, Boston, MA; 3) Geisinger Health System, Danville, PA; 4) Baylor College of Medicine, Houston, TX; 5) Partners Healthcare Personalized Medicine, Cambridge, MA; 6) Broad Institute of MIT and Harvard, Cambridge, MA.

While whole genome sequencing (WGS) has great potential to improve patient care by identifying predispositions for disease and informing treatment decisions, policymakers and payers are apprehensive about the potential of WGS findings to initiate a cascade of follow-up testing and screening that could yield limited clinical benefits. Concerns are particularly strong in specialty settings where WGS is already being used for diagnostic purposes and physicians may receive secondary findings that are unrelated to their areas of expertise. As part of the MedSeq Project, 100 patients (mean age 56, 43% female, 88% non-Hispanic white) with diagnoses of dilated or hypertrophic cardiomyopathy were randomized to meet with one of seven cardiologists (who were also study participants) to review their family history of disease alone (FH arm) or in conjunction with a WGS report (WGS arm). In questionnaires completed immediately following disclosure sessions, cardiologists indicated that they ordered or recommended follow-up for one participant randomized to the FH arm and four participants randomized to the WGS arm (2% vs 8%, p=0.20). Follow-up in the FH arm included a referral to cancer genetics in response to a family history of pancreatic cancer. Follow-up in the WGS arm included referrals to cancer genetics and endocrinology in response to findings about monogenic disease, and two screening procedures in response to risk information about cardiometabolic traits. Cardiologists rated the current utility of WGS reports no higher than they rated the current utility of the family history analysis (4.0 vs 3.9 on 10-point scales, p=0.62), on average, but tended to believe that the WGS reports would have greater utility in the future (5.1 vs 4.0 on 10-point scales, p=0.016). Furthermore cardiologists stated that the WGS reports improved overall clinical care beyond what family history alone could have achieved for 33% of patients. Results suggest that cardiologists perceived some utility in WGS, even though findings were unlikely to motivate them to order follow-up tests. In conjunction with previous MedSeq Project data, these findings also suggest that cardiologists were less likely than primary care physicians to act on WGS findings.

3013W

MyGeneRank app: Empowering patients with their genetic risk. *N. Wineinger, B. Schrader, B. Molparia, A. Lippman, E. Spencer, M. Rueda, E. Muse, E. Topol, A. Torkamani.* Scripps Translational Science Institute, La Jolla, CA.

Can the results from genome-wide association studies (GWAS) of common disease be adopted to inform clinical practice and health decision-making? Researchers have begun to address this question by summarizing numerous signals across the genome to assess overall genetic risk, often as a genetic risk score (GRS). In many cases, they have shown that these scores can meaningfully differentiate individuals with and without disease. Coronary artery disease (CAD) has become a popular focus of GRS estimation because: 1) it remains the most common deadly disease; 2) has heritability between 40-60% while massive GWAS meta-analyses results made freely available to other researchers; 3) the Framingham risk score, the most popular clinical assessment of CAD risk, performs exceptionally bad at predicting CAD; and 4) a number of behavioral and pharmaceutical preventative interventions exist. CAD researchers have previously shown that a GRS constructed using >49,000 markers provides better differentiation between cases and controls than one using only genome-wide significant markers. Meanwhile, others have shown that individuals at the highest quintile of genetic risk get the most benefit from lipid-lowering medications (i.e., statins) whereas individuals at the lowest quintile get limited to no benefit. Given the clear clinical benefit, yet practical computation challenge in assessing CAD genetic risk, how can patients get this information? And if so, what health decisions will they make from it? We developed the MyGeneRank app available through Apple's ReserachKit. MyGeneRank is designed to provide individuals with their relative genetic risk based on estimates obtained from published GRS literature. The app currently supports a GRS for CAD based on ~49,000 markers, but more risk scores for other diseases are planned. To participate, individuals provide us with access to their genetic data, currently only available through the 23andMe API. Computations, including imputation, GRS calculation, and comparison to reference populations, are performed on our servers and are returned to the user via the app. This entire process takes only a few minutes. Individuals are also asked to complete a short survey, and six months later a follow-up survey. Our overall goal is to provide individuals access to information on their genetic risk for, as of now, CAD and observe how such access influences health decisions.

3014T

Creation and implementation of a BC Registry for familial hypercholesterolemia. *A. Shokoohi[1], L. Cermakova[2], I. Priecelova[2], J. Frohlich[1,2].* 1) University of British Columbia, Vancouver, BC; 2) Healthy Heart Program Prevention Clinic, St. Paul's Hospital, Vancouver, BC.

Cardiovascular disease (CVD) is now the leading cause of death worldwide. Atherosclerosis is the most common pathological change underlying CVD, with high cholesterol levels proven as a major risk factor for its development. Familial hypercholesterolemia (FH), a common autosomal dominant genetic disease, causes high cholesterol levels in the bloodstream, leading to premature CVD. With a prevalence of 1:500 in the population, approximately 20 million people worldwide and around 8000 in British Columbia are carriers of one of the genes for FH. Although more common than cystic fibrosis, vast majority of FH cases still remain undiagnosed, which implies that health professionals lack awareness of FH, its diagnostic features, and consequences. The purpose of this project is to create a registry with the diagnosis of FH in British Columbia to simplify education and treatment, ultimately reducing morbidity and mortality from CVD through early diagnosis and effective disease management. Patients with FH were identified based on their family history, physical examination, and laboratory results and stratified as definite, probable, or possible FH according to their final score on The Dutch Lipid Clinic Network FH criteria. Cascade screening was used to track the mode of inheritance of the disease to identify affected family members. Thus far, we have identified over 1000 individuals with FH based on chart review, with 693 consented to join the registry. Further research will aim to identify and educate FH individuals, their families, and their physicians regarding the appropriate management of hypercholesterolemia using lifestyle measures and medications.

3015F

Genetic counseling referrals for autism spectrum disorder: Review of a prenatal genetic counseling program. *D. Cutillo, L. Heckman, S. Floyd, A. Donnenfeld, D. Ramsey.* Genetic Counseling, Integrated Genetics, Philadelphia, PA.

Autism Spectrum Disorder (ASD) affects 1 in 68 children in the United States (U.S. Centers for Disease Control and Prevention 2012). The purpose of this retrospective study was to track genetic counseling referrals for family history of ASD at Integrated Genetics over a three year time period from 2013-2015. A total of 157,093 patients were seen for comprehensive prenatal/preconception genetic counseling between January 1, 2013 and December 31, 2015. 32,707 patients (20.8%) were referred for a family history of birth defects, intellectual disability and/or genetic disorders (included referrals for ASD). Genetic counseling patients referred with the specific indication of ASD by year were: 2013: 439 patients (3.8%), 2014: 502 patients (4.5%), and in 2015: 518 patients (5.2%). Of note, an additional 6993 patients not referred for ASD history, reported a first and/or second degree relative affected with ASD during the genetic counseling session. Risk assessment confirmed all patients referred for ASD (n=1459) were at increased risk for ASD in a current or future pregnancy. Fragile X carrier testing and prenatal microarray were among genetic tests offered to patients in this referral group. The acceptance rate for fragile X carrier testing was 24.4% (1/355 patients tested positive for a premutation). 11.8% of patients had testing previously (no abnormal results reported) and 63.8% of patients declined testing. Prenatal diagnosis with microarray was accepted by 21/1459 (1.4%), all with normal results. A review of this data indicates an increasing referral pattern of ASD among patients presenting for prenatal/preconception genetic counseling. Patients presenting for genetic counseling related to ASD are seeking information on etiologies, recurrence risk and prenatal testing options. Comprehensive genetic evaluation of affected individuals utilizing genetic testing, including microarray and whole exome sequencing is expected to identify a cause in up to 25% of individuals with ASD and is an important option to discuss during prenatal/preconception genetic counseling. As seen in this study, testing at risk family members with Fragile X carrier testing and offering prenatal microarray fails to clarify potential risks in most families with a history of ASD. Ongoing education specific to ASD is a critical component of a prenatal/preconception genetic counseling program to meet the needs of this patient population. .

3016W

Attitudes towards facial transplants among individuals with neurofibromatosis. *R.L. Glaser[1], D. Singman[1], J. McNairn[1], V. Iannone[2].* 1) Dept of Biology, Stevenson University, Stevenson, MD; 2) Dept of Psychology, Stevenson University, Stevenson, MD.

Neurofibromatosis (NF), an autosomal dominant disorder, has a phenotype ranging in severity from café-au-lait spots to multiple large tumors (neurofibromas). Surgery can remove neurofibromas, but they usually regrow. Full facial transplants, which have been used to treat NF since 2013, prevent neurofibromas from reoccurring by replacing the patient's facial tissue with donor tissue. This is the first study to assess the response of individuals with NF to facial transplants for cosmetic and functional purposes. A 26 item online survey, advertised on NFMidAtlantic.org between June-September 2015, assessed the reactions of individuals with NF to facial transplants for cosmetic and functional purposes. In addition, data on self-esteem, social behaviors, visibility and severity of NF, as well as demographic data such as type of NF, gender, and age were also collected. SPSS was used to analyze the survey data using independent sample two-tailed t-tests and Pearson's correlation coefficient. Overall, facial transplants for both cosmetic and functional purposes were not supported by our study population. The type of NF, visibility, and severity of the phenotype did not significantly affect the response to facial transplants. Even though our study population did not support facial transplants in general, females were significantly more likely than males to consider a cosmetic facial transplant for themselves (p=0.042) and for others (p=0.005). Lower self-esteem correlated with a greater consideration for cosmetic facial transplants for themselves (-0.341, p=0.01) and for others (-0.221, p=0.05). However, self-conscious individuals were significantly more likely to consider cosmetic facial transplants only for others (p=0.044), not themselves (p=0.429). Interestingly, the average self-esteem score of our study population was significantly lower than that of a control population (27.5 vs. 31.0, p<0.0001) and that of people with other facial deformities (27.50 vs. 29.61, p=0.025). Our results are reminiscent of the attitudes regarding cochlear implants in deaf study populations and attitudes regarding prenatal testing for achondroplasia in achondroplasia study populations.

3017T

Genetic counseling for male patients with myotonic dystrophy type 1 deciding whether to have a child. *M. Matsuo, M. Urano, K. Saito.* Institute of Medical Genetics, Tokyo Women's Medical University, Tokyo, Japan.

Myotonic dystrophy ;type 1 (DM1; OMIM#160900), with myotonia and progressive muscular weakness, is the most common adult muscular dystrophy. DM1 is due to a CTG repeat expansion in the 3' UTR of the *DMPK* gene. The mean intergenerational CTG repeat expansion tends to be minimal when transmitted by the father but high when transmitted by the mother. Invasive prenatal genetic testing (GT) and preimplantation genetic diagnosis (PGD) are permitted only when the fetus may have a severe disorder according to "Opinions Concerning Prenatal Genetic Testing" and "Opinions Concerning Pre-implantation Diagnosis" from the Japan Society of Obstetrics and Gynecology. Considering the parental gender difference in severity, prenatal GT and PGD are under discussion for paternal transmission of DM1 in Japan. We herein report our genetic counseling experience with two male DM1 patients. Case 1, an asymptomatic Japanese male in his thirties whose father had DM1, requested pre-symptomatic GT before marriage to decide about conceiving a child. GT revealed an expanded allele with about 100 CTG repeats. He contemplated having prenatal GT or PGD abroad and whether or not to marry just after his GT. He married and fostered a child 8 years later. Case 2, an asymptomatic Japanese male in his forties, had three siblings with DM1. He requested pre-symptomatic GT to decide whether to conceive a child. The GT revealed that he had an expanded allele of about 100 CTG repeats. To date, he has had no children. Discussion It is difficult to determine fetal phenotypic severity by prenatal GT or PGD in pregnant women with DM1. Thus, testing is of limited value for allelic confirmation. Mildly affected fetuses are comparable to those with paternally transmitted disease and severely affected fetuses are subjects for prenatal GT. Severely affected congenital DM1 fetuses are comparable to those with maternally transmitted disease and are not suitable for prenatal GT. Allowances for prenatal GT and PGD need to be reassessed in relation to fetal severity by ethics committees of the Japanese Society of Obstetrics and Gynecology and / or genetics-related societies Our society regards parents giving birth to and raising a child as fully qualified adults. "Blood relation" and "pedigree" are traditional Japanese values, with relatives and the public expecting a couple reproduce. Thus, being "childless" and "fostering a child" are not alternatives in Japan. We need a mature society with diverse family values.

3018F

Long-term impact of Huntington's presymptomatic genetic testing: Interviews with at-risk individuals 20-30 years after testing. *R.L. Dvoskin[1], J.M. Bollinger[1], A. McCague[1,2], K.M. Stuttgen[2], B. Shpritz[3], J. Brandt[3,4], D.J.H. Mathews[1].* 1) Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD; 2) Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 3) Department of Psychiatry and Behavioral Science, Johns Hopkins University School of Medicine, Baltimore, MD; 4) Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD.

   To learn about the long-term impacts of genetic testing, we are conducting a follow-up study of participants from the presymptomatic testing program (PTP) of Johns Hopkins' Baltimore Huntington's Disease Project, one of the two initial programs in the U.S. We are conducting semi-structured interviews with at-risk probands who enrolled in the PTP between 1986 and 1996. Target enrollment is 20 people with an expanded HD repeat, 20 with normal repeats, and 10 who enrolled in PTP but dropped out before testing or disclosure. We anticipate completing enrollment in Summer 2016. We ask participants how their testing experience and knowledge of the result has influenced their life over the past 20-30 years, including decisions about career, children, and relationships. Nearly all participants reported positive feelings about their decision to enter the PTP and about their testing experience. Participants found the pre-test counseling extremely helpful. Some found the number of counseling sessions excessive; nevertheless, most mentioned the dangers of receiving one's HD risk status without sufficient preparation. To date, all (N=27) said if they were to do it over they would still be tested. Many believed knowing their risk status had a major impact on their life. For those with expanded repeats, positive long-term impacts included the relief of knowing and the ability to make informed decisions and plans regarding: long-term care and health insurance; reproduction; building social or family support; and how to spend their presymptomatic years. Negative impacts included fear of employment discrimination and guilt or concern for children who are now themselves at risk. For people with a normal repeat, positive effects included relief and the ability to live without uncertainty or symptomatizing; empowerment to leave an unhappy union or to pursue a new relationship; the ability to have children without fear of passing on HD risk; and motivation to pursue career goals. People varied in how they reacted to, processed, and communicated about their result. There were many instances of differing attitudes among at-risk siblings, which complicated family communication. Furthermore, many participants reported family trauma beyond HD, including alcohol abuse, physical abuse, and mental illness. These factors highlight the importance of considering an individual's family history, mental health, and social environment to be able to provide appropriate counseling around testing.

3019W

Identifying and counseling patients amenable to mutation-specific therapies in Duchenne Muscular Dystrophy (DMD): Knowledge of resources will fuel genetic counselors' impact. *E. O'Rourke[1], L. Bogue[2], D. Martin[1], M. Pastore[3], A. Smith[4].* 1) Sarepta Therapeutics, Inc., Cambridge, MA; 2) Parent Project Muscular Dystrophy, Hackensack, NJ; 3) Nationwide Children's Hospital, Columbus, OH; 4) University of Pittsburgh Medical Center, Children's Hospital of Pittsburgh, Pittsburgh, PA.

   Mutation specific therapies are currently in clinical trials for treating DMD, a progressive, life-limiting X-linked neuromuscular disorder caused by mutations in the *DMD* gene (Xp21.2) that result in a lack of functional dystrophin. Current approaches include nonsense mutation suppression and exon skipping. The goal of nonsense suppression is to read through the premature stop codon to produce functional dystrophin, whereas the goal of exon skipping is to restore the mRNA reading frame to generate internally deleted, functional dystrophin. Considering both approaches, more than 60% of DMD cases are potentially amenable.   Determining patient eligibility for mutation-specific clinical trials involves barriers that genetic counselors are uniquely positioned to help solve. Access to genetic testing is one such barrier. In a survey of 27 U.S. physicians who manage over 2,000 DMD patients, there was significant variability in the percentage of patients genotyped (~25% - 100%). Awareness of financially viable testing options like the Decode Duchenne program, which provides free genetic testing to eligible individuals, is essential.   Accurate interpretation of genetic test results represents a second barrier between patients and mutation-specific approaches. While nonsense mutations are categorically amenable to nonsense suppression, other *DMD* mutations vary in their amenability to exon-skipping therapy based on size and location in the gene. To counsel patients accurately, clinicians must first be able to discern if a mutation is appropriate for exon skipping and second, whether the specific mutation is amenable to a particular exon skipping therapeutic.   With this level of complexity, access to interpretation tools and guidance is paramount for genetic counselors to advise both patients and other providers. We present and review the *DMD* gene exon map, the Leiden DMD database (http://www/dmd.nl), the Decode Duchenne program website (www.duchenneconnect.org/decode), and the University of Utah mutation tables (http://www.genome.utah.edu/DMD/mutation_tables.cgi) as tools that counselors may use to help determine DMD patient eligibility to exon-skipping.

3020T

Perspectives on genetic testing and return of results from the first cohort of presymptomatically tested individuals at-risk for HD. *K.M. Stuttgen[1,2], R.L. Dvoskin[1], J.M. Bollinger[1], A. McCague[1,2], B. Shpritz[3], J. Brandt[3], D.J.H. Mathews[1].* 1) Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD; 2) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 3) Department of Psychiatry and Behavioral Science, Johns Hopkins University School of Medicine, Baltimore, MD.

For decades, Huntington's disease (HD) has served as a model for how we think about genetic testing, and its benefits and harms for at-risk individuals and their families. In 1983, HD was the first genetic disease mapped using DNA polymorphisms. Shortly thereafter, presymptomatic genetic testing for HD began in the context of two clinical trials. The presymptomatic testing program (PTP) of the Baltimore Huntington's Disease Project at Johns Hopkins University began in 1986 and enrolled 180 individuals. Experiences with this cohort influenced collective thinking about issues related to genetic testing. Challenges around these issues are still widely discussed and debated. This study is obtaining opinions on and attitudes toward genetic testing from people who enrolled in the Johns Hopkins PTP 20-30 years ago. One-hour semi-structured interviews are being conducted with 20 people found to carry an expanded HD repeat, 20 with normal repeats, and 10 who dropped out of the PTP before disclosure of test results. As part of the interview, participants are asked their opinions on the importance of autonomy in the decision to be tested, whether a formal testing protocol is necessary, whether online direct-to-consumer genetic testing for HD would ever be acceptable, and whether incidental findings (including the presence of HD or other genetic risk factors) should be returned in the context of whole exome/genome sequencing. Results to date suggest that participants believe that the decision to undergo testing should be autonomous, though a small number believe everyone at risk for HD should know his/her genetic status. Additionally, most participants believe that a formal protocol is necessary when undergoing genetic testing for HD. A small number felt that the protocol was helpful but that ultimately a patient has the right to know his/her genetic information without having to go through a formal protocol. Thus far, most participants have stated that DTC genetic testing related to serious disease is unacceptable. The majority of participants believe that those undergoing testing should be asked before testing whether s/he wants to be informed of any incidental or secondary findings. A small number of individuals believe patients should be told of all incidental findings so that they can 1) prepare themselves for the onset of a serious disease, such as HD, and 2) make lifestyle changes in an effort to prevent or mitigate their risk for diseases such as diabetes.

3021F

Well, good luck with "that": Reactions to learning of increased genetic risk for Alzheimer's Disease. *D.T. Zallen.* Dept Sci & Tech in Society, Virginia Tech, Blacksburg, VA. and Virginia Tech Carilion School of Medicine, Roanoke, VA.

The e4 allele at the *apolipoprotein E (APOE)* locus is a marker for increased risk for the common form of Alzheimer's disease (AD2 [MIM 104310]). Major professional organizations have recommended against this genetic test for asymptomatic individuals because of concerns about its effect on those who learn of higher risk (due to the presence of one or two e4 alleles) when there are no validated interventions to postpone or prevent this disease. Clinical trials carried out by the NIH REVEAL study reported that psychological distress from learning of higher risk is temporary and minor. In that study, in line with ethical guidelines, substantial genetic counseling was given to prospective participants. Also people were excluded if they failed to meet psychological criteria. It thus remains unclear if these findings apply to an unselected population of individuals who have such testing. Given the growing demand, it is important to understand the range of reactions associated with a higher-risk genetic-test result. We carried out 20 semi-structured research interviews with individuals who had already learned of their higher-risk status following *APOE* testing. They had undergone genetic testing to estimate their risk for Alzheimer's disease, or had learned of their risk inadvertently via genealogy testing or testing for other health problems. They were recruited through the ApoE4.info education and support group. Qualitative analysis of the interviews showed three main findings: (1) For about half of the participants, learning of their higher risk came as a shock and produced a period of painful, sometimes incapacitating, psychological upset. They were distressed about the failure of providers to prepare them for the information that the test would provide. (2) While nearly all felt that they had benefitted in the long term from life-style changes made after obtaining this genetic information, there was regret that they received only dire prognoses from their doctors and were left largely on their own to decipher medical literature and determine what steps they could take. (3) There was a great deal of concern expressed for those who, unlike themselves, had little support and may still be struggling with their initial shock. Based on these findings, there is definitely a responsibility to prepare people *prior* to any genetic testing for Alzheimer's risk and to actively assist them *afterward* in how best to deal with the results.

3022W

What is the economic impact of whole genome sequencing in child health? A cost-consequence analysis in autism spectrum disorder. *W.J. Ungar[1], K. Tsiplova[1,2], R.M. Zur[1,2], C.R. Marshall[3], D.J. Stavropoulos[3], S. Pereira[2], D. Merico[2], E.J. Young[3], S. Scherer[2]. 1) Child Health Evaluative Sciences, The Hospital for Sick Children Peter Gilgan Centre for Research and Learning, Toronto, ON, Canada; 2) The Centre for Applied Genomics, The Hospital for Sick Children Peter Gilgan Centre for Research and Learning, Toronto, ON, Canada; 3) Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada.*

   Purpose: Whole genome sequencing (WGS) is at the cusp of translation - poised to exert a profound effect on diagnosis in child health, with implications for health systems, decision-makers, clinicians, patients and families. While chromosomal microarray (CMA) is the first-tier genetic test in autism spectrum disorder (ASD), WGS offers promise in improving diagnostic yield but at a higher cost. The optimal deployment of WGS depends on its added value but deployment decisions are hampered by the absence of comprehensive estimates of associated costs. The objectives were to estimate the microcosts of WGS in ASD and to assess the incremental cost-effectiveness of alternative genetic test strategies. **Methods:** Patient-level and program costs for a clinical WGS service were estimated over 5 years from an institutional perspective. Labour, equipment, depreciation, supplies, follow-up testing, bioinformatics, interpretation, report writing and overhead costs for Illumina HiSeq2500 and HiSeqX platforms were estimated. Future costs were discounted at 3%. Parameter uncertainty was tested with probabilistic sensitivity analysis. An incremental cost-consequence analysis examined incremental costs per unit improvement in diagnostic yield for alternative genetic testing strategies that included CMA and whole exome sequencing (WES). **Results:** The cost per sample was US$2847 (95% CI 2745, 2946) on Illuminia HiSeq X and $4682 (4468, 4894) on Illumina HiSeq 2500 compared to $596 (572, 620) for CMA. Reagent supplies accounted for the largest proportion. Five-year program costs for 300 tests/year were $3.96 million (3.82, 4.10). The cost per additional ASD patient with a positive genetic diagnosis was $24,397 when substituting CMA with CMA+WES and $50,570 when substituting CMA with WGS HiSeq X. **Conclusions:** Although test improvements and newer platforms have resulted in lower laboratory costs, WGS remains costly. Incremental costs to replace older with newer technology exceeded $20,000 to detect an additional pathologic variant in ASD. Further improvements in diagnostic yield will increase the cost-effectiveness of WGS. Additional research is required to assess the impact of WGS in the ASD care pathway to determine effects on outcomes. This study provides comprehensive costs for use in economic evaluations of WGS in ASD and allows for a cost model that can be easily adapted to other pediatric conditions.

3023T

Ring14 International: A worldwide network to fight disorders of the 14th chromosome. *M. Crimi[1], Y. DeWoody[2], I. Deguisne[3], S. Hiwaitzi[4], E. Marin[5], J. Shutte[6], S. Azzali[1]. 1) Scientific Coordination office, Ring14 International, Milan(Italy); 2) Ring14 USA; 3) Ring14 France; 4) Ring14 England; 5) Ring14 Spain; 6) Ring14 Netherlands.*

   Chromosome 14 syndromes are rare genetic disorders. In some few cases, one of the two 14 chromosomes assumes the form of a ring resulting in the "Ring14 syndrome" (omim #616606), characterized by early onset refractory epilepsy, motor & mental retardation, autism and a multitude of other physical challenges. In other 14th chromosome syndromes, the chromatid pair loses or transfers genetic material sharing usually a clinical picture similar with "Ring14". Ring14 Association, founded in Italy in 2002, has recently evolved into Ring14 International (R14) to networking the local chapters worldwide located with the mission is to advance biomedical research towards best care and possible cure. R14 creates and coordinates the action of the independent national chapters, which gather individual families from single countries. R14 helps and assists families, divulges information and oversees the most efficient administration of internal resources. Basically, R14 is the only reference point for hundreds of families around the world and communicates in five languages. In addition to providing support to its families, R14 also promotes (and directly funds) biomedical research initiatives for diseases due to chromosome-14 rearrangements. For R14, the funding strategy has a pivotal role and really drive us to open a path towards new ways of research and clinical support. All funding decisions are subjected to peer-review by a panel of experts and any research initiative is always internationally managed. Most relevant results to-date: 1) 6 research projects directly funded (11 papers already published with the R14 support) on the molecular mechanisms underlying Ring14 and to creating in-vivo & in-vitro models; 2) Clinical projects supported, with a focus on the autistic traits and language impairments; 3) Biobanking project developed: hundreds of biological samples has been already collected (and available) in a biobank; 4) Database released: clinical records are digitalized and online searchable. Moreover, R14 collaborates with other international partners (such as Eurordis and RD-Connect) and plans yearly conferences with researchers and families. In the next future, R14 aims also to coordinate a large-scale project and to open new chapters, which will benefit of our full support for the start-up phase. In conclusion, we believe that the advocacy work being done by a patient association can be expanded beyond just improving the visibility of an underdiagnosed orphan disorder.

3024F

Is knowledge power? Family-centered outcomes from genomic sequencing in children with intellectual disability. *K.B. Brothers[1,2], K.M. East[3], W.V. Kelley[3], C.A. Rich[1], K.M. Bowling[3], E.M. Bebin[4], E.J. Lose[5], S. Simmons[4], J.A. Myers[1], G. Barsh[3,6], C. Finnila[3], D. Gray[3], S. Hiatt[3], N. Lamb[3], J. Whittle[3], M. Amaral[3], M. Thompson[3], R.M. Myers[3], M.A. Rothstein[2], G.M. Cooper[3].* 1) Department of Pediatrics, University of Louisville, Louisville, KY; 2) Institute for Bioethics, Health Policy, and Law, University of Louisville, Louisville, KY; 3) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 4) Department of Neurology, University of Alabama at Birmingham, Birmingham, AL; 5) Department of Genetics, University of Alabama at Birmingham, Birmingham, AL; 6) Department of Genetics, Stanford University, Stanford, CA.

Background The HudsonAlpha CSER Study is a translational study of the utility of whole genome sequencing for identifying a genetic cause in children or adults with intellectual disability. To date we have enrolled 332 families, with sequencing and analysis complete for 312 families. Due to ongoing scheduling of return of results visits, data collection, and data entry, data from 186 mothers are available for this analysis. Results Findings from these analyses are summarized in Table 1. Pathogenic Finding mothers (N=50) and VUS mothers (N=26) were significantly more likely to recommend sequencing (p<0.001) than No Diagnostic Finding mothers (N=110). Pathogenic Finding mothers also reported significantly higher utility from sequencing than No Diagnostic Finding mothers (p<0.001). VUS mothers reported utility intermediate between the other two groups, although differences between VUS and the other two groups were non-significant. Perceived severity and perceived control was measured at baseline and post return of results. Changes in perceived severity and perceived control from pre- to post-test measurements were small, and were not significantly different among the three result groups. Post-test anxiety also did not differ among the three groups. Conclusions Mothers who receive a diagnostic finding for their child's illness find greater utility in sequencing and are more likely to recommend sequencing than those who do not receive a diagnosis, even if the returned result is explained as a VUS. However, receiving a pathogenic finding or VUS is no more likely to increase perceived control than receiving no diagnostic finding. Levels of maternal anxiety are similar regardless of the outcome of sequencing. Ongoing interviews with parents will help contribute to understanding about the utility families derive from diagnostic sequencing results.

Family-Centered Outcomes Based on Diagnostic Finding Category .

	Pathogenic Finding (N=28)	VUS (N=17)	No Diagnostic Finding (N=63)	p values
Recommend Sequencing	6.56	6.85	5.94	<0.001
Sequencing Utility	5.94	4.36	3.39	<0.001
State Anxiety	38.84	35.62	35.09	0.266
Change in Perceived Severity	0.122	-0.384	-0.018	0.817
Change in Perceived Control	-0.36	-0.461	-0.227	0.239

3025W

TIDE Complex Diagnostic Clinic: An innovative model of multidisciplinary care for complex intellectual disability. *S. Race[1], R. Salvarinova[1], G. Horvath[1], A. Ghani[5], P. Eydoux[6], H. Vallance[6], W. Gibson[3], A. Kalenchuk[2], M. Van Allen[3], M. Connolly[1], S. Stockler[1], C. van Karnebeek[1,4,5].* 1) Department of Pediatrics, BC Children's Hospital, Vancouver, BC, Canada; 2) Department of Psychiatry, BC Children's Hospital, Vancouver, BC, Canada; 3) Department of Medical Genetics, BC Children's Hospital, Vancouver, BC, Canada; 4) Center for Molecular Medicine and Therapeutics; 5) Child and Family Research Institute, University of British Columbia, Vancouver Canada; 6) Dept of Pathology and Laboratory Medicine University of British Columbia, Vancouver, Canada.

Background: When the underlying cause of intellectual disability (ID) is identified patients and their families benefit because it can lead to improved genetic counselling, management and adaptation. However, the diagnostic odysseys for these patients are often long and expensive because of the etiologic heterogeneity of ID. Methods: The multidisciplinary Complex Diagnostic Clinic (CDC) was established in an effort to expedite the diagnostic process for ID patients with unexplained complex systemic and/or neurologic features. Patients are evaluated by 3-4 specialists in one morning. The specialists then meet for multidisciplinary rounds. **Results:** 95 children were evaluated during 27 clinics held over four and a half years. The ages of the patients ranged from 6 months-18 years. 45 were male and 50 were female. All the children had previously been seen by 2-12 specialist services. To date, the diagnostic yield of the CDC includes 32 confirmed and 17 working diagnoses (34% and 18% of children respectively). The diagnosis in patients was identified by: clinical exam in 7 chromosome micro-array in 3 single gene tests in 4 gene panel in 6 clinical whole exome sequencing in 5; and research exome in 7. These numbers will likely continue to increase as pending tests come in. In all cases, detailed phenotyping with clinical history and physical exam was essential for guiding the specific test and/or interpreting genomic data. In some cases the diagnosis enabled more individualized management with targeted intervention or prevention. Surveys showed positive feedback from both families and medical professionals. Chart reviews revealed cost-savings due to fewer trips to hospital and fewer tests via more streamlined evaluations **Conclusions**: The CDC represents an innovative model of multidisciplinary diagnostic care for complex intellectual disability. Careful phenotype along with close communication and collaboration among the specialists enhances the interpretation of relevant clinical, biochemical and genomic data. New diagnoses continue to be made possible due to the collective knowledge of the group, with improved satisfaction of patients, family and health care providers. Finally, diagnosis directly impacted management and treatment beyond genetic counseling and prognosis in 6 patients.

3026T

The impact of genetic counseling on knowledge and beliefs of an indigenous Filipino community with a high prevalence of otitis media due to an *A2ML1* **variant.** *E.M. Cutiongco-de la Paz[1,2], M. Pedro[3], T. Yarza[4], S.M. Lagrana[3], A. Amoranto[1], M.T. Domine[1], E.J. Jover[1], S.M. Leal[5], C.M. Chiong[3,4], R.L.P. Santos-Cortez[5].* 1) University of the Philippines Manila-National Institutes of Health (UPM-NIH), Pedro Gil St., Manila 1000, Philippines; 2) Philippine Genome Center, University of the Philippines, Diliman, Quezon City 1101, Philippines; 3) Philippine National Ear Institute, UPM-NIH, Taft Ave., Manila 1000, Philippines; 4) Newborn Hearing Screening Reference Center, UPM-NIH, Pedro Gil St., Manila 1000, Philippines; 5) Center for Statistical Genetics, Department of Molecular and Human Genetics, Baylor College of Medicine, 1 Baylor Plaza 700D, Houston, Texas 77030, USA.

   Previously we identified an *A2ML1* duplication variant that confers a four-fold risk for otitis media and induces middle ear microbial differences within an indigenous Filipino community with a ~50% prevalence of otitis media. As fulfillment of the agreement during free and prior informed consent for genetic research, we shared our exome and microbiome findings via a community meeting. Before the meeting, 13 out of 30 (43.3%) heads of households were interviewed regarding their knowledge and beliefs about otitis media. After the meeting, the heads of 24 households (80%) participated in genetic counseling and were asked the same pre-meeting interview questions. Majority (67%) of participants did not graduate from elementary school. Among those who were interviewed twice, after the community sharing the proportion of individuals who believed that otitis media has a heritable component doubled (from 36% to 77%; p=0.04) and those who believed that better personal hygiene (79%) and immunization (71%) can help alleviate otitis media burden increased to 100%. Among all respondents, the belief that it is normal for children to have ear discharge and hearing loss occurred in 42% and 21%, respectively, even after counseling. Those who believed that poor hygiene plays a role in the development of otitis media were younger (p=0.01), were less likely to be early adopters of *A2ML1* testing (p=0.04), submitted more DNA samples at later stages of the study (p=0.0004), and have a lower proportion of *A2ML1* variant carriers per household (p=0.048). Younger respondents also tend to believe that only children can have otitis media (p=0.02). Heads of households with a greater number and proportion of *A2ML1* variant carriers were more likely to believe that otitis media is heritable (p=0.03). When asked what they do when there is ear discharge, 83% reported cleaning their own ears usually with cotton swabs, however only 46% would seek clinical consult. Families with more members with chronic otitis media would clean their own ears (p=0.04), while participants who agreed to pre-counseling interview were more likely to seek clinical consult (p=0.02). Our experiences in sharing genomic information with a marginalized community highlight the challenges of community-based counseling within the context of poor health access, high disease prevalence, high population frequency of a disease-causal variant, and a complex trait with strong gene-environment interaction. .

More efficient diagnosis of patients with hearing and vision loss: Use of collaborative clinics and molecular genetics. *C. Sloan-Heggen[1,2], A. Ko[3], W. Pfeifer[4], D. Kolbe[1], C. Nishimura[1], K. Frees[1], A.E. Black-Ziegelbein[1], K. Booth[1], C. Campbell[1], S. Ephraim[1], P. Ranum[1], S. Shibata[1], D. Wang[1], A. Weaver[1], H. Azaiez[1], A. Drack[4], R. Smith[1,2].* 1) Otolaryngology, University of Iowa, Iowa City, IA; 2) Department of Molecular Physiology & Biophysics, University of Iowa College of Medicine, Iowa City, Iowa; 3) Department of Ophthalmology and Visual Sciences, University of British Columbia, Vancouver, BC; 4) Department of Ophthalmology and Visual Sciences, University of Iowa, Iowa City, IA.

   Hearing and vision are both integral to human interaction with our environment and each other. A syndrome affecting both of these senses can severely impact a person and leave them isolated. Diagnosis of such syndromes can be difficult because they are often nebulous with variable expressivity. Patients may be labeled with an incorrect or incomplete diagnosis for years, missing out on appropriate monitoring or testing and potential delay of symptom identification. To evaluate the benefit of a collaborative diagnostic process, we performed a retrospective study of patients referred to the Multidisciplinary Genetic Ophthalmology-Otolaryngology Clinic at the University of Iowa Children's Hospital. Individuals were seen by both an otolaryngologist and ophthalmologist at a single appointment. Patients were carefully evaluated clinically, diagnostically, and molecularly. Fourteen families (17 individuals) have been evaluated collaboratively to determine the most likely diagnosis. Eleven families (79%) were provided a likely molecular diagnosis (via targeted genomic enrichment and massively parallel sequencing or comparative genomic hybridization) consistent with the presenting phenotype; three families remain under molecular investigation but have likely clinical diagnoses. Importantly, as a result of this multidisciplinary clinic, nine patients received a refined diagnosis. In summary, close collaboration between multiple medical specialties, as well as integration of careful clinical and comprehensive molecular analyses, provides the best avenue through which an accurate diagnosis can be reached and future clinical direction and follow-up can be guided. In this cohort, the combined clinic has allowed for early visual monitoring for individuals with Usher syndrome and refined complex diagnoses like Waardenburg syndrome, Cowchock syndrome, and Baraitser-Winter syndrome.

3028W

Treatment research reporting trends for genetic eye diseases and patient sharing on Twitter: Implications for clinical communication. *T. Bubela, W. Luth, S. Kowal.* School of Public Health, University of Alberta, Edmonton, Alberta, Canada.

   Purpose Reports on highly experimental treatments such as bionic eye, gene therapy, and stem cell research give hope to patients with currently untreatable genetic eye diseases. News media is known to sensationalize translational research, leaving patients with incomplete information about therapeutic potential and research timelines. Research teams craft press releases to present findings; however, easy online information access and sharing allows for repeated reinterpretation of these findings as they move from press releases to newspapers, on to advocacy organizations, and between patients on social media. Our research on information pathways illustrates how reports of research progress change as they move through information outlets and among individual patients. Information accuracy and quality morphs, affecting communication requirements for clinicians and genetic councillors helping patients choose disease management options within current clinical realities. Thus, we also identify challenges and pose solutions for clinical communications about ocular treatment research. **Methods** We conducted a media analysis of press releases and traditional news media in Canada, the USA, and the UK to compare what stories were most heavily reported in which regions and how these stories were presented. Subsequently, we analyzed if and how ocular disease advocacy and support groups passed the same research news on to online users. Finally, we conducted an analysis of a decade of twitter conversations by patients around treatment research to identify which sources and stories patients most share and the ways in which patients discuss novel treatment research. **Results** News media and press releases: 1) overstate benefits and often omit risks of experimental treatments for ocular diseases; 2) conflate research with treatment or cure; and 3) misrepresent research timelines. Some advocacy websites present overly optimistic representations of research realities while others offer more balanced reports. Our twitter analysis shows the types and quality of sources patients and individuals follow and share. **Significance** Our research informs how clinicians can prepare to respond to overly positive reporting and who they should suggest that patients follow for treatment research information. We suggest using optimism towards the future of genetic eye disease research tempered by evidence to make clear the potential and timelines associated with therapies still in clinical trial phases.

3029T

Pharmacogenomics of age-related macular degeneration: A systematic review of the evidence. *A.M. Issa[1], V.S. Chaudhari[1], P. Pednekar[1], W.J. Foster[2].* 1) Personalized Medicine & Targeted Therapeutics, University of the Sciences in Philadelphia, Philadelphia, PA; 2) Dept of Ophthalmology and Dept of Bioengineering, Temple University, Philadelphia, PA.

   Age-related macular degeneration (ARMD) is the leading cause of blindness among older adults. Although the etiology of ARMD is not well understood, it is thought to include both environmental and genetic influences. There is an increased interest in understanding the genetics of ARMD, and particularly in the association of genotypes with therapeutic interventions for ARMD. We systematically assessed the evidence about genetic variants associated with ARMD, and the association of standard treatment options for ARMD with specific genotypes. Methods: A systematic review and quantitative assessment of the English- language literature on the genetics of ARMD between Jan 1996 – Nov 2015 was done. We performed searches using multiple databases including PubMed, Science Direct, Ovid Medline, and the Cochrane Collaboration. Two reviewers independently reviewed articles according to a priori established eligibility criteria using a standard screening form. Randomized controlled trials non-randomized trials, cohort and case control studies were included. Conference reports, commentaries, communications, descriptive and editorial studies were excluded. Results: We initially found 1477 articles related to ARMD genetics. Of these, 733 were original studies showing an association between ARMD and particular genetic variants or genotypes. Thirty one articles met eligibility criteria and showed an association between specific genotypes and specific interventions for ARMD. Of 64 different genetic variants, complement factor H (CFH) polymorphisms were suggested to play a role in ARMD susceptibilities in 124 studies. The genetic variant age-related maculopathy susceptibility 2 (ARMS2) was found to be associated with ARMD in 64 studies; high temperature requirement factor A1 (HTRA1) was suggested to be play a role as an ARMD susceptibility in 48 articles, and the VEGFA gene was associated with ARMD in 34 studies. CFH and ARMS2 was found to be most frequently associated with current standard therapeutic interventions, particularly with anti-VEGF. Conclusions:Current evidence suggests that CFH and ARMS2 appear to contribute the most to ARMD susceptibility. CFH and ARMS2 appear to be most closely associated with response to anti-VEGF therapeutic interventions. Further work remains to be done to explore further the associations between the identified genotypes and pharmacogenomic effects of ARMD interventions.   .

3030F

Coenzyme Q10 and pro-inflammatory markers in children with Down syndrome: Clinical and biochemical aspects. *H. El-Bassyouni[1], M. Zaki[2], E. Youness[3], J. Hussein[4], A. Tosson[5].* 1) Clinical Genetics, National Research Centre, Cairo, Cairo, Egypt; 2) Anthropometry Department, National Research Centre, Cairo, Cairo, Egypt; 3) Clinical Biochemistry Department, National Research Centre, Cairo, Cairo, Egypt; 4) Biochemistry Department, National Research Centre, Cairo, Cairo, Egypt; 5) Pediatrics Department, Abul Rish hospital, Cairo University.

Objective: Evidence of oxidative stress was reported in individuals with Down syndrome. There is a growing interest in the contribution of the immune system in Down syndrome. The aim of this study is to evaluate the Coenzyme Q10 (CoQ10) and selected pro-inflammatory markers such as interleukin 6 (IL-6) and tumor necrosis factor α (TNFα) in children with Down syndrome. Methods: Eighty six children (5-8 years of age) were enrolled in this case control study from 2 public institutions. At time of sampling the patients and controls suffered from no acute or chronic illnesses and received no therapy or supplements. The levels of IL-6, TNFα, CoQ10, fasting blood glucose and intelligent quotient were measured. Results: Forty three young Down syndrome children and forty three controls were included over a period of 8 months (January-August 2014). Compared with the control group, the Down syndrome patients showed significant increase in IL-6 and TNFα (P = 0.002), while CoQ10 was significantly decreased (P = 0.002). Also, body mass index and fasting blood glucose were significantly increased in patients. There was a significantly positive correlation between CoQ10 and intelligent quotient levels, as well as between Il-6 and TNFα. Conclusion: IL-6 and TNFα levels in young children with Down syndrome may be used as biomarkers reflecting the neurodegenerative process in them. Coenzyme Q10 might have a role as a good supplement in young children with Down syndrome to ameliorate the neurological symptoms.

3031W

Creating a medically actionable genetic screening panel for healthy individuals. *E.V. Haverfield, E.D. Esplin, B. Johnson, S. Gandomi, A. Lynch, S. Aradhya, R. Nussbaum.* Invitae Corporation, San Francisco, CA.

Background The 2013 ACMG policy statement recommended 56 genes for the return of incidental findings but noted that this list will, and should, evolve. Catalyzed by accelerating advances in clinical genomics, we generated an expanded gene list where pathogenic variants would be considered clinically actionable. **Methods** We reviewed the ACMG56 list, the ACMG Working Group process, and expanded gene lists published by multiple genomics groups. An expert panel of genetic counselors and medical and clinical geneticists reviewed the clinical actionability of individual genes beyond the ACMG56 using criteria such as penetrance, mode of inheritance, and the availability of published medical management recommendations. **Results** Our novel list of 124 clinically actionable genes includes the ACMG56 plus 17 conditions (24 genes) with increased risk for a cancer-related phenotype, three conditions (38 genes) with increased risk for a cardiovascular-related phenotype, and two conditions (6 genes) with increased risk for other medically actionable disorders, all of which have published guidelines for medical management. **Conclusions** The ACMG policy statement addresses pathogenic variants discovered by diagnostic whole-exome or whole-genome sequencing (WES or WGS). WES/WGS is increasingly available to healthy individuals seeking to proactively inform their healthcare. The high cost and mostly uninterpretable results of these broad tests are obstacles for integration into routine healthcare. A focused gene panel restricted to clinically actionable variants presents an opportunity for healthy patients to partner with their healthcare providers for preventive genetic testing with significant potential to inform personalized medical care. This can significantly impact current clinical genetics practices and necessitate the development of new models for clinical genetic counseling. With decreasing costs of and growing interest in this type of information, the transition from what are considered incidental findings to primary findings represents a novel opportunity for genetic information to be introduced into routine medical practice, which in turn can lead to increased clinical utilization for the preventive care of patients.

Metabolic diet app suite for inborn errors of amino acid metabolism. *G. Ho[1], K. Ueda[1], R. Houben[3], J. Joa[3], A. Geizen[1], B. Cheng[1], C. van Karnebeek[1,2].* 1) Department of Biochemical Disease, BC Children's Hospital, Vancouver, Canada; 2) Department of Pediatrics, Centre for Molecular Medicine & Therapeutics, Child & Family Research Institute, University of British Columbia; Vancouver, Canada; 3) Health2Media, Vancouver, Canada.

Background Inborn errors of metabolism although individually rare, form the largest group of monogenic disorders. The mutations in the genes result in a loss or gain of function in the protein produced, usually an enzyme or a transporter. This class of genetic diseases are particularly amenable through treatment targeting pathophysiology, often a lifelong dietary restriction combined with supplements and medications. *Objectives* To assist diet treated inborn errors of metabolism (IEM) patients with daily management of their diet. By developing a metabolic diet app suite, we are able to help patients with tracking their nutrient intake and adhering to the specific prescribed diet. *Design and Methods* Nutrient information is based on the Genetic Metabolic Dietitians International (GMDI) MetabolicPro™ database. The application suite was tested by biochemical geneticists, registered dietitians and parents of children with Pyridoxine Dependent Epilepsy and Phenylketonuria. Feedback was submitted through an online survey as well as through the diet app feedback function. The collected initial pilot tester feedback was positive and their suggestions were used to further improve the App suite. *Results* The metabolic diet app suite is a free, user-friendly, online app available on 2 platforms (computer and mobile device) via www.mdapp.org. Fifteen metabolic disorder specific apps and one protein tracking app were created, each containing nutrient information on over 100,000 different food products. The Diet Apps offer functions such as: secured personal user login/password, goal setting, daily intake tracking, food content checks, adding foods and homemade recipes, exportable daily food diary log, and developer feedback. General disorder information is also provided for each diet app.*Conclusion* The metabolic diet apps provide an individualized and reliable source of nutrient information, to aide families affected with IEMs to track and plan their meals. With the metabolic diet app, we hope to improve patient adherence, quality of life and personalization of care. Due to its specific nature, the metabolic diet app is a tool, and therefore not intended to be a replacement for medical-metabolic nutritional professional advice. Future research should evaluate its impact on patient adherence, metabolic control, quality of life and health-related outcomes.

3033F

A taxonomy of medical uncertainties in clinical genome sequencing. *B. Biesecker[1], P. Han[2], B. Bernhardt[3], R. Green[4], S. Joffe[5], B. Koenig[6], I. Krantz[7], K. Umstead[1], L. Biesecker[8].* 1) Social and Behavioral Research Branch, National Human Genome Research Institute, Bethesda, MD; 2) Center for Outcomes Research and Evaluation Maine Medical Center, Portland, ME; 3) Division of Translational Medicine and Human Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia PA; 4) Division of Genetics, Department of Medicine, Brigham and Women's Hospital, Partners Personalized Medicine, Harvard Medical School, Broad Institute of MIT and Harvard, Boston, MA; 5) Division of Medical Ethics and Health Policy, Perelman School of Medicine, University of Pennsylvania, Philadephia PA; 6) Institute for Health and Aging, University of California, San Francisco, CA; 7) Division of Human Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 8) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, Bethesda, MD.

Introduction: Clinical exome and genome sequencing (CEGS) are introducing new opportunities and challenges. Simultaneously these technologies are generating uncertainties of unprecedented scale that laboratories, clinicians, and patients need to manage. Building on an existing taxonomy of uncertainty in medicine, we developed a taxonomy for uncertainties in the use of CEGS in health care. Methods: Interviews with genomics experts were conducted to expand an initial genome taxonomy into its multiple dimensions. Findings were coded and analyzed and incorporated into a revised taxonomy. Multiple iterations were made after additional expert review. In parallel an interactive taxonomy website was developed to disseminate the taxonomy to researchers to engage them in its further refinement. Results: The proposed taxonomy divides uncertainty along three dimensions: source, issue, and locus, and further discriminates the uncertainties into five layers with multiple domains. We illustrate how the taxonomy can be applied to findings from CEGS and used to guide stakeholders through interpretation and implementation of variant results. Conclusion: The proposed taxonomy of uncertainties allows for better understanding of the unknown dimensions of the clinical implementation of CEGS. It also fosters standardization of terms related to uncertainties for research design, clinical guidelines and discussion of uncertainties of CEGS in publications.

3034W

Risk assessment and counselling training for non-genetics healthcare professionals: Competency-based education for the NHS sickle cell & thalassemia screening programme. *A. Sajoo[1], L. Oni[2], C. Peart[3], J. Walters[4].* 1) Department of Clinical Genetics, Guy's and St Thomas' NHS Foundation Trust, London, UK; 2) Brent Sickle Cell and Thalassemia Centre, Central Middlesex Hospital, London, UK; 3) South East London Sickle Cell and Thalassemia Centre, London, UK; 4) Faculty of Nursing & Midwifery, Kings College, London, UK.

In 2010, the National Screening Committee of the National Health Service (UK) put its PEGASUS hemoglobinopathy counsellors training course up for tender offering 25 funded places annually. Post-registration professional training is moving to Institutions of Higher Education. Background: A blended learning initiative was developed with two, two-day episodes separated by four weeks self-directed learning. Topics included National programme specifications, review of Medelian genetics, a survey of hemoglobinopathies and interpretation of lab reports. Culture, ethnicity, communication and counselling methods were discussed in the context of carrier identification, risk assessment, reproductive options and decision-making. The teaching team consisted of specialist nurses, academic and laboratory staff as well as a genetic counsellor. Audit, laboratory testing, reporting compliance and research issues were covered by guest lecturers. Outcomes included proficiency in genetic risk assessment, effective communication of lab results and reproductive options, as well as attaining genetic competencies. Learners agreed that their reactions to new material mimicked their patients' anxieties when receiving test results in pregnancy. Results: There was an average 80% evaluation response rate with 30-40 respondents each year. Comments are categorised into content, delivery and assessment. Teaching recessive genetics using the Punnett square and via 'mating games' were mentioned as being most effective teaching strategies. Particiants remarked on the interdisciplinary dynamic which enriched case studies. Those new in post appreciated the 'just in time' learning. Discussion: Evaluations demonstrated that learners began to feel confident integrating family history with laboratory results in the last two weeks of the course. Roleplay allowed learners to practice their skills. Barriers to learning included difficulty grasping complex genetic concepts and working out risks for rarer Hb variants. Scaffolding content, self-directed learning and networking with clinical colleagues and lab staff helped surmount barriers. Annual evaluation demonstrates that the curriculum meets the needs of highly skilled NHS staff. Learners have requested a longer course, update days and more time spent on rare variants. In response, course content has shifted, but no additional time is to be funded. Summary: Learners taking this course meet their nursing and midwifery-related genetic competencies.

3035T

A collaborative genetic and genomic education pilot for health insurer staff: Development and implementation of a 13-episode webinar series. *R. Wildin[1], S. Belinson[2], H. Brown[2], V. Pratt[3], D. Flannery[4], D. Messersmith[1], Inter-Society Coordinating Committee Insurer Education Working Group.* 1) Division of Policy, Communications, and Education, Nat'l Human Genome Research Inst., Bethesda, MD; 2) Blue Cross Blue Shield Association, Chicago, IL; 3) Indiana University, Dept. Medical and Molecular Genetics, Indianapolis, IN; 4) American College of Medical Genetics, Bethesda, MD.

Rationale: Equipping healthcare providers to incorporate genetics and genomics into clinical practice is a universally identified need, yet efforts have not addressed the requirements of insurer medical directors and staff. The National Human Genome Research Institute's (NHGRI) Inter-Society Coordinating Committee for Provider Education (ISCC) collaborated with the Blue Cross Blue Shield Association (BCBSA) to produce a webinar series targeted to this group. The goal was for insurers to understand genetic testing strategies, interpretations, outcomes, and utility for patient care, and how their use enhances sound health decision making for their insured. **Methods:** The ISCC's Insurer Education Working Group (WG) developed a list of topics essential to understand advances in genetics and genomics in clinical practice, and a case-guided lecture framework. Presenters were subject-matter experts identified by the WG members. BCBSA piloted the activity and assisted presenters in optimizing content and presentation format. Each month, new live webinar content was presented to pre-registered BCBSA staff through their learning system, with all sessions recorded. Primary outcomes included enrollment and attendance counts, standard learning evaluations, and participation in interactive post-presentation discussions. User access and view statistics for recordings posted publicly on https://www.genome.gov/27563343/ provide a secondary, continuing outcome measure. **Results:** Thirteen hour-long webinars were presented between June 2015 and June 2016. Individual session content included foundational genetics knowledge (language of genetics, choosing a test, what can be diagnosed), clinical pathology (validity and utility, CPT coding), clinical applications of next generation sequencing (hereditary cancer, non-cancer, targeted cancer therapy, genome sequencing), regulation, and ethical testing and counseling. On average, at least 60 staff attended the webinars. Evaluations and qualitative discussions indicated general interest in and appreciation for the content among attendees, along with desire for more definitive data supporting clinical utility. **Conclusions:** Insurer medical staff had, perhaps for the first time, access to organized lectures addressing advances in, uses of, and challenges for genetics and genomics in healthcare. Continued strong attendance throughout the year suggests novel information was imparted and sufficient value was found to propose expansion.

3036F

Familial Creutzfeldt-Jakob Disease: Case report and consequences of post mortem testing without appropriate genetic counseling. *K. Clift[1], K. Guthrie[1], E. Klee[2], N. Boczek[2], M. Cousin[2], P. Blackburn[1], P. Atwal[1].* 1) Center for Individualized Medicine, Mayo Clinic, Jacksonville, FL; 2) Center for Individualized Medicine, Mayo Clinic, Rochester, MN.

Here we present a case of an asymptomatic 53-year-old woman who sought genetic testing for Familial Creutzfeldt-Jakob Disease (fCJD [MIM 123400]) after inadvertently learning that her mother had fCJD. The patient's mother had a sudden onset of memory problems and rapidly deteriorating mental faculties in her late 70's, which lead to difficulties ambulating, progressive non-fluent aphasia, dysphagia and death within ~1 year of symptom onset. The cause of death was reported as "rapid onset dementia." The patient's family, unhappy with the vague diagnosis, aggressively pursued causation and submitted frozen brain tissue from the mother to the National Prion Disease Surveillance Center where testing revealed a previously described 5-octapeptide repeat insertion (5-OPRI) in the prion protein gene (PRNP [MIM: 176640]) that is known to cause fCJD. The family had additional questions about the implications of this result and thus independently sought out genetic counseling. While rare, fCJD is likely underdiagnosed due to clinical heterogeneity, rapid onset, early non-specific symptomatology, and overlap in the differential diagnosis of Alzheimer's disease and Lewy body dementias. When fCJD is identified, a multidisciplinary approach to return of results that includes the affected patient's provider, genetics professionals, and mental health professionals is key to the care of the family. We present an example case which discusses the psychosocial issues encountered and the role of genetic counseling in presymptomatic testing for incurable neurodegenerative conditions. Ordering physicians should be aware of the basic issues surrounding presymptomatic genetic testing and identify local genetic counseling resources for their patients.

Utilization of telehealth in a translational genome-wide sequencing clinic in British Columbia. *A.M. Elliott[1,2,3], C. du Souich[1,2,3], S. Adam[1], J. Gillis[4], C. van Karnebeek[3,4], A. Lehman[1,2,3], J.M. Friedman[1,2,3].* 1) Dept of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Provincial Medical Genetics Program, BC Women's Hospital and Health Centre, Vancouver, BC, Canada; 3) Child and Family Research Institute, Vancouver, BC, Canada; 4) Division of Biochemical Diseases, Dept of Pediatrics, BC Children's Hospital, Vancouver, BC, Canada.

Background: Telehealth (TH) involves the use of information and communication technology to deliver health services to patients over distance. The time and cost of travel can constitute a barrier for some families to access centralized tertiary healthcare services. The use of TH in genetic counseling for common indications (e.g. advanced maternal age, cancer) has been reported; however, its use with genome-wide sequencing has not been well characterized. The CAUSES Research clinic, a three-year initiative to sequence 500 British Columbia (BC) pediatric patients with suspected genetic disorders, provides patient evaluation, genetic counseling, exome sequencing (ES), clinical interpretation of the genomic data and follow up. All families receive both pre- and post test genetic counseling that includes discussion of complex issues related to ES and obtaining informed consent. Patients who live in remote areas and have been recently evaluated by a clinical geneticist are offered the option of TH. *Methods:* We analyzed the number and type of TH encounters within the CAUSES clinic process. Additional variables studied included indications for ES and regions of TH uptake within BC. *Findings:* TH has been utilized at multiple stages of the CAUSES clinic process. Of the first 145 families, 22 (16%) were seen via TH for their pre-test genetic counseling. Clinical indications for ES included: 17 patients with intellectual disability +/- other anomalies (e.g. dysmorphisms, seizures), 2 with multiple congenital anomalies, and 3 with complex disorders (e.g. myopathy). Seven of the 8 major regions of BC utilized TH with 31% of families residing on Vancouver Island, where access to the BC Children's Hospital is via air or ferry only. TH was also utilized to provide post-test genetic counseling (results) to families and for clinical presentations with referring physicians who practice in remote areas to discuss annotated variant lists. *Conclusions:* TH is well utilized in the CAUSES clinic, for pre- and post test genetic counseling as well as for clinical presentations/consultations with referring clinicians. TH is an important consideration when implementing ES in research and clinical programs, allowing access to this technology with informed genetic counseling for families in remote areas. Additional advantages include decreased cost and travel for patients and clinicians and reduced time away from family and community.

3038T

Scaling genetic counseling: A human-centered approach to creating an electronic GC platform (eGC). *E. Levin[1,2].* 1) Icahn School of Medicine at Mount Sinai 1 Gustave L. Levy Place New York, NY 10029-5674; 2) Helix Inc 1 CIRCLE STAR WAY FL 2 San Carlos, CA 94070.

  BACKGROUND: There are not enough genetic counselors (GCs) to meet the expanding genetic testing market demand, increasing wait times, and potentially negatively impacting both the patient and genetic counselor experience. To address this challenge, the Icahn School of Medicine at Mount Sinai sponsored an interaction design project to lead a 3-phase project to discover opportunities for developing a scalable platform that will help genetic counselors, patients, labs, and ordering providers and enhance the overall genetic/genomic testing experience. **DESIGN**: The project applied a qualitative, human-centered design approach to assess the current challenges and opportunities around prenatal carrier screening. Phase 1: Collaborate with key stakeholders to create concept sketches. Phase 2: Conduct deep, in-person user interviews with patients and/or couples who had gone through prenatal carrier screening in the previous 12 months as well as genetic counselors in both the clinic and lab. Phase 3: Design user experience architecture and key workflows based on iterative user feedback. **OUTCOMES**: Four main areas were identified for deep study: Automate and enhance workforce efficiencies; centralize data aggregation and documentation; enable on-demand information access and transparency; and improve user experience for all stakeholders. **CONCLUSIONS**: GCs are overloaded with logistics and repetitive tasks that steal time from actual counseling. Patients bounce back and forth across stakeholders almost at every step, creating an anxiety-inducing process in which they do not feel in control. As a result, the design team focused on creating two "experiences". The Patient Experience is a scalable, institution-agnostic self-service experience curated by the GCs. The Genetic Counseling Experience, is a primary tool to help stage the patient's journey and streamline operational workflows. Designs were created, tested, and iterated with both stakeholder groups to yield a detailed framework for software execution.

3039F

PhenoDB - A web-based next generation sequencing educational platform for medical and graduate students, residents, clinicians and counselors. *S. Liao[1], H. Wick[2], F. Schiettecatte[3], A. Hamosh[2], D. Valle[2], J. Bodurtha[2], N. Sobreira[2].* 1) Johns Hopkins University School of Medicine, Baltimore, MD 21205; 2) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD 21205; 3) FS Consulting, Salem, MA.

  Next Generation Sequencing (NGS) has become a major diagnostic tool throughout medicine. Its use has allowed for the molecular diagnosis of many inherited phenotypes and malignancies, identification of pharmacogenetic susceptibilities, and discovery of individual genetic variation that confers risk for common complex traits. Thus, it is critical for physicians in all areas of medicine to be familiar with NGS technology, indications, data analysis and interpretation, genetic counseling, and ethical considerations. Here we present an online, problem-based, teaching tool designed for medical and graduate students, residents, clinicians and counselors. It includes a didactic part and hands-on learning exercises that will allow the users to: i) understand the differences, applications and consequences of single gene, genes panels, WES and whole genome sequencing (WGS) in clinic; ii) become familiar with laboratory and analytic techniques used to generate NGS data; iii) become familiar with various databases and programs used to evaluate sequence data and interpret variants; iv) become familiar with variant classification criteria and incidental findings and how these results are reported; and, v) appreciate the need for pre- and post-test genetic counseling for sequence-based tests. The teaching tool was developed as part of PhenoDB, a web-based tool for storage and analysis of phenotypic and genomic data, freely available at www.phenodb.org (Sobreira at al., 2015). The hands-on learning exercises include 15 clinical cases created by adding specific published disease variants to HapMap WES data. The clinical cases are relevant to different medical specialities and the WES data can be analyzed using the PhenoDB Variant Analysis Tool. Each clinical case includes a list of questions that addresses one or more of the objectives listed above and that can also be used as an assessment tool. The didactic part is under development and includes a series of one hour classes specific for each objective that will be stored and made continuously available for access in the PhenoDB teaching tool together with the clinical cases. As of today, the PhenoDB teaching tool has been used to teach graduate and medical students, post-docs, medical genetics residents and counselors with positive evaluations. We plan on making this resource freely available on line for further dissemination and to enhance basic and applied understanding and use of genetic information in healthcare.

3040W

A community genomics initiative using blood banks for recruitment enables access to a diverse, altruistic population. *E. Ramos[1], M. McGinniss[1], E. Thorpe[1], L. Fosler[1], K. Schahl[2], D. Eklund[3], H. Bixenman[3], D. Morton[3], D. Wellis[3].* 1) Illumina, Inc., San Diego, CA; 2) InformedDNA, St. Petersburg, FL; 3) San Diego Blood Bank, San Diego, CA.

   Multiple studies are assessing the future of personal genome sequencing but the majority of participants fall into a narrow demographic profile – wealthy, highly educated and Caucasian. This lack of diversity is a barrier to assessing issues that may arise when implementing clinical whole genome sequencing (cWGS) in a population as diverse as that of the United States. Conversely, blood bank donor populations mimic U.S. population diversity. San Diego Blood Bank (SDBB), in collaboration with Illumina, initiated an IRB-approved pilot project to determine if blood banks can be used to recruit a diverse group of participants for genomics research.   SDBB sent a 13-question survey via email to approximately 150,000 active, inactive, and deferred donors. Donors were asked if they would be interested in participating in a research study that would follow people's health over time to understand risk and disease and what type of data they would be willing to provide. 7,177 unique responses were collected and 71.7% stated that they would provide genetic information. 70 individuals, demographically matched to the San Diego population, were enrolled in the study. The cohort's self-reported ethnicity was 27% Caucasian, 26% Hispanic/Latino, 13% Black/African-American, 11% Asian and the remainder other/two or more races. 67% (41/61) reported a household income of <$100,000.   Participants had cWGS and received interpreted results for about 1200 Mendelian disorders and a pharmacogenomics panel. The SDBB cohort was compared to a 2016 U.S. UYG cohort with a homogeneous "typical" profile. The average number of pathogenic/likely pathogenic variants per participant was similar between the SDBB and U.S. cohorts (2.17 vs 2.69). The average number of variants of unknown significance (VUS) was higher for the subset of the SDBB cohort that did not self-report as Caucasian only when compared to the U.S. UYG cohort (1150 vs 1046). Two SDBB participants (2.9%) had a likely pathogenic variant in one of the 56 "ACMG genes", which is consistent with other studies.   The U.S. Precision Medicine Initiative has committed to recruiting a diverse cohort of participants. This pilot demonstrates that blood banks are trusted entities that can be leveraged to recruit large numbers of diverse volunteers willing to participate in genomic research. Additionally, results suggest that while a higher VUS rate may be seen with increasing diversity, participants are equally likely to benefit from testing.

3041T

The Brazilian Initiative on Precision Medicine (BIPMed): The first publically available genomic database in Latin America. *C.S. Rocha[1], B.S. Carvalho[2], I. Lopes-Cendes[1] for the BIPMed Collaborative Group and the Brazilian Institute of Neuroscience and Neurotechnology.* 1) Department of Medical Genetics, School of Medical Sciences - Unicamp, Campinas, São Paulo, Brazil; 2) Department of Statistics, Institute of Mathematics, Statistics and Scientific Computing - Unicamp, Campinas, São Paulo, Brazil.

   Introduction: BIPMed is an initiative of five Research Innovation and Dissemination Centers established in the state of Sao Paulo, Brazil. Precision Medicine has emerged recently as a concept in which scientific knowledge and technology will come together to provide the basis for the 21st century medicine. It involves translational research, genomics and personalized medicine to propose a new level of data integration in order to improve health care. The BIPMed genomic database is the first product released by our initiative to fulfill the increasing need for publically available genetic and genomic information about the Brazilian population; however our aim is that it becomes a reference for data sharing for different populations in Latin America. BIPMed is also part of the Beacon Project, which is a data discovery engine supported by the Global Alliance for Genomics and Health (GA4GH). **Materials and Methods:** BIPMed genomic database is currently based on a software platform, the Leiden Open Variation Database and it was implemented as a fully web-based gene sequence variation database. The design of the database follows the recommendations of the Human Genome Variation Society and the principles and guidelines of the GA4GH for the ethical and responsible sharing of genomic and clinical information. In addition, two other databases were designed to store and display information from SNP-arrays and RNA-sequencing data. Furthermore, a platform able to integrate different genomic information is under development. **Results:** Currently, the database contains variants detected using whole exome sequence as well as SNP-genotyping from reference population ascertained based on their geographic origin in Brazil. In this dataset we identified over ten million variants in 20842 genes. There were 209 variants which were unique to the population studied. In addition, our genomic database has attracted world-wide attention and it has been accessed by an average of 165 hits daily from countries all over the globe. **Discussion and conclusion:** We expect the database to grow fast and include data-sets from disease cohorts as well as other types of –omics data. This platform, the first of its kind in Latin America, is intended to be used by clinicians and scientists worldwide, to obtain and share information about various aspects of genomic medicine and human health, as well as to support dissemination and training. Supported by: FAPESP, BRAZIL.

3042F

Lowering barriers to accessing genomic information: Enabling a search function within the ClinGen Resource. *M.S. Williams[1], C.L. Overby[2,4], W.S. Rubinstein[3,4], D.R. Maglott[3,4], T.H. Nelson[5], A. Milosavljevic[6], C.L. Martin[5], S.R. Goehringer[7], R.R. Freimuth[7], G. Del Fiol[8], B.S.E. Heale[9].* 1) Dir, Genomic Med Inst, Geisinger Health System, Danville, PA; 2) Johns Hopkins School of Medicine, Baltimore, MD; 3) The National Center for Biotechnology Information, Bethesda, MD; 4) National Institutes of Health, Bethesda, MD; 5) Geisinger Health System, Autism & Developmental Medicine Institute, Danville, PA; 6) Baylor College of Medicine, Houston, TX; 7) Mayo Clinic, Rochester, MN; 8) University of Utah, Salt Lake City, Utah; 9) Intermountain Healthcare, Salt Lake City, Utah.

    Statement of Purpose: The NIH-funded Clinical Genome Resource (ClinGen) is dedicated to building an authoritative central resource that defines the clinical relevance of genes and variants for use in precision medicine and research. The Electronic Health Record Working Group (EHRWG) ensures that the ClinGen resource is designed to be accessible to providers and patients through EHR and related systems. Here we describe the functionality and design choices for the ClinGen website (clinicalgenome.org) that allows searching across all ClinGen resources as well as selected external content collections. The technical aspects of the search function have been described elsewhere[1]. **Methods Used:** An initial resource list was compiled by the chair of the EHRWG and circulated to the ClinGen steering committee that identified additional resources. The expanded list was presented to attendees of the ClinGen session at the 2014 ASHG annual meeting to ensure completeness and assist prioritization. Once the resources were assembled on the webpage, the EHRWG enabled the search of resources by disorder, by medication or by gene name. To facilitate search term selection, the search interface assists users as they type by presenting terms and synonyms obtained from the resources. Functionality and design choices for the resource were presented to the ClinGen Steering Committee, and to attendees of the ClinGen session at the 2016 ACMG annual meeting. ACMG meeting attendees were encouraged to interact with a live version of the resource during the meeting. Over 30 individuals provided informal feedback which was compiled, summarized and documented. Web navigation statistics are being collected to provide additional usage data. **Summary Results:** Input from groups listed above was used to optimize the functionality and design choices. ClinGen native resources were added when available and optimized to return relevant annotated content for disease, gene and medication. Information was provided to non-ClinGen resources to facilitate return of content in response to a single query. Since 5/27/2015 over 5,000 searches have been performed. 36 different resources have been accessed following the search for a variety of topics. Future work will involve formal usability testing with a diverse group of end users and improve interfaces with EHRs. [1]Heale BSE, et al. Integrating Genomic Resources with Electronic Health Records using the HL7 Infobutton Standard. Appl Clin Inform (under review).

Development of Korean genome reference material. *J.N. Kim[1], I.C. Yang[3], Y.K. Bae[3], J. Sung[2].* 1) Seoul National University, Seoul, Seoul, South Korea; 2) Complex Disease and Genome Epidemiology Branch, Department of Epidemiology, School of Public Health, Seoul National University, Seoul, Korea; 3) Korea Research Institute of Standards and Science, Center for Bio-Analysis, Daejeon, Korea.

    The Asian Reference Genome Project aims to complement current reference genome (hg38) by adding Asian-specific alternative sequences. Although the hg38 is widely used in the field, demand and importance for ethnically specific reference genome sequences has been recognized. It was reported that this could be evidence for the emergence of novel sequences, resulted from integration of ethnically specific genomic information. In this project, therefore, we are developing Korean genome reference material to enable comparative characterization of Korean-specific sequences. To this end, the study is constructing an Asian-specific reference sequence based on deep sequencing of one individual (AK1), 3 trios and 2 identical twin pairs. One of the research products from the study will be the Korean genome reference material (gRM), which is similar to the reference material developed by the NIST (National Institute of Standards and Technology). A reference genomic DNA with known sequence will serve as a "correct answer" for different analytic platforms and bioinformatics tools, to evaluate the validity of diverse genome technologies. For development of the gRM, DNA after homogenizing was analyzed by multiple sequencing platforms including short read whole genome deep sequencing by Illumina (X10, depth x90), long read analysis by PacBio,(up to x100), and virtual long read analysis using 10X platform. The presentation summarizes the current status of gRM development. This study is open to collaborations at any level.

3044T

The Genomic Consultation: A clinical service designed to enrich patient selection for exome sequencing. *A. Lehman[1], C. du Souich[1], S. Adam[1], J. Gillis[2], C. Van Karnebeek[2], J.M. Friedman[1], A. Elliott[1].* 1) Dept Medical Genetics, Univ British Columbia, Children's and Women's Health Centre, Vancouver, BC, Canada; 2) Dept Pediatrics, Univ British Columbia, BC Children's Hospital, Vancouver, BC, Canada.

Background: Exome sequencing (ES) is not routinely available in British Columbia. Physicians must submit an application to the provincial insurer, the Medical Services Plan (MSP), and funding is granted in restricted situations. Recently, access to ES increased via establishment of the CAUSES research clinic (a 3-year initiative to perform parent-child trio ES for 500 BC pediatric patients), which prompted the development of a clinical Genomic Consultation Service (GCS) to provide genomic advice to physicians considering ES for their patients. Inclusion and exclusion criteria for ES were identified, and education sessions for referring physicians were conducted prior to GCS and CAUSES clinic launch. A panel to review GCS referrals was comprised of geneticists, a pediatric subspecialist, and genetic counselors. Medical records of patients are reviewed weekly, and genomic advice (e.g. targeted testing, genomic panel, ES, referral to Medical Genetics for further evaluation) is provided in a letter. The GCS was established in April 2015. Over 400 referrals were reviewed in the first year. *Findings*: Analysis of the first 350 GCS patients revealed the most common indication was intellectual disability (ID). Many patients had ID in combination with other anomalies. Median age was 7 years (average 7.8 years). Medical genetics was the most common referring discipline (58%), followed by biochemical diseases (19%) and neurology (12%). Others included hematology/oncology, general pediatrics, endocrinology, cardiology and neuropsychiatry. Outcomes: 67% of referrals were appropriate for ES and subsequently invited to participate in the CAUSES clinic; 12% were declined due to lack of suitability and a targeted clinical genomic test was recommended for 9%. The remainder received other advice, including referral to Medical Genetics for further evaluation or whole genome sequencing. *Conclusions*: The GCS enriches selection of patients suitable for ES and provides physicians with patient-specific genomic advice, which can support applications for insured funding. This service enhances clinical implementation of ES, a test perceived as costly to the health care system.

Patients and their families and friends as developers of medical treatments/devices. *V. Francisco[1], S.A. Oliveira[1], P. Oliveira[2].* 1) Instituto de Medicina Molecular, Lisboa, Portugal, Portugal; 2) Católica-Lisbon School of Business and Economics.

This study looks at the sources of health care innovations and finds that patients of chronic diseases and their non-professional caregivers have developed a very significant number of non-drug medical innovations that have proven valuable in dealing with their diseases, namely by improving their quality of life. Many of these innovations were also evaluated as novel by expert medical evaluators. In some cases, patients even saved their own lives. These innovations usually occur behind closed doors and might never be knowledge or used by anyone else. However, if successful solutions and knowledge were shared with other patients with similar need, it could improve the lives of many others. One way to intervene is to reduce the diffusion costs and develop a centralized inventory of patient developed solutions. With this in mind, Patient Innovation – https://patient-innovation.com – was developed as a nonprofit international, multilingual and open platform, designed to allow patients and caregivers to show and share the innovative solutions they developed to fight their diseases, as well as to foster collaboration among patients, caregivers and others. This experimental platform is aimed at increasing both the rate of patient innovations and its diffusion. Prestigious institutions and reputable individuals, including several Nobel Laureates, distinguished scholars and patient associations from around the world have endorsed it. From February 2014 to September 2015 the Patient Innovation platform collected and curated about 400 innovative solutions developed by patients and caregivers from 30 countries with the USA, Portugal, England, Australia and Brazil as the main contributors. In this poster we will report the developments of the project and the implications for health-care innovation practice and policy.

3046W

Workshop in applied genomic medicine: The outcome. *A.D. Gilbert[1], C.R. Marshall[1,5,6], P.N. Ray[1,3,4,5,6], S.W. Scherer[1,3,4,5], R.D. Cohn[1,2,3,4], S. Bowdin[1,2].* 1) Centre for Genetic Medicine, The Hospital for Sick Children, Toronto, Canada; 2) Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, ON, Canada; 3) Program in Genetics and Genome Biology, Research Institute, The Hospital for Sick Children, Toronto, ON, Canada; 4) Departments of Paediatrics and Molecular Genetics, University of Toronto, Toronto, ON, Canada; 5) The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, Ontario, Canada; 6) Genome Diagnostics, Department of Paediatric Laboratory Medicine, The Hosptial for Sick Children, Toronto, ON, Canada.

   Background: The introduction of clinical genome and exome sequencing (CGES) has placed clinical genetics healthcare professionals (CGHP) at the forefront of genomic medicine. These diagnostic modalities are changing not only the scope of medicine, but also the overall scope of practice for the CGHP. Designing relevant educational material and providing venues for geneticists and other health care providers to acquire the skills necessary to integrate CGES into patient care is of paramount importance. A team from SickKids, The Centre for Applied Genomics (TCAG), and the University of Toronto designed and hosted a workshop that addressed the evolving educational needs. **Goals:** *At the end of this workshop, participants will be able to:* integrate CGES into their clinical practice, assess phenotypic and bioinformatics data, debate counseling and ethical considerations, and describe translational and research methodologies. **Method:** SickKids Hospital hosted a 2.5 day applied genomic medicine case-based workshop combining a didactic component and interactive breakout sessions, focusing on the key components of performing clinical genomic sequencing and returning results. Experts from Canada, the US, and Ireland comprised the team of 19 instructors and facilitators. The target audience was primarily clinical genetic providers, trainees and bioinformaticians from across North America who are using CGES. To ensure the participation of both geneticists in training and geneticists in underprivileged nations, scholarships were available. **Results:** 39 genetic professionals from across North America registered for the workshop. Scholarships were awarded to all the trainees that applied. Data was obtained from a pre and post question set that was distributed and completed on the first and last day of the workshop. In addition, a feedback survey was electronically distributed to the attendees. 37 (95%) commenced the feedback survey, with 20 (54%) completing it. **Conclusion:** Based on the overwhelming positive feedback, this workshop was successful and achieved the educational goals set forth by the organisers. Further, 100% of the survey respondents agreed or strongly agreed that the workshop was excellent, and 100% would unequivocally encourage a colleague to attend in the future.

3047T

Enhancement of undergraduate education using a collaborative model to engage K-12 students through genetics literacy, human genetics and GMO investigation. *T.N. Turley-Stoulig[1], T.M. Tinney[2], O. Bell-Hanegan[1,2], K. Bokun[1], M. Celestine[2], R. Corbett[1], L. Davis[1], J. Frosch[1], J. Jacoby[1], I. Juarez[1], J. Khanal[1], A. McIntyre[2], M. McLaurin[1], K. Phan[1], K. Provost[1,2], S. Walker[1].* 1) Dept of Biological Sciences, Southeastern Louisiana Univ, Hammond, LA; 2) Northshore Technical Community College, Mandeville, LA.

   In the rapidly advancing field of genetics and the technologically fast-paced world of modern science, there is a monumental need to interest students in genetics, and STEM in general, early on not only for future study in science-related fields, but also to educate them so they may better understand advances being made as young adults growing up in such an era. The purpose of this study was to increase genetics-based knowledge and understanding, increase awareness of genetics technologies and research and encourage study in genetics and STEM disciplines in general for a range of students at progressive levels. We used an innovative, multi-dimensional approach involving a university/community college partnership coupled with outreach that spans the fields of genetically modified organisms (GMOs) and human genetics by bringing laboratory techniques of both disciplines into the classrooms of high school students, exposing them to genetics-based materials they would otherwise not encounter. Students were educated in basic genetics through a series of primer modules and trained in DNA isolation, PCR and GMO analysis through a series of practical modules. Instruction incorporated a variety of modalities, including animations and hands-on techniques. The study spanned the academic year and involved a ladder of learning whereby a cohort of trained undergraduate students from Southeastern Louisiana University became the teachers of a student cohort from Northshore Technical Community College. In turn, the undergraduate cohorts then team-taught high school students both in their high school classrooms and on the Southeastern campus. The introductory modules were sequenced as Primer Modules I and II, covering basic genetics concepts, human genetic disease, GMOs, and modern laboratory techniques. Practical Modules I and II provided laboratory extensions for conducting GMO experiments using techniques discussed in the Primer Modules. At the high school level, results showed an increase in student understanding of genetics concepts and a stronger interest in the study of cells and/or genes in the future. Similar results were seen for both undergraduate cohorts. We conclude that this approach improves the educational experience of community college and university undergraduate students as well as high school students and bridges the three groups in an invaluable learning experience. We plan to extend this study to evaluate the effectiveness of these methods further.

Supporting genetics in primary care: Investigating how theory can inform professional education. *B.J. Wilson[1], R. Islam[2], J.J. Francis[3], J.M. Grimshaw[1,2,4], J.A. Permaul[5], J.E. Allanson[6], S. Blaine[5,7], I.D. Graham[1,2], W.S. Meschino[8,9], C.R. Ramsay[10], J.C. Carroll[5,11].* 1) School of Epidemiology, Public Health and Preventive Medicine, Univ Ottawa, Ottawa, ON, Canada; 2) Centre for Practice Changing Research, Clinical Epidemiology Program, Ottawa Hospital Research Institute, Ottawa, ON Canada; 3) School of Health Sciences, City University London, London, UK; 4) Department of Medicine, University of Ottawa, Ottawa, ON, Canada; 5) Department of Family Medicine, Mount Sinai Hospital, Toronto, ON, Canada; 6) Department of Paediatrics, University of Ottawa, Department of Genetics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada; 7) STAR Family Health Team, Stratford, ON, Canada; 8) Genetics Program, North York General Hospital, Toronto, ON, Canada; 9) Department of Paediatrics, University of Toronto, Toronto, ON, Canada; 10) Health Services Research Unit, University of Aberdeen, Aberdeen, UK; 11) Department of Family and Community Medicine, University of Toronto, Toronto, ON, Canada.

Background Many studies have shown that barriers exist to the integration of genetic case finding into primary care. To obtain deeper insight into professional education strategies, we examined the determinants of three behaviors related to using breast cancer genetics referral guidelines effectively. Methods The behaviors of interest were: *taking a family history*, *making a risk assessment*, and *making a referral decision*. These mapped on to practice guidelines available to participants at the time of the study. Using vignettes of primary care consultations with hypothetical patients as a cue, we used the Theory of Planned Behavior to develop a survey instrument to capture data on intention for each behavior of interest (as a proxy outcome) and its predictors (attitude, subjective norm and perceived behavioral control), and mailed it to a sample of Canadian family physicians (FPs). Correlation and regression analyses explored the relationships between predictor and dependent variables. Results The response rate was 96/125 (77%). The predictor variables explained 38-83% of the variance in intention across the three behaviors. For the *family history* behavior, the data suggested that, although FPs appeared consistently supportive of family history taking in inherited cancer risk assessment, a proportion were in fact skeptical that this should be part of their own practice and, for some, low intentions were associated with lack of confidence. For the *risk assessment* behavior, we found a broad set of reactions, from respondents extremely positive in all respects, to those who clearly did not intend to carry out this behavior, saw no value in it, felt little pressure from colleagues to do it, and/or would not feel confident in doing it anyway. For the *referral decision* behavior, we found overall high intentions, but negative as well as very positive evaluations across all domains. The most striking was for perceived behavioral control. Our observations suggest potential utility in tailoring educational interventions specifically to address different barriers to using genetics in practice. For example, techniques such as social comparison or modelling may address skepticism that a behavior should be expected of a FP (subjective norm), whereas graded tasks or behavioral rehearsal may support low confidence about skills (perceived behavioral control). Conclusion Theory-based needs assessment may offer an effective approach to tailoring genetics education for FPs.

3049W

Discordance in selected designee for return and the legal recipient of genomic findings in the event of participant death. *L.M. Amendola[1], M. Horike-Pyne[1], S.B. Trinidad[2], S.M. Fullerton[2], B.J. Evans[3], W. Burke[1,2], G.P. Jarvik[1,4].* 1) Division of Medical Genetics, University of Washington, Seattle, WA; 2) Department of Bioethics and Humanities, University of Washington; 3) Center for Biotechnology & Law, University of Houston Law Center; 4) Department of Genome Sciences, University of Washington.

Introduction: The Office for Civil Rights in the U.S. Department of Health and Human Services has provided guidance that HIPAA-covered entities are allowed to disclose a deceased person's health records to: (1) a personal representative whom the decedent appointed, prior to his or her death and (2) members of the deceased person's family, even if the deceased person did not appoint them as a personal representative, unless the deceased person had expressed a preference not to disclose his or her information to them. **Methods**: The University of Washington NEXT Medicine Study of the Clinical Sequencing Exploratory Research (CSER) program previously reported participant preferences regarding designating an individual to receive their genomic results in the event of their death, including whether they want the results to be shared, and if so, with what person (PMID:26479557). Participants are also asked whether this designee is the executor of their will or estate. Participants were undergoing genetic testing clinically indicated by colorectal cancer risk. **Results**: Of 59 participants (31 males; 52%), 18 (31%) did not have a will or estate plan. Of those 41 with an estate plan, 28 (68%) had the same designee for their genomic data as their estate executor. Of these 28 participants, 27 designated their spouse/partner and 1 a family member. Thirteen of the 41 (32%) participants with an estate plan had designated someone other than their executor to receive their genomic results; 2 designated their spouse/partner and 11 a family member. Participants who designated a family member rather than a spouse/partner for receipt of their genomic results in the event of their death were more likely to have selected a different individual estate executor (Fisher's exact p <0.001). **Conclusions**: The participant is best positioned to specify whether and with whom they would like their genomic data shared in the case of their death. This work highlights that the individual deemed most appropriate by the participant to receive and disseminate genomic results may not be the same person they have chosen to administer their estate and thus may not have legal access within the current laws. These data were collected from patients for whom a genetic cancer test had been clinically ordered, thus, they support provision of the opportunity to choose such a designee on both research and clinical consent forms for genomic tests.

3050T

Adolescent decision-making regarding secondary findings in whole genome sequencing. *R. Byrne[1,7], R. Hayeems[2,6], M. Kaufman[3], K. Sappleton[4], D. Chitayat[1,5], C. Shuman[1,6,7], N. Monfared[1,6].* 1) Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, ON, Canada; 2) Program in Child Health Evaluative Sciences, The Hospital for Sick Children Research Institute, Toronto, ON, Canada; 3) Division of Adolescent Medicine, Department of Paediatrics, Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 4) Center for Innovation and Excellence in Child & Family Centered Care, The Hospital for Sick Children, Toronto, ON, Canada; 5) The Prenatal Diagnosis and Medical Genetics Program, Department of Obstetrics and Gynecology, Mount Sinai Hospital, Toronto, ON, Canada; 6) Centre for Genetic Medicine, The Hospital for Sick Children, Toronto, ON, Canada; 7) Molecular Genetics, University of Toronto, Toronto, ON, Canada.

Background: Genomic testing is widely used to diagnose adolescent patients with suspected genetic conditions. Such testing is preceded by an educational component to support informed decision-making. Recent research suggests that adolescents benefit from participation in medical decision-making regarding their health care. However, little is known about adolescents' understanding of the risks and benefits related to secondary findings (SFs) found in genomic sequencing. Identifying and understanding the factors that contribute to adolescents' decision-making about SFs will inform new approaches to education and consent for adolescents undergoing genomic sequencing. Objective: To explore factors that are important to adolescents in their decision-making process related to learning about SFs in genomic research. Study Design: Using semi-structured interviews, we explored the experiences of adolescents, ages 12-19, in their decision to learn about SFs in the context of the whole genome sequencing (WGS) in a research setting. Adolescents were previously offered WGS to determine the molecular etiology of their chronic medical condition. Interview questions were used to assess adolescents' understanding of SFs, awareness of the potential risks and benefits and the factors that adolescents consider when deciding to learn about SFs in genomic research. Results: Eight adolescents, ranging from 12-19 years of age, of whom 7/8 opted to learn about SFs were recruited. Thematic analysis of the transcripts using constant comparative analysis was conducted. To date, three sets of factors have emerged as influential with respect to decision-making about secondary findings: familial factors, including family history and parental discussion; personal health history; and perceived value of knowledge. Conclusion: Preliminary results from the study suggest that adolescents' personal health and family relationships impact their decision to learn about SF. This indicates the importance of exploring these factors with adolescents in the pre-test consent process for genomic sequencing.

3051F

NF1 & me: **Study of the impacts of neurofibromatosis type 1 on the lives of affected adolescents.** *F. Duplain-Laferrière[1], R. Drouin[2], C. Bouffard[1].* 1) Pediatrics, Universite de Sherbrooke, Sherbrooke, Quebec, Canada; 2) Pediatrics, Laval University, Quebec City, Quebec, Canada.

Adolescence is a critical moment wherein the learning of social life, love and sexuality, as well as academic skills largely determine the conditions of life as an adult. **Neurofibromatosis Type 1 (NF1)** is a genetic condition that may entail significant medical, aesthetic, psychosocial and learning-related problems. This period can be more difficult for those having the disease. There is a high risk of stigmatization, rejection and depression. *NF1 & Me* is a research project that focus on the perceptions, experiences and concerns of Canadian adolescents aged 15 to 19 years with a diagnosis of NF1. We want to: 1) determine their level of knowledge and what they would like or need to know regarding the clinical and genetic aspects of NF1, 2) know their concerns about its impact on their social life (school, work, company) and private life (sexuality, love, reproduction) and 3) Appraise the role and importance of intergenerational dialogue in their lives. **Methodology :** Asynchronous online text-based interview, in order to let all the necessary time for the participants to answer, in anonymity, without the consent of their parents. **Results :** Almost all the adolescents are well informed on the origin of NF1 and it's mode of inheritance. However, it is not easy to find resources when they have questions. They all mentioned negatives impacts of NF1 on their lives. The results also reveal the link between the interpersonal and intergenerational relationships with health and well-being. There is connection between the interpretation adolescents make of their parents' attitudes towards NF1 and the perception they have of themselves, their quality of life and their future. Those whose parents avoid talking about NF1 seem to have a more negative perception of NF1 and their prospects of success. NF1 adolescents who openly discuss their disorder with at least one parent, show healthy social interactions and seem to be more resourceful to take control of their lives. **Conclusion :** *NF1 & Me* will generate rapidly transferrable and unique results on the medical and psychosocial aspects of NF1 and the intergenerational and interpersonal communication. It leads to innovative approaches to help adolescents with NF1 and their families and educating them as well as health professionals to optimize their means of intervention and communication. *NF1 & Me* has the potential to be useful in the context of other genetic diseases, handicaps, psychological disorders and social problems.

3052W

Review of return of results policy, as reflected in clinical trial informed consent documents. *A. Franca[1], D.J.H. Mathews[2].* 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins School of Medicine, Baltimore, MD; 2) Johns Hopkins Berman Institute of Bioethics, Johns Hopkins Unitversity, Baltimore, MD.

The recent launch of the Precision Medicine Initiative, the move toward learning health systems, and the changing role of patients in research necessitates that we reconsider the responsibility of an investigator to communicate research results to participants. This reconsideration has been taking place in earnest for several years, through theoretical and empirical work on the return of results and incidental findings (IFs), resulting in several recommendations and guidances from scholars and organizations. In an effort to further inform this debate, we sought to understand the current landscape of practice regarding the return of results, as assessed through an analysis of informed consent documents. We began with a survey of institutional guidelines and/or policies (G/P) regulating informed consent at the top ten NIH-funded U.S. research institutions (USRI). Of these institutions, 8/10 had a G/P mentioning the return of individual results (IR). About half of these (4/10) were specific to genetic results. Five institutions had a G/P regarding IFs. Of these five, one was specific to imaging results, three were specific to genetic results, and one covered both genetic and overall IFs. We next analyzed 39 publicly available informed consent forms (ICFs) from clinical trials published in the New England Journal of Medicine (NEJM) between January 2014 and March 2016. Of the 39 ICFs, 35 addressed the return of research results. Of these 35 ICFs, 22 stated that they would return IR. Of these 22, 13 included specific exceptions regarding the return of results. A second set of ICFs derived from genetics-focused research projects were also analyzed, and included 10 ICFs; 7 that were procured by emailing corresponding authors of clinical trials performed at USRI and published in NEJM between January 2014 and March 2016 with the word "gene" in the title or abstract, and three from three of the five Centers for Mendelian Genomics. Seven of the 10 ICFs mentioned the return of IR. Of these, 6 stated that IR would be returned, and all 6 included specific exceptions. Our findings indicate that there is a tremendous amount of variation in policies, guidelines and practice with regard to the return of IR. We recommend additional guidance and outreach to provide uniformity among institutions in order to decrease variation and ensure research subjects at minimum understand what results will and will not be returned from any trial in which they are being asked to participate.

3053T

Online education and e-consent for preventive genomic screening: The *GeneScreen* **pilots.** *G. Henderson[1], R.J. Cadigan[1], K. Kuczynski[1], D. Skinner[1], C. Rini[1], R. Butterfield[1], A. Prince[1], M. Van Riper[1], M. Roche[1], K. Foreman[1], J. O'Daniel[1], D. Reuland[1], K. Muessig[2], J. Evans[1], K. Goddard[2].* 1) University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Center for Health Research, Kaiser Permanente NW, Portland, OR.

Programs that screen adults for rare, medically actionable conditions will likely use web-based education and consent. Yet, there is little evidence for the effectiveness of e-consent to convey study features, and harms and benefits of screening in healthy populations. In *GeneScreen*, we investigate issues raised by such screening, focusing on 11 medically actionable conditions. We piloted recruitment at a hospital-based primary care practice (n=425) and a research biobank (n=650). Individuals were mailed a brochure and letter directing them to the *GeneScreen* website. The website provided a summary of 14 study features relevant for informed consent, which could be expanded to display more information. *GeneScreen* "joiners" were surveyed about decision-making and understanding, and a subset were interviewed in more detail. Here we explore predictors of ease of deciding to participate and understanding of the main features of the study.   Of 1076 who were approached, 242 joined *GeneScreen* and completed the survey (23% response rate). 74% were from the biobank. The average age was 59 (range 24-95); and most were female (69%) and non-Hispanic White (83%). Median income was $75,000 - $99,999. Two-thirds had at least a college degree. The majority had good health literacy: only 12% reported difficulty reading medical information. Genetic self-efficacy was high (Mean 1.92 on a scale of 1-6, with 1 showing higher efficacy). Two-thirds of participants (67%) did not expand any of the 14 consent summary items; 11% expanded one, and 22% expanded two or more. On a 6-item scale measuring understanding of the *GeneScreen* study, the mean score was 4.52 (range 0-6). Most (81%) found the decision to join extremely or very easy. Telephone interviews (n=44) found that over two-thirds made the decision to join after reading the printed recruitment materials, before going online.   In multivariable analysis, difficulty in deciding to join was significantly associated with higher education, income, and greater number of consent summary items expanded, and negatively associated with genetic self-efficacy. Those who found the decision easy did not expand the consent summaries, perhaps having decided early in the process. Expanding more consent summaries was not associated with study knowledge; the only significant predictors were income and education. We discuss implications of these findings in the context of e-consent for genetic screening.

3054F

Chartering precision medicine: Addressing health disparities through effective engagement partnerships. *R. Isasi[1,2], M. Pericak-Vance[2,1].* 1) Dpt. Human Genetics, Miller School of Medicine, University of Miami, Miami, FL; 2) John P. Hussman Institute for Human Genomics.

Precision Medicine (PM) aims at improving the understanding of complex biological, environmental and lifestyle factors. It promises to revolutionize medicine by improving disease prediction, prevention, diagnosis and treatment. Increasingly, research is moving away from the traditional unidirectional model to one in which patients and other key stakeholders are fully engaged. Such engagement produces research that is more patient-centered, useful, and trustworthy and ultimately leads to greater use and uptake of research results by patient and the broader community. In the wake of PM, the problematic of health disparities has taken renewed importance. Against the backdrop of those purported benefits PM could bring, are concerns surrounding the fact that PM could actually end exacerbating existing disparities in health care, if its benefits are not equitable distributed. Key to the success of PM is to take into account the rich diversity of the USA population to ensure that the benefits of these advances accrue to all. The disproportional representation of ancestral-racial-ethnic minorities and socially disadvantaged populations in clinical translation efforts constitutes an important roadblock for the optimal implementation of PM. For PM to be effective as a meaningful stakeholders' partnership endeavour, novel regulatory, governance and ethical approaches would need to be conceptualized and implemented. Embracing a dynamic, culturally competent, consent model is one mechanism to increase recruitment and build a diverse cohort of well-informed and engaged participants. However, this approach requires refining mechanisms directed at recruiting and engaging participants and raising awareness, particularly with respect to underrepresented communities. Placing participants as co-producers in the planning, design and execution of PM also necessitates a cultural shift and the improvement of educational efforts directed at the general public (e.g. health literacy) and of healthcare professionals (e.g. cultural competence). The task at hand is thus, to identify and anticipate challenges as well as to generate strategies to leverage on the transformative power of PM to address health disparities. To that end, this presentaton will explore the use of novel technologies to increase the participation and engagement of underrepresented populations in PM.

3055W

Consent for newborn screening: Parents' and healthcare professionals' experiences of consent in practice. *S.G. Nicholls[1,2], H. Etchegary[3], L. Tessier[4], C. Simmonds[5], B.K. Potter[2], J.C. Brehaut[6,1], D. Pullman[7], R.Z. Hayeems[8,9], S. Zelenietz[4], M. Lamoureux[4], J. Milburn[4], L. Turner[10], P. Chakraborty[4,11], B.J. Wilson[2].* 1) Children's Hospital of Eastern Ontario Research Institute, Ottawa, Ontario, Canada; 2) School of Epidemiology, Public Health & Preventive Medicine; University of Ottawa, Ottawa, Ontario, Canada; 3) Clinical Epidemiology Unit, Faculty of Medicine, Memorial University, St John's, Newfoundland and Labrador, Canada; 4) Newborn Screening Ontario, Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 5) Health Research Unit, Faculty of Medicine, Memorial University, St John's, Newfoundland and Labrador, Canada; 6) Ottawa Hospital Research Institute, Ottawa, Ontario, Canada; 7) Community Health and Humanities, Faculty of Medicine, Memorial University, St John's, Newfoundland and Labrador, Canada; 8) Institute of Health Policy Management and Evaluation, University of Toronto; Toronto, Ontario, Canada; 9) Program in Child Health Evaluative Sciences, Hospital for Sick Children Research Institute, Toronto, Ontario, Canada; 10) Provincial Medical Genetics Program, Eastern Health, St John's, Newfoundland and Labrador, Canada; 11) Department of Pediatrics, Faculty of Medicine, University of Ottawa, Ottawa, Ontario, Canada.

Background: Consent processes for newborn bloodspot screening (NBS) are variable, with a lack of descriptive research that depicts how the offer of NBS is made to parents. Methods: We explored the experience, in practice, of consent for NBS. Semistructured interviews in two Canadian provinces were held with: (1) parents of children offered NBS (n=32) including those who declined NBS; and (2) health-care professionals involved in the NBS process (n=19). Data on recollections of NBS, including consent processes, were utilized to identify emerging themes using the method of constant comparison. Results: The meaning of consent, responsibilities, and practical requirements for practice, varied between individuals. Based on reported experiences, three themes were relevant to NBS consent: (1) The 'offer' of NBS; (2) content and timing of information provision; and (3) the importance of parental experiences for consent decisions. Recollections of consent for NBS were similar between jurisdictions, with notable practice variaton between healthcare provider specialities. Excepting midwives and their patients, NBS was viewed as a routine part of giving birth, with little evidence of an informed consent process. Although most parents were satisfied, respondents suggested information about NBS be provided long before the birth. For parents who declined screening, consent was not purely an abstract decision based on benefits and harms, but was also an in-the-moment decision informed by experiences of blood draw procedures. Discussion: These results raise important questions for researchers and those responsible for NBS programs regarding the kind of information-seeking parents engage in before labor. Whose reposnsibility is this: is there any onus on parents to engage in information seeking before the birthing process? Other questions relate to why one group of practitioners view informed consent as less onerous than others, or to study actual practitioner–parent appointments with a view to explore why (or if) information on NBS is not routinely offered in prebirth appointments. These research foci could help inform practical processes for parental information provision and consent. Accounts of parents who declined screening highlight the influence of parental experiences with the heel prick process in screening decisions, and the potential importance for pain management during blood draws.

3056T

Cultural influences on genetic testing in Japanese university students.
H. Numabe[1,2], M. Wakai[2], H. Kawashima[2]. 1) Department of Genetic Councelling, Ochanomizu University, Bunkyo-ku, Tokyo, Japan; 2) Clinical Genetics Centre, Tokyo Medical University Hospital, Tokyo Japan.

In Japan, genetic testing has been carried out using similar methods with accuracy comparable to western countries. However, the implementation of testing is influenced by various factors such as population policy, economic situation, and the medical system of government, as well as the bioethical view of each individual. Especially, culture plays a substantial role in genetic medicine and reproductive medicine. It is thus imperative to take cultural influence into consideration when giving genetic counseling and genetic testing to patients and clients in Japan. We made the questionnaire survey of Japanese university students on genetic diagnoses. The questionnaire consisted of properties of the student, considerations to spiritual matters, acceptability of an artificial abortion, the time of the beginning of human life, and considerations to various genetic testing. Students were from life science courses, nursing course, and medical course of universities in Tokyo. In Japan, acceptability of genetic testing correlates closely with student's recognition of the time of the beginning of human life. Students who recognize the life start from the fertilization or within 15 days after fertilization are not acceptable to prenatal and pre-implantation tests. On the other hand, students who recognize the life start after 22 weeks of gestational age or after birth are acceptable to them. We make an interim report.

Return of secondary findings and clinical sequencing — Formulating a policy in Japan. *N. Ohashi, K. Kato.* Osaka University, Suita, Japan.

Recently genome sequencing techniques in the medical and research fields have made remarkable progress, and personalized medicine using genome information is expected to become available in the near future in Japan. However, when promoting genomic medicine such as clinical sequencing, various ethical, legal, and social issues arise. One such issue is the handling of secondary findings—usually called incidental findings (IFs)—from clinical sequencing. Although in some of the countries such as United States many genomics researchers as well as ELSI researchers have discussed the issue, there has been little analysis and policy making in Japan. Our group, supported by the new funding agency AMED (the Japan Agency for Medical Research and Development), has been working on the issue. First of all, we have investigated the actual state of advanced medical institutions that will encounter this issue. We have also conducted a survey of policies that have been proposed and implemented abroad. Through our survey and analyses, we have found the following results. □The most advanced activities are found in the field of cancer research and some organizations are returning the results of IFs to patients. □Some organizations have prepared procedures including method of consent, decision making and counseling. They may serve as guiding examples to others in Japan. □Most of the organizations consider the ACMG (the American College of Medical Genetics and Genomics) recommendations and list of genes/mutations useful. On the other hand, there are other issues such as disclosure to family members, lack of databases for interpretation, who takes responsibility for the decision making, etc. We are now preparing a tentative policy with a proposal list of genes and procedures of returning results that we hope are suitable to Japanese clinical settings. In this presentation we will introduce the draft policy and discuss its challenges.

3058W

Motivations and concerns of biobank participants in allowing family access to research samples and data after their death. *J.E. Olson[1], E.M. Winkler[2], J.T. Bublitz[1], M.A. Hathcock[1], J.E. Pacyna[3], J.B. McCormick[1], C. Radecki Breitkopf[1], R.R. Sharp[3].* 1) Health Sciences Research, Mayo Clinic, Rochester, MN; 2) Center for Individualized Medicine, Mayo Clinic, Rochester, MN; 3) Biomedical Ethics Program, Mayo Clinic, Rochester, MN.

   Introduction: Biobank data and samples retain their value after participants' deaths. Posthumous access to biobank samples may be valuable to family members of the deceased, but few studies report on participant preference for family access to samples and research results after participants' death. At consent, 2% of Mayo Clinic biobank participants elected to not allow their family to access their biobank samples after their death. **Study Aim**: To understand the motivations, reasons, and concerns of persons who participate in Biobanks but <u>do not</u> want their samples and/or data shared with family members after their death. **Methods**: We conducted a mailed survey of 840 participants in the Mayo Clinic Biobank who had restricted family access to samples (restrictors) after their death and an age- and sex-matched sample of 840 participants who had allowed family access to samples (allowers). Surveys were mailed twice with an interval of 30 days, followed by phone calls to non-responders. Included in the survey were investigator-initiated items reflecting motivations and concerns about family access and published measures of self-concealment, and family environment (cohesiveness, expressiveness and conflict). **Results**: In all, 1164 (69%) responded and had usable data. Stability of family access choice was strong among the original allowers: 95% (553/580) continued to allow access to their sample. In contrast, only 23% (136/584) of original restrictors continued to restrict sample access. Among current allowers, "the potential for my family to benefit" (78.7% reported it was very important) and "the possibility of learning something new about our family history" (56% reported it was very important) were strong motivators. Among current restrictors, privacy of their health information was the most important factor for their choice (39% reported it was very important). Current allowers scored higher on family cohesion than current restrictors (7.8 vs 6.1, respectively; p<0.0001) and lower in self-concealment (15.7 vs 20.6, respectively; p<0.0001). **Conclusions:** Biobank participants hold different preferences regarding family access to their samples, and these preferences may change over time, particularly among those who initially wish to restrict access. At the time of consent, participants may benefit from anticipatory guidance regarding their views on family dynamics and issues related to privacy, health history and benefit within the family.

3059T

The sharing of genomics and health-related data from children: A case of big data and little ethics? *V.N. Rahimzadeh[1], C. Schickhardt[2], J. Friedman[3], M.C. Cornel[4], S. Pfister[5], D. Avard[6], D.F. Vears[7], K. Sénécal[8], W. Pinxten[9], C. Fernandez[10], S. Plon[11], A. Thorogood[12], B.M. Knoppers[13], E. Winkler[2].* 1) Centre of Genomics and Policy, McGill University, Montreal, QC, Canada; 2) University Hospital Heidelberg, Heidelberg (Germany); 3) Co-Lead GA4GH Paediatric Task Team, University of British Columbia (Canada); 4) Co-Lead GA4GH Paediatric Task Team, VU University Medical Center, Amsterdam (The Netherlands); 5) Professor and Head of Division Pediatric Neurooncology at the German Cancer Research Center Heidelberg; 6) Centre of Genomics and Policy, McGill University (Canada); 7) Centre of Biomedial Ethics and Law, KU University, Leuven (Belgium); 8) Coordinator, Paediatric Task Team GA4GH, Centre of Genomics and Policy, McGill University (Canada); 9) University UHasselt (Belgium); 10) IWK Health Centre, Dalhousie University (Canada); 11) Texas Children's Cancer Genetics Clinic (Clinic), Baylor College of Medicine,; 12) Coordinator Regulatory and Ethics Working Group (GA4GH); 13) Co-Lead, Regulatory and Ethics Working Group (GA4GH), Director, Centre of Genomics and Policy, McGill University (Canada).

   With the sequencing of the human genome, biomedical research has increasingly become a data-intensive venture that requires collaboration between researchers and institutions. Understanding how data sharing practices and policies (dis)enable scientific collaboration in genomics and related –omics disciplines is therefore critical to accelerating clinical innovation in Canada. Genomic research involving children can further accentuate this need, as their inability to consent underpins their status as a vulnerable population in research but nevertheless warrants their inclusion in research. Sharing research data fulfills dual imperatives inherent to any bench-to-bedside translational endeavor: a scientific imperative arises in the need to determine underlying genetic determinants of disease, and an ethical imperative arises to deliver on the anticipated benefits upon which the risks to research participants rest. For research ethics review committees (REC) and data access committees (DAC), genomics raises chiefly informational rather than physical risks. These risks require that RECs and DACs ensure data-specific, albeit proportional protections for children. Concerns regarding data privacy and security can be accentuated when children are involved [3], particularly when use of data for future, as-yet unspecified research is the norm rather than the exception in the data-intensive sciences. Collaboration among researchers who share data has nevertheless led to significant advancements in understanding childhood diseases; most notable of these include in pediatric oncology, rare genetic disease and autism. Children enjoy a right to informational privacy despite their inability to consent alone to participate in data-intensive science research. The data to be shared may also be of immediate or future relevance to the child's health, such as genetic data, and which may take on new significance as data-intensive science unearths new understanding(s) between genomics and human disease etiologies. This research investigates specific regulatory requirements for pediatric data sharing in relation to data protection, data usages and the ethical justifications for doing so in the data-intensive science research disciplines. Based on this scoping regulatory assessment, we discuss the ethical implications of children as data donors and active agents in the advancement of pediatric research in the data-intensive sciences.

Protection of genomic information by amended Japanese Personal Information Protection Laws. *N. Yamamoto, K. Kato.* Osaka University, Suita, Osaka, Japan.

In Japan, genomic information has now been put under legal protection for the first time ever because of the amendment to the Personal Information Protection law last year. There are mainly three Information/data protection laws in Japan: the "Act on the Protection of Personal Information (PPI Act)", the "Act on the Protection of Personal Information Held by Administrative Organs (PPIHAO Act)", and the "Act on the Protection of Personal Information Held by Incorporated Administrative Agencies (PPIHIAA Act)". The PPI Act includes the basic principle for all of the Acts, so an amendment of the PPI Act has started in 2013 prior to the other two, and enacted in September 2015. The PPIHAO and PPIHIAA Acts are now under review. In the amended PPI Act, genomic information was included in the definition of personal information. This is a welcome change because until now patients, research participants and consumers of genetic testing have been exposed to the risk of an invitation of privacy by breach. In addition, the amendment has raised concerns about genomic privacy, security and genomic industries among people at a deep level that has not been witnessed before in Japan. This offers an important opportunity to develop social trust and understanding between researchers and the public regarding how genomic information should be used in the future. However, some problems must be addressed as soon as possible. For example, it is an urgent matter to harmonize some particular aspects of the amended PPI Act and conventional research ethics such as how to handle informed consent when a subject's data is to be used in further research. We must ensure that patients' privacy is protected while at the same time encouraging scientific research. We have been involved in various activities to deal with these urgent matters. In this presentation, we will introduce our Genomics and Society Unit that was established in April 2016 to strengthen genomic ELSI as well as some practical solutions (e.g., a new informed-consent form) that we have proposed in every-day genomic research, including data sharing through public databases.

3061W

Personalized genomics clinics: A model for delivery of genetics care. *M. Sabbadini, J.T. Shieh, A.M. Slavotinek.* Department of Pediatrics, University of California, San Francisco, San Francisco, CA.

By targeting numerous genes simultaneously, whole exome sequencing (WES) has had a transformative impact on patient care in the few years since its inception as a clinical test. Its ability to identify a diagnosis in approximately 25% of patients with a suspected, but previously unidentified, genetic condition is revolutionary. The availability of WES and its use for screening without an identified genetic diagnosis has also increased the accessibility of genetic testing to providers who are not trained in this specialty. However, the nuances of the consent process, the complexity of test ordering, the difficulty in accurate variant interpretation, and the need for re-analysis and longitudinal follow-up for patients with variants of unknown significance (VUSs) or negative exome results make the presence of a clinician trained in genetics an invaluable asset towards realizing the full potential of genomic testing. The optimal clinical model for the incorporation of WES into patient care is not yet known. The Individualized Medicine clinic at the Mayo Clinic and Sick Kids Genome Clinic in Toronto are two published models of genomics clinics centered on the provision of genomic testing and both of them have a strong emphasis on research and data collection. In 2013, at UCSF, we established a personalized genomics clinic (PGC) for the consent process and testing, genetic counseling, results interpretation and long-term follow up for patients who undergo WES. Patients are referred to our clinic by UCSF genetics providers as well as by providers from other specialties from within our institution and externally. Patients can be referred for evaluation, consent/testing and for results provision/interpretation. Most commonly, cases were referred to PGC at the stage of results interpretation or for re-analysis following previous WES with VUSs or no variant reported. The clinic also includes a registry function whereby patients with VUSs can be contacted for annual results review. We present our clinic structure as a model for accurate and comprehensive patient-centered clinical implementation of genomic testing. Our clinic model provides support for the intrinsic advantages of establishing dedicated clinics for WES. Moreover, it delineates the value of genetics provider involvement in the genomic testing process with the goal of taking advantage of the full potential of WES while limiting the possible risks of such test.

3062T

Attitudes towards centralized biorepositories among patients in Cleveland, OH: Implications for the Precision Medicine Initiative Cohort Program. *J.N. Cooke Bailey[1,2], W.S. Bush[1,2], A. Slaven[3], M. Schachere[3], D.C. Crawford[1,2], J.R. Sedor[3,4,5], J.F. O'Toole[3].* 1) Epidemiology and Biostatistics , Case Western Reserve University, Cleveland , OH; 2) Institute for Computational Biology, Case Western Reserve University, Cleveland , OH; 3) Division of Nephrology, Department of Medicine, MetroHealth Medical Center, Cleveland, OH; 4) Department of Physiology and Biophysics, Case Western Reserve University, Cleveland , OH; 5) Department of Medicine, Case Western Reserve University, Cleveland , OH.

   The Precision Medicine Initiative, announced by the White House in early 2015, promises to revolutionize patient care by incorporating clinical, environmental, personal, and 'omics data in electronic health records (EHRs) for decision support at the point of clinical care. To accelerate this vision, the National of Institutes of Health in consultation with academic, healthcare, mHealth, and patient advocacy leaders, is launching the PMI Cohort Program (PMI-CP), an ambitious national effort to ascertain one million Americans for precision medicine research. A requirement of this cohort is the submission of electronic health records and biospecimens to a central biorepository facility funded by the government for storage and further processing for data generation and analysis. While this centralized biorepository model provides quality control and is cost-effective compared with a federated model, it is unclear what impact this requirement will have on ascertainment, which is expected to be socioeconomically, geographically, and racially diverse. To understand the potential impact this model has on ascertainment, we are surveying patients participating in a precision medicine research project at MetroHealth in collaboration with the Institute for Computational Biology at Case Western Reserve University in Cleveland, Ohio, a diverse metropolitan area with 20% of residents self-described as African American in the 2010 U.S. Census. MetroHealth is an academic, public provider, integrated tertiary care system serving northeast Ohio with a vendor-based EHR. The payer mix includes 21% uninsured, 24% Medicaid, 18% Medicare. Results currently include responses from 37 patients; 72% were African American, 55% were female, and average age was 61. Regarding willingness to participate in the PMI, 61% of patients responded favorably to submitting health records and genetic data to a national biorepository coordinated by the government. Only ~39% of patients indicated that return of results was very important whereas ~23% did not want results at all. When asked if they would be willing to install an application on their mobile device to track their health and to send that data to a national center, ~52% responded favorably to both. These responses, while preliminary, indicate that the attitudes of patients in a diverse health care environment towards the PMI-CP are varied.

3063F

A growing market for clinical exome sequencing. *G.W. Hooker[1], T.A. Murphy[1], K.E. Woodall[2], J.D. Schneider[1].* 1) NextGxDx, Franklin, TN; 2) University of Tennessee, Knoxville, TN.

   Introduction: Innovations in DNA sequencing are driving rapid growth and change in the genetic testing marketplace. As the cost to sequence a single base pair goes down, many laboratories have been able to enter new, competitive sectors of the market. One particularly competitive sector of the market is clinical exome sequencing. These tests command some of the highest per-test costs in the market, likely due to the greater analytic infrastructure needed to return high-quality reports. A more recent development in the market has been increasing willingness on the part of health insurance plans to pay for exome sequencing. In this analysis, we aimed to describe growth in the market and in the exome sector specifically, from Sep. 1st, 2014 to June 1st, 2016. We also studied pricing of clinical exome tests, to understand pricing changes in light of market growth and evolutions in reimbursement policy. **Methods:** Drawing from online lab catalogs, we curate and maintain a data resource of genetic tests offered by US CLIA-certified clinical labs. We collect information on all tests offered by these labs, as well as other test attributes such as methodology and test prices. We tracked new tests entering and exiting the market on a month-to-month basis and compared average costs per test from Sep. 2014 to June 2016. **Results:** Over this time period, we saw a net of 6,583 new tests enter the market (9.5 new tests/day). Among exome tests, we saw a net of 22 new products enter the market. The number of labs offering exome sequencing increased from 16 in Sep. 2014 to 26 in June 2016. Overall, there was a 20% decrease in the price per clinical exome from $7085/exome to $5700. Notably, however, since July 2015, the price per clinical exome has risen by 8% from a low of $5265, driven mainly by new tests entering the market at higher prices. Also during this time, coverage for exome sequencing has expanded, with 3 of the top 10 commercial health insurance plans covering exomes for eligible patients in 2015. **Conclusions:** Overall, costs in the exome sequencing sector decreased while the supply of tests on the market increased. However, this trend partially regressed in the presence of increasing private insurance coverage for these tests. The dynamic nature of the market suggests payers and clinicians can achieve value through contract negotiation, lab selection and utilization management. Ultimately, this has the potential to increase patient access to genetic tests.

3064W

Genetic counselors' experiences with clinical whole genome sequencing in a diverse healthy population. *M. McGinniss[1], E. Ramos[1], E. Thorpe[1], L. Fosler[1], K. Schahl[2], K. Trzupek[2], A. Hata[2], T. See[2], D. Eklund[3], H. Bixenman[3], D. Morton[3], D. Wellis[3].* 1) Illumina, Inc, San Diego, CA; 2) InformedDNA, St. Petersburg, FL; 3) San Diego Blood Bank, San Diego, CA.

Clinical whole genome sequencing (cWGS) for healthy individuals is rapidly gaining acceptance as cost is decreasing and success rates in identifying disease-causing variants are increasing. Studies are assessing the impact of cWGS, but the majority of early adopters have a narrow profile of racial diversity (mostly Caucasian). This lack of diversity is a barrier to understanding how genetic counseling for cWGS can be optimized for a population as diverse as that of the United States. The growing availability and uptake of cWGS highlights the importance of re-evaluating current genetic counseling methods to provide innovative approaches to address the increasing demand of genetic counseling services. We performed an IRB-approved pilot project between the San Diego Blood Bank (SDBB) and Illumina, where cWGS was offered to 70 SDBB blood donors whose demographics represented the diverse population of San Diego. The SDBB cohort was 27% Caucasian, non-Hispanic (19/70), 26% Hispanic/Latino (18/70), 13% Black/African-American (9/70), 11% Asian (8/70), 7% American Indian/Alaskan Native (5/70), and 4% Native Hawaiian or other Pacific Islander (3/70). The remaining 11.5% of participants (8/70) reported two or more races. Certified genetic counselors at InformedDNA conducted post-test telephone genetic counseling sessions, which included family and medical history collection, results disclosure, follow-up recommendations, and psychosocial assessment. Counseling metrics, including preparation time, counseling time, and time spent on documentation were tracked and compared to the 2016 National Society of Genetic Counselors (NSGC) Professional Status Survey (PSS). Average time spent counseling participants was 66 minutes with 39% of counseling sessions taking 45-60 minutes. Average time spent preparing for patients and completing a consultation summary was 18 and 35 minutes. These patient care metrics are comparable with what has been reported for in the 2016 NSGC PSS (41.8% of initial counseling sessions taking 45-60 minutes; 40.2% of preparation time taking 15-30 minutes; 31.7% of follow-up taking 15-30 minutes). This pilot study demonstrates the feasibility of providing consistent genetic counseling services to a diverse healthy cohort with cWGS results. The ability to integrate telephone genetic counseling services into cWGS also supports increasing diversity in study populations as it decreases issues of availability of and access to local genetic counselors.

3065T

Do primary care physicians manage genome sequencing results appropriately? Results of an expert panel evaluation. *E.F. Schonman[1], M.F. Murray[3], J.B. Krier[1,2], C.L. Blout[1], D.W. Bates[1,2], R.C. Green[1,2,4,5], J.L. Vassy[1,2,6], The MedSeq Project.* 1) Brigham and Women's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Geisinger Health System, Danville, PA; 4) Partners Healthcare Personalized Medicine, Cambridge, MA; 5) Broad Institute of MIT and Harvard, Cambridge, MA; 6) Section of General Internal Medicine, VA Boston Healthcare System, Boston, MA.

Background: As genome sequencing (GS) becomes increasingly available, there are concerns that primary care physicians (PCPs) may mismanage patients' variants, particularly since insufficient empiric evidence exists to develop practice guidelines for most genes and phenotypes. We used quantitative expert review to rate PCP management of real GS variants. **Methods:** The MedSeq Project is a trial of GS among healthy adult patients. Patients and their PCPs received a GS report, including monogenic disease variants classified as pathogenic, likely pathogenic, or variant of uncertain significance (VUS): favor pathogenic. For each patient with a monogenic variant, we created a clinical vignette summarizing his/her health history, variant pathogenicity, and the PCP's clinical management of the result. We recruited a panel of 11 clinical genetics experts to rate the PCP's management in each vignette, using the 9-point RAND/UCLA Appropriateness Scale (1-3: inappropriate; 4-6: neither appropriate nor inappropriate; 7-9: appropriate). In round 1, panelists independently rated PCPs' actions and overall management. In round 2, panelists convened to discuss actions for which a quantitative disagreement index indicated disagreement about how to rate appropriateness. After discussion, panelists could change their initial ratings. After each round, panelists gave recommendations for general guidelines for variant management by PCPs. **Results:** Of 50 GS patients, 11 received a new monogenic result. In round 1, panelists agreed how to rate the overall management of all 11 vignettes: 8 were rated as managed appropriately, 2 inappropriately (pathogenic variants in *LXH4* and *F5*), and 1 neither appropriately nor inappropriately (VUS in *ARSE*). Panelists disagreed how to rate the appropriateness of 3 of 26 specific actions from 3 different vignettes, but in round 2, they reached consensus on 2 of these actions (stating no evidence of porphyria and chondrodyslplasia punctata in patients with *PPOX* and *ARSE* variants, respectively). They remained in disagreement about a PCP's explanation of inheritance of an *HFE* variant. Panel discussion resulted in a preliminary 6-item guideline for PCPs managing GS variants. **Conclusion:** According to expert geneticist review, PCPs managed GS variants appropriately in the majority of cases in our study. Analysis of case mismanagement, including misinformation and errors of omission, may help shape future genomic medicine practice guidelines for PCPs.

3066F

Recommendations of researchers and physicians about inherited chromosomally integrated human herpesvirus 6. *V. Noël[1], R. Drouin[2], L. Flamand[3], C. Bouffard[1].* 1) Université de Sherbrooke, Sherbrooke, QC, Canada; 2) Université du Québec à Montréal, Québec, QC, Canada; 3) Université Laval, Québec, QC, Canada.

The human herpesvirus 6 (HHV-6) has the unique capacity to integrate telomeres of the chromosomes (ciHHV-6) of nucleated cells after infection. ciHHV-6 can therefore be found in gametes and be transmitted from one generation to the next and through organ and tissue donation. This worrisome situation affects between 40 and 70 million people around the world and may be associated with illnesses (encephalitis, infertility, cancers, etc.), of which some are fatal. Despite its consequences, this phenomenon has attracted little interest in scientific and public health milieus. To highlight the importance of this issue, several researchers and physicians go so far as to publish warnings in basic research articles in purely scientific journals. This uncommon phenomenon, prompted us to investigate these concerns. Thus, our objective was to know the solutions they propose in order to identify their clinical and socio-ethical concerns. METHOD: Qualitative design used asynchronous online text-based interviews (combine questionnaire and chat box) with 13 researchers and physicians working on HHV-6. Qualitative generale inductive analysis with the use of NVivo11 software. RESULTS: Researchers and physicians suggested four types of interventions: 1) the establishment of a screening program in the context of grafts and transplants; 2) medical information on the integrative capacity of HHV-6 and pathogenicity of ciHHV-6; 3) reevaluation of types of antiviral drugs and doses to counteract the adverse effects of pharmacological treatments and standardize the therapeutic treatment plan; 4) standardization of diagnostic tests to prevent false positives or negatives. CONCLUSION: It was very interesting to note the convergence of opinions and the recommendations of the participants. These first data on the topic respond to needs expressed by researchers and physicians concerned by the ciHHV-6 in their practices. In this sense, the results of this research can guide the thinking and decision-making process to improve and harmonize practices and the wellbeing of affected individuals and populations. .

3067W

The NIGMS Human Genetic Cell Repository: An invaluable resource and a research participation opportunity for individuals with inherited diseases and chromosomal abnormalities. *S. Wert, M. Berkowitz, L. Brown, T. Schmidlen, D. Requesens, N. Turan.* Coriell Institute for Medical Research, Camden, NJ.

The NIGMS Human Genetic Cell Repository was established at the Coriell Institute for Medical Research, an independent non-profit research institution, in 1972 by the National Institute of General Medical Sciences (NIGMS). The NIGMS Repository provides a readily accessible, centralized resource for cell lines and genetic material from individuals with genetic disorders, including heritable diseases and chromosomal abnormalities, and from individuals from various geographical locations for studies on human diversity. Samples are also collected from unaffected, first-degree relatives of individuals with genetic disease, and from apparently healthy individuals for the study of human variation. The primary goal of the NIGMS Repository is to stimulate and facilitate biomedical research, teaching, and the diagnosis and prevention of human genetic diseases by establishing and maintaining a repository of high quality, uncontaminated, well characterized, and clinically well-documented cell lines and DNA and making these resources available to investigators throughout the U.S. and abroad. The NIGMS Repository contains more than 11,300 cell lines, including human iPSC lines, and 5,600 DNA samples, representing over 900 OMIM phenotypes. The NIGMS Repository is an invaluable resource and samples have been used for genetic testing assay development, validation and proficiency, identification of novel genes, exploration of gene function and expression, and generation iPSC lines. To date, there have been over 6,000 publications citing NIGMS Repository samples. The NIGMS Repository is also an important resource for clinicians and genetic counselors as it offers an opportunity for patients and families to contribute to the research process in addition to, or in the absence of, the availability of clinical testing or disease-specific research. Sample donation requires a blood or tissue specimen and completion of an informed consent, a submission form, and a clinical data summary.

3068T

Benefits, risks, and perceived utility of newborn genomic sequencing: Comparing parents' and physicians' baseline attitudes in the Baby-Seq Project. *H.A. Peoples[1], A.M. Gutierrez[1], S. Pereira[1], J.O. Robinson[1], L. Frankel[1,2], M. Towne[3], M. Helm[5], C.A. Genetti[3], I.A. Holm[3,4], A.H. Beggs[3,4], R.C. Green[4,5,6,7], A.L. McGuire[1].* 1) Center for Medical Ethics and Health Policy, Baylor College of Medicine , Houston , TX; 2) Department of Psychological, Health, and Learning Sciences, University of Houston, Houston, TX; 3) Division of Genetics and Genomics, The Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA; 4) Harvard Medical School, Boston, MA; 5) Division of Genetics, Brigham and Women's Hospital, Boston, MA; 6) Partners Healthcare Personalized Medicine, Cambridge, MA; 7) Broad Institute of MIT and Harvard, Cambridge, MA.

   Background: Efforts are ongoing to explore the impact of integrating genomic sequencing (GS) into newborn clinical care. Concerns have been raised about the risks of providing incidental GS results to parents of newborns yet parents' perceptions of this technology compared to newborn screening (NBS) are unclear. We examined attitudes toward NBS and GS among newborns' parents and physicians. **Methods**: The BabySeq Project is a randomized controlled trial exploring the utility of GS for parents of newborns in the NICU and Well-Baby nursery. Parents of enrolled infants complete surveys at 4 time points in their baby's first year of life. Physicians are surveyed throughout the study. Survey domains for parents and physicians include attitudes toward and perceived utility of NBS and GS. Chi square tests were used to measure between-group differences in perceived utility and attitudes toward NBS and GS. Open-ended responses were categorized by theme. **Results**: The majority of parents (81%, n=159) and physicians (97%, n=67) agreed that there are health benefits associated with NBS. Fewer parents (18%) than physicians (33%) agreed that there are risks associated with NBS (p=.022). A smaller majority of parents (67%) and physicians (57%) also agreed that there are health benefits associated with GS. More physicians (73%) than parents (35%) agreed that there are risks associated with GS (p<.001). In open-ended responses, physicians listed early intervention as the main benefit of GS while parents also listed family planning and knowing what to expect in the future. Both parents and physicians identified psychological distress, genetic discrimination, impact on family, and the nature and potential uncertainty of GS results as risks. Parents felt that receiving their child's GS results will be more important in 10 years (82%) compared to now (61%). Physicians reported that GS will be more useful in 10 years compared to now for diagnosis (90% vs. 64%) and for managing their patients' care (85% vs. 58%). **Conclusions**: At baseline, parents reported fewer perceived risks of NBS and a more favorable risk/benefit tradeoff for GS than physicians. Parents also identified additional expected benefits of GS. Results suggest that parents may have a broader conception of the utility of GS than physicians. Continued data collection will determine whether these attitudes persist after parents receive their baby's GS results.

3069F

Genomic newborn screening: Public health policy considerations and recommendations. *K. Sénécal[1], J.M. Friedman[2,3], M.C. Cornel[4,5], A.J. Goldenberg[6], K.J. Lister[7], D.F. Vears[8], Global Alliance for Genomics and Health Regulatory and Ethics Working Group Paediatric Task Team.* 1) Centre of Genomics and Policy, Human Genetics, McGill University, Montreal, Quebec, Canada; 2) Department of Medical Genetics, University of British Columbia, Vancouver, Canada; 3) Child and Family Research Institute, Vancouver, Canada; 4) Section Clinical Genetics, Department of Clinical Genetics, Amsterdam, Holland; 5) EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Holland; 6) The Center for Genetics Research Ethics and Law, Department of Bioethics, Case Western Reserve University, Cleveland, Ohio, USA; 7) Office of Population Health Genomics, Public Health Division, Department of Health, Government of Western Australia; 8) Centre for Biomedical Ethics and Law, Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium.

   Recent research has demonstrated that genomic technologies, such as exome or whole genome sequencing, can identify genetic causes of rare paediatric diseases more effectively than conventional clinical and laboratory methods. However, the nature of this technology and its potential to identify additional information about the child being tested raise a range of ethical concerns, particularly when these technologies are applied in a public health setting, such as newborn screening (NBS). The Paediatric Task Team of the Global Alliance for Genomics and Health's Regulatory and Ethics Working Group considered these issues, developed a framework addressing key issues, reviewed the literature against this framework and then refined their findings in an iterative manner. This led to the development of recommendations to guide clinical laboratory scientists and policy makers regarding the use of genomic technologies for population-based NBS. We recommend that NBS by genomic methods should only be considered as an add-on to current screening programs, and should *not* replace current techniques unless equal or better sensitivity and specificity has been shown. Genomic NBS that has appropriate clinical utility should be equally available and accessible to every infant in the jurisdiction. Sharing of data on pathogenic and benign variants within the population(s) screened is needed for interpretation of variants. Publicly-funded universal newborn screening by genomic methods should be limited to diseases that can be effectively treated or prevented early in life. The program should guarantee treatment and follow-up of infants found to be affected by the targeted diseases.

3070W

Preemptive clinical pharmacogenetic testing in children: Patient and parent preferences. *S.K. Ring[1], C.E. Haidar[1], N. Kornegay[1], J.M. Hoffman[1], U. Broeckel[2], W.E. Evans[1], K.E. Nichols[3], M.V. Relling[1], K.R. Crews[1].* 1) Department of Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN; 2) Department of Pediatrics, Medical College of Wisconsin, Milwaukee WI; 3) Department of Oncology, St. Jude Children's Research Hospital, Memphis, TN.

Consent processes for research protocols that include genetic testing ideally address return of primary results as well as secondary or incidental findings. The PG4KDS study, which clinically implements preemptive pharmacogenetic testing in children, genotypes pharmacogenes in a CLIA-certified laboratory. PG4KDS provides a process for implementing gene/drug pairs into the electronic health record (EHR), and for returning test results to patients. We describe parent and patient preferences regarding participation and return of results. The informed consent process provides education (through verbal and written materials) on differences between pharmacogenes and disease-risk genes and on reporting test results. Procedures are defined for sharing primary pharmacogenetic results and incidental findings that may link pharmacogenes to future disease risk. Pharmacogenetic genotype results are placed in the EHR and accompanied by interpretations and clinical decision support for gene/drug pairs. Secondary or incidental findings considered for return to participants are those that carry a higher risk than baseline, are clinically actionable, and contribute information on risk that is beyond what would be found in the course of normal health care. Thus, parents may not opt out of receiving incidental findings for minors. Patients over age 18 may select whether or not to receive incidental findings related to disease risk. Patients and families may select whether they want to be contacted when a gene test result is added to the EHR; notification is through a letter describing the resulting phenotype and an interpretation. Of 3333 patients approached, 3209 (96%) have enrolled. Reasons for refusing participation included privacy concerns (n=12), enrollment in too many studies (n=12), concern over extra blood collection (n=11), family members not agreeing (n=11), distrust of DNA research (n=5), progressive disease (n=4), religious beliefs (n=1), other reasons (n=2) or no reason given (n=66). To date, 3121 participants (97%) have elected to receive their gene test results; 13,768 letters have been mailed and placed in the EHR. Of 224 participants who reached age 18 years, 223 (99.6%) agreed to continue participation as adults; 221 (99%) have elected to be notified of disease risk. These findings suggest a high rate of willingness to be informed of preemptive genotype results and incidental disease risk findings, and a low rate of concerns that prevent participation.

3071T

Sharing genetic information with family: Responses before and after receiving pharmacogenomics results. *M. Smith[1], S.A. Aufox[1], A. Espinoza[1], L.J. Rasmussen-Torvik[2].* 1) Ctr Gen Med, Northwestern Univ, Chicago, IL; 2) Department of Preventive Medicine, Northwestern University, Chicago, IL.

Pharmacogenomic (PGx) variants have been well established as an important cause of variable drug response. However, implementation of PGx testing in clinical care has been slow. The goal of this study was to begin to develop strategies for the optimal implementation of PGx data into the clinical environment. We assessed the utility of PGx information to patients and whether they intended to share results with family. Methods: Patients were offered PGx testing through their primary care physician's (PCP) office. Testing included clinical grade results on 3 drug-gene pairs: Simvastatin, Clopidogrel, and Warfarin. Patients were selected based on likelihood of being prescribed one of the three drugs in a 3-year period. Participants completed three surveys: A 37 item survey at the time of consent and a 31 item survey that was sent to participants at 1 and 6 months post return of results. The surveys included questions about demographics, plans to use and share PGx results (pre) and how results were used and shared (post). We report here the results of participants' intent to share PGx results with family and their reports of sharing results with family at 6 months post-result return. Results: 750 participants were enrolled, received results on all three PGx drug-gene pairs, and completed at least the baseline survey. 352 completed the 1-month follow up survey and 279 completed the 6-month survey. Participants were 57% male; 48% White, 25% African American, and 6% Hispanic; 75% reported they had children and 60% had a college or post graduate degree. At baseline, 39% of participants planned to share results with family. At six months, 33% of participants reported they had told family about their results. Participants with children were more likely to have shared their results with family (37%) vs participants without children (20%) (p=.01). Thirty-five percent of non-Hispanics had shared results by 6 months versus 6% of Hispanics (p=.02). Having a genetic result for increased risk for variable drug response was not correlated with having shared results with family. Intention to share PGx test results with family at baseline was not highly predictive of having shared those results at 6 months. Summary: Being of non-Hispanic ethnicity and having children were two factors correlated with sharing PGx results.

3072F

Patient-centered deep phenotyping using the Human Phenotype Ontology. *M. Haendel[1], N. Vasilevsky[1], M. Engelstad[1], E. Foster[1], C. Mungall[2], S. Köhler[3], P. Robinson[3].* 1) Oregon Health and Sciences University, Portland, OR, USA; 2) Lawrence Berkeley National Laboratory, Berkeley, CA, USA; 3) Charite – Universitätsmedizin Berlin, Germany.

In rare or undiagnosed diseases, physicians rely upon genotype and phenotype information in order to compare abnormalities to other known cases and to inform diagnoses. To maximize the usefulness of accurate phenotyping for clinical diagnosis and to build cohorts of patients for gene discovery, a standard vocabulary is essential. Towards this end, the Human Phenotype Ontology (HPO) (http://www.human-phenotype-ontology.org/) was developed as a standardized vocabulary of phenotypic abnormalities encountered in human disease to facilitate "deep phenotyping", whereby symptoms and characteristic phenotypic findings (a phenotypic profile) are captured using a logically constructed hierarchy of over 12,000 terms. The HPO has been utilized to great success for assisting computational phenotype comparison against known diseases, other patients, and even model organisms to support diagnostics. Although the cost and ease of collecting and analyzing genomic data has improved rapidly, collecting structured phenotypic data has not become more standardized, convenient, or less expensive, limiting algorithmic approaches. Thus a major challenge in clinical care and research aimed at understanding genetic diseases is phenotyping patients accurately, yet efficiently. Conversely, patients are often the best sources of information about their symptoms and phenotypes and there is an opportunity to have them perform self-phenotyping using the HPO. However, the labels and synonyms in the HPO primarily use medical terminology, which can be difficult for patients and their families to understand. In order to make the HPO more accessible to non-medical experts, we systematically added new synonyms using non-expert terminology (i.e., layperson terms) to the existing HPO classes or tagged existing synonyms as layperson. As a result, the HPO contains over 6,000 layperson terms. This patient-centric version of the HPO is being utilized in patient-centered rare disease websites, in patient community platforms and registries, to validate patient phenotyping clinical instruments, and to enhance the deep phenotyping being performed in the clinic.

3073W

Between open and controlled? A registered access model. *S.O.M. Dyke[1], E. Kirby[2], M. Shabani[3], A. Thorogood[1], M. Linden[4], I. Lappalainen[4], J. Rambla De Argila[5], M. Fiume[6], S. Sherry[7], K. Kato[8], B.M. Knoppers[1].* 1) Centre of Genomics and Policy, Faculty of Medicine, McGill University, Montreal, Quebec, Canada; 2) Public Population Project in Genomics and Society, Montreal, Quebec, Canada; 3) University of Leuven, Leuven, Belgium; 4) ELIXIR, Hinxton, UK; 5) Centre for Genomic Regulation, Barcelona, Spain; 6) DNAstack, Toronto, Ontario, Canada; 7) National Centre for Biotechnology Information, US National Library of Medicine, Bethesda, MD, USA; 8) Department of Biomedical Ethics and Public Policy, Graduate School of Medicine, Osaka University, Osaka, Japan.

As data sharing policies in genomics strive to keep pace with the state of the science, we currently face a situation in which only two established mechanisms exist for data to be consistently shared: *open access,* when data are freely published on the World Wide Web; and *controlled access,* where qualified researchers apply for access on a project-by-project basis and their research plans are reviewed, often by a committee. While both models have served the research community and scientific progress well, plans for greater integration of datasets and informatics platforms call for a new, intermediate model of data access that would enable rapid access for a wider range of users to data presenting a level of ethical and legal risk. In order to expand data access options in this way, we conducted an ethical-legal analysis of research ethics and other legal and administrative frameworks applicable to data sharing and access. In particular, we determined which elements of controlled access mechanisms should be retained to provide proportionate protections involving both user identification and agreement to a general set of responsibilities while considerably simplifying the data access application process. The novel data access model we propose is called *registered access* and comprises a three-stage registration process: Authentication, Attestation and Authorization. It is based on the notion that broad categories of users can be granted access to data according to their roles (e.g., *bona fide* researcher or clinical care professional). All three stages of registered access pose ethical and legal questions which we have addressed with guidance. As we build automated systems to pilot the registered access model with ELIXIR - Europe's infrastructure for life science information - and the Scientific Demonstration projects of the Global Alliance for Genomics and Health (The Beacon Project, The Matchmaker Exchange and The BRCA Challenge), we are confronting and resolving a number of ethical and legal challenges raised by access to existing technological and administrative resources (e.g., academic infrastructure). We also report on current efforts to support the registration of a large and diverse community of clinical care professionals.

3074T

Structured care for individuals at risk for familial cancer syndromes in a family medicine residency. *W. Feero[1], E. Edelman[2], K. Reed[2], T. Ingram[2], N. Fischer[1], K. Lafferty[3], S. Miesfeldt[3].* 1) Maine-Dartmouth Family Medicine Residency, Fairfield, ME; 2) The Jackson Laboratory, Genomic Education, Bar Harbor ME; 3) Maine Medical Center Research Institute, Scarborough, ME.

Background: The patient centered medical home (PCMH) is one model for providing coordinated, longitudinal care for chronic conditions in primary care. Whether the PCMH can be adapted to care for individuals at-risk for familial cancer syndromes in primary care is unknown. Objective: To establish and evaluate clinical and educational infrastructure to support self-sustaining nursing "Cancer FHx Wellness Visits" as a PCMH-based care model for those at risk for Lynch and hereditary breast and ovarian cancer syndromes in a single large (10+10+10) family medicine residency in rural Maine. Methods: Model included: i) tailored education for common familial cancer syndromes (residents [4 hrs], faculty [4 hrs], and nursing [2 hrs]); ii) clinic-based materials to facilitate patient engagement, collection/interpretation of cancer-related family history data and appropriate referral for cancer genetic counseling services; and iii) establishment of workflows/billing processes for program sustainability. Model evaluation included i) assessment of provider education/perception of care coordination through pre-/post-surveys, ii) assessment of patient perception of care coordination through post-genetic counseling survey and iii) utilization of services. Results: Project began in the 2015-2016 academic year. Post-education, physician groups showed statistically significant improved confidence in: eliciting a family history; assessment of hereditary cancer risk; making appropriate referrals; discussing risks and benefits of cancer genetic testing; and providing risk reduction counseling. Providers experienced significant increases in genetic knowledge self-efficacy; however, content expertise as measured by knowledge questions showed little change. Providers reported improved knowledge of where to refer patients for genetic services. Preliminary analysis of provider perceptions of care coordination at 6 months showed statistically higher scores from baseline for faculty but not residents. Conclusions: A PCMH-based model of "Cancer FHx Wellness Visits" and targeted educational interventions improved provider confidence in identifying and managing individuals at-risk for familial cancer syndromes. Additional data are needed to determine if the program is sustainable and improves patients' perceptions of care.

3075F

GenomeConnect: An update of engaging patients in data sharing efforts through an online patient registry. *J. Koenig[1], D.R. Azzariti[2], D.H. Ledbetter[1], C. Lese Martin[1], V. Rangel Miller[3], H. Rehm[2,4,5,6], E. Rooney Riggs[1], K. Wain[1], W.A. Faucett[1].* 1) Genomic Medicine Institute, Geisinger Health System, Danville, PA; 2) Laboratory for Molecular Medicine, Partners Personalized Medicine, Boston, Massachusetts, USA; 3) PatientCrossroads, San Mateo, California, USA; 4) The Broad Institute of Harvard and MIT, Cambridge, Massachusetts, USA; 5) Harvard Medical School, Boston, Massachusetts, USA; 6) Department of Pathology, Brigham & Women's Hospital, Boston, Massachusetts, USA.

Rapid advances in and increased use of genetic testing are resulting in the identification of genomic variation at a rapid rate, but the impact of much of this variation on human health often remains indeterminate, particularly if the variants are novel or rare. Connections between laboratories, clinicians, researchers, and patients are needed to facilitate genomic discovery, variant classification, and patient support efforts. GenomeConnect (genomeconnect. org), an online patient registry developed as part of the NIH-funded Clinical Genome Resource (ClinGen) project, serves as a secure way for individuals and families to connect with one another, participate in research, and engage in data sharing efforts which enhance variant interpretation. By enrolling in GenomeConnect, participants' share their genomic and health information through an online health survey and by uploading a copy of their genetic testing report. Their data are prepared for de-identified data sharing with approved, public databases to facilitate interpretation of genetic variants. Participants also have the ability to connect with one another, as well as with clinicians and researchers. Using the secure online portal, participants can search based on diagnosis, age, or US state. Participants also can elect to receive information about clinicians, laboratories, or researchers trying to connect with them. Individuals with variants in candidate genes also can connect through GenomeConnect's involvement in Matchmaker Exchange, a resource for patients, clinicians, and researchers to search for genetic and phenotypic matches in an effort to determine if a genetic variant in a candidate gene is the explanation for a particular condition. As of May 2016, the growing community currently includes 557 participants from 49 states and 20 countries. Participants have reported more than 200 different diagnoses, including chromosome abnormalities, childhood and adult onset single gene disorders, mitochondrial conditions, and genomic variants in a total of 153 genes. Five percent of GenomeConnect participants have the potential to match with another participant based on gene, 26% could match on a specific diagnosis, and 86% could match on US state. Overall, GenomeConnect provides a means for participants to connect with others while providing clinicians, laboratories, and researchers with genetic and health information that will allow for advances in genomic medicine.

3076W

Engaging families in research by targeting their concerns. *B. Smith-Pack-ard, H. Rocha, K. Fultz, S. Smith, S. Martin, W.A. Faucett, Simons Variation in Individuals Project (Simons VIP).* Genomic Medicine Institute, Geisinger Health System, Danville, PA.

The Simons Variation in Individuals Project (Simons VIP) is an online support community and registry for individuals with a known genetic etiology related to autism. Recruitment goals were met for the initial copy number variants (CNVs) of interest, including 16p11.2 and 1q21.1, and the community expanded to include a number of genes reported to be associated with autism risk, with the continued goal of characterizing the phenotype and natural history of these genetic changes. Various techniques to engage families and encourage enrollment have been explored, including newsletters, webinars, article summaries, social media interaction and addressing family concerns. These efforts serve a dual purpose: they provide resources to support the community and feedback to engage participants. Investigating family-raised questions and treating families as community researchers are unique methods of patient engagement. Fostering a collaborative relationship gives families the opportunity to voice concerns they have noted and allows the study team to acknowledge and explore these concerns. The process of addressing family questions begins with an informal survey to collect more information. Data are shared back with the group, and depending on responses, a pilot project may be developed to investigate further. For example: • 16p11.2 families shared that their children "run hot;" this information was corroborated by responses to an initial survey and a project was developed to track body temperature continuously over three days using a wearable monitoring device. • *SCN2A* families asked for information about the seizures their children experience. To capture this information, an online survey was implemented to allow families to view de-identified responses. The study team can also match family respons-es to lab reports to explore whether the specific variant plays a role in seizure development. Patient engagement has been a key component of Simons VIP. Developing research around questions raised by families and sharing results has helped to strengthen the partnership between families and the study team. Being able to grow a large cohort of families with rare genetic changes is an important first step in facilitating research and may help attract the interest of researchers and aid in the development of new studies and possible targeted clinical interventions. Developing strategies to encourage family interest and participation is a key factor in keeping families engaged.

3077T

Transitioning NIPT to general practice: ELSI challenges in the healthcare organization. *L. Parham[1], L. Manace Brenman[2].* 1) Jurisprudence and Social Policy, University of California, Berkeley, Berkeley, CA; 2) Medical Genetics, Kaiser Permanente Northern California, Oakland, CA.

The use of non-invasive prenatal testing (NIPT) using cell-free DNA (cfDNA) is rapidly expanding in prenatal care. The majority of patients receive con-sultation and ordering for this screening test in a general obstetrics practice, rather than a specialty genetics or maternal fetal medicine setting. As such, general practice clinicians, including obstetricians, prenatal nurses, and health education personnel, are educating and consenting pregnant women on their options regarding this novel genetic technology with complex clinical utility and limitations, particularly vis a vis traditional maternal serum and integrated prenatal screening options. NIPT use, and public demand, is also quickly mov-ing from high-risk to general prenatal populations, just as the options for what components of the test are included is increasing from chromosome aneu-ploidy with or without fetal sex to higher resolution chromosomal copy number variation screening. This presents ethical, legal, and social implications (ELSI) challenges to healthcare organizations to adequately educate non-specialized personnel and their patients about the use of a dynamic and fast-develop-ing technology. Recently, our managed care organization transitioned NIPT education, ordering, and negative resulting for pregnant women of advanced maternal age from specialty genetics consultation to the general women's health practice. Using 30 in-depth clinician/staff and patient interviews, and 80 hours of clinic observation, this study tracks the impact of launching NIPT in a general obstetrics setting, focusing on issues of informed consent and coun-seling practices, and policy and practice adjustment as the testing steadily moves from high-risk patients to the general prenatal population.

3078F

Familial consequences in 25% at-risk individuals after presymptomatic testing for Huntington disease. *A. Bonnard[1], A. Herson[1], C. Boucher[1], S. Staraci[1], M. Gargiulo[2], A. Durr[1,3].* 1) APHP Department of Genetics, Groupe Hospitalier Pitié-Salpêtrière, Paris France; 2) Laboratoire de Psychologie Clinique et Psychopathologie, EA 4056, Université Paris Descartes, Sorbonne Paris Cité, Institut de Psychologie, Paris, France; 3) Institut du Cerveau et de la Moelle, INSERM U1127, CNRS UMR7225, Sorbonne Universités – UPMC Université Paris VI UMR_S1127, Paris, France.

   Presymptomatic testing (PT) refers to the option of being tested for an inherited disease prior to onset. Testing for Huntington disease (HD) is usually restricted to individuals at 50% risk in whom the parent is diagnosed with HD. An individual at 25% risk requests testing with full knowledge that his/her parent does not want to know his/her status. International recommendations states that extreme care should be exercised when PT would provide information about another person who has not requested it. Since the 1992, PT is offered in our center (University Hospital Salpêtrière, Paris). The goal of our study was to i) compare outcome of 25% at risk individuals to those of 50%; ii) assess how test information was disclosed in the family and to the parent. In the case of an unfavorable result, this "double knowledge" has major implications for futures relationships between offspring and the transmitting parent. Psychological issues, particularly the impact to become a "messenger of bad news" for parents and siblings is amplified in this case. We assessed information about pre-test and post-test including age, gender, parent status, motivation for testing, result of the PT and contacted 25% at risk individuals by phone and invited them for an semi-structured interview. There were 1488 individuals at 50% risk and 159 at 25% who took the test between 1992 and 2016. The mean time since testing request was similar in both groups [10.9 years ± 6.4 vs 11.4 years ± 6.5 p=0.416]. 25% at risk were younger at first contact [30.7±9.7 years (13-78) vs 35.1±12.1 years (11-90), p<0.001] and had less often children [42/153 (27%) vs 661/1437 (46 %), p=0.001]. The 50% requested their result after multidisciplinary testing procedure more often than the 25% [1041/1488 (69.9%) vs 93/159 (58.5%), p=0.001], and they were more often carriers of the mutation in *HTT* gene [42% (434/1041) vs 13% (12/93), p<0.001]. Our results showed significant differences between the 25% and 50% at risk groups. Seven interviews were conducted, 5 lost for follow up. One paradoxal reaction occured with a suicide in the 25% at risk group, in a non carrier individual. Detailed psychological outcomes will be reported. .

3079W

Long QT syndrome: A genetic test in the context of a diagnostic algorithm. *E.R. Lockhart[1], C. Greene[2], V.Y. See[3], S. Vashist[2], I.M. Lubin[1].* 1) Division of Laboratory Systems, Centers for Disease Control and Prevention, Atlanta, GA; 2) University of Maryland School of Medicine, Clinical Genetics Service and Department of Pediatrics, Baltimore, MD; 3) University of Maryland School of Medicine, Cardiovascular Medicine Division and Department of Medicine, Baltimore, MD.

   <u>Introduction</u> Long QT syndrome (LQTS) is a hereditary autosomal dominant disorder of cardiac electrical activity that can lead to sudden cardiac arrest (SCA). Timely diagnosis can lead to life-saving therapies. LQTS is typically diagnosed by finding prolonged QT interval on EKG, but a significant percent of affected individuals have normal QT intervals. DNA testing in LQTS evaluation can inform diagnosis, guide personalized therapy, and identify at-risk family members. By developing a diagnostic algorithm of LQTS as a specific use, we gain insight regarding the utility, limitations, and opportunities for integrating genetic testing into LQTS evaluation that can also be used as a model for other diagnostic scenarios.   <u>Methods</u> The LQTS diagnostic algorithm was derived from common practices at the University of Maryland School of Medicine and published professional guidelines. A use case was derived based upon the scenario of a teen with loss of consciousness during athletic activity. This use case served as a framework to address several questions: 1) What is the optimal time to order a genetic test? 2) What are the implications of using genetic tests in light of family history? 3) How are findings that do not establish pathogenicity handled? And 4) How do genetic test results influence treatment decisions?   <u>Results</u> Independent of family history, genetic testing is not immediately ordered because other testing is more expedient to establish LQTS diagnosis. Family history may not always be informative and decisions made as a consequence can influence the significance placed on ordering genetic testing. While several multi-gene panels are available, the choice of testing and the interpretation of variants that are not clearly pathogenic remain a challenge. Parameters specific to each of these decision points are further evaluated.   <u>Conclusion</u> The placement and use of genetic testing within the diagnostic algorithm could be influenced by other types of testing performed, family history, the intended use of the test selected, turn-around-time, and the perceived usefulness of the test results for informing medical decisions. Findings from this case study suggest the need to review diagnostic algorithms with respect to the optimal placement and use of molecular genetic tests for making a diagnosis.

3080T

Learned lessons one-year experience of massive-scale crowd-sourcing platform for genomes and phenomes. *Y. Erlich[1,2], A. Gordon[2], J. Yuan[1,2], D. Zielinski[2], R. Aufrichtig[2], D. Speyer[1,2], J. Pickrell[2,3].* 1) Department of Computer Science, Columbia University, New York, NY; 2) New York Genome Center, New York, NY; 3) Department of Biological Sciences, Columbia University, New York, NY.

Precision medicine is a data-hungry endeavor. However, traditional cohort ascertainment strategies poorly scale and necessitate substantial investments to obtain genomics data, conduct physical exams and lab tests, and assess familial history. But are these really required in today's world? Between 2-3 million people already have access to their digital genome. In addition, the human population has produced zettabytes (10^{21}) of digital data just in the last few years, conveying massive amount of digital phenotypes. Here, I will present our successes in repurposing participants' data for ultra-large scale genetic studies. In ASHG2015, we launched a website called DNA.Land, where participants can contribute their digital genome, genealogical information, and phenotypes. During its eight months of operation we collected about 23,000 genomes from people all over the world. Our approach relies on simple concepts of autonomy, reciprocation, and a respectful consent form to facilitate participation. In this process, we learned important lessons on developing a scalable website to collect massive amount of information, engaging the general public via digital media to address privacy concerns, and return results that matter to participants. These lessons can vastly facilitate other large-scale projects that aim to digitally recruit participants, such as the Precision Medicine Initiative.

Human genetics at the National Research Centre in Egypt: History, achievements and challenges. *M.A. El Gammal, M.S. Aglan, S.A. Temtamy.* Human Genetics and Genome Research, National Research Centre, Cairo, Dokkie, Egypt.

The National Research Centre (NRC) in Egypt is a multidisciplinary research institute that has a wide spectrum of research fields and interests. It is the largest of all institutions affiliated to the Ministry of Scientific Research in Egypt. It was established in 1956 as a national center to conduct basic and applied research. The Division of Human Genetics and Genome Research (HGGRD), as one of the most distinguished divisions at the NRC, had its origins as the Department of Human Genetics which had been established in 1976 by Prof. Samia Temtamy and small number of scientists. In our presentation we will introduce the journey of the HGGRD at the NRC through 40 years of expansion and development. We will also highlight the achievements and challenges of this unique field of science in Egypt as one of the largest Arab Mediterranean countries. .

3082W

GWS-KQ: A genome-wide sequencing knowledge questionnaire for family testing. *P.H. Birch[1], S. Adam[1], R.R. Coe[1], M.B. Connolly[2], M.K. Demos[2], E. Toyota[2], M.J. Farrer[3], J.M. Friedman[1].* 1) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Division of Neurology, Department of Pediatrics, University of British Columbia, Vancouver, BC, Canada; 3) Centre for Applied Neurogenetics, Djavad Mowafaghian Centre for Brain Health, University of British Columbia, Vancouver, BC, Canada.

    Purpose: We created the GWS-KQ to assess parents' knowledge and understanding of the possible ramifications of genome-wide sequencing (GWS) in family trios (two parents and an affected child) participating in a research study. We were unable to find a published, validated tool that assessed parents' comprehension of issues relevant to trio GWS.   **Method:** A literature review, consultation with genetics health care experts, and interviews and focus groups with parents who had already gone through GWS identified topics deemed important when making informed GWS choices. The issues selected included the nature of genomes, exomes, and incidental findings; the probability of making a diagnosis; variants of uncertain significance; the impact of results on family members; recurrence risks; and insurance implications. Multiple-choice questions were formulated and subjected to several rounds of testing, first with students, staff, and genetics experts, and subsequently with parents. After item analysis and final modification, we administered the questionnaire to 102 GWS-naïve parents of children with epilepsy, both before and after a genetic counselling intervention prior to exome sequencing.   A test-retest analysis of the final 21 questions was performed, two weeks apart, on an independent data set of 27 previously-counselled parents of children having GWS for unknown disorders.   **Results:** In the epilepsy study, parents' mean knowledge scores increased from 44% on the first administration to 65% on the second administration after a genetic counselling intervention (paired t-test, $p < .001$). The questionnaire was internally consistent (Cronbach's α = .83), and responses for each item were significantly correlated with the parents' overall scores (mean $r = .48$ [range .26 to .67], $p < .01$ for all items). In the test-retest study, knowledge scores were consistent ($r = .90$, $p < .001$; mean difference = +2%). Mean time to administer is about 10 minutes.   **Conclusion:** The GWS-KQ questionnaire is quick to administer; appears to have face validity, internal consistency, and sensitivity to change; and demonstrates test-retest reliability. We used GWS-KQ in a research study, but it might also be helpful as a clinical screening tool to identify areas of patients' uncertainty prior to genetic counselling for GWS.

3083T

Physician-patient communication of genome sequencing results in diagnostic odyssey cases. *C.S. Bloss[1], D.L. Boeldt[2], C. Cheung[3], A. Torkamani[2,4], J.R. Friedman[5].* 1) Department of Psychiatry, University of California, San Diego, La Jolla, CA; 2) Scripps Translational Science Institute, Scripps Genomic Medicine, Scripps Health, La Jolla, CA; 3) The Qualcomm Institute of Calit2, University of California, San Diego, La Jolla, CA; 4) Department of Integrative Structural and Computational Biology, The Scripps Research Institute, La Jolla, CA; 5) Rady Children's Hospital, San Diego, CA.

    Introduction: Many believe it will ultimately be the job of physicians to communicate genomic information to patients given the relative dearth of genetic counselors and medical geneticists in the U.S. Often cited concerns, however, are that physicians as a group are not trained in genomics and thus their ability to understand, use, and communicate genetic results to patients is unclear. Therefore, we conducted a controlled, quantitative study of physician-patient communication in a case series of diagnostic odyssey patients.   **Methods:** We evaluated physician return of results in the context of an ongoing study of the utility of genome sequencing for diagnosis of rare and idiopathic diseases. Using a modified version of the Medical Communication Competence Scale (MCCS), we leveraged a pre/post experimental design that compared patients' ratings of their physician's communication generally (pre-sequencing) versus his/her communication of genomic results (post-sequencing). These ratings were then directly compared to physicians' self-ratings of their communication of the genomic results.   **Results:** The first 10 cases sequenced in the parent study participated in this study. Across all 10 cases, patient ratings of their physicians' general communication were high (mean pre-sequencing MCCS=123.3 out of 140), suggesting these patients/families had good relationships with their physicians and perceived them to be good at communicating medical information generally. Post-sequencing, however, all 10 patients/families rated their physician's communication of the genetic results as worse than their general communication (mean post-sequencing MCCS=107.6; pre vs. post, p=.010). Furthermore, physicians themselves (with two exceptions) rated their own communication of the genetic results lower than did the patients (physician self-rating MCCS=96.8). We did not observe a relationship between the results of the sequencing (e.g., whether a diagnosis was found) and the ratings of physician communication.   **Conclusions:** Physician-patient communication of genetic information is increasingly important as personal genome sequencing becomes more widely available in clinical settings. Findings from our controlled, quantitative case series study, however, suggest that even physicians with strong communication skills, good patient relationships, and experience with challenging diagnostic odyssey cases may have difficulty relaying genomic information to their patients.

3084F

Recruiting students to the field of genetic counseling – A local effort.
C.A. Campbell[1], S. Feely[2], T.K. Grider[2], J. Phetteplace[2,3], K. Shipley[4], H.M. Bombei[5], J. Marcy[5], J.L. Mancuso[6], K.M. Panzer[5], S. Romoser[5], K. Wiens[5], R.J.H. Smith[1]. 1) Iowa Institute of Human Genetics, University of Iowa, Iowa City, IA; 2) University of Iowa, Department of Neurology, Iowa City, IA; 3) University of Iowa, Department of Internal Medicine Division of Cardiology, Iowa City, IA; 4) University of Iowa, Holden Comprehensive Cancer Center, Iowa City, IA; 5) University of Iowa, Stead Family Department of Pediatrics, Division of Medical Genetics, Iowa City, IA; 6) University of Iowa, Department of Obstetrics and Gynecology, Iowa City, IA.

There is an increasing demand for genetic counselors throughout healthcare, industry, and research. Efforts are underway to increase the number of genetic counselors trained each year. The Iowa Institute of Human Genetics (IIHG) sought to proactively attract students to the field with the hope of growing our future local workforce. We will describe local efforts undertaken to recruit students to the field of genetic counseling. The main aims of this initiative were: 1) raise awareness among students about genetic counseling; 2) prepare students for genetic counseling graduate school. To date, we have utilized a strategic approach for implementation of diverse activities to accomplish these aims. We will present our programmatic framework and considerations when implementing activities such as target populations, genetic counselor engagement, cost, support, activity evaluation, and benefits. Activities developed to date include; Careers in Human Genetics Day, Applying to Genetic Counseling Programs event, Genetic Counseling Summer Internship, and assistance with graduate school interview preparation, clinical shadowing and present at local schools upon request. Target populations include high school and college students, recent graduates, educators.   Success of the programs is measured by participant evaluation. IIHG Genetic Counseling interns have been highly successful in applying to graduate school 7 of 8 interns accepted to graduate school, and one student elected to take a gap year. In addition, a study conducted by the Association of Genetic Counseling Program Directors found in 2014 Iowa led the nation in recruiting students to the field of genetic counseling. Although there is not a genetic counseling graduate program in Iowa, this initiative has allowed us to begin to prepare for a program, and increase our local workforce 1.5 fold in 3 years. These activities can be implemented by genetic counselors who wish to be involved with student development, or to assist in overview genetic counselor workforce development. Our activities utilize multiple genetic counselors, but can be modified based on local resources or be implemented by a single genetic counselor. We believe that communities without genetic counseling training programs can help aid in the national efforts by increasing awareness and recruiting high school and college level students to the field of genetic counseling.

Satisfaction with receiving genome sequencing results in a preconception population: Implications for future large scale sequencing.
T.L. Kauffman[1], K. Bergen[1], M.J. Gilmore[2], P. Himes[2], M.C. Leo[1], F. Lynch[1], L.M. Amendola[3], S. Punj[4], P.D. Robertson[5], C. McMullen[1], C.S. Richards[4], D.A. Nickerson[5], G.P. Jarvik[3,5], B.S. Wilfond[6], K.A.B. Goddard[1]. 1) Center for Health Research, Kaiser Permanente, Portland, OR; 2) Department of Genetics, Kaiser Permanente Northwest, Portland, OR; 3) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 4) Department of Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR; 5) Department of Genome Sciences, University of Washington, Seattle, WA; 6) Seattle Children's Research Institute, Treuman Katz Center for Pediatric Bioethics, Seattle, WA.

A variety of modalities is available for disclosing results of genetic testing, including in-person or telephone visits, telemedicine, and mailed letters. Studies evaluating various approaches to pre-test genetic counseling in the context of either cancer syndromes or carrier and prenatal testing have found a high level of satisfaction with all of these modalities, but methods of post-test counseling and results disclosure have not been explored. As part of the Clinical Sequencing Exploratory Research (CSER) consortium, we looked at satisfaction with post-test counseling and results disclosure from genome sequencing for preconception carrier status via in-person visits (for abnormal results) or letters (for normal results).   Women eligible for the study had a preconception or prenatal carrier test ordered by their provider, were planning a pregnancy, and were Kaiser Permanent Northwest members. Women could receive carrier results on ~750 conditions; they could also receive additional findings on ~100 medically actionable conditions. Abnormal findings were disclosed during an in-person genetic counseling session. Normal results were disclosed via a letter. Participants were surveyed 2 weeks after receipt of results about their satisfaction with the method by which the carrier and additional findings were disclosed. The 6-item satisfaction scale has a possible score of 6-30, with higher values indicating greater satisfaction.   Eighty women completed a survey following disclosure of carrier findings: 61 had in-person visits, and 19 received letters. Sixty-six women who received letters notifying them of normal results for additional findings completed a survey. Mean and standard deviations (SD) of satisfaction scores for the letter and in-person visit for disclosure of carrier results were 22 (SD=6.1) and 26 (SD=3.7), respectively. Mean satisfaction for the letter for disclosure of normal additional findings was 23 (SD=3.7).   Overall satisfaction was high for disclosure of results via both in-person genetic counseling visits and letters, although there was slightly less satisfaction with the letters. Based on individual survey item responses, the language in the letters could be refined for clarity. While we returned only normal results via letters, future studies could explore the possibility of using letters to disclose abnormal results. This could save substantial cost and time, and make preconception genome sequencing more feasible in a clinical setting.

Genetic counseling training and services in the Asia region. *M. Laurino[1,2], D. Sternen[3], J. Thompson[4], K. Leppig[5,6]. 1) Fred Hutchinson Cancer Research Center, Seattle, WA; 2) University of the Philippines, Malia, Phillippines; 3) Seattle Children's Hospital, Seattle WA; 4) BC Cancer Agency, Vancouver, British Columbia; 5) Group Health Cooperative, Seattle WA; 6) Department of Pathology, University of WA, Seattle, WA.*

The Genetic Counseling Pre-Conference Workshop (GCPCW) was held on September 16, 2015 in Hanoi Vietnam, prior to the 11th Asia Pacific Congress for Human Genetics. A total of 71 signed registrants attended the GCPCW. Representatives from Australia, Hong Kong, India, Indonesia, Malaysia, Philippines, Singapore, Taiwan, Thailand, and Vietnam reported on the status of genetic counseling in their respective country. Five countries (Australia, India, Philippines, Singapore, and Taiwan) have developed master's level genetic counselor training programs. Of the remaining five countries, four provide other models of genetic counselling training, ranging from genetic disease-specific courses lasting 3-5 days to a master's program in biomedical science with a genetic counseling focus.   The pre-conference also included a case-review breakout session and a discussion of needs for those providing genetic counseling in the Asia Region. Pre-conference and post-conference questionnaires were returned by 57 and 44 individuals, respectively. Of the 42 registrants who did not identify themselves as current students in training, 86% stated that they were currently providing genetic counseling and had training ranging from an undergraduate degree to MD with fellowship training. 100% of registrants strongly agreed or agreed that their expectations of the pre-conference were met, 98% would attend a similar pre-conference with preferred topics including best practices in genetic counseling, East vs. West counseling differences, communication skills, cross- cultural training, and research studies pertinent to genetic counseling .   The GCPCW provided a forum for those who currently provide genetic counseling in the Asia region to address the challenges and needs of genetic counseling in the region. Participants cited that the most useful information obtained during the GCPCW was the availability and status of genetic counseling in the Asia region, followed by learning of shared challenges, professional networking, opportunities for collaboration, the need to promote awareness of genetic counseling, and the development of accreditation. The formation of the Professional Society of Genetic Counselors in Asia was announced at the GCPCW and will provide an ongoing resource for education, advocacy and collaboration for genetic counselors working in Asia.

3087F

Carrier screening program for Cree Encephalitis and Cree Leukoencephalopathy: Long-term knowledge and carrier status retention in high school students. *J. Le Clerc-Blain[1], V. Gosselin[2], A. Bearskin[3], J.E. Torrie[2], G.A. Mitchell[1,4], B.J. Wilson[5], A. Richter[1,4], A.M. Laberge[1,4]. 1) CHU Sainte-Justine Research Center (Montreal, QC, Canada); 2) Cree Board of Health and Social Services of James Bay (Chisasibi, QC, Canada); 3) Eeyou Awaash Foundation (Chisasibi, QC, Canada); 4) Medical Genetics Division, CHU Sainte-Justine and Department of Pediatrics, University of Montreal (Montreal, QC, Canada); 5) School of Epidemiology, Public Health and Preventative Medicine, University of Ottawa (Ottawa, ON, Canada).*

BACKGROUND: Cree Encephalitis (CE) and Cree Leukoencephalopathy (CLE) are two neurodegenerative autosomal recessive conditions with high carrier rates in the James Bay Cree communities of Northern Quebec (Canada). Education/counselling sessions are offered to high school students (≥ 14 years) through the CE-CLE carrier screening program (CSP), a population-based CSP developed by local health authorities in collaboration with the Eeyou Awaash Foundation (a community family support group). OBJECTIVE: To describe high school students' knowledge of the CE-CLE CSP 6-12 months after their education/counselling session, and evaluate their carrier testing result retention. METHODOLOGY: Surveys were handed out before (survey A), after (survey B), and 6-12 months (survey C) following the CSP education sessions to Quebec secondary 3-5 (grades 9-11 equivalent). Data was collected on demographics, knowledge of CE-CLE, attitudes about screening, and carrier status retention. Knowledge questions were compared between participants who answered all three surveys using t-tests (n=50). Participants' answers about their carrier status were compared to their test results in the clinical database. RESULTS: Of 359 eligible students, 134 (37%) answered survey A. Of these, 71 (53%) answered survey B and 72 (54%) survey C. Ages ranged from 14-20 years. Twenty-three (17%) were either pregnant or already had at least one child. Twelve (9%) reported a positive family history for CE or CLE. Out of 14 knowledge questions, the mean number of correct answers was 4.5 (survey A), 7.3 (survey B) and 6.9 (survey C). Between pre-screening (A) and immediate post-screening (B) surveys, we observe a significant increase in the number of correct answers (p=0.003). The number of correct answers 6-12 months post-screening (C) is slightly lower than right after screening (B), but this difference is not significant (p=0.68). Knowledge remains significantly higher 6-12 months post-screening (C) than pre-screening (A) (p=0.01). Out of 72 students who answered survey C, 62 (86%) remembered correctly participating or not in the screening. Out of the 54/72 (75%) students who did the screening test and for whom results were available, 34/42 (81%) accurately remembered their carrier status. CONCLUSION: Post-screening knowledge and carrier status retention is encouraging, pointing to the lasting impact of the CE-CLE CSP education sessions on high school students. This program may serve as a model for other CSPs.

3088W

Development of a practice model of genomic counseling for actionable complex disease and pharmacogenomics. *K. Sweet[1], A.C. Sturm[1], S. Hovick[2], T. Schmidlen[3], E.S. Gordon[4], K.E. Ormond[5], B.A. Bernhardt[6], J. O'Daniel[7], J. McElroy[8], L. Scheinfeldt[3], A.E. Toland[1], J.S. Roberts[9], M. Christman[3].* 1) Division of Human Genetics, Ohio State University Wexner Medical Center, Columbus, OH; 2) School of Communication, Ohio State University, Columbus, OH; 3) Coriell Institute for Medical Research, Camden, NJ; 4) 23andMe, Mountain View, CA; 5) Department of Genetics, Stanford University School of Medicine, Stanford, CA; 6) Division of Translational Medicine and Human Genetics, University of Pennsylvania, Philadelphia, PA; 7) Department of Genetics, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 8) Center for Biostatistics, Ohio State University, Columbus, OH; 9) Department of Health Behavior & Health Education, University of Michigan School of Public Health, Ann Arbor, MI.

Given the movement towards both multi-gene testing and online patient access, optimization of genomic counseling (GC) services to support multiplex results delivery is needed. More information on patients' motivations, preferences, and informational needs are essential to guide the development of new, more efficient practice delivery models that capitalize on the existing strengths of a limited genetic counseling workforce. To explore this, we sought to define essential content and process elements through formative research with participants receiving multiple (n= 26) online actionable complex disease and drug response results via the OSU-Coriell Personalized Medicine Collaborative. Semi-structured telephone interviews were conducted with study participants who had either telephone GC (TGC; community cohort, n=31; mean age 46.8 years) or in person GC (IPGC; chronic disease cohort, n=20; mean age 60 years). Interviews were used to a) clarify participant expectations and impressions of GC; b) determine the most and least valuable components of the IPGC and TGC models; and c) identify preferences for follow-up GC. Transcripts were analyzed using a Grounded Theory framework. Although all participants felt satisfied with the GC received, there was expressed need for a more participant-driven GC model, more control over the results discussed, more personalized risk reduction recommendations, and the option of follow-up counseling for new results. Based on these findings we developed a novel GC practice model which involves patient completion of an online survey, after receipt of online results and before GC, to select test results and provide personal questions they would like to cover in GC, and to indicate preferences for counseling modality (telephone, online or in-person). The individual preferences and questions are used to tailor the GC session and personalize result communication and risk reduction recommendations. Newly developed visual aids and result summary reports break down areas of risk (genetic, family history, lifestyle) for each disease to facilitate viewing of multiple risk results at once. Post GC, summary reports are actively routed to the participant and physician to encourage review and follow up on recommended disease prevention/risk reduction actions. The GC practice model has been evaluated in 44 new study participants, and is adaptable for use in large-scale genomic sequencing efforts.

Exploring the content and process of returning results from exome sequencing. *S.A. Walser[1], A. Werner-Lin[1], S. Biswas[2], R. Mueller[1], B.A. Bernhardt[1].* 1) University of Pennsylvania, Philadelphia, PA; 2) Children's Hospital of Philadelphia, Philadelphia, PA.

In an NIH-funded Clinical Exploratory Sequencing Project, the PediSeq study, we are offering exome sequencing to children with unexplained hearing loss, sudden cardiac arrest, mitochondrial disease, platelet function disorders or neurodevelopmental disability. In addition to diagnostic results, families can opt to learn findings that are actionable in childhood and adulthood, and carrier status. We analyzed 25 audiotaped return of results (ROR) sessions conducted by one or several of 7 genetic counselors or 6 physicians. Eleven families received pathogenic and 7 possibly pathogenic results relating to the indication for testing, 3 received medially actionable secondary findings and 14 received carrier status results. Sessions ranged from 7 to 100 minutes. In most sessions, clinicians presented results by following a 14 page results report and providing technical details about the variants found and sequencing limitations. Families asked many clarification questions attempting to understand and personalize results. Many families scanned ahead of clinicians in the report to learn additional findings. Clinicians presented diagnostic pathogenic mutations as "we found the answer". Families responded with satisfaction that their diagnostic odyssey was over, disappointment results would not modify treatment, or relief from guilt. Both negative and uncertain diagnostic findings were presented by the clinician with a promise that scientific advances might provide future clarity. Families responded to such results with disappointment, confusion, resignation, suspicion, hope or surprise. Although most received carrier status results, many families commented that they had expected more secondary findings, particularly for common adult diseases. Some believed their risk for conditions such as cancer was reduced because of the lack of secondary findings. Multiple families incorrectly expected exome sequencing results would be available on all family members who provided a study-related blood sample. We conclude that structuring ROR sessions around a complicated results report and the clinicians' use of excessive technical language may confuse and overwhelm families, and not address their main concerns: management based on test results and risk of common diseases. Pre-test informed consent sessions focusing on realistic expectations of sequencing results and the limitations of sequencing might better prepare families for the kinds of results returned. .

3090F

Raw DNA availability and downstream implications for genetic service providers. *C. Wang[1], N. Thomas[1], T. Norkunas[1], M. Flynn[2].* 1) Boston University School of Public Health, Boston, MA; 2) Boston University School of Medicine, Boston, MA.

Raw DNA data and corresponding online interpretation services are widely available to the public, yet little is known about their downstream impact on genetic service providers. We conducted a survey to examine the extent to which consumers of these personal genetic services are reaching out to genetic counselors and to identify issues stemming from any clinical encounters. A total of 83 genetic counselors completed a web-based survey that was administered via listservs of the National Society of Genetic Counselors in Spring 2016. Among respondents, 53% (N=44) had been contacted by a patient to schedule an appointment following the use of an online service to interpret raw DNA data; mean number of patients was 3.84. Among the counselors contacted, 72% indicated they had seen at least some of these patient cases in clinic. Disease categories for counseling requests included cancer (52%), neurology (21%), metabolism (17%), pediatrics (10%) and psychiatric (10%). In preparation for these cases, 64% of counselors researched the DNA interpretation service, 52% consulted genetic databases, and 16% contacted the service that interpreted the raw DNA. Average amount of time to prepare for these cases was 2 hours (range 0-6 hours). Online services used by patients included Promethease (58%), LiveWello (23%), Genetic Genie (8%), and GEDMatch (4%). Reports generated from these services were rated poorly by genetic counselors based on clarity of format (mean 1.83; 1=unclear to 5=clear) and informativeness (mean 1.54; 1=not at all informative to 5=extremely informative). When asked to weigh the benefits versus limitations of raw DNA interpretation services, 77% of counselors felt the limitations outweighed the benefits, 12% were neutral, and 11% felt the benefits outweighed the limitations. Notably, counselors who had never seen a case were more likely to feel that the benefits outweigh limitations compared to those who had seen a case (16% vs. 4%). Qualitative responses highlight challenges to counseling, including unrealistic expectations for counselors to interpret the (long) reports or raw DNA, overemphasis by patients on the legitimacy of the information within the reports, and patient frustrations if the session did not provide them with answers they were searching for. Overall, the availability of raw DNA data poses several challenges to genetic counselors who will increasingly be faced with requests by consumers to assist in data interpretation.

3091W

A novel framework for optimizing the value of personalized medicine co-dependent technologies. *P. Akude, R. Mahjoub, M. Paulden, C. McCabe.* Emergency Medicine, University of Alberta, Edmonton, Alberta, Canada.

The arrival of personalized medicine has led to an increasing recognition of the need to reconcile the evidence requirements for test and treatment technologies. In this research, we develop a method for combining evidence on the test(s) and treatment components of co-dependent technologies that identify the cost effective cut-points on the test components for pre-specified values of the Willingness to Pay for Health. The framework we propose consists of three tests (genotypic diagnosis, phenotypic expression and therapy responder status) and a treatment. The first test identifies the existence of the health condition. Based upon the presence of the condition of interest, the second and third tests characterize the ability to respond to therapy and the phenotypic expression (which places a limit on the ability to benefit from therapy) respectively. We identify two decision variables – the cut-point for the probability of responding to therapy and the cut-point for the phenotypic expression that leads to treatment. For a given probability of response, patients who are identified to benefit from treatment are administered a new treatment while other patients are prescribed standard care. The effectiveness of the therapy in responders and non-responders is exogenously determined. We show that for a given probability of response, the optimal cut-point for the test of phenotypic expression is identified at the point at which benefits to a responding patient means that the patient is indifferent between the new treatment and standard care. We present a series of analyses exploring the relationship between the distributions of the probability of responding to therapy, phenotypic expression and the net benefit from the new technology. Our analyses demonstrate that the benefit from the adoption of personalised medicine co-dependent technologies can be optimized by treating response probability and phenotypic expression as decision variables not exogenously determined parameters.

3092T

Predictors of anxiety and depression in caregivers of children with chronic conditions of unknown but suspected genetic origin. *N.I. Drago-jlovic[1], A.M. Elliott[2], J.M. Friedman[2], L.D. Lynd[1], CAUSES Study Group.* 1) Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, British Columbia, Canada; 2) Department of Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada.

Background: Caregivers of children with chronic health conditions tend to have increased anxiety and depression when compared to parents of healthy children. The lack of a diagnosis has been shown to act as a major psychological stressor for parents, but it remains unclear whether this is purely a result of the associated uncertainty, or whether the additional burden imposed by diagnostic investigations plays a role. **Objective:** To explore the association between healthcare utilization of children with idiopathic chronic conditions of suspected genetic origin enrolled in the CAUSES genome-wide sequencing clinic at British Columbia Children's Hospital and caregiver mental health. **Method:** One parent of each child was invited to complete an online survey that measured her or his mental health and the child's healthcare resource utilization. The Patient Health Questionnaire depression scale (PHQ-8; range 0-24) and the GAD-7 scale (range 0-21), a screening tool for generalized anxiety disorder, were used to assess the presence and severity of depression and anxiety, respectively. Parents reported their child's number of healthcare system encounters in the 6 months prior to survey completion and how many of these were primarily related to obtaining a diagnosis. The number of hours spent providing extra care due to the condition was used as an indicator of the condition's severity. Ordinary least squares (OLS) regression was used to test for associations with depression or anxiety scores. **Results:** 52 parents completed the questionnaire. Average healthcare resource utilization was 8.7 [IQR: 4 to 14] encounters, with 3.4 [0 to 4] being diagnosis-related and 5.2 [2 to 8] otherwise. The two types of encounters were not correlated (r = - 0.15, p = 0.29). Average scores were 5.0 [1.0 to 7.5] for depression and 5.7 [2 to 7] for anxiety. *Table 1:* OLS regression coefficient estimates for potential drivers of parental mental health. Standard errors in parentheses. + p < 0.10 * p < 0.05

	Depression	Anxiety
Total # of medical encounters	0.31 (0.12)*	0.19 (0.10)+
Hours of extra care per week	-0.02 (0.02)	-0.01 (0.01)
Child's age (years)	-0.34 (0.16)*	-0.06 (0.13)
N =	47	51
Adjusted R^2 =	0.18	0.02

Discussion: The number of healthcare encounters of the child was positively associated with the parent's levels of both depression and, to a lesser extent, anxiety.

3093F

Evaluating the cost-effectiveness of sequential monitoring tests. *R. Mahjoub, P. Akude, M. Paulden, C. Hollman, C. McCabe.* University of Alberta, Edmonton, Alberta, Canada.

A monitoring test is a test that is repeated in a patient over a period of time to identify changes in the patient's medical status. In this study we extend upon the existing literature for monitoring tests, allowing the test to be administered repeatedly for more than two periods, as well as incorporating the "treat without testing" and "skip test" strategies in each period. We also include "treat" or "do not treat" sub-strategies under the "skip test" strategy. Then for this setting, we examine the cost-effectiveness of a monitoring test and investigate the optimal strategy in each period. We also investigate the optimal cut-offs for test scores in those periods, in which it is optimal to apply the test. We illustrate with a numerical example using data from a Ca125 test for monitoring ovarian cancer. Our results show that the net health benefits resulting from the monitoring test and the treatment will be maximized if we optimize simultaneously for the test score cut-off points, re-test intervals, and the treat or do not treat sub-strategies. We conclude that optimal test cut-offs in a monitoring regime are population case-mix and health system specific and should not be assumed to be portable. To assume portability is to reduce the population health impact (value) of test technologies.

3094W

Primary care providers' experiences and perceptions of personalized medicine. *J.C. Carroll[1,2], T. Makuwaza[1,2], D. Manca[3], N. Sopcak[3], J.A. Permaul[2], M.A. O'Brien[1], R. Heisey[1,4], E.A. Eisenhauer[5], J. Easley[6], M. Krzyzanowska[7,8,9], B. Miedema[6], S. Pruthi[10], C. Sawka[8], N. Schneider[N/A], J. Sussman[11], R. Urquhart[12,13], C. Versaevel[3], E. Grunfeld[1,14] on behalf of CanIMPACT.* 1) Department of Family and Community Medicine, University of Toronto, Toronto, ON, Canada; 2) Ray D. Wolfe Department of Family Medicine, Sinai Health System, Toronto, ON, Canada; 3) Department of Family Medicine, University of Alberta, Edmonton, Alberta, Canada; 4) Department of Family and Community Medicine, Women's College Hospital, Toronto, ON, Canada; 5) Department of Oncology, Queen's University, Kingston, ON, Canada; 6) Department of Family Medicine, Dalhousie University, Fredericton, NB, Canada; 7) Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada; 8) Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; 9) Cancer Care Ontario, Toronto, ON, Canada; 10) General Internal Medicine, Mayo Clinic, Rochester, Minnesota, US; 11) Department of Oncology, McMaster University, Hamilton, ON, Canada; 12) Beatrice Hunter Cancer Research Institute, Halifax, NS, Canada; 13) Department of Surgery, Dalhousie University, Halifax, NS, Canada; 14) Ontario Institute for Cancer Research, Toronto, ON, Canada.

Context: Lack of knowledge in addition to systemic and practice issues impair the ability of primary care providers (PCPs) to embrace genomic medicine. Better understanding of PCPs' attitudes towards genomic medicine is needed to inform implementation of personalized medicine (PM) into primary care. **Objective:** To assess PCPs' experiences and perceptions of PM and their desired role, with a focus on cancer. **Design:** Qualitative study. **Setting:** Urban and rural inter-professional primary care team practices in Alberta and Ontario, Canada. **Participants:** Family physicians, nurses, nurse practitioners, physician assistants. **Method:** Semi-structured focus groups were conducted, audio-recorded, and transcribed. Analytic techniques were informed by grounded theory including coding, interpretations of patterns in the data and constant comparison. **Findings:** 5 focus groups with 51 participants in total were conducted; 2 in Alberta, 3 in Ontario. PCPs described limited experience with PM, citing breast cancer and prenatal care as main areas of involvement. They expressed concern over their lack of knowledge, particularly identifying appropriate patients for referral for genetic counseling and testing and were often unaware of the benefits of genetic testing. In some circumstances PCPs relied on personal experiences to inform their attitudes and practice. Participants anticipated an inevitable role in PM primarily because patients seek and trust their advice. Concern was expressed about the magnitude of information and pace of discovery in PM, particularly in direct-to-consumer personal genomic testing. PCPs described unfamiliarity with genetics specialists and clinics, which affected referrals. Increased knowledge, closer ties to genetics specialists and relevant, reliable PM resources accessible at point of care were considered important for successful implementation of PM. **Conclusions:** PCPs are prepared to discuss PM but they require better resources. Models of care that support a more meaningful relationship between PCPs and genetics specialists should be pursued. Continuing education strategies need to address knowledge gaps including identification and management of patients at increased genetic risk and direct-to-consumer genetic testing. PCPs should be mindful of using personal experiences to guide care. .

3095T

Status of trainee funding in ABMGG laboratory training programs. *T. Cowan[1], A. Cherry[1], M. Basehore[2], R. Schreck[3], L. Jeng[4].* 1) Stanford University School of Medicine, Stanford, CA; 2) Fullerton Genetics Center, Asheville, NC; 3) Cedars-Sinai Medical Genetics Institute, Los Angeles, CA; 4) University of Maryland School of Medicine, Baltimore, MD.

Funding sources for American Board of Medical Genetics and Genomics (ABMGG) laboratory fellows has been an ongoing concern for laboratory training in Biochemical Genetics, Cytogenetics and Molecular Genetics. With anticipated growth in Personalized Medicine, there is an increasing need for laboratorians certified in genetic laboratory specialties. In order to evaluate the current funding sources for laboratory trainees in ABMGG accredited programs, the Association of Professors of Human and Medical Genetics (APHMG) Laboratory Fellowship Program Director's Special Interest Group (SIG) surveyed training programs. A survey link was sent via Qualtrics Survey Software to program directors, training directors, and program coordinators at 45 institutions. Thirty-nine responses were received from 30 programs. About half of the respondents indicated that they have guaranteed funding for their trainees; of these, the main sources utilized by programs include a combination of institutional funds (54%), laboratory operating budget (64%), research grants (18%) and NIH training grants (10%). Some respondents indicated other sources including commercial laboratories and other internal and external funding. A similar survey was administered to ABMG laboratory training program directors in 2010, and showed similar trends. Of interest, 63% of programs said they could possibly accept additional trainees if more funding was available. Identifying consistent, guaranteed funds to support laboratory fellowship trainees would increase the ability of many of our existing training programs to train additional qualified work force to provide necessary genetic testing.

3096F

Common threads: Reflective practice connecting medical genetics concepts across an integrated curriculum. *S. Dasgupta.* Department of Medicine, Biomedical Genetics, Boston University School of Medicine, Boston, MA.

Recent curricular surveys have identified increasing numbers of medical schools moving towards integrated pedagogical models. At the same time, AAMC data indicates that the average proportion of the pre-clerkship curriculum dedicated to medical genetics is approximately 2%[1]. An integrated curriculum structure risks diluting the genetics concepts until the discipline identity is lost. To help preserve the identity of genetics within an integrated curriculum, a longitudinal reflective practice was introduced into the first year Principles Integrating Science and Medicine (PrISM) curriculum. This activity was tied to a series of patient visits held in four distinct modules of the PrISM curriculum. Following each patient session, the students were given an in-class reflective writing prompt. For the first two sessions, the anonymous writings focused on the stories' connections to their own lives and values, and subsequent sessions were paired with preceding patient visits. For example, the students' fall semester writings from meeting the parent of a child with trisomy 18 were returned to their peers for further comment after a spring semester session featuring a self-advocate with Down Syndrome. The writing guided students to contrast the similar genetic etiology and dramatically different prognoses of these conditions. Likewise, the students' fall semester reflections about women harboring hereditary breast and ovarian cancer-predisposing mutations were returned to their peers in the spring semester, after meeting a guest with multiple family members affected by Huntington's Disease. While both are single gene disorders with genetic testing options, the ability to select risk reducing procedures in one was juxtaposed with receiving a prediction for an incurable disease in the other. By structuring these reflective writings to highlight the common threads and contrasting outcomes between conditions, the students engaged with the clinical relevance of the genetics content and grappled with the ethical ramifications of genetic testing.   [1]Plunkett-Rondeau J, Hyland K, Dasgupta S. Training future physicians in the era of genomic medicine: trends in undergraduate medical genetics education. *Genet Med*. 2015. doi:10.1038/gim.2014.208.

3097W

Awareness, respect, and confidence: Increasing community conversation about genetics through a multi-faceted and interdisciplinary approach. *M. Gelbart[1], J. Kung[1], L. Tomaselli[1], D. Waring[1], E. McMillan[2], T. Wu[1].* 1) Personal Genetics Education Project, Department of Genetics, Harvard Medical School, Boston, MA; 2) Sanford Program for the Midwest Initiative in Science Exploration (PROMISE), Sanford Research, Sioux Falls, SD.

The Personal Genetics Education Project (pgEd.org) is using innovative strategies to hold community conversations and raise awareness about advances in genetics and the related ethical and social issues. pgEd is launching a new project, ARC: Building Awareness, Respect, and Confidence through Genetics, that aims to partner with teachers across all disciplines to stimulate dialogue about cutting-edge scientific and social developments in personal genetics within high schools and the broader community. First, we are creating curricular resources and adaptations for the public that revolve around the theme of genetics and identity, including modules on sex and gender, race and ancestry, intelligence and cognition, and gene editing. Second, we are developing an interdisciplinary professional development workshop for educators in urban Massachusetts and rural South Dakota communities, in partnership with the Sanford PROMISE. The first implementation of this workshop will take place in summer 2016, and we are anticipating ~50 teachers to attend from in and around Boston and across the nation. ARC will be integrated into the broader platform of pgEd's activities to engage audiences through schools, libraries, communities of faith, television and film, Congressional briefings, and social media. We will report on the most recent developments in these areas including foundational work with the Cornerstones of Science and library partners, our most recent Congressional briefing on the intersection of genetics and space travel, initial conversations with faith leaders, and pgEd's Industry Forum for Forging Community Partnerships.

3098T

The impact of personal experience with direct-to-consumer genetic testing on physician readiness. *E.S. Gordon, E. Kim, J. Cintron, R. Gold, J. Pollard, E. Nelson.* 23andMe, Mountain View, CA.

In recent years, there has been a shift towards patient empowerment in healthcare, punctuated by policy changes. In 2014, HIPAA was updated to allow patients to receive test results directly from laboratories. In 2015, the National Society of Genetic Counselors and the Association for Molecular Pathology updated their position statements in support of direct access genetic testing provided certain conditions are met. In the same year, the FDA granted marketing authorization to 23andMe for its Bloom Syndrome carrier status test, the first directtoconsumer genetic test (DTCGT), paving the regulatory path forward for more DTCGTs. Due to increased access, primary care providers (PCPs) are more likely to encounter patients inquiring about this type of testing but they may not be prepared. The role of personal genetic testing (PGT) as a potential tool for improving PCPs' awareness of and readiness for genomics has been suggested by researchers but has not been demonstrated. To assess the impact of PGT on PCP comfort with DTC-GT in the primary care setting, we analyzed previously collected data from a convenience sample of PCPs (MD, DO, NP and PA) who visited the 23andMe medical professional website between Oct 21, 2015 and Jan 22, 2016. 140 PCPs consented to the survey program with 70 completing all requirements, which included a pre-PGT survey, DNA kit registration, review of their personal 23andMe reports and post-PGT survey. The surveys were administered via online survey portal QuestionPro. Survey responses from 70 PCPs were analyzed using a o ne-sample z test, to identify differences between pre- and post-PGT. Following their PGT experience, significantly more PCPs reported feeling "very comfortable" interpreting DTCGT (47% vs. 26%, P<0.05) and making medical recommendations based on DTCGT (29% vs. 12%, p<0.05); whereas prior to PGT, the majority of respondents were "somewhat comfortable". In addition, respondents reported that their firsthand PGT experience was somewhat or very important for understanding carrier testing in general (77%), genetic testing in general (82%), key genetic concepts in general (77%) and utility of carrier testing in clinical care (77%). This study suggests potential value in PGT for PCPs to enhance comfort in dealing with DTCGT results; however the generalizability of these results is limited by the convenience sample used. Further exploration of the impact of PGT on PCPs naive to DTCGT is warranted.

3099F

Genetics Home Reference website as a point-of-care resource in the genomic medicine era. *K. Greenberg[1], S. Calvo[2], H. Collins[1], L. Forman Neall[3], S. Morrison[2].* 1) ICF International, Fairfax, VA; 2) U.S. National Library of Medicine, NIH, Bethesda, MD; 3) Medical Science & Computing, LLC, Rockville, MD.

With faster and cheaper genome sequencing technologies and the President's Precision Medicine Initiative, genetic data is becoming an integral component of health care. All clinicians will need a grasp of human genetics to be able to provide care in this era of genomic medicine. Genetics Home Reference (https://ghr.nlm.nih.gov/), a trusted consumer website from the U.S. National Library of Medicine, conveys complex genetic information through brief, plain language summaries of genetic conditions and associated genes. While the site is an excellent resource for the general public, it is also a point-of-care resource for clinicians to enhance their understanding of the role of genetics in medicine. A recent redesign of the Genetics Home Reference website improves its usability on mobile devices, making the site readily available for consultation. On a smartphone or tablet, clinicians can easily access information about more than 1,100 genetic conditions, including rare disorders unfamiliar to most physicians. They can also find summaries for more than 1,300 genes, all the chromosomes, and mitochondrial DNA, which can help put into context genetic testing results and aid in understanding the genetic basis of a diagnosis. The redesign also enhances overall usability of the website, making it easier for users to find information of interest. Navigation is streamlined, with in-text links that help users more easily move between related pages, and colors and icons that help distinguish the website's different content areas. In addition, condition summaries contain text-linked images that can be useful visual aids for understanding the features of a condition. Furthermore, clinicians can provide patients with printed versions of site content, making the information available to those without access to the Internet. In addition to particular conditions and genes, patients might find especially useful the website's primer *Help me Understand Genetics*, which discusses basic genetic concepts, such as how gene mutations affect health, how conditions are inherited, and how genetic testing is done. The Genetics Home Reference website is a useful point-of-care resource for clinicians as genetics becomes more important in health care. Improvements to the site, such as better navigation, mobile responsiveness, and the addition of educational images, will enhance the clinician's experience of using the site.

3100W

An online tool for applying the ABMGG laboratory training program milestones. *L. Jeng, J. Kleinberger.* University of Maryland School of Medicine, Baltimore, MD.

Recently, the American Board of Medical Genetics and Genomics (AB-MGG) announced the release of milestones for laboratory-based training to improve consistency of training and trainee evaluation. These milestones are a required component of training evaluations as of July 2016. In order to assist programs in using the milestones as part of the evaluation process, we have developed a simple online tool that enables programs to record which milestones have been successfully achieved by a trainee. The tool is available at http://ljeng28.wix.com/jeng-resources. When initially launched, the tool displays a list of twelve competencies (eg. Perform laboratory testing) under competency domains (eg. Patient Care). Clicking on a competency expands a list of milestones under that competency. Individual milestones can then be checked off after accomplished. The tool totals the number of milestones achieved under each competency plus each competency domain and provides a percentage of the total milestones. The trainee's progress in achieving milestones can be easily summarized by the tool in either a single page "Short PDF" showing the number of milestones achieved for each competency and competency domain or a four page "Extensive PDF" showing each milestone and whether or not it has been achieved. Either PDF version can be printed or saved and provides space to enter trainees name, date, comments and signatures, either by hand on the print out or by using a PDF editing program. This tool provides a simple way for programs to quickly implement the milestones into the evaluation process at regular intervals and to develop open communication between with the trainee regarding his or her progress on the milestones.

3101T

Development of a consent resource for genomic data sharing in the clinical setting. *E.R. Riggs[1], D. Azzariti[2], A. Niehaus[3], S. Goehringer[1], E. Ramos[3], H.L. Rehm[2,4], C.L. Martin[1], ClinGen Education Working Group.* 1) Autism and Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA; 2) Partners Healthcare Personalized Medicine, Boston, MA; 3) National Human Genome Research Institute, NIH, Bethesda, MD; 4) Harvard Medical School, Boston, MA.

Data sharing between clinicians, laboratories, and patients is essential for improvements in genomic medicine. The need for broad access to individual data must be balanced with respect for patient autonomy and privacy. Acknowledging that obtaining consent for sharing is hindered by lack of time and resources, the National Institutes of Health's (NIH) Clinical Genome Resource (ClinGen) is developing broad data sharing consent resources for use by clinicians and clinical laboratories, including a 1-page consent form and brief online videos. The consent form contains language consistent with the NIH Genomic Data Sharing Policy and NHGRI Informed Consent Resource, and the videos provide information on key topics, such as risks and benefits of data sharing (clinicalgenome.org/share). ClinGen held interviews and focus groups in 4 US cities with key stakeholders [clinicians (n=40), clinical laboratory staff (n=33), and community members (n=48)] for feedback. Preliminary thematic analysis suggests that participants feel that genomic data sharing is a worthwhile endeavor. Clinicians and laboratories cited potential to aid interpretation of variants of uncertain significance, and community members viewed it as a way to contribute to the "greater good." Participants noted that a brief consent was essential, but that the videos provided valuable information. Community members requested more information on the benefits of data sharing, while clinicians and laboratory staff were concerned with "over-promising" on benefits. To assess comprehension of concepts related to genomic data sharing, participants completed a 5 question knowledge assessment before and after reviewing materials. After review, community members' knowledge significantly improved (57% vs. 91% correct, $p \leq 0.01$), suggesting the resources effectively communicate data sharing concepts. ClinGen hopes these resources will provide a straightforward way to share genetic and health information, and help the scientific community capitalize on the largely untapped resource of data generated through routine healthcare.

3102F

Insights into residents' utilization of clinical genetics skills and services and medical genetics educational experiences. *E. Syverson, T. Pollin, S. Dixon, M. Blitzer, J. Plamondon.* University of Maryland School of Medicine, Baltimore, MD.

As genetics becomes increasingly integrated into other medical specialties, it has become the responsibility of clinicians to acquire skills and knowledge that allow them to provide genetics services or to accurately refer patients to medical genetics specialists. Although there has been a recent educational push to prepare physicians, more targeted education is necessary. In order to achieve this and identify where additional education is needed, further research is needed to identify to what extent clinicians are using clinical genetics skills and services in their own practice. This study attempts to explore new physicians' usage of core clinical genetics skills, their referral patterns to medical genetics specialists, and their experiences in medical genetics education.Residents from the University of Maryland Medical Center (n=57) were surveyed regarding these topics. In regards to clinical genetics skills, pedigrees are rarely taken and approximately 40% of residents rarely or never engange in genetic counseling when confronted with a genetic indication. Approximately half of residents have ordered genetic tests in the past, but it was largely indicated that they are not confident in their knowledge of the tests they are ordering. Overall we found that educational exposures directly involving genetics specialists or specifically revolving around clinical genetics skills were associated with a higher frequency of engagement in genetic counseling. Higher numbers of exposures, as well as those involving genetics professionals, were associated with higher feelings of adequacy with medical school genetics education. We also found that educational interventions that continue on throughout residency may be helpful in encouraging the utilization of clinical genetics skills. Residents who received lectures about genetic testing during residency were twice as likely to order genetic testing than those who did not receive such lectures, and the exposures most associated with referrals to medical genetics specialists occurred during residency. This pilot study provides a broad overview of clinical genetics practices of this cohort of new doctors. Encouragingly, the vast majority of respondents utilize genetic counselors and medical geneticists. However, further education should be provided to physicians to give them the confidence and skills they need to manage genetics patients when medical genetics specialists are not available.

3103W

Genomics in family medicine: Views of community-based providers. *S.B. Trinidad[1], S.M. Fullerton[1,2], L.M. Amendola[3], W. Burke[1,3], G.P. Jarvik[2,3].* 1) Bioethics & Humanities, University of Washington, Seattle, WA; 2) Department of Genome Sciences, University of Washington, Seattle, WA; 3) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA.

Introduction: As next-generation sequencing technologies move from research settings into the clinic, primary care providers (PCPs) will often be on the front lines of explaining and managing results. Previous research has reported limited PCP knowledge of genetic concepts. The growing number of patients tested, uncertainty associated with incomplete penetrance and variants of uncertain significance, and the potential for additional, non-solicited results add to the challenge. This study explored the views of community-based PCPs with respect to the implementation of genome-scale testing in primary care. **Methods**: The University of Washington NEXT Medicine Study of the Clinical Sequencing Exploratory Research (CSER) consortium conducted semi-structured telephone interviews with PCPs practicing in community settings. Topics included views about genome-scale testing and what kinds of additional findings would be useful in primary care. **Results**: We interviewed 19 family medicine physicians (58% female; 89% non-Hispanic white; mean age 44; 13 mean years in practice) affiliated with the WWAMI (WA, WY, AK, MT, ID) region Practice & Research Network. Most (18/19) participants reported being "somewhat familiar" with genetics. Most (N=13) considered pharmacogenetic results to be most useful and common disease risk least useful (N=11); opinions were mixed regarding risk for rare treatable disease (4 reported most useful, 4 reported least). Although they expected genetic specialists to order tests and provide initial counseling, most felt that PCPs would be better positioned than specialists to help patients understand and use genetic information. Participants outlined a unique role for family medicine PCPs in educating patients, clarifying relevant values, and identifying utility. They believed that their emphasis on family history and disease prevention, their long-term relationships with patients and families, and their skills in patient-centered communication and shared decision-making enable them to frame genetic results in ways that are meaningful to patients. **Conclusions**: Family medicine PCPs are interested in helping patients and families comprehend and use genome-scale results. Further research should explore opportunities for team medicine and a rational division of labor with respect to genomics in family medicine; training and education for PCPs and their staff in genetics and risk communication; and clinical decision support.

3104T

Genetics and health sciences education pipeline for elementary, middle, high school (K-12) and undergraduate underrepresented minorities (URM) in the sciences at the Louisiana State University Health Sciences Center (LSUHSC). *F. Tsien[1], M. Moore[1,2], A. Umrigar[1], A. Augustus-Wallace[3], D. Mercer[1].* 1) Dept of Genetics, School of Medicine, LSU Health Sciences Center, New Orleans, LA; 2) Dept of Biostatistics, School of Public Health, LSU Health Sciences Center, New Orleans, LA; 3) Division of Diversity and Community Engagement, School of Medicine, LSU Health Sciences Center, New Orleans, LA.

   The Louisiana State University Health Sciences Center in New Orleans (LSUHSC) has created a science and genetics educational pipeline through the Science Youth Initiative (SYI) and the Research Experiences for Underrepresented minorities (REU) programs. The long term goals are to ultimately increase the number of Underrepresented Minorities (URM) in the sciences, especially in genetics. The SYI program: The hands-on experiments, workshops, and educational videos are coordinated with elementary, middle, and high school (K-12) teachers to maximize learning and complement their curriculum. Since 2009, the SYI has reached > 2100 K-12 students. In Orleans parish, we reached 1365 K-12 students, of which 68% are URMs. Diverse LSUHSC trainees from the Schools of Medicine, Graduate Studies, Public Health, and Allied Health help educate the K-12 students. 1) Goals of the SYI: improve science academic achievements, introduce diverse role models in the sciences, increase awareness of genetics and science careers, and provide LSUHSC trainees instruction in communication skills to the lay public. Topics range from strawberry DNA isolation (elementary schools), to forensics and HeLa cells (high schools). The REU program: Since 2014, the NSF-funded REU program has provided internships to 10-13 URM high school and undergraduate students/year. General topics include population genetics, molecular and cellular biology, cancer research, chromatin instability, mutation analysis, translational research, personalized medicine, and bioinformatics. 2.) Goals of the REU program: develop scientific problem solving skills, learn state-of-the-art laboratory techniques, develop scientific communication skills, and receive resume writing instruction for competitive application to medical or graduate school. Following the REU program, most students co-author scientific publications and conference presentations, and/or obtain part-time laboratory employment during academic year. Participating schools include rural, urban, public/charter, private schools, and historically black colleges and universities (HBCUs). Assessments are by qualitative and quantitative participant surveys, mentor evaluations, and by using the NSF-REU common assessment tool. Students are tracked via an on-line NSF reporting system. These programs have provided opportunities to K-12 and undergraduates interested in the sciences, especially genetics, and helping them achieve their career goals.

3105F

The Genomics ADvISER - A Genomics decision AiD about Incidental SEquencing Results. *Y. Bombard[1,2], M. Clausen[2], E. Glogowski[3], K. Schrader[4], M. Robson[5], A. Scheer[1,2], M. Evans[1,2], J. Hamilton[5], K. Offit[5], N. Baxter[1,2], K. Thorpe[1], L. Lerner-Ellis[1,6], A. Laupacis[1,2].* 1) University of Toronto, Toronto, Ontario, Canada; 2) Li Ka Shing Knowledge Institute, St Michael's Hospital, Toronto, Ontario, Canada; 3) GeneDx, Gaithersburg, Maryland, USA; 4) BC Cancer Agency, Vancouver, British Columbia, Canada; 5) Memorial Sloan Kettering Cancer Center, New York, NY, USA; 6) Mount Sinai Hospital, Toronto, Ontario, Canada.

   Background: Guidelines recommend doctors inform patients of their incidental genomic sequencing (GS) results, yet there are limited tools to support patients' decisions about which results they wish to learn. **Aims:** To develop & evaluate a decision aid (DA) to guide patients' selection of incidental results. **Methods: (1)** Development: We used the Ottawa Decision Support Framework to develop a DA. Incidental results are categorized based on Berg *et al's* binning scheme. Category 1=medically actionable variants; Category 2= common disease SNPs; Category 3= Mendelian disease variants; Category 4=early-onset neurological variants; Category 5=carrier results. **(2)** Evaluation: We used cognitive task analysis, interviews and surveys to evaluate the usability, validity & acceptability of our DA. Cancer patients were recruited through clinics. Analyses include content analysis & descriptive statistics. **Results: (1)** We created an interactive online DA. It begins with an animated video on GS, the categories of incidental results & their harms/benefits, and then engages participants in a values clarification exercise. After providing summaries of participants' preferences, it tests their understanding of the categories, with correct answers provided after. It ends by asking participants to select the categories of incidental results they want to learn. **(2)** We evaluated the DA's usability with 11 patients in 2 rounds; the majority were <60 yrs old (6/11), female (7/11), had high levels of health literacy (6/11) & education (6/11) but low computer literacy (7/11). Interviews demonstrated strong face validity & content comprehension. Patients could describe the categories well & liked their organization but had trouble recalling which number corresponds with each category. Most patients found the amount of information 'just right' (8/11), clear (9/11) & balanced (10/11). All patients felt that the information was sufficient to reach a decision; that the DA was easy to use & would recommend it. We modified our DA to aid patients' recall of categories & are re-testing it. **Conclusion:** We created and evaluated an innovative patient-centered tool to support the clinical delivery of incidental GS results. Our DA fills critical care gaps given limited genomics expertise & capacity to convey the large volume of incidental GS results & their myriad of implications. Our DA may ultimately improve the quality of patients' decisions, save clinicians counselling time & health care costs.

3106W

P4'' medicine as a social phenomenon. *C. Bouffard[1], G. Lapointe[1], R. Drouin[2,3].* 1) Université de Sherbrooke, Sherbrooke, Québec, Canada; 2) Université Laval, CHU de Québec, Québec, Canada; 3) Université du Québec à Montréal, Montréal, Canada.

Just a few decades ago, Personalized Medicine (PM) was barely a pharmacogenomics research & development project, based on the idea that a medication's effects vary in accordance with the individual genetic profile. Subsequently, precision and genomic medicine developed under the term PM. Nowadays, in the synergy of the academic, medical, industrial and political institutions, PM is on the way to becoming "P4" medicine. In this context, several governments, in partnership with the private and parapublic sectors have made PM a research and development priority in order to improve both the wealth and health of individuals and the overall economy.   However, the success of this project implies raising technological, clinical, economic, organizational, ethical, legal and social challenges for which we are not prepared. P4 medicine is not limited to genomic technologies or to a change in medical paradigm, it is rather a social project, solidly structured and financed and involves important changes in medical practices, explanatory models of the disease, economic and social behaviours; meaning of responsibility in terms of health and well-being and health products and services regulation. Despite the expected benefits, P4 medicine leads to clinical, social and ethical issues that we have to be able to identify. In order to be aligned with coherent long-lasting solutions, in-depth knowledge of its development and institutionalization conditions are required as well as knowing what interests are at stake. We need to have adequate approaches to anticipate and respond effectively to the changes that the P4 medicine will bring about. Nonetheless, it is firstly necessary to 1) establish a clear definition of PM, 2) recognize it as a social phenomenon and, 3) develop functional inter- and transdisciplinary collaborative approaches.

3107T

Transethnic genetics: Implications for precision medicine and the study of complex traits across diverse populations. *B.C. Brown[1], N. Zaitlen[2].* 1) Department of Computer Science, University of California Berkeley, Berkeley, CA; 2) Department of Medicine, University of California San Francisco, San Francisco, CA.

Complex disease phenotypes vary in their global distributions due to a combination of genetic and environmental differences, but the mechanisms underlying these differences remain largely unknown. While the majority of genetic studies of disease have been conducted in European populations, the number of multi-ethnic disease cohorts is increasing. This provides a new opportunity to compare complex trait genetics across populations. Some researchers have argued that disease genetics are conserved between populations, because GWAS hits frequently replicate. In recent work, we examined this hypothesis by developing a novel statistical method to estimate the correlation of per-SNP causal variant effect sizes (ρ_{ge}) between populations. This correlation is 1.0 when SNP effect sizes are identical in both populations. We found that ρ_{ge} between European and East Asian cohorts is only 0.46 (0.05) for rheumatoid arthritis and only 0.62 (0.08) for type-2 diabetes. Similarly, we found that the mean ρ_{ge} of the genetic effects influencing gene expression between Yoruban and European cohorts is only 0.32 (0.01). Here, we explore the implications of these discoveries for clinical practice and complex disease research in diverse populations. We argue that while there may be many SNPs with statistically significant effects in both populations, the magnitudes of these effects can differ dramatically on average. We focus on the case of using complete knowledge of the effects sizes in one population to predict disease risk in another population, rigorously quantifying the area under the receiver operating characteristic curve as a function of ρ_{ge}. If a goal of precision medicine is to implement accurate predictors of disease risk into clinical practice, then our results demonstrate that the failure to study diverse populations is a gross inequity, because classifiers based on European studies will not be accurate enough to be used in non-Europeans. Thus, in the current paradigm people of European descent will disproportionately reap the benefits of precision medicine. Finally, we discuss the genetic mechanisms that could result in a genetic correlation less than 1.0, including differential tagging, rare variant and non-additive effects. In light of this we argue that understanding the causes of transethnic disease differences is required to fully understand complex trait genetics. All together, this necessitates increased genetic studies of disease in non-European populations.

3108F

Attitudes regarding personal genome sequencing among healthy early adopters: Findings from the PeopleSeq Consortium. *E.D. Esplin[1], E. Haverfield[1], D.E. Nielsen[2,3,4], E.F. Schonman[2,3], E. Ramos[5], M. McGinniss[5], S. Tucker[6], D.G.B. Leonard[7,8], R.C. Green[2,3,4,9] for the PeopleSeq Consortium.* 1) Invitae, San Francisco, CA; 2) Department of Medicine, Division of Genetics, Brigham and Women's Hospital, Boston, MA; 3) Harvard Medical School, Boston, MA; 4) Broad Institute of MIT and Harvard, Cambridge, MA; 5) Illumina, Inc., San Diego, CA; 6) Tucker Medical, Singapore, Singapore; 7) Department of Pathology and Laboratory Medicine, University of Vermont College of Medicine , Burlington, VT; 8) University of Vermont Health Network, Burlington, VT; 9) Partners Personalized Medicine, Boston, MA.

Background: With growing opportunities for healthy adults to access personal genome sequencing (PGS), it is increasingly important to understand their attitudes about and intended applications for PGS. The PeopleSeq Consortium is surveying ostensibly healthy individuals who have undergone PGS through commercial or research avenues to understand their attitudes toward and expectations for PGS. Methods: Respondents included in this analysis purchased PGS through Illumina's Understand Your Genome® program, which provides a clinically focused report to participants through an ordering physician, followed by access to their raw genome sequence introduced at an educational symposium. Survey items examine decision-making about pursuing PGS and general attitudes regarding PGS. Results: Respondents (n = 237) were on average 53 years old, white (90%), and highly educated (61% doctorate or professional degree), with high household income (89% ≥ $100,000). Most were married (52%), male (58%), and had children (76%), and 41% were healthcare providers or clinical researchers. The majority (54%) indicated that it took them one day or less to decide to pursue PGS. The most common reason for pursuing PGS was "finding out about personal disease risk" (23%, n = 150). Of the 52% who reported talking with someone when making their decision, most (81%) reported speaking with family members. Fifty-two percent agreed that health insurance should cover PGS, and 62% agreed that personal genomic information should be part of a standard medical record. Thirty-eight percent agreed that the government should put more effort into regulating PGS. Conclusion: The majority of individuals made the decision to pursue PGS quickly and many did so without meaningful medical consultation or counselling. A minority favored increased government regulation of PGS, possibly reflecting the libertarian perspectives of these early adopters. A majority agreed that there should be insurance coverage of PGS for healthy individuals and supported incorporating genomic information into the medical record. The future goals of the PeopleSeq Consortium are to assess medical, behavioural and economic outcomes by surveying additional varied PGS cohorts that return genomic information to ostensibly healthy individuals.   .

3109W

Genomic patents, past and present: Empirical findings, challenges, and implications. *C.J. Guerrini[1], A.L. McGuire[1], M.A. Majumder[1], R. Cook-Deegan[2].* 1) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 2) Sanford School of Public Policy, Duke University, Durham, NC.

In 2013, the U.S. Supreme Court determined that naturally occurring DNA cannot be patented because it is a product of nature that is categorically excluded from patenting. Meanwhile, in a succession of contemporaneous cases, the Court articulated a test for evaluating the patent eligibility of innovations that has been criticized as so manipulable as to be almost meaningless. The conventional wisdom that has emerged in the wake of this modern legal history is that the ability to patent gene-related compositions and methods for identifying and manipulating genetic information has been severely limited. With funding from the National Human Genome Research Institute, we set out to determine whether this understanding is empirically justified. Utilizing a mixed-methods approach, first, we analyzed the file histories of over 300 gene-related patents to identify challenges to genomic patenting resulting from the application of evolving legal rules and professional practices. Second, we conducted semi-structured interviews of over 25 leading genomic innovators, patent lawyers, and patent scholars to obtain first-hand knowledge of legal, policy, and business strategies and trends relevant to genomic patenting. During this session, we will report baseline quantitative and qualitative findings and discuss the implications of our data for genomic innovation and investment. Our findings include evidence that patent protection of genomic innovations has become less robust and more costly in recent years as well as divided expert opinions about the practical and ethical implications of the shifting legal landscape on genomic research and clinical practice.

3110T

Determining critical communication issues for the genetic testing process. *M.L.G. Hallquist[1], A.H. Buchanan[1], W.A. Faucett[1], M. Cho[5], K. Brothers[2], C.R. Coughlin II[3], L. Hercher[4], L. Hudgins[5], S. Jamal[6], H. Levy[7], H. Peay[8], M. Roche[9], M. Stosic[10], M. Smith[11], W. Uhlmann[12], K. Wain[1], K.E. Ormond[5].* 1) Genomic Medicine Institute, Gesisinger Health System, Danville, PA; 2) University of Louisville, Louisville, KY; 3) University of Colorado, Denver, CO; 4) Sarah Lawrence College, New York, NY; 5) Stanford University, Palo Alto, CA; 6) Hospital for Sick Children, Genome Diagnostics Lab, Toronto, ON, Canada; 7) Johns Hopkins University, Baltimore, MD; 8) RTI International, Washington, DC; 9) University of North Carolina, Durham, NC; 10) Natera Inc. San Carlos, CA; 11) Northwestern University, Evanston, IL; 12) University of Michigan, Ann Arbor, MI.

　Given the lack of genetic specialists world-wide and an increasing use of genomics across many medical specialties, genetic testing is increasingly being ordered by clinicians without training in genetics. These clinicians often have limited experience with the complex ethical, legal, social, medical, and logistical issues (ELSIPlus) associated with genetic testing. ClinGen's Consent and Disclosure Recommendations (CADRe) workgroup is developing tools to improve communication and patient experience of genetic testing. We have developed a rubric to identify an appropriate communication strategy at the time of consent based on the nature of the gene in question and empiric evidence about such testing. Where possible, we depart from the familiar paradigm of pre- and post-test counseling in deference to the need for a stream-lined process. We are using a mixed-methods design of surveys and focus groups to conduct a formative evaluation to assess responses to the rubric from genetics clinicians, non-genetics clinicians, and individuals who have undergone genetic testing. Using snowball recruitment for an anonymous online survey, 60 genetics professionals reacted to the CADRe-recommended communication approaches for common testing indications for five genes. For all genes surveyed, the majority agreed with the CADRe rubric recommendation for the indications of diagnostic testing, confirmatory testing, and familial variant testing. When testing an *unaffected consultand* with an unavailable proband, respondents recommended an *increased* level of communication due to concerns about residual risk, communication with family members, and ensuring patient understanding of benefits and limitations. To date, we have conducted four focus groups, and will complete five more by early fall. Participants in the non-genetic provider and patient focus groups thought most genetic testing discussions should begin with a trusted clinician (e.g., primary care provider) and that the conversation should be tailored to the interests of the patient, with additional discussion, referral to genetic counseling, or educational materials as appropriate. Genetics providers stressed the importance of their involvement in return of results. Results of the survey and focus groups provide formative input to guide the continued development of the rubric and associated materials as we aim to address ELSIPlus considerations of genetic testing ordered by a diverse group of clinicians.

3111F

Views of patients and their parents regarding the incidental or secondary findings obtained from whole exome and genome sequencing: A literature review. *A. Inaba[1], E. Takamine[1], M. Matsukawa[1], A. Yonei[1], S. Kosugi[1,2].* 1) Kyoto University, Kyoto, Japan, Kyoto, Japan; 2) Clinical Genetics Unit, Kyoto University School of Public Health, Kyoto, Japan.

　[Background] Whole exome sequencing (WES) and Whole genome sequencing (WGS) with next-generation sequencing technology have started to be used as a clinical diagnosis. These sequencing technologies generate a large amount of data including both primary results and incidental or secondary findings (IF/SF). There is no general consensus on how to manage IF/SF in Japan. Therefore, it is necessary to discuss how IF/SF by WES/WGS should be treated in research or clinical settings. **[Purpose]** The purpose of this literature review is to understand and analyze views of patients or their parents regarding the results particularly on IF/SF obtained from WES/WGS. **[Method]** We searched original articles dealing with IF/SF by WES/WGS on online databases (PubMed, Web of science, ICHUSHI web) which were published from 2010.11 to 2016.5. **[Results]** Twelve articles among a total of 261 met our criteria. Five articles of the twelve investigated patients or their parents who have undergone WES/WGS. The majority of the patients and parents desired to receive not only the primary results but also IF/SF particularly related to diseases which are treatable or preventable. They felt responsible for managing their own or their child's health conditions. However, some did not want to know IF/SF because it is a psychological burden for them. It seems that patients and parents tend to consider benefits more importantly than the risks of receiving IF/SF. Some patients and parents desired to choose which findings should be returned. **[Conclusion]** This review suggested that additional support before and after WES/WGS regarding IF/SF is required. We will continue to discuss how to manage the results of WES/WGS in clinical setting in Japan.

3112W

Expert's opinion on child's capacity for informed assent in genomic research: A focus group study. *I. Ishiyama[1], Z. Yamagata[2].* 1) Tokoha University, Fuji, Shizuoka, Japan; 2) University of Yamanashi, Chuo, Yamanashi, Japan.

[Background] Current opinion on the ELSI concerning genetic testing in children by the ASHG points that children should be included in the informed-assent or -consent process to the extent that they are capable, in certain approaches. Previously, we conducted a survey and clarified the attitude of the Japanese general public on children's capacity for informed assent in genomic studies. While the answers were incoherent, people with high level of scientific literacy could express their views and tended to answer that younger children are capable for assent. A qualitative study focusing on experts with high level of literacy was required for seeking good process of assent. In this study, we aimed to explore the views of experts engaged in a medical study on child's capacity for assent in genomic researches. [Methods] A semi-structured focus group interview was conducted in March 4, 2016. The study participants were comprised of 6 female research coordinators (age, 30-49) who engaged in a birth cohort study in Japan (years of experience, 3-5). They all had a nurse qualification, 1 had a public health nurse and 1 had a school counselor. We asked to talk about their views on obtaining informed assent, capable child's age for assent, and how to assess the child's capacity for assent. Particular attention was given to the interview, such as voluntary consent and participant's anonymity. The two-hour group discussion was audio-taped, transcribed and thematically analyzed. [Results] A thematic analysis showed the following six themes: 1) Recognition of importance at the same time difficulty of obtaining informed assent; 2) Perception of the potential risk to decrease in follow-up rate due to children's valid objections; 3) Expectation of the relation between child's capacity for assent and learning social studies as well as science studies in school; 4) Prediction of the association between child's capacity for assent and psychological independence; 5) Objection to assess a child's capacity before obtaining assent by using the development inspections; 6) Intention to deal with obtaining assent, if needed, in an intelligible language tailored to the smaller age children. [Discussions] Experts emphasized the individual differences of children and disagreed to use the development inspections. It was indicated that a child's capacity for assent might be assessed by a measure individualized for each research project, and specialized for the typical research contents.

3113T

Clinician views of public health newborn screening using next generation sequencing technologies: Implications for policy. *G. Joseph[1], F. Chen[2,3], C.F. Young[4], B.A. Koenig[2,3].* 1) Anthropology, History, and Social Medicine, UCSF, San Francisco, CA; 2) Institute for Health and Aging, UCSF, San Francisco, CA; 3) Institute for Human Genetics, UCSF, San Francisco, CA; 4) California State University, Stanislaus.

Advances in genomic technologies, such as whole genome sequencing (WGS), present both practical and ethical challenges to traditional public health newborn screening (NBS). While broad debate exists among clinicians surrounding how, when, and even if to return findings from clinical WGS, little research has investigated clinicians' perspectives on the potential expansion of public health NBS with WGS. As part of a larger study of stakeholder views on NBS with WGS, we conducted three focus groups with 23 clinicians (physicians, certified nurse midwives, and nurse practitioners) representing specialties traditionally involved in NBS (neonatology, obstetrician/gynecology, pediatrics, midwifery, maternal fetal medicine, pediatric bone marrow transplantation, and pulmonary care). Our design included clinicians practicing in both the prenatal and postnatal settings. Discussion topics explored clinician perspectives on: 1) current NBS; 2) the implications of expanded NBS for a) return of results; b) consent practices and c) storage and use of results for research and NBS program quality improvement; and 3) policy recommendations. Audio recordings of the focus groups were transcribed verbatim and analyzed for thematic content. Three key themes emerged: 1) contested clinical responsibility with respect to patient education and the interpretation of NBS results; 2) perceived tension between the practical implementation of WGS NBS (informed consent, return of results, costs for follow-up care) and the obligation under public health policy to balance benefits and burdens of population-wide screening; and 3) the need for greater interdisciplinary collaboration, specifically with genetic counselors, to interpret and return genomic results. Participants expressed enthusiasm about some types of information that can be gleaned from WGS NBS data, such as actionable pharmacogenetic variants. This enthusiasm was tempered however, by clinicians' experience of feeling overwhelmed with current responsibilities and their belief that WGS NBS should not be implemented without additional informed decision-making and parental consent processes. Importantly, this study contributes to an understanding of how clinicians across practice specialties interact with parents and each other regarding NBS. Clarifying stakeholders' goals and values with regard to public health NBS is critical to developing policies needed to appropriately incorporate WGS into NBS.

3114F

Gene editing technologies: What's new in policy. *E. Kleiderman[1], R. Isasi[2], B.M. Knoppers[1].* 1) Centre of Genomics and Policy, McGill University, Montreal, Quebec, Canada; 2) Dr. John T. Macdonald Foundation, Department of Human Genetics, Institute for Bioethics and Health Policy, University of Miami, Miami, FL, USA.

With the arrival of CRISPR, human genome editing is easier and more accessible than ever before, offering both potential for scientific and therapeutic advancement, while bringing ethical, legal and social (ELSI) tensions back to the forefront. Similar apprehensions have been expressed with recombinant DNA technology, embryonic stem cell research, human cloning and more recently, preimplantation genetic diagnosis (PGD) and mitochondrial replacement therapy (MRT). The purpose of our study is to assess and compare the current regulatory and policy frameworks and issues surrounding human germline editing, PGD and MRT. Against the backdrop of a published 16 country study (Science 2016; 351:337-339), we conducted a more in-depth comparative analysis of the regulatory frameworks encompassing gene editing technologies in four countries: Canada, France, the United Kingdom (UK) and the United States (US). These countries were selected, as they represent a spectrum of approaches to the different technologies being compared, and all have recent regulatory/legislative developments (2015-2016). We highlight and address key similarities and differences between the three technologies within the regulatory frameworks of each country, such as varying levels of acceptance and regulation, common concerns, and overall limits and thresholds. Furthermore, we pinpoint the overarching ELSI questions and suggest solutions for tackling the discussion of risks associated with editing the germline. We support a cautious approach that inclusively engages stakeholders in discussion. These findings support the idea that PGD and MRT can be used as potential models for approaching the regulation of human germline genome editing and help address society's concerns about the coming of an era of slippery slopes, 'designer babies' and playing God.

3115W

Content analysis of third party interpretation tools for direct-to-consumer genetic testing data. *S.C. Nelson[1,2], S.M. Fullerton[3].* 1) Public Health Genetics, University of Washington, Seattle, WA; 2) Biostatistics, University of Washington, Seattle, WA; 3) Bioethics and Humanities, University of Washington, Seattle, WA.

Background: Direct-to-consumer (DTC) genetic testing gives people access to interpreted reports based on their genetic data and the ability to directly download their (uninterpreted) genotype data file (GDF). Many third party tools and websites have been created where DTC customers can pursue additional, self-directed interpretation of their GDF. It is important for the genetics community to understand why and how consumers are using their genotype data in DTC/third party systems, as it may provide insight into what will happen as additional routes to personal genetic data access open up. For example, recent regulatory changes (45 C.F.R. § 164.524) allow individuals to directly access their full record from HIPAA-covered laboratories, which for clinical sequencing tests could include vast amounts of uninterpreted sequence data. In addition, some participants and researchers have expressed support for giving ("raw") genotype data back to participants. **Methods:** We conducted a structured content analysis of over a dozen online third party interpretation tools, defined as tools/sites where users can upload their GDF and receive some type of information/interpretation. Tools were identified from a variety of sources, including media stories, blog posts, peer reviewed scientific literature, conference presentations, and personal sources. We tracked features such as types of information returned (ancestry, health, relatedness); who created the tool and why; ability to contribute to research; and privacy and security measures. **Results:** We found that most tools were created by either academic groups, for-profit companies, or citizen science genealogists. Many sites focus on returning genealogy and ancestry information (e.g., GEDMatch and GenomeMatePro). A few provide some health-related interpretation (e.g., Promethease, openSNP, and Interpretome). For several platforms, a prominent feature is the ability to share or donate data, either to other users (e.g., openSNP) or to the scientists who run the site (e.g., DNA.land). **Discussion:** The variety of third party tools suggests a wide range of motivations among creators and users, in addition to a spectrum of validity for the information returned. Future research will explore how and why DTC customers use these tools, with the goal of gaining insights into how expanding access to genotype data from research and medicine may unfold.

3116T

Adolescent attitudes towards genetic testing for adult-onset conditions from essays submitted to a national competition. *A. Rahm[1], L. Bailey[1], O. D'Accordo[2], Y. Munishor[2], C. Miller[2], E. Davidson[2], B. Wolf[3], K. Pulliam[3], H. Zhang[3], M. Dougherty[3], L. Hercher[2], M. Williams[1].* 1) Genomic Medicine Institute, Geisinger Health System, Danville, PA; 2) Human Genetics, Sarah Lawrence College, Broxville, NY; 3) American Society of Human Genetics, Bethesda, MD.

 Background: Genetic testing has become increasingly popular, however, questions and concerns surround when to test children for adult-onset conditions. A position statement from the ASHG published in 2015 reaffirmed its original position that testing for adult-onset conditions should be deferred until adulthood. Information is lacking on the attitudes and opinions of adolescents themselves about the subject. The 2016 ASHG DNA Day Essay Contest asked 9-12th graders to choose an adult-onset genetic condition and defend or refute the ASHG position statement. **Methods:** Essays submitted to ASHG's 2016 national DNA Day Essay Contest by teachers on behalf of students underwent thematic analysis. Teachers could submit up to 6 student essays per class for up to 3 classes. Participants were informed that essays may be used for research purposes and that winning essays may be published online. This study was reviewed by IRB and determined to be exempt. All essays submitted by students were analyzed for the condition chosen, agreement or disagreement with the ASHG statement, and reasons for their position. Demographic information including gender, grade, school type, and state were also analyzed. **Results:** 1241 student essays were submitted from 44 US states (87%) and other countries (13%). More females submitted essays than males (67% vs. 33%). Over 100 adult-onset conditions were discussed across all essays, although 60 conditions were each discussed only once. The most commonly discussed conditions were Huntington's disease (N=466 essays, 38%), followed by BRCA-related breast or ovarian cancer (N=205, 17%), and Alzheimer's disease (N=118, 10%). Students were evenly split whether they agreed or disagreed with the ASHG recommendation, however, slightly more agreed to defer testing for Alzheimer's (59%) or Huntington's (57%) compared with BRCA (42%). Reasons for deferring testing included potential psychological harm and anxiety, while reasons for wanting testing included prevention and life planning. Factors such as family history and personal anxiety were given as reasons for the need for choice. Additional analyses are ongoing and will be presented. **Conclusions:** The DNA Day essays provide valuable insights into the attitudes of adolescents regarding genetic testing for adult-onset conditions. Additional research is needed to understand the psychosocial impact of learning genetic information for adult onset-conditions in healthy adolescents.

3117F

Measures of self-reported outcomes from receiving genetic results among underserved racial and ethnic populations: A systematic review. *A.E. Tattersall, J-H. Yu.* Department of Pediatrics, University of Washington, Seattle, WA.

 The majority of translational research on return of genome sequencing results has focused on European Americans affected by rare genetic conditions. As studies of clinical translation of genome sequencing are expanded to include and focus on underserved populations including racial and ethnic populations, establishing the relevance of outcomes currently under investigation, the applicability of existing self-reported measures, gaps in available measures and their measurement properties will be important to ultimately assess equitable benefit. To this end, we are conducting a systematic literature review of studies that measure self-reported outcomes from receiving either genetic test results or research results among patients and participants from underserved racial and ethnic populations. Abstracts of potential primary research articles were identified from MEDLINE, PsychInfo, and CINHAL using MeSH search terms to capture parameters of interest including genetic information, outcomes, and populations. A total of 1332 unique references have been compiled and their abstracts are being reviewed to identify articles that meet the following criteria: English language, published between January 1, 1986 and February 24, 2016, and report quantitative measures. Based on abstract review, approximately 15% will meet initial inclusion criteria, while the remaining either do not constitute a research article or fail to report an outcome of genetic results disclosure. After potential articles are reviewed, the final set will be coded for their studied measures (e.g., definition, number of items, response method, type of measure), the context of their use (e.g., study, population, mode, languages, population comparisons), and measurement properties (e.g., validity and reliability). This analysis will inform availability of measures for particular domains, their evidence of validity in specific populations, and degree to which differences between populations have been observed and are to be expected. This systematic review will also propose recommendations for future measures development and related outcomes research.

3118W

Laboratory directors' opinions regarding the FDA's proposed regulatory oversight of Laboratory-Developed Tests (LDTs). *A. Taylor[1], K. Johansen Taber[2], E. Leeth[3], K. Leuer[3], C. Wicklund[1].* 1) Northwestern University, Chicago, IL; 2) American Medical Association, Chicago, IL; 3) Lurie Children's Hospital, Chicago, IL.

Background: In October 2014 the FDA released a draft guidance defining its framework for regulatory oversight of Laboratory Developed Tests (LDT's). The introduction of the FDA's draft guidance generated considerable debate with several medical and laboratory organizations releasing formal statements in response. Since laboratory directors are a major stakeholder in this discussion, and will be considerably affected by any change of LDT oversight, we interviewed laboratory directors in a structured manner to provide their insights on the debate. *Methods*: Participants were drawn from a variety of laboratory settings including academic institutions, private companies and hospital based laboratories. A semi-structured interview guide was developed to explore director's opinions on current oversight of LDTs, the FDA's draft guidance and suggestions to modify oversight. The guide was piloted with a senior laboratory member of Lurie Children's Hospital in Chicago, to ensure we were obtaining the desired information. No changes were made to the interview guide. Interviews were conducted over the telephone, recorded and transcribed verbatim. Transcripts were then coded for themes. *Results*: Twelve interviews were conducted. Twenty themes were identified and organized into five categories; concerns with the draft guidance, opinions on current oversight, recommended modifications to oversight, considerations with developing oversight and opinions of the FDA as an organization. Most notably, participants were concerned about the increased laboratory burden associated with adhering to the FDA's draft guidance. They were worried about the unintended consequences such as closure of laboratories and the negative impact on patient care. Participants want the FDA to release an updated draft guidance with more detail before it is finalized. However, they would prefer to see a modernization of current oversight and an increase in resources for the relevant governing bodies such as CLIA and CAP. *Conclusion*: The results of this study contribute to a better understanding of the concerns held by laboratory directors regarding not only the FDA's draft guidance but oversight of LDTs in general. Several themes emerged in our data that should be considered by any governing body developing oversight for LDTs. Discussion between the FDA and professional laboratory organizations is warranted as many of the concerns held by our participants will have an impact on patient care.

3119T

Minorities" in precision medicine: Perspectives from federally qualified health centers and community-based organizations. *J.-H. Yu, A.E. Tattersall.* Pediatrics, University of Washington, Seattle, WA.

Efforts to build large precision medicine (PM) cohort studies are motivated, in part, by an ethic of social justice, inclusion and partnership with underrepresented and underserved communities. Yet, in addition to the promise of benefits through genomic medicine, inclusion of these communities into genomic studies presents potential for harm such as group stigma and discrimination. As precision medicine researchers engage federally qualified health centers (FQHC) and community-based organizations (CBO) to recruit underserved populations, how to transparently present and weigh such potential benefits and harms to patients and members is an ethical and practical challenge for FQHC providers and CBO leaders and staff. Based on a developing framework for considering benefits and harms (GBH), we have and are continuing to conduct interviews (n=23) with FQHC medical directors and CBO executive directors about the feasibility of recruiting their patients and members for a national PM cohort study, attitudes toward genomic research participation, and potential risks and benefits of genome sequencing including return of incidental findings. Many participants viewed PM research through a social justice lens, expressed concerns about contributing to group harms such as racial discrimination and stigma, and expected community- and individual-level engagement by researchers about study goals and methods. While all recognized great potential for PM-tailored treatments, most were highly skeptical about their patients' or members' abilities to benefit from genomic results in practice and offered both barriers and potential facilitators. Interviews further clarified the important role FQHC-providers and CBO-staff play in helping patients/community members learn about and weigh potential benefits and harms, and making participation decisions in the context of individuals' health issues and community health priorities. Healthcare providers and community leaders of underserved populations are increasingly partnering with PM researchers and playing a key role in framing the potential benefits and harms of research participation. Relationships between providers-patients and community leaders-members offer unique opportunities to support decisions about genomic and precision medicine research participation. Their perspectives will be important to ensuring that the benefits of genomic and precision medicine are equitably realized by underserved and underrepresented communities.

3120F

When to take a family history: Assessing impact on genetic counseling outcomes. *C. Slomp[1,2], E. Morris[1,2], A. Inglis[1,2], A. Lehman[1], J. Austin[1,2].* 1) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Department of Psychiatry, University of British Columbia, Vancouver, BC, Canada.

   BACKGROUND: Documentation of family history is a cornerstone of genetic counseling (GC) practice. Various strategies for obtaining family histories have evolved (e.g. pre-GC appointment online questionnaires), often to increase the efficiency of generating a product for assessing genetic risk and informing genetic testing. However, the process of patient counsellor interaction to document a family history can be useful in building rapport, which is key to optimal patient outcomes of GC. No studies have evaluated the effect of the timing or method of obtaining family history on patient outcomes of GC. HYPOTHESES: Patients whose family history was obtained by phone prior to GC (Group 1) would have greater increases in a) empowerment and b) self-efficacy than patients whose family history was collected during the GC appointment (Group 2). METHODS: We conducted a retrospective chart review in a specialist psychiatric GC clinic, using data from Feb 2012-March 2016. Family history is either documented by phone prior to GC, or at the beginning of the GC session, and patient outcomes are routinely tracked: pre-GC, and 1 month after GC empowerment is measured with the Genetic Counseling Outcome Scale (GCOS) and self-efficacy is measured by the Illness Management Self Efficacy scale (IMSES). Patients who completed GCOS and IMSES at both time points were included in the analyses (independent T-Tests and Mann-Whitney tests comparing change in GCOS and IMSES scores from pre- to post-GC between Groups 1 and 2). RESULTS: 130 patients completed scales at both time points, and were included in analyses. There were significant increases in GCOS and IMSES scores from pre- to post- GC but no difference between groups in the magnitude of change in score. CONCLUSIONS: This study suggests that obtaining family history prior to versus during the GC appointment results in similar patient outcomes for empowerment and self-efficacy. Future research could compare in person and web-based family history documentation.

3121W

Can our Manga cartoon, as a medium for promoting family health history and human genetics to the public, cause anxiety of learning their own family health history? *E. Takamine[1], Y. Hiraoka[2], M. Torishima[1], A. Inaba[1], M. Matsukawa[1], A. Yonei[1], Y. Tabara[3], T. Wada[1], S. Kosugi[1].* 1) Department of Medical Ethics and Medical Genetics, Kyoto University Graduate School, Kyoto, Kyoto, Japan; 2) Riken; 3) Center for Genomic Medicine, Kyoto University Graduate School.

   [Background] Today, genetic technology has been rapidly advancing and genetic testing is largely available in medical practice. In Japan, we have little chance to learn human genetics at school, and we, genetic counselors and medical geneticists, should play a vital role to promote human genetic literacy of the public for providing optimal genetic services. "Family Health History (FHH)" (1) is an accessible tool that can capture genetic information, lifestyle and environmental factors, (2) allows health care providers to diagnose conditions and to assess risks and (3) increases health and genetic knowledge for the individual and the family. Therefore, we developed a manga booklet, as a new educational implement of human genetics and FHH. We conducted a pilot study to undergraduate students last year. The results showed that about half of them have more interest in talking about FHH with their family. However, approximately 40% of them answered that they would feel anxious about learning their own FHH. [Purpose and Method] The purpose of this study is to investigate the details of the anxiety caused by learning about FHH through the manga, which will be expected to give genetic experts ideas of how to approach clients' anxiety during genetic counseling sessions. We will send the manga to 40 public health nurses and several hundred adults throughout Nagahama City, Shiga, Japan this year. Participants will be asked to answer to a questionnaire after reading the manga. [Results and Discussion] According to a previous study conducted on college students in the U.S. about learning their own FHH, some answered that they would feel destined to develop the diseases which run in their family. Our study targets a large population of ordinary people. Also, there are no studies reported which measure anxiety of learning their own FHH in Japan. Therefore, this study will be the first one which focuses on this topic and could give genetic counselors and medical geneticists ideas of easing the different types of anxiety which clients could experience. Additionally, we are in the process of translating the manga into English.

3122T

What's the best way to educate people about genomics? Applying user centered design to consumer genomics education. *S. Briggs, R. Goldfeder, C. Liu.* Helix, San Carlos, CA.

The frequency of genetic testing has risen in recent years in both clinical and non-clinical (direct to consumer) settings. In direct to consumer genetics alone, Ancestry.com and 23andMe have each reported over 1 million individuals genotyped through their services to date. Despite this rise, many consumers remain unfamiliar with the technology and what insights can and cannot be gained from DNA. Furthermore, while significant research has been done comparing self-reported understanding of genetic concepts and results pre and post genetic testing, less has focused on how people would prefer to learn in this context. Our aims were to: 1. Test comprehension of genetic terms, concepts, and limitations, segmented by consumers who had either prior experience with or no experience with DNA testing; 2. Understand preferences and attitudes towards learning in general and specifically in genetics; 3. Gauge levels of perceived trustworthiness when different entities create and deliver genomic content. We surveyed 1000 people to understand user preferences around genomics education. The questions covered self reported learning styles, behavioral preferences, and knowledge about genetics. The results of this study provide both a qualitative and quantitative approach to designing effective resources for individuals to learn about their own DNA. This will be of critical importance when consumers will have the choice to pick genomic products interpreting specific parts of their genome.

3123F

The business of direct-to-consumer genetic testing: A complex moral challenge. *B.R. Haddad[1], S.D. Zaatari[2], L. Wathieu[3], K.T. FitzGerald[4].* 1) Department of Oncology, Georgetown University Medical Center, Washington, DC; 2) School of Medicine, Georgetown University, Washington, DC; 3) McDonough School of Business, Georgetown University, Washington, DC; 4) Pellegrino Center for Clinical Bioethics and Department of Oncology, Georgetown University Medical Center, Washington, DC.

The emergence of companies offering direct-to-consumer (DTC) genetic testing continues to generate significant debates and controversies among geneticists, medical professionals, ethicists, and in the public. Consequently, many moral challenges arise that are complex, ambiguous, and potentially devastating. Our study addresses the question: what do companies need to do to get this business "morally right" while the industry is still in its infancy? Our interdisciplinary team, with expertise in marketing, ethics, and genetics, identified and analyzed key practices of DTC genetic testing companies that raise moral challenges inherent to the industry (e.g., data ownership, research participation, presentation of results, marketing appeals used, etc.). Our goal in addressing these challenges is to set these companies on an effective course towards sustainable market success. To help us understand the latest industry developments, we conducted extensive phone and in-person interviews with seven key players at two leading DTC genetics testing companies, at a company specialized in testing for ethnic origins, and at a research organization that uses genomic data voluntarily provided by DTC users. We reached recommendations in the following areas, critical for the success of the DTC genetic testing industry: (1) the imperative to report genetic results to consumers in a manner that sufficiently and tangibly integrates known relevant contextual determinants (e.g., family history, behaviors, environment); (2) the imperative to report results in a manner that empowers consumer decision making (e.g., by referring to the efficacy and costs of actions that consumers might want to undertake); (3) the imperative to address the heavily emotional implications of genetic information ahead of testing and at the point of disclosure, and to avoid manipulating this emotional context for the sake of recruiting customers; (4) the imperative to pursue scientific validity and certification by public and private agencies; (5) the imperative to involve consumers fairly in the profits derived from the use of their data. Instead of reaching a final set of guidelines for industry self-regulation, our purpose is to engage companies offering DTC genetic testing, the public, scientists and medical professionals, ethicists, and government regulators, in a broad and diverse conversation around best business practices in DTC genetic testing which can help DTC companies "do it right.".

3124W

108,000 and counting: A review of the consenting process for Geisinger's MyCode® Biobank. *C. Flansburg, M.L.G. Hallquist, W.A. Faucett, D.J. Carey, The. MyCode Team, D.H. Ledbetter.* Genomic Medicine Institute, Geisinger Health System, Danville, PA.

The Geisinger MyCode® Community Health Initiative biobank began enrolling participants in 2007. The consent was updated in 2013 to include the return of actionable results with placement in the electronic health record (EHR). Support from the Geisinger patient community has been strong, with more than 108,000 individuals enrolled in the project toward a goal of 250,000 participants. ~90% of individuals agree to participate. Consent includes permission to: collect a sample when the participant has a clinical blood draw, perform genetic analysis, use information from the EHR for research purposes, recontact, share samples and health information with other researchers, and disclose actionable results to the participant and their providers. Over 40,000 participants were enrolled in 2015 by an average of 18 consenters working throughout the Geisinger Health System. Consenters have access to the EHR, which is used to track eligible patients and to record consent status. Consenting occurs in the clinic waiting room, at patient registration, once patients are roomed, or at checkout, based on the individual clinic flow. When approaching a potential participant, a consenter reviews the important aspects of the MyCode consent, answers any questions, and provides the written consent for review by the participant. Successful consenting requires collaboration with clinic leadership and clinicians in a model that adapts to the unique needs of each clinic. Consenters are the front line of MyCode, the first contacts with patients and the main community representatives of this project. Ongoing educational opportunities, such as Geisinger's C.I.CARE training and reviews of returned results, are provided to consenters for their education. Patient Satisfaction surveys indicate that individuals have positive experiences when approached by consenters. Consenters have many resources for responding to patient questions, including genetic counselors, laboratory staff, and study personnel. In addition to consenters embedded in clinics, in Nov 2015, we established online consenting for MyCode which requires an individual to have an account on our patient portal, MyGeisinger. To date, 2,752 participants have consented online and many have contacted the MyCode team for information. Additional opportunities for individuals to enroll in MyCode include events such as health fairs and consent via mail. Lessons learned in the development of the consenting process for MyCode will be shared.

3125T

Decision-making around secondary findings in genomics: Insights from whole-genome and whole-exome sequencing recipients. *M. Mackley[1,2], M. Parker[3], H. Watkins[1,2,4], E. Ormondroyd[1,4].* 1) Division of Cardiovascular Medicine, Radcliffe Department of Medicine, University of Oxford, Oxford, UK; 2) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK; 3) Ethox Centre, Nuffield Department of Population Health, University of Oxford, Oxford, UK; 4) NIHR Oxford Biomedical Research Centre, Oxford, UK.

The return of secondary findings (SF) in whole-genome and -exome sequencing (WGS) is a subject of much debate. As WGS moves into routine clinical practice, policies around SF must take into account values and preferences of stakeholders. To inform this issue, we recently completed a systematic review of qualitative and quantitative studies that investigated stakeholder views on SF in WGS. We found that, while there was agreement that 'actionable' findings should be available, there was no consensus on what was considered 'actionable'—the balancing of rights and responsibility variably influenced stakeholder views. Furthermore, we found that many studies were probing the wrong knowledge in assessing literacy; our findings suggest that truly informed decisions require an understanding of the implications of WGS and possible findings, rather than technical details. The majority of studies came from the US, emphasizing a need for wider perspectives on SF in WGS to be explored. Molecular Genetic Studies of Individuals and Families at Risk of Inherited Disease (MGAC) is a WGS study that preceded the NHS England 100,000 Genomes Project in Oxford, and recruits adults and children with diverse rare diseases. Frequently a trio design is used, wherein unaffected parents and affected child are recruited. During informed consent, adult participants are offered choices about whether to receive secondary findings: incidental, and/or additional screening of selected genes based on the ACMG list. In order to address gaps highlighted by our systematic review we are investigating the views of adult participants in MGAC. Participants are sent a questionnaire eliciting understanding and motivation for WGS, and invited to participate in semi-structured interviews. In particular, decision-making around SF disclosure and participant appreciation for the implications of SF will be investigated. Thematic analysis of interview data is being undertaken. Eighty-eight adult participants are eligible to participate, and questionnaires have been distributed by post (current response rate = 28%). Data will be presented from analysis of interviews completed to date. Preliminary analysis suggests that participants feel empowered by their ability to make decisions around SF, but want to share responsibility. Some participants, based on their experience of genetic disease, appreciate the context-dependency of WGS results—suggesting that broader or dynamic forms of consent should be considered.

3126F

Patients' perceived utility after receiving whole genome sequencing. *J.O. Robinson[1], K.D. Christensen[2], P.M. Diamond[3], L. Jamal[1], K. Lee[1], H. Peoples[1], C. Blout[2], J.L. Vassy[2,4], R.C. Green[2,5,6], A.L. McGuire[1] for the MedSeq Project.* 1) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 2) Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 3) University of Texas School of Public Health, Houston, TX; 4) VA Boston Healthcare System, Boston, MA; 5) Partners HealthCare Personalized Medicine, Cambridge, MA; 6) Broad Institute of MIT and Harvard, Cambridge, MA.

　Background: Genome sequencing is increasingly being integrated into clinical care as a diagnostic and screening tool. Patients' perceived utility of this information is unclear. **Methods:** The MedSeq Project is a randomized clinical trial comparing whole genome sequencing (WGS) to standard of care which included a review of family history (FH) information, in two study cohorts, healthy primary care patients and cardiology patients with cardiomyopathy diagnoses. Patients were surveyed at baseline (BL) and 6-months (6-mos.) after results disclosure to assess multiple domains, including 6 questions about perceived utility of the study results (WGS or FH). **Results:** Of 200 enrolled patients, to date 168 have completed the 6-month follow-up survey. The percentage of participants who perceived utility in study results decreased from baseline to the 6-month follow-up on all items: impacting medical decision-making (87% BL vs. 32% 6-mos.), affecting medical treatment (85% BL vs. 50% 6-mos.), identifying disease risk (80% BL vs. 60% 6-mos.), influencing medications (73% BL vs. 16% 6-mos.), impacting end-of-life planning (46% BL vs. 13% 6-mos.), and influencing reproductive decisions (33% BL vs. 12% 6-mos.; all $p<0.05$). Decreases in perceived utility differed across randomization arms for 2 of the 6 utility items: identifying disease risk (3% WGS vs. 28% FH, $p<0.001$) and influencing treatments (16% WGS vs. 37% FH, $p=0.008$). Changes on all other items did not vary significantly by randomization status ($p>0.05$). Adjusted logistic regression model analysis showed that participants who were randomized to WGS, compared to FH, were more likely to report utility for identifying disease risk (OR=7.7, 95% CI=2.8-21.3) and influencing medical treatment (OR=2.6, 95% CI=1.4-5.0), regardless of study cohort. **Conclusions:** Six months after receiving WGS or FH information participants in both arms perceived less utility in their study results than they anticipated there to be at baseline. However, both WGS and FH were perceived to have some utility in all areas assessed at follow-up. WGS was perceived to have greater utility than FH for identifying disease risk and influencing medical treatments. These findings have implications for pre-test counseling. Clinicians should help set realistic expectations about the types of information patients will receive from WGS and the utility of WGS, and even FH information.

Reporting practices for next generation sequencing technologies: A qualitative study with laboratory personnel. *D. Vears[1], K. Sènècal[2], P. Borry[1].* 1) Center for Biomedical Ethics and Law, KU Leuven, Leuven, Belgium; 2) Centre of Genomics and Policy, McGill University, Montreal, Canada.

　Next-generation sequencing (NGS) technologies are revolutionizing genetic diagnosis, both in research and clinical contexts, by identifying causative mutations in previously undiagnosable individuals, influencing their treatment and providing important information to their families. However, these technologies also have the potential to identify additional genomic information that is unrelated to the illness under investigation, such as variants in genes with unknown significance (VUS) and mutations in genes causing phenotypes extraneous to the clinical question (incidental findings, or IFs). Recommendations by professional bodies outlining which findings should be reported by laboratories to the clinician requesting the test are inconsistent, particularly regarding the duty to search for variants unrelated to the clinical question. Little is known about which variants laboratories are reporting and how they are using guidelines to make decisions about this.　To address these questions, in-depth interviews were conducted with 25 laboratory personnel in Europe, Canada and Australasia to explore actual reporting practices for diagnostic NGS. Interviews were transcribed, deidentified and analysed using inductive content analysis. Reporting practices were then compared with published guidelines to determine whether their testing policies were in line with current guidelines.　Reporting of IFs differs between laboratories. Some laboratories limit their reporting to variants considered to be causative of the phenotype under investigation. Others report IFs to varying degrees. Decisions about which variants to report often involves detailed discussions, involvement of multidisciplinary committees, and consideration of factors such as actionability or medical relevance. There was also considerable variation in the filtering strategies that participants described. While some laboratories use quite stringent filtering in order to limit the number of IFs that are identified, others are less strict, allowing identification of these variants. Only a small number of laboratories actively search for variants unrelated to the clinical question.　Our study highlights that laboratories are still grappling with decisions about which variants to report from NGS. These findings will assist laboratories to learn from each other's experiences and refine reporting procedures.

3128T

Negotiating the research-clinical interface in genomic medicine: Analysis from the CSER Consortium. *W. Burke[1], L. Amendola[2], E. Clayton[3], R. Green[4], J. Harris-Wai[5], G. Henderson[6], G. Jarvik[2], B. Koenig[5], L. Lehmann[7], A. McGuire[8], P. O'Rourke[9], C. Somkin[10], B. Wilfond[11], S. Wolf[12]. 1) Bioethics and Humanities, University of Washington, Seattle, 98195, WA; 2) Medicine (Medical Genetics), University of Washington, Seattle 98195, WA; 3) Center for Biomedical Ethics and Society, Vanderbilt University, Nashville 37232, TN; 4) Medicine (Genetics), Brigham and Women's Hospital and Harvard University, Boston 02115, MA; 5) Institute for Health Aging, UCSF School of Nursing, San Francisco 94118, CA; 6) Social Medicine, University of North Carolina, Chapel Hill 27599, NC; 7) Center for Bioethics, Brigham and Women's Hospital and Harvard University, Boston 02115, MA; 8) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston 77040, TX; 9) Human Research Affairs, Partners HealthCare, Boston 02115, MA; 10) Division of Research, Kaiser Permanente, Oakland 94612, CA; 11) Treuman Katz Center for Pediatric Bioethics, Seattle Children's, Seattle 98101, WA; 12) Consortium on Law and Values in Health, Environment and the Life Sciences, University of Minnesota, Minneapolis 55455, MN.*

The NIH-funded Clinical Sequencing Exploratory Research (CSER) Consortium seeks to support translation of genomic and exome sequencing into clinical applications. CSER studies generally occur in clinical settings and results may have implications for patient care. These studies provide insights into the challenges of combining research and clinical activities in translational genomics. Prior literature has contrasted norms and rules of research vs. clinical care, but little is known about how investigators navigate these issues. **Methods**: Each of nine CSER study teams completed a survey on how the research-clinical interface was manifested in their study, problems raised and solutions devised. The survey queried study consent procedures; involvement of research and clinical personnel; use of a research or clinical lab; return of research results; where results are recorded; legal issues raised; procedures coverd by the research budget vs. billed to insurer; and views of the study team on the interface between genomic research and clinical care. <u>Results:</u> All CSER studies use consent procedures to identify research processes. Several studies use dedicated research spaces and research personnel to differentiate research activities. Studies vary in their use of a CLIA-certified clinical lab vs. CLIA confirmation of research results. Most studies return research results to participants, but the scope of return differs. Studies vary in placement of results in the research record, medical record, both, or depending on participant choice, and in whether results are returned by research or clinical personnel. Studies note participant confusion related to the research-clinical distinction, e.g., confusion between research and clinical consents or a participant directing questions about clinical follow-up to research personnel. Legal issues considered include privacy, malpractice, HIPAA, genetic discrimination, and CLIA. Studies vary in what is billed to the research budget vs. insurers. Problems noted include limited availability of clinical follow-up to pursue genomic findings, and divergent perspectives held by researchers and clinicians. **Conclusions:** Developing an evidence base for clinical sequencing compels researchers, clinicians and participants to navigate the interface between research and clinical care. The CSER studies reveal key challenges and evolving strategies.

3129F

Implementing genomics into clinical practice: A collaborative approach to removing barriers. *C.L. Gaff[1], I. Macciocca[1,2], M. Martyn[1,3], E. Forbes[1], S.M. White[2,4], Z. Stark[2], D. Schofield[3,5], N. Mupfeki[1], K. Alam[3,4], P. James[4,6], A. Roberts[6,7], M. Ryan[8], T. Day[6], M. Walsh[2], P. Kwan[6], P. Perucca[6], A. Boussioutas[4,6], T. Tan[2], W. Wilson[9], G. Taylor[2], A. Oshlack[3], G. Brett[1,2], E. Creed[1,7], E. Wilkins[1,6], N. Thorne[1], T. Bakker[1], Melbourne Genomics Health Alliance. 1) Melbourne Genomics Health Alliance, VIC, Australia; 2) Victorian Clinical Genetics Services, VIC, Australia; 3) Murdoch Childrens Research Institute, VIC, Australia; 4) University of Melbourne, VIC, Australia; 5) University of Sydney, NSW, Australia; 6) Melbourne Health, VIC, Australia; 7) Walter and Eliza Hall Institute, VIC, Australia; 8) Royal Children's Hospital, VIC, Australia; 9) CSIRO, NSW, Australia.*

Widespread change within and across organisations is needed to resolve the numerous barriers to genomics in healthcare. The Melbourne Genomics Health Alliance is taking a collaborative approach to this task. Ten independent healthcare, research and academic organisations are working together to embed change in practice "starting with the patient and working backwards". We conducted a 2-year demonstration project to build genomics capability, prospectively evaluate the impact of genomic sequencing and identify paths to full implementation. We assessed the processes of genetic counselling, variant interpretation and reporting, information management, data sharing and data linkage. Common systems, tools and policies were developed and applied across the participating hospitals and laboratories. Clinicians offered whole exome sequencing (WES)-with targeted gene analysis in parallel with standard care to 316 patients with one of five clinical indications, enabling condition-specific and common approaches to be identified. Three accredited laboratories collaborated in sequencing and reporting of results. Evaluation data were collected from clinical records, participant surveys and interviews with 32 clinicians (7 disciplines) and 14 other stakeholders. The impact of WES varied by indication. Targeted WES increased detection for 3 of the 4 germline conditions and changed patient management in 2 of these to date. WES was highly cost effective for infants with features of known monogenic conditions: AUD $5,047 per diagnosis for singleton WES compared to AUD$27,050 for standard care. WES as a first tier test would achieve a saving per additional diagnosis of AUD$2,182 (95%CI: 129.92 - 5,855.02). Clinicians identified processes that are perceived as critical for the successful application of genomics (e.g. patient selection) and others that support adoption.(e.g. multidisciplinary variant review). There was no consensus on return of predictive information. Pre-test genetic counselling was effective; more than 75% of participants answered knowledge questions correctly. 93% agreed to share their data for research. 6% expressed concerns related specifically to genomics. This comprehensive evaluation provides crucial insights into pathways to progress the introduction of genomic medicine collaboratively. Models proposed by clinicians will be presented. The results are informing implementation of systems that meet the needs of both the workforce and patients.

Improving access to genetic services: Needs assessment data from the National Regional Genetic Collaboratives System. *A.S. Keehn[1], D.M. Maiese[1], M. Lyon[1], J. O'Leary[2], S. Alexander[2], C. Kaye[3], NCC Evaluation Workgroup Members.* 1) American College of Medical Genetics and Genomics, Bethesda, MD; 2) Genetic Alliance, Bethesda, MD; 3) University of Colorado School of Medicine, Denver, CO.

   Purpose To strengthen and support the genetic and newborn screening capacity of the states and to improve the availability, accessibility, and quality of genetic services and resources for individuals with, or at risk for, genetic conditions and their families is the mission of the National Coordinating Center and the seven Regional Genetic Service Collaboratives (NCC/RC system). The NCC is administered by the American College of Medical Genetics and Genomics (ACMG), in partnership with the Genetic Alliance as a subcontractor for the National Genetics Education and Consumer Network. The RCs are funded under separate Health Resources and Services Administration (HRSA) grants. Now in its 12th year, the NCC/RC system has common evaluation data elements related to HRSA priorities and Healthy People 2020 objectives that focus on care coordination (e.g., medical home and transition from pediatric to adult care); telegenetics; newborn screening capacity and long-term follow-up. **Methods** In 2015, the NCC conducted listening sessions and fielded national surveys to individuals and families with genetic conditions and genetic service providers (medical geneticists, genetic counselors, metabolic dietitians, and other genetic professionals). The ACMG Member Directory, listservs from national and RC partners, and social media were used to electronically distribute the surveys. **Summary of results** Across the country genetic services needs are not being met. Our findings show: most genetic professionals work in university or children's hospitals; the majority of their time is spent in clinical care; two thirds of geneticists report that their current wait time for a non-emergency appointments is greater than one month with respondents at children's hospitals reporting the longest wait time; and use of telemedicine is low. Barriers to access include too few clinical geneticists and genetic counselors; geographic disparities; costs of testing and lack of reimbursement; and lack of education. Potential solutions include better care coordination, more genetics professionals, telemedicine, increased acceptance of billing codes by insurers, increasing genetic competency for non-genetics professionals, and making genetic counseling separately reimbursable. The NCC is funded by *U22MC24100*, awarded as a cooperative agreement between the Maternal and Child Health Bureau/Health Resources and Services Administration, Genetic Services Branch, and the ACMG.

3131T

Disseminating best practice in ELSI research to support the translation and uptake of high value precision medicine technologies in Canada: The Precision Medicine Policy Network. *S.K. Genuis[1], F. Rousseau[2], B. Knoppers[3], B. Wilson[4], M. Wolfson[5], T. Bubela[6], C. McCabe[1].* 1) Department of Emergency Medicine, University of Alberta, Edmonton, AB, Canada; 2) Department of Molecular Biology, Medical Biochemistry and Pathology, Université Laval, Quebec, QC, Canada; 3) Department of Human Genetics, McGill University, Montreal, QC, Canada; 4) Department of Epidemiology and Community Medicine, University of Ottawa, Ottawa, ON, Canada; 5) School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, Ottawa, ON, Canada; 6) School of Public Health, University of Alberta, Edmonton, AB, Canada.

   Precision Medicine promises to improve clinical care and efficiencies in health care. Despite significant government investment, this promise has not yet been achieved. There are significant barriers to the successful implementation of precision medicine technologies in Canada and internationally. Many of these barriers are related to the ethical, legal and social implications of Genomics research (ELSIs). In 2013 Genome Canada (GC) funded 17 Genomics and Personalized Health (GAPH) Large Scale Applied Research Projects focused on bringing genomics technologies to market. By 2015 it had become clear that ELSI knowledge was siloed within individual projects. Genome Canada recognized that substantial added value could be obtained by synthesizing this knowledge and experience that has developed within the research teams. On January 1, 2016, Genome Canada provided funding for the *Precision Medicine Policy Network*, a collaborative 'learning network' of the 17 Projects. Focusing on four, high priority themes (Research Ethics; Health Economics & Health Technology Assessment; Knowledge Translation & Implementation Science; and Intellectual Asset Management & Commercialization) the Network has brought together expertise from the 17 GAPH Projects and from academic, policy and private sector communities. Through critical appraisals and consensus workshops, the Network is developing good practice guides for each of the priority areas. Over the next two years, the network will be delivering pan-Canadian training workshops to support their dissemination.

Effect assessment of genome research supporting policy and program alteration in Korea. *S. Moon, K. Jang, H. Kim.* Korea Institute of Science&Technology Evaluation and Planning, Seoul, South Korea.

Most of the times, research in innovative fields such as genomics develops with close relation to public funding. This report analyzes genomics research in Korea with regard to governmental research supporting policy alteration. In very recent years, research funding programs for genomics in Korea has experienced dramatic change. Unlike other life sciences area, genomics research funding has adopted a multi-departmental program format, which emphasizes collaborational policy mix and shared roles and responsibilities. We will discuss the effect of this multi-departmental support with emphasis on budget accumulation and allocation, composition of research topics so that the envelope of research moves towards common goal. We also focus on the changes that have been made to supporting policy that can influence researchers in the field, including legal and ethical issues, and database generation, standardization and information sharing. We expect to shed light on connection between research policy and laboratory research, which could strengthen future policy design and execution to accelerate meaningful findings in human genomics.

Regional genetic service models: What's out there and what could the US learn for future genetics services delivery models? *C. Kaye[1], A.S. Keehn[2], M. Lyon[2], M.S. Watson[2], D.M. Maiese[2], S. Alexander[3], J. O'Leary[3], NCC RSSM Workgroup and Advisory Commitee Members.* 1) SOM, Dean's Office, Univ Colorado, Parker, CO; 2) American College of Medical Genetics and Genomics, Bethesda, MD; 3) Genetic Alliance, Washington, D.C.

Purpose To understand the current landscape of regional models of healthcare delivery across the United States (and the genetics service in the United Kingdom) in order to consider potential future regional models of genetics support services. The National Coordinating Center for the seven HRSA Regional Genetic Service Collaboratives (NCC/RC system), housed at the American College of Medical Genetics and Genomics (ACMG), pursued a comprehensive review and development of future regional support service models. **Methods** In 2015, a small working group sponsored by the NCC, the Regional Support Service Models Workgroup (RSSM WG) and an Advisory Committee (AC) considered a set of 35 recommended regional service delivery models, comprehensively reviewing 13 of those models via telephone interviews completed by individual workgroup members. The RSSM workgroup also reviewed national needs assessments of genetics providers and consumers of genetic services completed by the NCC and its partner, the National Genetics Education and Consumer Network (NGECN). Using reviewed models and the genetics service priorities and needs identified through the needs assessments, the RSSM workgroup then developed eight models of regional genetic services that could be considered in the future. **Summary of results** Center reviews revealed key themes: collaborative model can be very effective; support to outreach clinics can vary; no model provides mental health support; data collection—registries and robust databases—can be a very powerful tool for long-term success; and genetics and primary care workforce issues are real. The national needs assessment identified the following priorities: data collection, education and training, efficient practice, family engagement, formal partnerships, and practice support. This work led to the identification of eight regional support service models that range from a regional genetics education and TA center (similar to an ECHO model) to a genetic service data center to a quality improvement model. The models, their pros and cons, and timelines have been developed and reviewed by the RSSM WG and AC, offered for open comment for a month, revised and edited, and finalized. The NCC and NGECN are funded by *U22MC24100*, awarded as a cooperative agreement between the Maternal and Child Health Bureau/ Health Resources and Services Administration, Genetic Services Branch, and the ACMG.

3134T

Integrative personal omics profiling during periods of diet or infection perturbations. *M. Snyder[1], W. Zhou[1], B. Piening[1], K. Contrepois[1], G. Gu[1], S. Leopold[3], T. Mishra[1], D. Perleman[2], B. Leopold[3], E. Sodergren[3], T. McLaughlin[2], G. Weinstock[3], Integrative Human Microbiome Project consortium.* 1) Genetics, Stanford University, Stanford, CA 94305; 2) Division of Endocrinology, Stanford University School of Medicine, Stanford, CA 94305; 3) The Jackson Laboratory for Genomic Medicine, Farmington, CT 06030.

While significant genetic and environmental risk factors are known to contribute to the development of Type 2 Diabetes (T2D), overall our ability to predict which individuals will develop T2D and when this will occur is woefully inadequate. To better understand these factors, we present a longitudinal multi-omic personalized profiling of comprehensive blood- and microbiome-based analytes that we apply to track the progression to T2D in a cohort of 100 individuals over periods of health, illness and weight gain and loss. Multi-omic profiling (transcriptome, proteome, metabolome etc.) revealed significant differences in multiple 'omes between prediabetics and healthy controls at steady state, implicating pathways related to chronic inflammation and insulin regulation as well as novel connections to T2D. A subset of participants was then placed on a short-term high caloric diet and profiled by longitudinal multi-omics approach. The dietary perturbation was associated with a wealth of biomolecular expression changes concomitant with weight gain and spanning multiple 'omes including the microbiome, and the omic response to weight gain differed between prediabetics and healthy controls. In another subset of participants who went through respiratory viral infections, their multi-omic profiling, including the microbiome, responded distinctly to different illness stages during the infection. Overall, multi-omic profiles of individuals are unique to themselves regardless diet or illness perturbations. Together, these large-scale longitudinal data offer a novel and comprehensive view of the dysfunction in cellular networks associated with the progression to T2D and may offer new strategies for predicting and preventing the disease.

3135F

Making humanized major histocompatibility complex (MHC) mice to study Graves' disease. *P.L. Chen[1,2,3], K.C. Chen[2], T.C. Chang[3].* 1) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 2) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan; 3) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.

Graves' disease (GD, MIM 27500), the global leading cause of hyperthyroidism and thyroid eye disease, is an autoimmune disease with both clinical and academic significance. To further investigate the mechanism of GD, and also to develop possible novel treatment and/or prevention methods, murine models have the potential to provide invaluable insights. Most immune-related human diseases actually lack good animal models. Technology advances (such as recombineering, pronuclear injection-based mouse targeted transgenesis (PITT) and CRISPR/Cas9) in recent years would open a new era of excellent humanized animal models. Previously animal models involved in MHC were mostly simple transgenic lines. There are syntenic regions between human and mouse MHC loci/genes, but the correlations are far from perfect. More sophisticate humanized MHC knock-in design holds the promise to shed light on the mechanism of human immune-related diseases. We aimed at generating mouse lines carrying various *HLA-DRB1* alleles. We started with the embryonic stem cells from the C57BL/6N line, and therefore future backcrossing to the B6 background will not be necessary. We successfully achieved first targeting; the mouse *H2-Aa* was replaced with human *HLA-DRA* gene, which was retrieved from human BAC RF11-379F19. We then accomplished the second targeting by replacing mouse *H2-Ab1* with human *HLA-DRB1* gene. It is noteworthy that the human *HLA-DRB1* gene was retrieved from human BAC CTD-2510D15, and we later noticed that the sequence at the splice donor site was "AT" (instead of "GT") at the +1 and +2 position of intron 1, which was predicted to cause abnormal splicing results. We then successfully corrected the sequence from "AT" to "GT" at the targeting vector, which was 28,770 bp in size before the final blastocyst injection. Future validation and phenotyping will be needed after we get the mice carrying human HLA genes. Humanized MHC mice could provide important help to study GD and possible other immune-related human diseases/phenotypes.

3136W

Large scale analysis of HLA-peptide interactions. *H. Miyadera[1,2,3], Y. Okabe[2,3], K. Tokunaga[3], E. Noguchi[1].* 1) Department of Medical Genetics, University of Tsukuba, Tsukuba, Ibaraki, Japan; 2) Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine, Ichikawa, Chiba, Japan; 3) Department of Human Genetics, The University of Tokyo, Bunkyo-ku, Tokyo, Japan.

   Genes encoding the human leukocyte antigens (*HLA*) are associated strongly with a variety of immune related disorders including infectious diseases and autoimmune disorders. However, exact mechanisms of *HLA*-disease association have remained elusive for most of these diseases. To identify disease-relevant self- and foreign peptides and uncover mechanisms of *HLA*-disease association, we devised an assay to screen for HLA-binding peptides for a large numbers of *HLA* allele products.   Methods: We used cell-surface HLA expression assay (Miyadera, et al. 2015, JCI) to screen for peptides that are potentially presented by HLA class II, including *HLA-DQ*, *-DR*, and *-DP*. First, we established stable cells for HLA class II alpha subunit using murine fibroblast cells (NIH3T3) as a host cells. The stable HLA class II alpha-cells were transiently transduced with HLA class II beta subunit, which is fused to peptides. The level of cell surface HLA expression for each HLA-peptide combination was measured by flow cytometry and used as an estimate of HLA-peptide interaction.   Results: We validated the assay using the peptides that are known to bind strongly or weakly to certain HLA allele products. We then extended the analysis to screen for self- and foreign peptides that might be involved in certain HLA-associated diseases including narcolepsy, type 1 diabetes, and hepatitis B. In addition to peptides, allelic differences in the intrinsic stability of HLA-DQ, -DR, and -DP were also estimated to analyze potential association between HLA stability and disease susceptibility. .

3137T

A rapid genotyping research assay for determining basic ABO RhD blood types and CCR5 status. *E. Schreiber[1], T. Nong[2], J.H. Lee[2].* 1) Thermo Fisher Scientific, Genetic Sciences Division, South San Francisco, CA; 2) Thermo Fisher Scientific, One Lambda Division, Canoga Park, CA.

   Purpose: Bone marrow registries require high resolution HLA genotyping information of donor specimen for matching them with their future recipients. For optimal outcome it is further desirable to use bone marrow of identical or compatible ABO RhD/CE blood types between donor and recipient. In order to aid research in this area, we have developed a rapid research assay that utilizes DNA isolated from buccal swaps of past marrow donors to determine the genotypes of the ABO blood antigens and the presence (+) or absence (-) of the RhD antigen. In addition the assay also determines the presence or absence of a 32 bp deletion in the CCR5 gene. Homozygous carriers of the deletion are resistant to HIV-1 infection and thus could be valuable stem cell donors for HIV-infected recipients.   Methods: The research assay is based on a single multiplex-PCR reaction with 5 fluorescently-labeled and 12 allele-specific primers followed by capillary electrophoresis on an automated Applied Biosytems 3500 Genetic Analyzer. The primers for the human ABO gene target 4 SNPs in exons 6 and 7 allowing the determination of the A, A2, B, O1,2 and O3 alleles. The peak pattern generated on the sequencer is analyzed by GeneMapper® software and the resulting peak/genotype table is translated into a genotype/phenotype status report using standard spreadsheet software. Results: We have verified the assay by analyzing a panel of DNA samples with known blood group antigens and CCR5 gene types and found it to be 100% comparable. Conclusion: Taken together, this easy to use, inexpensive and rapid research assay may prove useful in the future towards the development of an assay that could be used for the stratification or identification of bone marrow donors and other areas of public health studies. For research use only. Not for use in diagnostic procedures.

3138F

Characterizing haplotype diversity at the immunoglobulin heavy chain locus across human populations using novel long-read sequencing and assembly approaches. *C.T. Watson[1,2], M. Laird Smith[2,3], W. Gibson[2], O. Rodriguez[2], M. Pendleton[2], P. Comella[2], L. Harshman[4], W.A. Marasco[5,6], E.E. Eichler[4], R. Sebra[2], J. Korlach[3], A.J. Sharp[2], A. Bashir[2].* 1) Department of Biochemistry and Molecular Genetics, University of Louisville School of Medicine, Louisville, KY; 2) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Pacific Biosciences, Menlo Park, CA; 4) Department of Genome Sciences, University of Washington, Seattle, WA; 5) Department of Cancer Immunology & AIDS, Dana-Farber Cancer Institute, Boston, MA; 6) Department of Medicine, Harvard Medical School, Boston MA.

The human immunoglobulin heavy chain locus (IGH) remains among the most understudied regions of the human genome. Recent efforts have shown that haplotype diversity within IGH is elevated and exhibits population specific patterns; for example, our re-sequencing of the locus from only a single chromosome uncovered >100 Kb of novel sequence, including descriptions of six novel alleles, and four previously unmapped genes. Historically, this complex locus architecture has hindered the characterization of IGH germline single nucleotide, copy number, and structural variants (SNVs; CNVs; SVs), and as a result, there remains little known about the role of IGH polymorphisms in inter-individual antibody repertoire variability and disease. To remedy this, we are taking a multi-faceted approach to improving existing genomic resources in the human IGH region. First, from whole-genome and fosmid-based datasets, we are building the largest and most ethnically diverse set of IGH reference assemblies to date, by employing PacBio long-read sequencing combined with novel algorithms for phased haplotype assembly. In total, our effort will result in the characterization of >15 phased haplotypes from individuals of Asian, African, and European descent, to be used as a representative reference set by the genomics and immunogenetics community. Second, we are utilizing this more comprehensive sequence catalogue to inform the design and analysis of novel targeted IGH genotyping assays. Standard targeted DNA enrichment methods (e.g., exome capture) are currently optimized for the capture of only very short (100's of bp) DNA segments. Our platform uses a modified bench protocol to pair existing capture-array technologies with the enrichment of longer fragments of DNA, enabling the use of PacBio sequencing of DNA segments up to 7 Kb. This substantial increase in contiguity disambiguates many of the complex repeated structures inherent to the locus, while yielding the base pair fidelity required to call SNVs. Together these resources will establish a stronger framework for further characterizing IGH genetic diversity and facilitate IGH genomic profiling in the clinical and research settings, which will be key to fully understanding the role of IGH germline variation in antibody repertoire development and disease.

3139W

Comparative study reveals superior performance of WGS compared to WES in a real-world study of human Mendelian diseases. *Y. Huang[1], J. Hughes[2], J. Zhuang[2], M. Lenardo[3], H. Sun[3], J. Milner[3], R. Goldback-Mansky[4], H. Runz[1], J. McElwee[1].* 1) Genetics and Pharmacogenomics, Merck Research Labs, Boston, MA; 2) Computational Genomics & Genetics, Merck Informatics IT, Boston, MA; 3) National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD; 4) National Institute of Arthritis and Musculoskeletal and Skin.

Next-generation sequencing has established itself as the *de facto* choice for measuring genome-wide genetic variation in clinical and research settings. The effectiveness of its practical application, however, largely depends on carefully selecting the appropriate sequencing technology, namely whole genome sequencing (WGS) or whole exome sequencing (WES). Providing base pair level resolution of the genome, WGS is more attractive for complete details of one's genetic makeup. On the other hand, WES offers a more affordable solution cost-wise. The drawback is that WES covers only ~50-65M base pairs of the genome using various capture reagents (e.g., Agilent SureSelect™ v5 and Nimblegen SeqCap v3). In order to establish a best-practice guidance for sequencing studies, it is important to understand the strengths and weaknesses of each technology. In the present study, we provide an objective evaluation on the two sequencing technologies in a large-scale, real-world human sequencing analysis. A cohort of 208 subjects exhibiting Mendelian immune diseases was sequenced with both WGS and WES. We compared WGS and WES for the identification and interpretation of genes and variants in the ensemble consensus coding sequences (CCDS) as a consistent target region of interest for Mendelian and functional genetics. WGS showed significantly better coverage, with an average 99% of CCDS covered at 10x or greater by WGS compared to 91% in WES. In addition, WGS has significantly fewer bases (20,950 for WGS vs. 37,273 for WES) that are not mapped. The majority (71.9% for WGS vs. 47.6% for WES) of these were found to be deletions in dbSNP. WGS also exhibits more uniform coverage across genome while WES shows higher level of variability across target regions. The average coefficient of variation of WGS is 10-fold smaller than that of WES, 1% vs. 10% respectively. In particular, WES suffers from low coverage in genes with high GC content (e.g., CEBPB, TNFRSF4, SOCS1) as well as GC rich regions (e.g., 5' UTR and first exons). When inspected at individual gene level, as many as 374 genes have >95% of their coding regions well-covered by WGS compared to <70% coverage in WES. These differentially-covered genes include 41 (12%) genes relevant for Mendelian disease, such as APOE, INS, and PDX1. In summary, WGS delivers superior power for variant calling in many regions of the genome, with greater mappability, more uniform coverage, and better performance in high GC content regions.

The Ion S5™ ExT Workflow: Enabling rapid, automated, long-read sequencing for the Ion S5™ sequencing system. *G.M. Lowman[1], M. Landes[1], V. Mozhayskiy[1], X. Peng[1], G. Luo[1], R. Lyons[1], M. Shenasa[2], L. Ong[2], J. Ghadiri[2], C. Buie[2], A. Gulati[2], J. Dinis[2], A.G. Jung[2], S. Lee[2], A. Pomorski[2], T. Burgess[2], P. Thwar[2], E. Linch[1], L. Miller[1], C. Hoff[2], C. Duncan[1], D. Mazur[1], A. Mongan[2], K. Lam[3], K. Beutner[3], Y. Saito[3], J. Lee[3], W. Zhang[1], M. Andersen[1], P. Vander Horn[1].* 1) Thermo Fisher Scientific, 5781 Van Allen Way, Carlsbad, CA 92008; 2) Thermo Fisher Scientific, 180 Oyster Point Blvd. South San Francisco, CA 94080; 3) One Lambda, 21001 Kittridge St., Canoga Park, CA 91303.

The Ion S5™ ExT templating and sequencing reagents for the Ion S5™ sequencer provide a fully automated and rapid sample-to-answer solution enabling a wide range of applications including research in human leukocyte antigen (HLA) genotyping, immune repertoire sequencing, bacterial identification, and metagenomic analysis with read lengths greater than 600bp. This unique workflow permits a single day turnaround time, including sample templating, sequencing, and analysis, which is imperative for applications where time is of the essence. The Ion S5™ExT system provides flexibility in semiconductor chip selection for large-scale studies where sample number, cost, and automation is critical or smaller studies where answers are needed quickly. By combining rapid templating technology and automation on the Ion Chef™, ExT technology supports read lengths greater than 600bp with less than 30 minutes of hands-on time. When paired with the Ion Xpress MuSeek™ library preparation kit, an 8-hour DNA-to-answer workflow becomes a reality. The benefits of the ExT workflow are shown in HLA genotyping studies where longer Ion Torrent reads demonstrate improved coverage bridging exons and in high-GC regions. The concordance rate between the longer read protocol-derived genotypes and those generated by TypeStream™ auto-analysis was 99.7% for the HLA-A, B, C, DRB1, DQB1, DPB1 and DRB 345 loci combined. Importantly, reads in excess of 600bp provide a route for HLA genotyping to unambiguously establish the gametic phase between alleles. Metagenomic studies show the benefit of longer reads to improve species level characterization in 16S samples, and extending read length enables sequencing the full variable region of the TCR(α,β) immune repertoire.   *For Research Use Only. Not for use in diagnostic procedures. .

Single-cell transcriptional profiling identifies rare cell types with gene markers for classification and prognosis in acute myeloid leukemia. *A. Sartori[1], E. Falconnet[1], P. Ribaux[1], S.E. Antonarakis[1,2,3], T. Matthes[2], C. Borel[1].* 1) Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland; 2) University Hospitals of Geneva, Geneva, Switzerland; 3) iGE3 Institute of Genetics and Genomics of Geneva, Switzerland.

Acute myeloid leukemia (AML) is a particularly aggressive blood cancer difficult to treat because of its recurrence affecting differentiation of hematopoietic progenitors. It is hypothesized that relapse of AML is due to incomplete eradication of leukemic stem cells (LSC) with self-renewal and leukemia-initiating properties. Our ultimate goal is to characterize LSC based on their transcriptional profiling. Evidence suggests that CD34+CD38− cell population is enriched for LSCs but they remain rare and difficult to identify. Thus, we present a single-cell RNA-seq approach to characterize CD34+CD38- sorted cells in 2 AML individuals (AML1(M0), AML2(M5)) at the time of diagnosis and in 4 unaffected individuals (N). For 311 single-cells, 1764 genes were detected on average (RPKM>10). We identified 763 and 858 significantly differentially expressed genes in AML2 and AML1, respectively using D3E. We demonstrate that the captured AML cells possess the hallmarks of LSC. The top highly expressed genes are stem markers including *SOX4, CD74, CD69* and *CXCL8*. In particular, *HOXA-B* cluster genes appeared markedly dysregulated demonstrating their leukemia-initiating capability. Gene ontology revealed enrichment for annotation of apoptotic resistance and self-renewal capacity as well. Furthermore, 3 distinct clusters of co-expressed genes were identified that distinguished between N cells and AML cells with M0 and M5 (SEURAT-tool). Finally, we hypothesized that prognostic gene-expression signature is present at diagnosis. Using TCGA RNA-seq and clinical datasets, we identified genes whose expression correlated with AML patient survival. We confirmed their differential expression in AML single-cells and thus, their contribution in leukemogenesis and potential relevance for clinical-outcome prediction.

3142W

Utilizing integrative omics to identify phenotypic subtypes of childhood asthma. *R.S Kelly[1], A. Dahlin[1], A.C Wu[1], M.J McGeachie[1], D.C Croteau-Chonka[1], C.B Clish[2], J. Celedón[3], S.T Weiss[1], J.A Lasky-Su[1].* 1) Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 2) Broad Institute of MIT and Harvard, Boston, MA; 3) Division of Pediatric Pulmonary Medicine, Allergy and Immunology University of Pittsburgh, Pittsburgh, PA.

Background: Asthma is a major global public health problem, but its heterogeneous nature is poorly understood. Integrative omic studies represent a novel approach to characterize asthma subtypes and their underlying biology. **Methods:** Metabolomic and transcriptomic profiling was performed on serum of 381 asthmatic children from a genetically isolated Costa Rican population (CR). After quality control and processing, four liquid chromatography mass spectrometry platforms and whole genome sequencing yielded 8185 endogenous metabolites and 25060 unique transcripts, respectively. Hierarchical clustering was used to identify groups of asthmatic children with similar transcriptomic, metabolomic and integrated omic profiles. The epidemiological, immunological and clinical characteristics of the different clusters were compared, and the genes and metabolites driving the formation of the clusters were identified using one-way ANOVA. Validation was performed using an independent cohort of 612 asthmatic children (CAMP). **Results:** Asthmatic children were clustered into groups based on their transcriptomic (n=5 clusters), metabolomic (n=5 clusters) and integrated (n=5 clusters) profiles. There was high concordance between the clustering of children under all three profiles. The clusters could be broadly defined by asthma severity (lung function and exacerbations), age of onset, atopy and vitamin D status. The clusters were most clearly defined using the integrated profile. Interrogation of the integrated profiles identified 268 genes and 69 metabolites as drivers of cluster formation, including both novel and established asthma associations. Pathways underlying phenotypic heterogeneity in asthma; including glycerophospholipid, sphingolipid, tryptophan and linoleic acid metabolism, were enriched among the genes and metabolite variants, and the variants could be annotated to disorders of lung function and immunity. Validation in CAMP identified four clusters with similar phenotypic patterns to those in CR. Moreover, the drivers of these clusters were replicated in CAMP on both an individual variant and pathway level. **Conclusions:** As one of the first and largest integrative omics studies of childhood asthma this study demonstrates and validates the use of omic profiles to classify asthma sub-phenotypes. Interrogation of the profiles reveals biological mechanisms discriminating between the subtypes, paving the way for future biomarker development and targeted therapeutics.

3143T

Proteomic peptide screening of dried blood spots for primary immunodeficiency, Wilson disease and cystinosis. *S. Hahn[1,2], S. Jung[2], J. Whiteaker[3], L. Zhao[3], H. Yoo[4], T. Torgerson[1,2], H. Ochs[1,2], W. Gahl[5], A. Paulovich[3].* 1) Department of Pediatrics, University of Washington, Seattle Children's Hospital, Seattle, WA; 2) Seattle Children's Hospital Research Institute, Seattle, WA; 3) Fred Hutchison Cancer Research Center, Seattle, WA; 4) Department of Pediatrics, Ulsan University College of Medicine, Asan Medical Center, Seoul, Korea; 5) National Human Genome Research Institute, National Institute of Health, Bethesda, MD.

Background: Newborn screening (NBS) has proven to be highly effective at reducing healthcare costs, improving outcomes, and avoiding long-term disability in affected children. Unfortunately, many attractive candidates for NBS are characterized by the absence or modification of proteins for which there are currently no cost-effective screening methods. Among these are Primary Immunodeficiency Diseases (PIDD), Wilson Disease (WD) and Cystinosis. Objectives: Our goal is to develop a high-throughput, multiplex, proteomic screening assay for a variety of genetic conditions. We hypothesized that peptide immunoaffinity enrichment coupled with Liquid Chromatography-Selected Reaction Monitoring-Mass Spectrometry (immuno-SRM) can be utilized as a rapid, inexpensive approach to detect CD3ε (for SCID), WASP (for WAS), BTK (for XLA), ATP7B (for WD) and Cystinosin (for Cystinosis) in Dried Blood Spots (DBS).**Methods:**. Several candidate peptides were screened by *In Silico*, BLAST search, then selected based on detectability and response in LC-MS/MS analyses followed by polyclonal antibody generation for enrichment. We analyzed target peptides for BTK, CD3ε, WASP, ATP7B and Cystinosin in DBS using SRM mode with 6500 QTRAP (ABSCIEX). Blood samples from patients were spotted on filter paper, dried and stored at -80 °C until use.**Results:** Two BTK targeted peptides were absent or markedly reduced in two XLA patients compared to normal controls, while the other target peptides designed to detect SCID, WAS in the XLA patients were normal. Cystinosin peptide was absent in two Cystinosis patients (57-kb del homozygotes). Lastly, the results of DBS samples from 5 controls and 7 confirmed WD patients showed that the assay readily distinguished affected from controls. The assay showed a linear response ($r^2 = 0.99$) spanning the peptide concentration of 27 to 16,765 pmol/L (0.7 to 417 femtomoles). The median CV for all points on the response curve was 7.8%. Intra- and interassay imprecision from the normal control were 8.89% CV and 7.57% CV, respectively. ATP7B protein marker in DBS at various temperatures was stable for a week.**Conclusions:** This is very compelling evidence that immuno-SRM assays can be used as a highly sensitive platform for DBS protein analysis in the low-picomolar range. When multiplexed, there is a significant potential to screen various congenital disorders lacking specific protein markers.

3144F

Diagnosis of adenylosuccinate lyase deficiency by metabolomic profiling in plasma reveals a phenotypic spectrum. *T. Donti[1], G. Cappuccio[1,2], L. Hubert[1], J. Neira[1], P. Atwal[1], M. Miller[1], A. Cardon[3], V. Sutton[1], B. Porter[4], F. Baumer[4], M. Wangler[1], Q. Sun[1], L. Emrick[1,3], S. Elsea[1].* 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Translational Medical Sciences, Section of Pediatrics, Federico II University, Naples, Italy; 3) Section of Pediatric Neurology and Neuroscience, Baylor College of Medicine, Houston, TX; 4) Stanford Medical School, Stanford, CA.

   Adenylosuccinate lyase (ADSL) deficiency is a rare autosomal recessive neurometabolic disorder that presents with a broad-spectrum of neurological and physiological symptoms that typically include intellectual disability, seizures, and global developmental delays. Mildly affected individuals present mainly with autistic features. *ADSL* produces an enzyme, adenylosuccinate lyase, with binary molecular roles in *de novo* purine synthesis and purine nucleotide recycling. The biochemical phenotype of ADSL deficiency, accumulation of SAICAR and succinyladenosine (S-Ado) in biofluids of affected individuals, serves as the traditional approach for diagnosis, with targeted quantitative urine purine and CSF analysis employed as the predominant method of detection. Diagnosis of rare neurometabolic disorders typically requires the use of targeted analyte analyses, limiting the use of this approach in cases without typical presentation of disease. Using an alternative method, untargeted metabolomic profiling, an analytical scheme capable of generating semi-quantitative z-score values for over 900 unique compounds in a single analysis of a plasma specimen, we diagnosed of ADSL deficiency in 3 individuals from 3 families presenting with a broad spectrum of features ranging from mild to severe intellectual disability with or without seizures. A fourth child was identified in one of these families using targeted purine analysis, further illustrating the phenotypic variability, even within the same family. These findings were confirmed with targeted quantitative biochemical analysis and molecular genetic testing revealing novel and known mutations in *ADSL*. The use of untargeted metabolomic screening for neurometabolic disorders has the potential to identify patients with enzyme deficiencies that may present on the mild end of the reported spectrum, reducing time and cost of diagnosis. Undifferentiated phenotypes, such as intellectual disability, seizures, and hypotonia, are common among many inborn errors of metabolism and diagnosis dependent upon specific, targeted testing has classically stood as a hurdle in the initial diagnosis and subsequent treatment. The findings presented here demonstrate the clinical utility of metabolomic profiling in the diagnosis of ADSL deficiency and highlights the potential of this technology in the diagnostic evaluation of individuals with neurologic phenotypes. .

Characterization of the poly-T variants in the *TOMM40* gene using PacBio long reads. *A. Sethuraman, K. Eng, J. Gu, P. Baybayan, S. Kujawa.* Pacific Biosciences, Menlo Park, CA.

   Genes associated with several neurological disorders have been shown to be highly polymorphic. Targeted sequencing of these genes using NGS technologies is a powerful way to increase the cost-effectiveness of variant discovery and detection. However, for a comprehensive view of these target genes, it is necessary to have complete and uniform coverage across regions of interest. Unfortunately, short-read sequencing technologies are not ideal for these types of studies as they are prone to mis-mapping and often fail to span repetitive regions. Targeted sequencing with PacBio long reads provides the unique advantage of single-molecule observations of complex genomic regions. PacBio long reads not only provide continuous sequence data though polymorphic or repetitive regions, but also have no GC bias.   Here we describe the characterization of the poly-T locus in *TOMM40*, a gene known to be associated with progression to Alzheimer's, using PacBio long reads. Probes were designed to capture a 20 kb region comprising the *TOMM40* and *ApoE* genes. Target regions were captured in multiple cell lines and sequencing libraries made using standard sample preparation methods. We will present our results on the poly-T structural variants that we observed in *TOMM40* in these cell lines. We will also present our results on probe design optimization and barcoding strategies for a cost-effective solution.

3146T

Identification of large pathogenic structural variants using next generation genome mapping technology. *E. Vilain, H. Barseghyan, W. Tang, M. Almalvez, E. Douine, H. Lee, S. Nelson.* Human Genetics, UCLA School of Medicine, Los Angeles, CA.

Whole exome/genome sequencing (WES/WGS) has become more routine and affordable with the capability of reliably identifying single nucleotide variants (SNVs), small insertions and deletions (INDELs). However, this approach does not allow the identification of a full spectrum of genetic variants in the human genome. Primarily, WES/WGS relies on short-read sequences that are mapped to a reference human genome without genome assembly. These sequencing methods miss on identification of large insertions/deletions/copy number variations in repetitive regions of the genome and are not capable of easily detecting other structural variations (SVs) such as inversions and translocations. In order to overcome these limitations we used Next Generation Mapping through nanochannel arrays (BioNano Irys System) that produce high-resolution images of fluorescently labeled native-state DNA molecules (up to 1Mb in size) for genome assembly and SV detection on a series of patients diagnosed with Duchenne Muscular Dystrophy (DMD). Multiplex ligation-dependent probe amplification (MLPA) was previously performed on all patients and several carrier mothers to identify which exons were deleted or duplicated. Using this strategy we successfully identified the intronic breakpoints within the *Dystrophin* gene where patients had a deletion or duplication. The identified deletions ranged from 30kb – 200kb, and insertions ranged from 10kb – 150kb in size both encompassing several exons and introns. Next Generation Mapping also successfully identified heterozygous SVs in carrier mothers of DMD patients indicating the ability of the method to distinguish between homozygous and heterozygous variants. Along with SVs identified in *Dystrophin* gene we have also on average identified 800 insertions, 500 deletions, 100 inversions and 50 translocations. To filter out likely benign SVs we used a database containing SVs from healthy individuals. Although we observe that SVs are less common than SNVs and INDELs in population they account for a significant fraction of genetic variation. Next Generation Mapping is poised to identify potential pathogenic SVs in patients with negative WES/WGS and to provide, in a single test, a combination of analysis of copy number variants and of large structural variants. This approach can be incorporated in the clinical diagnostic strategy of undiagnosed patients.

3147F

Unraveling the genetic basis of atypical cerebral palsy. *I. Blydt-Hansen[1], A. Matthews[2-4], M. Tarailo-Graovac[2-4], B. Al-Jabri[5], H. Vallance[6], G. Sinclair[6], R. Salvarinova[1], C.J. Ross[3,4], W.W. Wasserman[2-4], H. Goez[5], G. Horvath[1], C.D. van Karnebeek[1,2,4].* 1) BC Children's Hospital, Division of Biochemical Diseases, Vancouver, BC, Canada; 2) Centre for Molecular Medicine and Therapeutics, Vancouver, BC, Canada; 3) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 4) Child & Family Research Institute, Vancouver, BC, Canada; 5) Department of Pediatrics, Stollery Children's Hospital, University of Alberta, Edmonton, Alberta, Canada; 6) Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada.

Background: Cerebral palsy (CP) is a debilitating life-long condition, often presenting with co-morbidities such as intellectual disability, movement disorder or epilepsy. Though classically deemed environmental (eg oxygen deprivation pre/perinatal brain insult), monogenic conditions can mimic CP. Timely diagnosis is essential for proper management and counseling, especially in the case of neurometabolic diseases that mimic CP and are amenable to treatment. **Aim**: To report all families with atypical CP (additional symptoms including intellectual disability and dyskinesias) in whom TIDEX whole-exome sequencing (WES) identified a monogenic disorder during the period 2011-2016. **Methods:** WES analysis with a customized bioinformatics pipeline was initiated in 23 exquisitely phenotyped families with unexplained atypical CP. Variants were filtered against public and in-house databases to identify rare variants which were also predicted to be damaging by *in silco* tools. Accounting for the growing number of CP genes, we performed targeted analysis, ie virtual gene panel of known and suspected CP and movement disorder genes, with subsequent untargeted analysis of the whole exome using our TIDEX pipeline. **Results:** Contributing to the neurogenetic presentation, an autosomal de novo mutation was found in 14 families, a recessive mutation in 6, a hemizygous variant in 2 and an X-linked de novo mutation in 1. In the cases of CSTB and PAK3 deficiency, targeted treatment with neurotransmitter supplements was enabled by a genomic diagnosis. Furthermore, our findings expand the phenotype of three conditions. In at least three other cases, the affected individual's described phenotypes appeared to be caused by variants in two distinct genes (blended phenotypes). **Discussion**: Traditionally, functional or model organism studies are preferred to establish a gene as disease causing. However, such studies are costly, time consuming and not feasible for all CP genes. Rather, to prove disease causality of unreported CP genes, identifying unrelated families with similar phenotypes and different variants in the same gene will be required. Further identification of CP genes may improve diagnosis, reveal treatment targets and unravel pathophysiology of this complex and heterogeneous disease. As our understanding of atypical CP improves, we will be able to better understand early brain development and inform families regarding disease progression and genetic counseling decisions.

3148W

Improved sensitivity for clinically relevant variants using orthogonal sequencing. *J. Thompson, E. White, N. Chennagiri, N. Vena, A. Seman, S. Hosseini, B. Wu.* Res & Development, Claritas Genomics, Cambridge, MA.

We have previously shown that using independent Next Generation Sequencing platforms provided improved sensitivity for detecting exomic variants in the well-defined regions of standard reference samples. However, it is not straightforward to compare results in other parts of the exome and extrapolate to clinically relevant variants. To assess the ability of dual platforms to improve results, we examined the likely/possibly pathogenic variants found in more than 50 exome-based Regions of Interest. As previously observed~90% of all variants were orthogonally confirmed with identical sequencing results found on both the Illumina NextSeq and the Ion Torrent Proton platforms. Variants reported to patients included those that were sufficiently well studied as to be classified as Pathogenic/Likely Pathogenic by ACMG guidelines. In addition, Variants of Uncertain Significance (VUS) were found in genes known to be disease causing but the specific variants could not be unambiguously classified as pathogenic were also reported. Among the P/LP/VUSs, most were orthogonally confirmed but there were also examples of variants found exclusively on the NextSeq or exclusively on the Proton. If only a single platform had been used, these variants would have been missed and not reported to the patient. The number of genes that are 100% covered at >20x increased 42% when the Proton coverage was added to the Illumina analysis. Thus, this method is shown to deliver confirmed variants in a timely fashion while expanding the sensitivity for identifying rare, disease-relevant variants.

3149T

Improved performance of whole genome sequencing detects a *SYNGAP1* mutation in siblings with epilepsy with myoclonic-atonic seizures and photosensitivity. *M.J. Cowley[1,2], Y. Liu[3], K.L. Oliver[3,5], G. Carvill[4], C. Myers[4], V. Gayevskiy[1], M. Delatycki[6], Y. Zhu[7], K. Ying[1], D. Miller[1], P. Morris[1], A. Statham[1], H. Mefford[4], M.F. Buckley[8], S.F. Berkovic[5,6], M. Bahlo[3], I. Scheffer[5,6,9,10], M.E. Dinger[1,2], T. Roscioli[1,2,11].* 1) Kinghorn Centre for Clinical Genomics, Garvan Institute of Medical Research, Sydney, NSW, Australia; 2) St Vincent's Clinical School, University of New South Wales, Darlinghurst, Australia; 3) Population Health and Immunity Division, Walter and Eliza Hall Institute, Melbourne, Australia; 4) University of Washington Department of Pediatrics, Genome Sciences, Seattle, USA; 5) Epilepsy Research Centre, Department of Medicine, University of Melbourne, Austin Health, Heidelberg, Australia; 6) Austin Health, Melbourne, Australia; 7) Department of Medical Genetics, Royal North Shore Hospital; 8) SEALS laboratory, Prince of Wales Hospital, Randwick, NSW, Australia; 9) Florey Institute, Melbourne, Australia; 10) Department of Paediatrics, University of Melbourne, Royal Children's Hospital, Australia; 11) Department of Medical Genetics, Sydney Children's Hospital, NSW, Australia.

We have recently achieved ISO15189 accreditation for clinical whole genome sequencing (WGS) for diagnosing rare Monogenic Disease, using the Illumina HiSeq X Ten platform, the first facility in the Southern Hemisphere to achieve this. Here we report WGS results in a non-consanguineous family of Ashkenazi-Jewish descent with two sisters with epilepsy with myoclonic-atonic seizures and photosensitivity. During an extensive 5-year diagnostic odyssey, they were investigated with targeted sequencing of known epilepsy genes using Molecular Inversion Probes (MIPs), followed by Whole Exome Sequencing (WES), with no aetiology identified by either technology. Using WGS, we identified a 13-bp heterozygous duplication in *SYNGAP1* (chr6:g.33400507_33400519dup) which was only present in both children, consistent with inheritance from a gonadal mosaic parent. Heterozygous mutations in *SYNGAP1* are consistent with the epileptic encephalopathy phenotype. We present an analysis of the events that confounded this molecular diagnosis. The reads containing the duplication were unmapped in the MIPs data using BWA v0.5.9, which is likely due to the large duplication at the end of the 101bp read. By increasing the gap extension parameter (-e=20) we were able to detect the mutation within the previously unmapped reads. The WES analysis used the hg19 reference genome, which contains 7 alternative MHC haplotypes. One of these contains *SYNGAP1*, resulting in two identical copies in the reference genome, and most reads having a mapping quality of 0. Mapping the WES reads to GRCh37 or with BWA-MEM v0.7.12 to GRCh38, which supports alternate haplotypes, revealed the mutation. In the WGS analysis, the longer 150bp reads, and the use of BWA-MEM v0.7.10 with the GRCh37d5 reference genome allowed the reads to map appropriately, and led ultimately to the identification of the duplication. This case study highlights that technical confounders can lead to missed diagnoses, and that the appropriate aligner for the reference genome should be used. We propose that alternative analysis pipelines, and/or WGS should be performed where a diagnosis has not been achieved using targeted sequencing and that all forms of possible inheritance should be considered.

3150F

Identification of novel Ras superfamily nucleotide-binding protein alterations in individuals with brain malformation using Missense-Depleted Regions (MDRs) in population exomes. *J. Shieh[1], X. Ge[1], H. Gong[1], K. Dumas[1], J. Litwin[1], J.J. Phillips[1], Q. Waisfisz[2], M.M. Weiss[2], Y. Hendriks[2], S.F. Nelson[3], W.W. Grody[3], H. Lee[3], P-Y. Kwok[1].* 1) University of California, San Francisco, CA USA; 2) VU University Medical Center, Amsterdam, The Netherlands; 3) University of California, Los Angeles, CA USA.

Purpose: Genomic sequence interpretation can miss clinically-relevant variants even with detailed medical genetics phenotyping of individuals. Missense variants are numerous in the exome, and affected genes may lack disease association. Methods: Here we apply population exome data to identify intragenic missense-depleted regions, MDRs, genome-wide that may be important in disease. We used MDR ranking to evaluate nondiagnostic patient exomes. Exome sequencing routinely yielded over 400 rare missense variants per individual. MDR ranking was then used to prioritize exome variants. With the addition of these these methods we identify a new gene association with pediatric brain malformation. Summary of Results: By applying these methods to nondiagnostic exome data, we identified a novel gene association for human brain malformation. We found novel *de novo* missense variants that affect the GDP/GTP-binding site of *ARF1* in three unrelated patients. Corresponding functional analysis indicates ARF1 GDP/GTP-activation, as measured by antibody pulldown, is affected by specific missense mutation associated with heterotopia. These findings expand the genetic pathway underpinning neurologic disease that classically includes *FLNA* and *ARFGEF2* and supports decreased ARF1/GEF function in disease. Using functional ontology, top-ranked MDR-containing genes were highly enriched for nucleotide-binding function, suggesting these as potential candidates for human disease. This is further supported by the recent identification of such genes in disease. We suggest routine consideration of MDR in exome interpretation may help identify strong genetic factors for rare undiagnosed conditions, and potentially infertility and embryonic conditions contributing to preterm loss.

3151W

Whole genome methylation profiles of single neurons. *R. Mulqueen[1], J. Sinnamon[2], G. Mandel[2], B.J. O'Roak[1], A. Adey[1,3].* 1) Department of Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR 97239, USA; 2) Vollum Institute, Oregon Health & Science University, Portland, OR 97239, USA; 3) Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR 97239, USA.

DNA methylation is a stable epigenetic modification with roles in regulation and differentiation. During development methylation is critical in defining neuronal cell function. However, methods used in previous studies are inherently limited; samples prepared using thousands of cells, shroud population substructure and neuronal heterogeneity. To address this shortcoming, we modified and optimized a single-cell whole genome bisulfite sequencing method (Smallwood et al. 2014; Farlik et al. 2015). Nuclei are flow sorted into individual wells, bisulfite converted and adapter tagged by random nonamer priming. Libraries are then amplified, barcoded and sequenced on the Illumina NextSeq 500 platform. By decreasing reaction volumes, using a dual indexing strategy, and reducing our protocol to a single well reaction, we improved upon previously described methods in terms of cost and scalability of library preparation. This renders cell population specific methylation analyses more tractable. We first applied our protocol on primary cultures of wild type mouse hippocampal neurons. Methylation libraries constructed for 92 single neurons had a 78.2% (72/92 nuclei) quality control pass rate with stringent filters. Counts as low as 300K uniquely aligned reads were sufficient to reproduce expected global methylation patterns and quantitation trends over CG islands and gene bodies, corroborating our strategy. We compared these to libraries constructed from a model of Rett Syndrome (RTT [MIM 312750]), a neurodevelopmental disorder caused primarily by mutations in the gene encoding epigenomic regulatory protein *methyl-CpG binding protein 2* (MECP2; Amir et al. 1999). The mutant neuronal library pool of 92 single neurons passed quality control at a rate of 71.7% (66/92 nuclei) and recapitulated known RTT methylation patterns, with no significant change in global methylation rate compared to wild type (Student's t-test, p>0.35; Gabel et al. 2015). We next intend to leverage the single cell information we have produced to quantify differences in locus specific variability and between neuronal epigenetic subtypes that are not possible to investigate with bulk preparation methods. With our high cell count, low coverage approach, we will assess unresolved changes in mean methylation levels and variability in a genomic locus and cell population specific manner. We plan to use this method as a nuanced approach to elucidate epigenomic dysregulation in complex tissue.

3152T

Deciphering the complex interplay between genetics, metabolomics and proteomics in Alzheimer's disease. *P. Proitsi[1,2], M. Kim[3], S. Policicchio[1], J. Xu[3], S. Newhouse[1,4], L. Whiley[3], M.K. Lupton[5], K. Ling[1], C. Johnston[1,4], M. Sattlecker[1,4], S. Lovestone[6], C. Legido-Quigley*[3], J.F. Powell[1], R.J.B. Dobson[1,4], The AddNeuromed consortium.* 1) King's College London, IoPPN, London, UK; 2) MRC Unit for Lifelong Health and Ageing (LHA), UCL, UK; 3) King's College London, Institute of Pharmaceutical Science, London, UK; 4) NIHR Biomedical Research Centre for Mental Health and Biomedical Research Unit for Dementia at South London and Maudsley NHS Foundation Trust, UK; 5) QIMR Berghofer Medical Research Institute, Brisbane, Australia; 6) Department of Psychiatry, University of Oxford, Warneford Hospital, Oxford, UK.

Alzheimer's disease (AD) is a devastating illness, with no effective treatments and lack of an early diagnosis. Blood metabolites have emerged as promising AD biomarkers. They are easily accessible, functional intermediate phenotypes that represent a molecular "fingerprint" in health and disease, and their integration with genetic and other omics data has increased our understanding on the interplay of multiple layers of biological organization. We recently performed a comprehensive blood lipidomics study on ~300 AD patients and controls replicating previous as well as reporting novel associations between blood lipids and AD clinical diagnosis, disease progression and brain atrophy. The aim of this study was to scrutinize the complex interplay between genetic variation (>6.4M SNPs), blood lipids (2225 features generated using Ultra-Performance Liquid Chromatography/Mass Spectrometry) and protein levels (1000 proteins measured using a Slow Off-rate Modified Aptamer (SOMAmer)–based capture array ("SOMAscan", SomaLogic, Inc)) in 180 AD patients, 189 controls and 38 people with Mild Cognitive Impairment. We first 1) performed an mGWA analysis to survey regions of the genome associated with blood lipids. We then sought to 2) identify blood lipids associated with established AD genetic variants, 3) identify loci that influence AD-related blood lipids and 4) investigate statistical colocalization of genetic risk variants for AD and for AD lipids. Next, we 5) integrated lipid and genetic data with blood protein data for 198 individuals to explore lipidomic-proteomic associations and investigate whether genetic variation driving AD lipids is associated with protein levels. Finally, 6) we performed Mendelian Randomization to determine whether blood lipids lie in the causal pathway to AD. We report novel associations between a number of loci and blood lipids. We also report associations between 4 AD risk SNPs and Phosphatidylcholine and Triglyceride molecules. We found >20 AD lipids to be associated with at least one locus at $P<5*10^{-8}$ with 11 passing Bonferroni correction. Integration of lipidomic and proteomic data revealed strong associations with proteins including Lp-PLA2 and Adiponectin and MR analyses point to causal links between lipids and AD. Ours is the first study to examine the interplay of genetics, blood lipidomics and proteomics in AD and demonstrates the utility of using multi-omics integrative approaches to understand the mechanisms underlying AD.

Development of a protocol of RNA extraction from skin biopsy for RNA Sequencing studies and its application in the identification of biomarkers implicated in painful and painless Idiopathic Peripheral Neuropathy. *S. Santoro[1], I.D. Lopez[2,10], M. Sorosina[1], A. Zauli[1], A.M. Osiceanu[1], L. Grevendonk[1], S. Peroni[1], R. Lombardi[3], D. Cazzato[3], M. Marchi[3], C.G. Faber[4], M. Sopacua[4], M.M. Gerrits[5], R. Almomani[5], J.G. Hoeijmakers[4], I.S. Merkies[4,5], H. Fadavi[6], R.A. Malik[7], D. Ziegler[8], G. Boenhof[8], S.D. Dib-Hajj[9], S.G. Waxman[9], G. Comi[1,2,10], A. Quattrini[2,10], G. Lauria[3], F. Martinelli Boneschi[1,10].* 1) Laboratory of Human Genetics of Neurological Disorders, San Raffaele Scientific Institute, Milan, IT; 2) Laboratory of Neuropathology, San Raffaele Scientific Institute, Milan, IT; 3) Neuroalgology Unit, Neurological Institute Carlo Besta, Milan, IT; 4) Department of Neurology, Maastricht University Medical Center, Maastricht, NL; 5) Clinical Genetics, Maastricht University Medical Centre, Maastricht, NL; 6) Centre for Endocrinology and Diabetes, University of Manchester and Central Manchester NHS Foundation Trust, Manchester, UK; 7) Division of Cardiovascular Medicine, University of Manchester, Manchester, UK; 8) German Diabetes Center, Medical Faculty Heinrich Heine University, Düsseldorf, DE; 9) Department of Neurology, Yale University School of Medicine, New Haven, CT, USA; 10) Department of Neurology, San Raffaele Scientific Institute, Milan, IT.

Neuropathic pain is a frequent clinical symptom occurring in the context of Peripheral Neuropathy (PN) and causing a significant impact on patients' quality of life. However, it is unpredictable, since not all of the individuals with PN develop pain. We hypothesized that the identification of a transcriptomic signature in skin components from fresh human skin biopsy and peripheral blood could be used to better understand the pathophysiology of neuropathic pain and to identify individuals at risk. With this purpose, we developed and optimized a protocol for RNA extraction from human skin biopsy, usually collected to make diagnosis, to explore the transcriptome using mRNA Sequencing in 4 painful and 4 painless PN patients and 6 age- and sex-matched healthy controls. We developed a protocol characterized by the following steps: 1) collection of biopsy and storage in a RNA stabilizing solution; 2) embedding and storage in liquid nitrogen; 3) cryosection; 4) staining with hematoxylin and eosin; 5) microdissection of the following tissues: A) border between epidermis and dermis - B) dermis - C) glands - D) whole biopsy; 6) RNA extraction. From 11 processed skin biopsies, we obtained the following mean quantities and DV_{200} values of RNA respectively for the 4 tissues: A) 59 ng and 88%, B) 36 ng and 82%, C) 22 ng and 78%, D) 52 ng and 88%. Although the quantity and quality of extracted RNA was poor, they fulfilled recommended parameters for RNA-Seq. Extracted RNA was enriched using the Illumina TruSeq RNA Access Library Prep Kit and paired-end sequenced (2x101bp) on the Illumina HiSeq 2500 platform. Quality control parameters from the sequencing of a first biopsy were successful. We obtained a mean of $9x10^6$ reads per tissue with 96% of total aligned reads on hg19 and 75% on coding regions. As expected, a high correlation coefficient was found between different skin tissues with the lowest between A and C (0.929) and the highest between B and C (0.978). Sequencing on additional samples, as well as analyses of differential gene expression comparing the different phenotypes in different tissues and peripheral blood, are ongoing. We conclude that the implemented protocol is efficient in extracting RNA from skin biopsy of enough quality to be used for RNA Sequencing and that our project will help to identify novel biomarkers of disease and potential targets for focused pharmacological approaches.

High-throughput functional analysis of *PTEN* variants reveals geno-type-phenotype relationships. *T.L. Mighell[1,2], S. Evans[2], B.J. O'Roak[1,2].* 1) Neuroscience Graduate Program, Oregon Health & Science University, Portland, OR; 2) Department of Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR.

The PI3K/mTOR pathway is a critical regulator of cell survival, growth, and proliferation. A crucial negative regulator of this pathway is phosphatase and tensin homolog (PTEN [MIM 601728]), which is frequently mutated in tumors. Interestingly, *PTEN* mutations have also been observed in individuals with autism and macrocephaly ([MIM 605309]), as well as various phenotypic presentations collectively known as PTEN hamartoma tumor syndrome (PHTS, e.g. [MIM 158350]). Despite its clear relevance to human health, we are still unable to predict the phenotypic outcome for the majority of *PTEN* genotypes. Some recent studies suggest that a *subset* of autism-associated variants retain greater phosphatase activity than cancer- and PHTS-associated variants. Making use of a *humanized* yeast model (Rodríguez-Escudero *et al.*, 2005), we seek to fully explore this hypothesis by performing saturation mutagenesis of *PTEN* and characterizing the phosphatase activity of thousands of mutations in parallel. In yeast expressing human *PIK3CA*, toxicity results from the conversion of the phosphatidylinositol (4,5)-bisphosphate (PIP_2) pool to PIP_3. Co-expression of PTEN rescues yeast growth by restoring the essential PIP_2 pool. However, catalytically dead PTEN variants are unable to rescue, thereby coupling the catalytic competence of a PTEN variant to cell growth. We adapted this system for highly multiplex mutation evaluation in an inducible competitive liquid culture system, thus permitting the assessment of thousands of variants in a single experiment using massively parallel DNA sequencing as readout. We have directly synthesized oligonucleotide probes encoding all possible codons at each position of PTEN (n=25,389) for cloning in a yeast expression vector. Using an *in vitro* recombination approach, mutation probes are introduced in parallel onto an otherwise wild-type *PTEN* background. We show in pilot experiments expected results for known catalytically dead and hypomorphic mutations. Our data allows for quantitative description of enzymatic activity. By subjecting a PTEN saturation mutagenesis library to this selection experiment, we will illuminate most or all residues that are important for phosphatase activity. This will inform understanding of basic protein properties of PTEN and will assist in the interpretation of variants observed in human genomes. Coupling genomic discovery with high-throughput functional analyses is paramount to advancing precision genomic medicine. .

3155T

Creating induced neurons directly from human adult fibroblasts provides a model system to elucidate the molecular effects of the 22q11.2 deletion. *C. Purmann[1,2], K. Tanabe[3], Y. Zhang[2], C.E. Ang[3], J. Hallmayer[1], M. Wernig[3], A.E. Urban[1,2].* 1) Department of Psychiatry & Behavioral Sciences, Stanford University, Palo Alto, CA; 2) Department of Genetics, Stanford University, Palo Alto, CA; 3) Institute for Stem Cell Biology and Regenerative Medicine and Department of Pathology, Stanford University, Palo Alto, CA.

22q11.2 Deletion Syndrome is caused by a common chromosome abnormality and a prominent point of entry for the analysis of the genetic basis of schizophrenia and autism. However, many dozen genes are affected by the deletion alone, and the effects are likely to be highly cell-type specific. Here, we present a novel method that allows for the direct induction of neuronal cells (induced Neurons, iN) from adult human fibroblast cells (previously only possible from perinatal fibroblasts). We applied this novel protocol to fibroblasts from 22q11.2 deletion patients and carried out extensive genomic and epigenomic analyses of the resulting iNs. We included fibroblasts from three 22q11.2 deletion patients and three control probands. Reprogramming into iNs via recombinant virus resulted in cells with neuronal phenotype and staining for relevant markers such as MAP2 and PSA-NCAM after approximately 21 days of culture, compared to several months for the standard route via iPSCs. RNA and chromatin were collected at the fibroblast and iN stages. Transcriptome-patterns were analyzed using RNA-Seq (also for micro-RNAs), and chromatin states were analyzed using ATAC-Seq. Established data analysis pipelines for each data type were employed. On both levels of molecular analysis, iN cells carrying the 22q11.2 deletion showed clear deletion-specific dysregulation. Genes expressed in iNs and within the deletion-boundaries were down-regulated while genome-wide both up- and down-regulation could be observed. Chromatin conformation was also clearly impacted by the presence of the 22q11.2 deletion. Principal-component-analysis showed clear clustering of patient vs. control iNs using the overall ATAC-Seq signals. For individual chromatin regions both increased and decreased chromatin compaction is observed. Our results show that with the iN method it is now possible to generate neuronal cells directly from adult human fibroblasts, in which a defined genetic lesion will lead to a well-observable molecular phenotype. For 22q11.2 Deletion Syndrome, we present gene-by-gene effects of the deletion on gene expression in human neuronal cells as well as the observation that the deletion also affects a critical level of the epigenomic regulation of gene activity.

Next-generation mapping, a highly sensitive and accurate method for interrogation of clinically relevant structural variation. *A. Hastie, A.W. Pang, J. Lee, T. Anantharaman, W. Andrews, M. Saghbini, H. Cao.* BioNano Genomics, San Diego, CA.

   Structurally complex loci underlie many diseases. These loci can be very challenging to resolve by currently available methods such as karyotyping, Arrays, PCR-based tests and next-generation sequencing (NGS). Next-generation mapping (NGM) using the BioNano Genomics Irys® System offers a high-throughput, genome-wide method, based on direct visualization of extremely long genomic fragments, able to interrogate genome structural variants (SVs) in the range of one kilobase pairs to hundreds of kilobase pairs. The Irys System uses extremely long range information to span interspersed and even long tandem repeats making it suitable for elucidating the structure and copy number of complex regions of the human genome, such as complex pseudogene and paralogous gene families. Clinically relevant regions often contain genes with paralogs and other complex repetitive structures complicating the interpretation of data and diagnosis of disease. We have used two hydatidiform mole cell lines (homozygous human cell lines) to simulate a diploid genome and measure sensitivity to homozygous and heterozygous SV detection. We found 87% sensitivity to heterozygous SVs and 99% sensitivity to homozygous SVs (2 kbp and up). We also present several examples of SVs at complex genetic loci by NGM, such as those made up of tandem repeats, paralogous gene families, and loci flanked by segmental duplications. Examples of variants at tandem repeats are tRNAs, kringle IV, and *D4Z4*. An important variable length tandem repeat is *D4Z4*, which is associated with facioscapulohumeral muscular dystrophy (FSHD). FSHD muscular dystrophy is strongly associated with a low copy number (< 10 units), occurring in 95% of FSHD cases. Copy number of tandem repeats is extremely hard to measure accurately with available methods, but we show that NGM using the Irys System can accurately measure the copy number of *D4Z4* as well as haplotype the repeat array and differentiate the gene from a paralog that occurs on another chromosome. A second class of complex SVs involves genes with paralogs such as amylase and *UGT2B17*, two genes whose copy number have been shown to be associated with human health. We demonstrate that NGM using the Irys System is proving to be a highly accurate and sensitive method for detection of clinically relevant SVs.

3157W

Mendeliome sequencing increases the diagnostic yield in patients with unexplained intellectual disability by 30% (a single center experience). *A. Rump[1], L. Mackenroth[1], A. Kahlert[1], J. Lemke[2], E. Krajcir[1], A. Kruger[1], F. Kuhlee[1], F. Stubner[1], A. Tzschach[1], E. Schrock[1], N. Di Donato[1].* 1) Institute for Clinical Genetics, Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany; 2) Institute for Human Genetics, University Clinic Leipzig, Leipzig, Germany.

   Introduction Advances in deciphering the genetic causes for impaired development have always been accompanied by advances in technology. In the past, array-CGH technology has boosted the detection rate significantly; but up to 50% of children with developmental delay still remain undiagnosed. Since the latest technological advance, next generation sequencing (NGS), has the power to improve the diagnostic yield tremendously, we applied this method to 57 index patients with developmental delay or intellectual disability (ID) and pre-excluded genomic imbalances. **Method** Genomic DNA samples of 28 parent-child trios plus 29 individuals were analyzed for mutations in 4813 genes, using the TruSightOne gene panel on the MiSeq platform (Illumina, San Diego, CA). After sequencing with median target coverage of 80-fold and mapping to hg19, sequence variants were called by two independent platforms: the GATK pipeline installed on the MiSeq and the CLC Biomedical Genomics platform (Qiagen, Hilden, Germany). All *de novo* variants, homozygous variants with heterozygosity in both parents and compound heterozygous variants were analyzed as well as hemizygous variants in male patients. These variants were screened for clinical und molecular concordance (i.e. disease-association of the gene, published mutation). In addition, all splice-relevant variants, all frameshift and nonsense-mutations were screened for clinical concordance. The results were discussed in a team of clinicians and molecular geneticists, relevant variants were validated by Sanger-sequencing. **Results** Using the mendeliome in a diagnostic setting, we established a diagnosis in 16 of the 57 index patients (28%). For seven further patients, we found one or two possibly causative candidates (13%). 5 patients (9%) showed incidental findings which either made treatment or surveillance necessary (homozygous MUTYH-mutations, SDHA-mutation) or led to an increased risk for a recessive disease in children (PAH- or CFTR-mutations). **Conclusion** Mendeliome next generation sequencing significantly increases the diagnostic yield in patients with ID unsolved by previous routine testing (array-CGH, conventional karyotyping). However, variant interpretation remains challenging and requires standardized procedures for using the new technology in a standard diagnostic setting.

RNA-seq, an important tool do discover non-exonic disease causing variants. *L. Kremer[1,2], D. Bader[3], C. Mertes[3], G. Pichler[4], T. Schwarzmayr[1], R. Kopajtich[1,2], A. Iuso[1,2], E. Konarikova[1,2], G. Kastenmüller[1], P. Lichtner[1], T. Strom[1,2], T. Meitinger[1,2], A. Lombes[5], D. Ghezzi[6], P. Freisinger[7], F. Distelmaier[8], J. Gagneur[3], H. Prokisch[1,2].* 1) Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany; 2) Institute of Human Genetics, Technische Universität München, Munich, Germany; 3) Computational Biology, Department for Bioinformatics, Technische Universität München, Munich, Germany; 4) Department of Proteomics and Signal Transduction, Max-Planck Institute of Biochemistry, Martinsried, Germany; 5) Inserm UMR 1016, Institut Cochin, Paris, France; 6) Unit of Molecular Neurogenetics, Foundation IRCCS, Institute of Neurology "Carlo Besta", Milan, Italy; 7) Department of Pediatrics, Klinikum Reutlingen, 72764 Reutlingen, Germany; 8) Department of General Pediatrics, University Children's Hospital, Heinrich-Heine-University Düsseldorf, 40225 Düsseldorf, Germany.

Whole exome sequencing (WES) has proven to be a valuable tool for genetic diagnosis and is therefore underway to be implemented at an early stage in the diagnostic algorithm of genetic disorders. Yet, in at least 50% of the patients WES does not reveal the disease causing variant and a significant part of these variants might be regulatory. In principle, whole genome sequencing (WGS) approaches allow the discovery of all variants, coding and non-coding. The drastically increased number of rare variants detected via WGS, however, makes variant prioritization and interpretation challenging. In order to study regulatory variants by means of expression outliers, abnormal splicing, or monoallelic expression we applied RNA sequencing in 96 fibroblast cell lines derived from mitochondrial disease patients from which 50% remained without a molecular diagnosis after WES. Some already underwent whole genome sequencing (WGS). A systematic analysis identified in each sample on average 7 monoallelic expressed variants, 8 expression outliers and about 4 splice defects. As an example, follow-up experiments of an expression outlier identified an intronic variant to create an additional exon. The new exon resulted in a frameshift and a premature stop codon which leads to the absence of the encoded complex I assembly factor. For systematic validation of regulatory variants we performed quantitative proteomics. In case of the complex I assembly factor defect proteomic analysis revealed global complex I reduction, which was partially rescued upon lentiviral transduction of the wildtype allele. In another sample monoallelic RNA expression resulted in significantly decreased protein level being less than 3%, confirming the causal role of this variant for the clinical presentation of the patient. In conclusion, we show that detection of expression outliers, abnormal splicing and monoallelic expression by RNA-seq can unravel non-exonic pathogenic variants. By this approach we already provided a genetic diagnosis for 10% of unsolved WES cases. Validation of further candidates is ongoing. .

3159F

Rapid, single cell RNA-Seq from mature auditory hair cells. *P.T. Ranum[1], A.M. Sheffield[2,3], A.T. Goodwin[2], H. Liu[4], D.Z.Z He[4], R.J.H Smith[1,2,3].* 1) Interdisciplinary Graduate Program in Molecular & Cellular Biology, The University of Iowa Graduate College, University of Iowa, Iowa City, IA 52242, USA; 2) Molecular Otolaryngology and Renal Research Laboratories, Carver College of Medicine, University of Iowa, Iowa City, IA 52242, USA; 3) Department of Otolaryngology, Head and Neck Surgery, Carver College of Medicine, University of Iowa, Iowa City, IA 52242, USA; 4) Department of Biomedical Sciences, Creighton University School of Medicine, Omaha, NE 68178, USA.

Auditory hair cells are critical mechanosensory cells at the heart of the auditory system. The presence of healthy hair cells is a prerequisite for hearing function and their absence underlies many forms of deafness. Recent advances in ultra-low input RNA-Sequencing (RNA-Seq) technologies have enabled transcriptome profiling and pathway analysis of auditory hair cells. These experiments have the potential to provide novel insight into how hair cells respond to damaging insults and may allow us to identify pathways for drug development to prevent hair cell death. Here we describe the unpublished results of our work toward the development of a rapid and affordable single cell RNA-Seq protocol that can be used to isolate and characterize the transcriptomes of rare cell types like auditory hair cells. We have performed this protocol on mouse inner and outer auditory hair cells at P15 (the onset of hearing), P35, and P70 timepoints. Our data robustly differentiate between inner and outer hair cell types, and demonstrate the expected transcriptional variability between single cells. We have also sequenced groups of pooled cells to determine how cell number impacts transcript detection sensitivity and biological variation. We utilized pool/split and ERCC spike-in controls to assess and differentiate between biological and technical variation between samples. The resulting datasets provide a wealth of temporal and cell-type specific information about mature auditory hair cells. This information provides a foundation for studies designed to map the molecular pathways of auditory hair cells in disease states with the goal of identifying pathways that can be targeted to preserve hearing function.

3160W

A custom targeted next generation DNA sequencing capture panel for age-related macular degeneration. *R. Torene[1], F. Yang[1], Y. He[1], M. Sultan[2], T. Schlitt[2], A. Fernandez[2], C. Wache-Mainier[2], T.M. Morgan[1], J. Laramie[1], L. Ferrara[1], M. Roguska[1], J.F. Reilly[1], T. Dryja[1], P. Zamiri[1].* 1) 250 Massachusetts Avenue, Novartis Institutes for BioMedical Research, Cambridge, MA, USA; 2) Fabrikstrasse 2, 4056, Novartis Institutes for BioMedical Research, Basel, Switzerland.

   Purpose: Age related macular degeneration (AMD) is the leading cause of legal blindness in the developed world. Early AMD, characterized by accumulation of drusen, often progresses to either neovascular AMD or geographic atrophy (GA), affecting about 1 million people in the US, and millions more worldwide. Twin studies have demonstrated a significant genetic influence, but whole genome sequencing is not yet cost-efficient. Thus, we designed an NGS hybridization capture solution to comprehensively identify variants related to AMD and applied it to 486 patients with GA.   **Methods:** We targeted the exons and flanking sequence for 68 loci known to be associated with AMD risk, AMD progression, or response to AMD therapies, as well as complement genes. Sequencing was performed using an Agilent SureSelect custom capture approach with 10,698 probes covering 693 kb of sequence. The captured DNA was then sequenced using the Illumina HiSeq 2500 platform. DNA from 486 patients with GA were sequenced with an average read depth in targeted regions of about 50X and concordance with TaqMan candidate SNP genotyping of >99.5%.   **Results:** The targeted NGS data were used to calculate polygenic risk scores (PRS) based on 19 SNPs previously implicated in AMD by GWAS. The PRS was significantly higher in the patients with GA than in individuals without AMD ($p < 0.01$). We also used the AMD targeted panel to identify carriers for Stargardt's variants in the *ABCA4* gene. Although these patients can have an AMD-like phenotype, they may not respond to therapies that target AMD. Many of the GA patients were carriers for Stargardt's-associated variants. Besides these known variants, we identified rare (< 1% allelic frequency in 1000 Genomes) variants in *ABCA4* and other AMD relevant genes that are predicted to be damaging to the protein product. It remains to be determined whether these rare variants impact GA progression or treatment response.   **Conclusion:** We designed a targeted sequencing panel to enable cost-efficient (approximately $200/sample) genotyping of known variants as well as novel or rare variants in clinical trials. The data generated by this panel can be used for a variety of analyses to better understand AMD incidence, progression, and response to therapies.

3161T

Recommendations for best practices for genomics knowledge management in a cloud-based contextual knowledge hub. *X. Xu, J. Hull, J. Cohen, W. Fields, P. George, M. Kaganovich, D. Gross, D. Caplan.* SolveBio, New York, NY.

   Purpose: Next generation sequencing and other high throughput data generation technologies has lead to an explosion in the breadth and quantity of experimental and curated reference data. These datasets should be actionable assets and provide valuable insight into research and clinical questions. However, the lack of systems and technologies to index, standardize, and share data, as well as robust visualization and analysis platforms, results in analysis inefficiencies. For example, a highly trained clinical geneticist currently requires 54 minutes to interpret the the clinical significance of a single variant (Dewey 2014). This analysis and interpretation inefficiency is the major bottleneck in the NGS pipeline and is a serious barrier to the promise of precision medicine. The purpose of this project was to reduce the data use burden for geneticists, translational scientists, bioinformaticians, and clinicians. **Methodology**: We have created a cloud-based contextual knowledge hub that indexes structured and unstructured genomics data from publicly available databases, commercial data providers, and private user-generated sources. The hub implements many best practices for data management, including, but not limited to, data versioning and dating, fully documented data provenance, harmonization for content and field types. Additionally we have created a browser interface and an application programming interface (API) so that the data is accessible to a wide scope of users; from scientists to clinicians to enterprise software engineers. **Results & Future Directions**: As of June 2016, the knowledge hub has integrated 71 publicly available data sources into 1.39 billion independent records and 33.7 billion datapoints into one single platform. Here, we present our recommendations for best practices, current models, and technical and logistical challenges involved in genomics data integration and sharing. Our future efforts will focus on lowering the data integration barrier to allow for more serendipitous encounters between previously silo'ed data repositories to advance genetics research and development and clinical genetics.

Identification of novel pathways linked to Bardet-Biedl Syndrome (BBS) using a multi-omic strategy to implement biomarker discovery. *R. Davies[1], D. Kelberman[1], G. Otto[1], F. Minnecci[1], J. Gratton[1], J. Kenny[1], G. Madhan[1], X. Wang[1], S. Dowle[1], T. Peltola[2], T. Tukiainen[2], S. Kaski[2], C. Bacchelli[1], P.L. Beales[1].* 1) National Institute for Health Research Biomedical Research Centre at Great Ormond Street Hospital for Children, NHS Foundation Trust and University College London Institute of Child Health, London, UK; 2) Helsinki Institute for Information Technology HIIT, Aalto University, Helsinki, Finland.

Genetic diagnosis of rare diseases has accelerated exponentially over the last 5 years due to the advent of advances in next generation sequencing technologies. It is estimated that by 2020 the genes known to cause most remaining undiagnosed genetic disorders will be identified. Despite this, development of successful therapeutic methods for both rare and common disorders has lagged behind the pace of genetic diagnostics. One factor that must be taken into account is that every individual is unique, and that looking one-dimensionally at the genome alone will provide limited information on the underlying pathobiology. To overcome the complexity of this challenge, we have established a multi-dimensional deep phenotyping framework implementing whole genome sequencing, RNA-sequencing, and targeted proteomic and metabolomic assays, combined with clinical phenotype information as a novel strategy for the study of rare diseases.Bardet-Biedl Syndrome (BBS) is a rare autosomal recessive pleiotropic disorder, characterised by loss of vision, obesity, renal dysfunction, learning difficulties and hypogonadism. This multi-system phenotype is caused by defects in genes involved in ciliogenesis and intraflagellar transport, the proteins of which localize to the primary cilia. We have obtained disease relevant tissue, including models derived from induced pluripotent stem cells, from a defined set of clinically well-characterised BBS patients. These individuals all harbor the same underlying diagnosed variant (*BBS1* c.1169T>G/p.M390R) but exhibit considerable phenotypic heterogeneity in their clinical presentation.Through RNA-sequencing of patient fibroblasts we have uncovered over 4000 differentially expressed genes leading to the identification of multiple pathways involved in cell metabolism, maintenance and signaling that are disrupted in BBS patients compared to controls. Integrated burden testing, using variants identified by whole genome sequencing, has revealed genetic variation in distinct ciliopathy related pathways that contribute to the overall mutational load of the disease. As a result, we have devised a disease-specific multi-dimensional molecular map, featuring integrated data from the phenome, genome, transcriptome, proteome and metabolome. This wealth of rich information has provided us with exciting new avenues, in which we can discover novel therapeutic targets, and define biomarkers that can be implemented to predict and pre-empt the onset of disease.

3163W

Ultra-sensitive droplet digital PCR for detecting a low-prevalence somatic *GNAQ* mutation in Sturge-Weber syndrome. *Y. Uchiyama[1,2], M. Miyajima[3], M. Masataka[4], M. Nakashima[1], N. Matsumoto[1].* 1) Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan; 2) Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Gunma; 3) Department of Neurosurgery, Juntendo University Graduate School of Medicine, Tokyo, Japan; 4) Department of Biostatistics, Graduate school of Medicine, Yokohama City University, Yokohama, Japan.

Droplet digital PCR (ddPCR), a method for detecting DNA quantity, is useful for determining somatic mutation rates utilizing TaqMan probes. In this study, the detection limit of copy numbers of genomic DNA by ddPCR was determined based on Poisson distribution. Peptide nucleic acid (PNA), which strongly hybridizes to target lesions, can inhibit target amplification by PCR. Therefore by combination of PCR with PNA and ddPCR (PNA-ddPCR), detection limit could be lowered. We revisited a somatic *GNAQ* mutation (c.548G > A) in patients with Sturge-Weber syndrome (SWS) using ddPCR and PNA-ddPCR. Importantly among three mutation-negative patients by previous next generation sequencing, two patients had the *GNAQ* mutation with less than 1% of mutant allele frequency. We also confirmed the same *GNAQ* mutation in three blood samples and one saliva sample. These data clearly indicates that ultra-sensitive method should be utilized in detecting the low-prevalence somatic *GNAQ* mutation in SWS.and that the mutation is derived from the mesoderm.

3164T

The first 200 diagnostic whole genome sequencing referrals from Australia: Results and recommendations. *T. Roscioli[1,2,4,5], M. Buckley[1,2,3], P. Budd[1,2], L. Burnett[1,2,3], L. Constantinescu[1,2], J. Copty[1,2], M. Cowley[1,2], M. Dinger[1,2], L. Ewans[1,2], M. Gonzalez[1,2], V. Gayevsky[1,2], T. Groza[1,2], W. Kaplan[1,2], M. Lubka-Pathak[1,2], B. Lundie[1,2], J. Mattick[1,2], S. Mead[1,2,3], A. Minoche[1,2], M. Pinese[1,2], D. Saroufim[1,2], D. Schofield[2,6,7], A. Statham[1,2], J. Stockmyer[1,2], B. Terrill[1,2], K. Ying[1,2].* 1) Garvan Institute of Medical Research; 2) The Kinghorn Centre for Clinical Genomics (KCCG) at the Garvan; 3) SEALS Genetics, NSW Health Pathology Service; 4) St Vincent's Clinical School, University of New South Wales, Australia; 5) Department of Medical Genetics, Sydney Children's Hospital, Australia; 6) Murdoch Children's Research Institute, Australia; 7) Faculty of Pharmacy, the University of Sydney, Australia.

Background**:** The Kinghorn Centre for Clinical Genomics (KCCG) was recently accredited for diagnosing germline pathogenic variants using the Illumina HiSeq X-Ten whole genome sequencing (WGS) system, as the first facility in the Southern hemisphere. Aims**:** To describe the results of diagnostic WGS in childhood and adult Mendelian disorders, summarise analysis methodologies and provide recommendations to maximize the utility of clinical referrals. Subjects and Methods**:** Referrals were submitted from clinical geneticists and non-genetic physicians working with genetic counsellors, including families with adult-onset movement disorders, intellectual disabilities, cardiomyopathies and immunodeficiencies. 200 consecutive samples were assessed at the KCCG diagnostic genomic facility. Sequencing libraries were prepared using Illumina TruSeq DNA preparation kits, robotic instrumentation, and sequenced on Illumina HiSeqX sequencers with 2x150bp reads, equivalent to an average genome-wide coverage of >30x, with 95% of the genome covered to >20x depth. Raw sequencing reads were aligned to the genome using BWA-MEM with SNVs and indels identified using GATK HaplotypeCaller, filtered with the Seave system and reported by genomic pathologists. Results**:** The overall diagnostic rate was 50% with the largest phenotype group, Intellectual Disability having likely causative pathogenic variants identified in 54%, skewed to *de novo* events. The majority of successful gene diagnoses were in trio-based analyses confirming additional utility from testing family units. Requests for specific single gene analyses extracted from WGS did not result in diagnostic findings also confirming that a broader panel or whole genome approach is most valuable. A number of unsuspected genomic findings altered clinical diagnoses, confirming the combined utility of a clinical genomic classifications. Extending the diagnostic pipeline to copy number variant analysis will be discussed.

5-day Rapid Paediatric Sequencing (RaPS) for rare disease gene identification in children on the Paediatric Intensive Care Unit at Great Ormond Street Hospital (GOSH). *H.J. Williams[1], S. Drury[2], L. Ocaka[1], C. Bacchelli[1], L. Jenkins[2], L.S. Chitty[2], M.J. Peters[3], P.L. Beales[1], GOSgene.* 1) UCL Institute of Child Health, London, United Kingdom; 2) NE Thames Regional Genetics Laboratory, Great Ormond Street Hospital, Barclay House, 37 Queen Square, London; 3) UCL Institute of Child Health and Great Ormond Street NHS Foundation Trust, London, United Kingdom.

The use of Whole Genome Sequencing (WGS) for the identification of genes that cause rare diseases is well documented. We sought to evaluate the utility of WGS in a clinical setting that is likely to benefit greatly from a rapid genetic diagnosis and to this end we have highlighted the Paediatric Intensive Care Unit (PICU) at Great Ormond Street Hospital (GOSH). In the first instance, we aimed to deliver a turnaround time, from sample ascertainment to candidate variants of potential clinical significance, in under a week. For the pilot project we have identified 10 patients (run as family trios) from the PICU ward that have an immediate clinical need, present with a phenotype of suspected genetic etiology and for whom the rapid identification of a causative gene could have a positive impact on clinical management. Our Rapid Paediatric Sequencing (RaPS) pipeline begins with notification from a senior clinician on PICU of a suitable case that has consented to the study. We next collect blood samples which undergo rapid DNA extraction and WGS library preparation within the accredited diagnostic laboratory at GOSH. Here the sequencing takes place on an Illumina Hiseq (proband) and Nextseq (pooled parents) both on rapid-run mode. The resulting sequence data is analysed by GENALICE using their propriety software to map and call variants. Interpretation of the data utilises QIAGEN Ingenuity Variant Analysis software. Our pilot project data has shown we are able to return actionable findings to the PICU clinicians within 5 days of the initial consent. Of the 10 patients processed as part of this pilot we have identified 3 patients with a gene known to cause the underlying disease and 2 patients with genes that are novel candidates for the disease. In the remaining 5 patients we have so far been unable to identify any actionable variants.

3166W

Whole exome sequencing re-analysis boosts diagnosis in Mendelian disorders: Recommendations for laboratory practice. *L.J. Ewans[1,2], M.J. Cowley[1,2], Y. Zhu[3], V. Gayevskiy[1], K. Ying[1], C. Walsh[4], E. Lee[4], E. Kirk[4,5,6], A. Colley[7], A. Turner[5,6], D. Mowat[5,6], L. Worgan[7], M-L. Freckmann[5,6], R. Sachdev[5,6], M. Field[3], D. Miller[1], P. Morris[1], M. Buckley[4], M.E. Dinger[1,2], T. Roscioli[1,2,5].* 1) Kinghorn Centre for Clinical Genomics, Garvan Institute of Medical Research, Darlinghurst, New South Wales, Australia; 2) St Vincent's Clinical School, University of New South Wales, Darlinghurst, Australia; 3) Newcastle GOLD Service, Hunter Genetics, Waratah, NSW, Australia; 4) SEALS laboratory, Prince of Wales Hospital, Randwick, NSW, Australia; 5) Department of Medical Genetics, Sydney Children's Hospital, Randwick, NSW, Australia; 6) School of Women's and Children's Health, University of New South Wales, Australia; 7) Clinical Genetics Department, Liverpool Hospital, NSW, Australia.

   Background: Mendelian disorders are clinically and genetically heterogeneous making them ideally suited to diagnosis through whole exome sequencing (WES). Diagnostic potential is estimated to be between 25-30%, with re-analysis of data proposed to improve the diagnostic success.   Aims: To assess the diagnostic potential of WES in a Mendelian cohort with comparison to subsequent re-analysis at a 12 month time point.   Methods: WES was performed in a cohort of 54 patients from 37 families with unsolved Mendelian disorders in which there had been extensive prior investigation. The majority of patients presented with intellectual disability, with the remaining diagnoses including: skeletal dysplasias, retinitis pigmentosa, haematological disorders, seizures, metabolic disorders, and dysmorphic syndromes. WES data from Illumina HiSeq 2500 sequencers was filtered using the GEMINI (Genome MININg) software underlying the in-house SEAVE platform. The most likely inheritance model was applied to each family and further filtering was performed using pathogenicity scoring systems such as CADD (Combined Annotation Dependent Depletion) to assist prioritization of disease-causing mutations. Re-analysis was performed at a 12 month time point with an improved clinical interpretation pipeline.   Results: Initial analysis of WES data identified a diagnosis in a known disease gene in 30% (11 of 37 families) of the cohort. Following subsequent re-analysis, this improved to 38% (14 of 37 families). This was due to interim novel gene discovery, extended phenotype information, and improvements to the clinical interpretation pipeline.   Discussion: The diagnostic success of WES in Mendelian disorders is significantly improved with re-analysis of data at a 12 month time point. Recommendations for clinical interpretation pipelines include: obtaining accurate phenotype information, use of in-house databases of variants, updated variant prioritisation tools including gene annotation and incorporation of population data, and collaboration between referring clinicians and laboratories. It is also recommended that resources are provided to ensure re-analysis of historical genomic data to maximize diagnostic utility.

Multi-omic approaches towards personalised medicine for rare diseases. *D. Kelberman[1,2], G. Otto[1,2], F. Minneci[1,2], R. Davies[1,2], J. Gratton[1,2], J. Kenny[1,2], G. Madhan[1,2], X. Wang[1,2], S. Dowle[1,2], T. Peltola[3], T. Tukiainen[3], S. Kaski[3], N.J. Sebire[1,4], L.R. Wedderburn[1,4], K. Nistala[1,4], N. Shah[4], J. Kammermeier[1,4], K. Pritchard-Jones[1,4], W. Mifsud[1,4], J.C. Sowden[1], M. Bitner-Glindzicz[1], S. Rahman[1,4], G.E. Moore[1], C. Bacchelli[1], P.L. Beales[1,2].* 1) UCL Institute of Child Health, University College London , London, United Kingdom; 2) National Institute for Health Research Biomedical Research Centre at Great Ormond Street Hospital for Children NHS Trust, London, UK; 3) Helsinki Institute for Information Technology HIIT, Aalto University, Helsinki, Finalnd; 4) Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK.

   Large genetic sequencing programmes for Mendelian diseases are underway internationally, but these only address the genomic landscape in a single dimension; that of defining disease-causing variants. Patients affected by rare diseases and carrying the same primary genetic defect can markedly vary in their expression of clinical phenotypes or response to therapies. We have established a new programme of research to address a major challenge in understanding how other genomic variants and non-genetic factors influence disease variability. This pilot project has developed strategies to investigate the basis of variability in human disease, initially in a select number of rare diseases with clinically well characterised patients. Selected diseases include: Bardet Biedl syndrome, Juvenile Dermatomyositis, Wilms' tumour, very early onset inflammatory bowel disease, Usher syndrome, mitochondrial disease and Silver Russell syndrome. Using multiple technologies including whole genome and RNA sequencing, mass spectrometry and targeted proteomic and methylation assays, we have undertaken in depth phenotyping at the molecular level to identify variation in coding and non-coding RNA, protein, metabolites and epigenetic factors measured in disease relevant tissues in conjunction with genetic variation. Initial preliminary investigations of individual datasets for specific projects have highlighted a number of cellular pathways that can be further explored for their role in disease pathology or in response to particular therapies. Following the initial analysis of individual omics data, the combined integration of these multi-omic datasets with clinical information within patient subgroups will allow the identification of biomarkers to assist in the prediction of disease severity, risk of developing specific complications, and/or stratify patients for appropriate or novel therapies depending on the disease in question. It is expected that the methodological strategies being developed will also offer the opportunity to show proof of principle for a broader range of applications as well as the better understanding of the molecular pathology of disease. This will suggest new avenues or targets and markers for the most efficacious treatments in a move towards stratified or personalised medicine for rare diseases.

3168F

Identification of age-related patterns in human extracellular RNA in serum. *D.F. Dluzen[1], S. De[2], W.H. Wood[2], K.G. Becker[2], A.B. Zonderman[1], T. Tanaka[3], L. Ferrucci[3], N. Noren Hooten[1], M.K. Evans[1].* 1) Laboratory of Epidemiology and Population Sciences, National Institute on Aging, NIH, Baltimore, MD; 2) Laboratory of Genetics, National Institute on Aging, NIH, Baltimore, MD; 3) Translational Gerontology Branch, National Institute on Aging, NIH, Baltimore, MD.

   Extracellular RNA (exRNA), circulating in the blood, have been identified and used as markers for human development, aging and disease. However, these studies have been limited in scope, either by profiling one subtype of RNA species (e.g. microRNA [miRNA]) or profiling RNAs of a particular transcript size (e.g. small or large). Here, we have sequenced both large and small RNAs from human serum under one comprehensive analysis within the context of normal aging. We hypothesized that age-related changes in exRNAs are important for normal aging and age-related degenerative processes. Total RNA was isolated from serum from young (30-35 yrs) and old (80-85 yrs) African American females chosen from the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study or the Baltimore Longitudinal Study of Aging (BLSA). Total RNA-seq was performed on the Ion Torrent Proton and sequences were aligned against the human genome version 19 using separate protocols to identify linear RNA, miRNA, or circular RNA (circRNA). There was an average of 9 million reads per individual. We identified mRNA, miRNA, long non-coding RNAs (lncRNA), small nucleolar RNA (snoRNA), ribosomal RNA (rRNA), transfer RNA (tRNA), circRNA, and Y RNA transcripts. The total number of unique RNA transcripts varied by individual; however, the percentages of each transcript subtype were similar. In general, the distribution of highly abundant mRNAs was more variable in older individuals. There were a number of shared mRNAs, e.g. *NOTCH2NL*, which were abundant in both young and old. We sequenced 458 unique miRNAs throughout the entire cohort, 94 of which are present in every individual. 95 miRNAs were unique to only older individuals and 74 were present only in young. There were significant age-dependent changes in serum abundance of *C19orf48* (mRNA), *MTND1P23* and *SNHG10* (lncRNA), *SCARNA5* (snoRNA), *RNA5SP338* (rRNA), and several miRNAs, including miR-16, -191, -26a, -24, -21, and let-7g. Pathway analysis revealed that the top pathways associated with exRNAs profiled in old individuals was oxidative phosphorylation and mitochondrial dysfunction. We will examine the relationships between the identified RNA species and nutritional, physiological, psychosocial, and cognitive parameters in order to identify novel, age-related circulating RNA biomarkers and related regulatory pathways.

Construction of a highly efficient platform CNVplex for the detection of chromosomal aneuploidies. *L. Haibo[1], X. Jingjing[1], W. Ting[1], L. Hong[1], M. Jun[1], Z. Qin[1], L. Minjuan[1], L. Yinghua[1], J. Zhengwen[2], L. Deyuan[2].* 1) Center for Reproduction and Genetics, Suzhou Municipal Hospital, Suzhou, JiangSu, China; 2) Genesky Diagnostics (Suzhou) Inc., SIP, Suzhou, JiangSu, China.

   Chromosomal aneuploidies was an important reason for miscarriage at the early stage of pregnancy, and chromosome karyotype analysis of chorionic villi could provide valuable information for genetic counselling and prenatal care in future pregnancies. A novel technique CNVplex was developed by modifying the multiplex ligation-dependent probe amplification (MLPA) method. 170 pairs of probes were designed for 24 human chromosomes, and each chromosome contains at least 5 pairs of probes. Each probe is composed of a oligonucleotide complementary to the target sequence and the universal sequence to allow PCR amplification with the fluorescent primer pairs. After hybridization, ligation and multiple PCR amplification, the amplified products were separated by size and color using capillary electrophoresis, and the relative amount of target sequences were calculated according to the amount of PCR products. 236 samples of chorionic villi with chromosomal abnormalities determined by karyotype analysis and MLPA in our center before were selected and re-analyzed by CNVplex. Except for 19 samples which could not be analyzed by CNVplex, including 5 samples with quality problems and 14 samples with polyploidies or chromosome structural abnormalities, the detection rate of chromosomal aneuploidies by CNVplex is 92.4%, which is higher than that of karyotype analysis (56.4%) and MLPA (67%) (p<0.01). In conclusion, CNVplex is more sensitive and efficient in the detection of chromosomal aneuploidies than karyotype analysis and MLPA, and it could be applied clinically as an alternative to MLPA.

3170T

High accuracy genotyping with duplex sequencing. *J.C. Roach[1], D. Mauldin[1], M.J. Hipp[2], E. Smith[2], G. Glusman[1], S.R. Kennedy[2].* 1) Family Genomics, Institute for Systems Biology, Seattle, WA; 2) Department of Pathology, University of Washington, Seattle, WA.

   Identifying needles in haystacks has become increasingly important for genomic applications. As technical accuracy of key technologies increases, the size and complexity of the haystacks we may search also increase. False discovery rates are a limiting factor in high-throughput genomic pipelines, as these ultimately bottleneck at procedures performed by humans. Increases in technical accuracy lead to decreases in false discovery rates. For gene- and marker-level applications (e.g., STS marker searches for a classic disease), technical accuracy must reach ~1:500 to reduce a domain of ~20,000 genes to tens of candidates. For genome-level applications such as identification of a rare detrimental SNV responsible for a birth defect, technical accuracy must reach ~1:5,000. This is the typical accuracy of current high-throughput sequencing, and has resulted in the explosion of disease-variant identifications in the last half decade. False discovery rates are particularly poignant in forensic applications — they may lead to false convictions. We now have the opportunity, and the need, to look for needles in a haystack, where the haystack may be any haystack on the planet. Applications include identification of variants in stem cells within anlages of developing tissues, tumor subclones that are possible keys to cures, and traces of a sexual criminal diluted in other genomes. Each of these applications involves computational dissection of mixtures of DNA. If technical error is higher than the fraction of a mixture DNA component, it becomes difficult or impossible to recognize and distinguish component genomes in mixtures. Current mass-marketed sequencing technologies cannot distinguish trace genomes mixed with other genomes in excess. Duplex Sequencing is designed to decrease uncorrected technical error, and enables analysis of complex trace mixtures. Duplex Sequencing assays each strand of DNA independently. The two strands of dsDNA are labeled and separated before amplification and sequencing. The same technical error must occur on both strands in order to avoid detection and correction. Duplex Sequencing offers the ability to accurately detect a minor allele fraction of ~1:50,000, extending the reach of sequencing to previously intractable challenges in stem-cell biology, oncology, and forensics. We are developing protocols to apply Duplex Sequencing to problems in forensics, including the analysis of degraded samples and complex mixtures of multiple genomes.

Sasaki[3,7].* 1) Division of Biomedical Information Analysis, Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Nishitokuta, Yahaba, Shiwa, Iwate 028-3694, Japan; 2) Division of Biobank and Data Management, Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Nishitokuta, Yahaba, Shiwa, Iwate 028-3694, Japan; 3) Iwate Tohoku Medical Megabank Organization, Disaster Reconstruction Center, Iwate Medical University, 2-1-1 Nishitokuta, Yahaba, Shiwa, Iwate 028-3694, Japan; 4) Department of Neurosurgery, School of Medicine, Iwate Medical University, 19-1 Uchimaru, Morioka, Iwate 020-8505, Japan; 5) Department of Internal Medicine, School of Medicine, Iwate Medical University, 19-1 Uchimaru, Morioka, Iwate 020-8505, Japan; 6) Department of Anatomy, Iwate Medical University, 2-1-1 Nishitokuta, Yahaba, Shiwa, Iwate 028-3694, Japan; 7) Division of Ultrahigh Field MRI, Iwate Medical University, 2-1-1 Nishitokuta, Yahaba, Shiwa, Iwate 028-3694, Japan; 8) Division of Biomedical Information Analysis, Iwate Medical University, 2-1-1 Nishitokuta, Yahaba, Shiwa, Iwate 028-3694, Japan.

   PURPOSE: In genome cohort studies, accurate omics information that comprises SNPs, DNA methylation (DNAm) rates, and gene expression levels is often not provided mainly owing to omics status is physically unstable, differs among cell types, and changes over time. Thus, we attempted to establish optimized blood sampling protocols for omics analyses that can be used in genome cohort studies. METHODS: To examine the influence of sample collection/transportation methods on the stabilities of DNAm and RNA, we extracted DNA and RNA from blood specimens processed by multiple protocols such as with/without nucleic acid stabilizer, using different blood collection tubes, extraction methods, and transportation conditions, and then measured DNAm rates using DNA microarray and expression levels using next-generation sequencer. Second, to optimize cell-sorting protocols, cells were sorted using various cell separation solutions, collection tubes, and cell sorters, and we then examined the amount and purity of nucleic acids of the sorted specimens. Third, to evaluate the effect of time on omics variations, we withdrew blood from 2 volunteers 24 times for 3 months, and then measured the DNAm rates using DNA microarray and expression levels using next-generation sequencer. We also measured body temperature, blood count, and high-sensitivity C-reactive protein. RESULTS: We found that the refrigerated transportation of the blood cells purified immediately after blood withdrawal and containing cell solubilizer (Promega, Madison, WI, USA) was the most stable method for RNA measurements. We also confirmed that DNAm conditions were altered during specimen processing and transportation, mainly owing to variations in cell composition, which can be normalized by estimating the cell ratios in the samples. For cell sorting methods, we readily purified various blood cells through the combined use of the CPT Tube (BD Biosciences, Franklin Lakes, NJ, USA), Mono-Poly Resolving Medium (DS Pharma Biomedical, Osaka, Japan), and SH800 cell sorter (SONY, Tokyo, Japan). Regarding chronological changes, we found substantial variations in the expression levels of some genes, but verified that most DNAm sites were stable for several months and showed approximately 2% temporal variations. CONCLUSION: We established optimized protocols for collecting and transporting blood samples to improve the precision of DNA methylation and RNA analyses in genome cohort studies.

GRIN (Genomic Research and Innovation Network): A sustainable infrastructure for pediatric data sharing. *K.L. Sund[1], S. Biswas[2], M. Heinz[3], T. Glauser[1], K.D. Mandl[3], I. Krantz[2].* 1) Cincinnati Children's Hospital, Cincinnati, OH; 2) Children's Hospital of Philadelphia, PA; 3) Boston Children's Hospital, MA.

The most significant barrier to research in pediatric personalized medicine is the ability to identify sufficiently large patient cohorts with in depth, consistent phenotyping and genotyping, coupled to the computing capabilities to correlate and interpret information to advance discovery and improve care. The extreme phenotypes found in pediatric patients represent a tremendous opportunity to understand many aspects of disease, but the first step is to confirm a correlative relationship between phenotype and the underlying genomics. The Genomic Research and Innovation Network (GRIN) is a collaborative effort between 3 pediatric institutions: Boston Children's Hospital, Children's Hospital of Philadelphia and Cincinnati Children's Hospital. The vision is to accelerate genomic discoveries in pediatric populations by creating a collaborative data sharing network at the institutional level. A key principle of the network is the collective ability of our centers to pursue well-designed, carefully selected research studies through broad sharing of genetic/genomic data associated with well-characterized phenotypic information and to link this data to a federated biobank of specimens. The team approach will also make it possible to leverage the strongest expertise for any given phenotype to improve interpretation and meaningful functional research studies. GRIN is currently piloting collaborative studies across the three sites to demonstrate feasibility of data sharing between pediatric centers. Simultaneously, we are developing the necessary regulatory, legal and bioinformatics infrastructure to scale to multiple diverse projects at an institutional level. GRIN infrastructure includes aligned institutional enrollment protocols, cloud-based data sharing and a portal to query a virtual biobank/data bank to for biospecimens and genomic data related to specific variants or phenotypes. To sustain this collaborative effort over time, the GRIN has developed a strategic model to use this existing infrastructure to engage appropriate industry partners in a service model. Such engagement will enhance pediatric academic research over time so that we can foster advances in phenotype-genotype interpretation and translation to patient care. GRIN will bring a much-needed pediatric focus to cohort expansion, genomic data sharing, interpretation, and matching expertise across existing and future member institutions with the ultimate goal to improve clinical outcomes. .

3173T

Targeted sequencing using advanced molecular inversion probes (MIPs) for discovery and validation in Mendelian disease trios. *S. Suresh, K. Jefferson, H. Halvensleben, D. Green, R. Bannen, M. Brockman, T. Richmond, D. Burgess.* Roche NimbleGen, Madison, WI.

Progress in understanding the genetic components of human diseases has been bolstered by next-generation targeted sequencing technologies. Emerging techniques that promise to improve throughput, cost and turnaround time include molecular inversion probe (MIP)-based methods, which enable rapid and simple workflows to detect sequence variation in inherited disease and cancer. We have developed a streamlined HEAT-Seq targeted enrichment assay, for variant discovery and validation. It utilizes advanced versions of MIPs with unique molecular identifiers incorporated into probes to identify PCR duplicates, improve sensitivity, and reduce false-positive calls. Previous studies using MIPs failed to address a key barrier to the widespread adoption of this technology, e.g., the difficulty of designing probes and probe-sets that yield uniform sequence coverage over the target. We addressed this issue by developing an empirical database-driven approach. All of the probes in the database have been assigned empirically derived performance scores. Consideration of individual probe performance in the design process allows generation of custom probe sets which typically produce more uniform coverage relative to previous methods. The efficiency of our approach was validated using three HEAT-Seq gene panels targeting cancer and inherited disease. Our analyses indicate improved performance compared to previous methods for two important metrics: (1) percentage of functional probes in the initial probe-set, and (2) sensitivity of SNP detection. The data suggest HEAT-Seq target enrichment system is an efficient, sensitive and cost-effective tool for targeted sequencing. To demonstrate the efficacy of HEAT-Seq target enrichment assay for identifying genetic variants in Mendelian disease, we studied two trios segregating rare autosomal recessive neurological disorders: Ataxia Telangiectasia (AT) and Familial Dysautonomia (FD). The AT mutation is a G>A coding mutation in exon 55 of *ATM*. The FD mutation is a T>C transition in a splice acceptor of *IKBKAP*. The mutations in both trios were previously described. We characterized the samples using both a large gene HEAT-Seq discovery panel that included *ATM* and *IKBKAP*, and a small validation panel that targeted only *ATM* and *IKBKAP*. The results show HEAT-Seq target enrichment system is a fast and cost-effective assay for identifying genetic variation for both discovery and genotyping/validation applications in Mendelian disease.

3174F

Human gene mapping: Historical review. *A.A. Khedr[1], S.A. Temtamy[2], M.A. Awadalla[3].* 1) Human CytoGenetics , National Research Center, Cairo, Egypt; 2) Clinical Genetics, National Research Center, Cairo, Egypt; 3) Pediatric& Genetics, Faculty of Medicine, Ain Shams University.

   The science of Human genetics can be rooted 1500 years ago where the blood disorder Hemophilia was mentioned in the Talmud. However, the idea concerning genetics really started with the work of M.G. Mendel in 1865**.** His work was only appriciated, following the indepedent work of W.S.Sutton & T. Boveri in 1902, who proposed the chromosome theory of heridity and the relation of those minute colored structures with the phenomenon of inheritance proposed by him. The science of human genetics witnessed the first revolutionary advance in its feild in late fifties by the assignment of the Duffy blood group gene on an autosome , however , it was untill early eghities when it was located to ch.1q12-21. Fudemamental to progress in molecular genetics was the discovery of restriction enzymes which became the scalpel for dissecting the human genome. The launching of the human gene mapping project aiming to sequence the entire 3 billion base pairs resulted in explosion of information that the entries of McKusick Catalogue of Mendalian Inheritance (MIM) increased from 1487 in the first edition in 1966 to 4500 in the 9th edition in 1990. After 50 years of his first edition,the OMIM entries are 23,528 to date. We aim to review updates in various methods of human gene mapping, starting from Linkage sudies through cytogenetics and FISH to the late advances in the molecular technology including methylation specific PCR(m-PCR), Multiplex ligation-dependent probe amplification (MLPA) CGH, Array CGH, Microarray CGH ; their principles, imporance, genetic significance, and the benifits they added to our knowledge of the human genome in general and to genetic disease in particular.

A novel sgRNA tagging technology identifies and addresses heritable clonal heterogeneity in CRISPR screens. *A. Biton[1,2,5], M. Boettcher[3,5], S. Covarrubias[3,5], J. Blau[3], H. Wang[4], N. Zaitlen[1], M. McManus[3].* 1) Department of Medicine, Lung Biology Center, University of California, San Francisco, San Francisco, California, USA; 2) Centre de Bioinformatique, Biostatistique et Biologie Intégrative (C3BI, USR 3756 Institut Pasteur et CNRS), Paris, France; 3) Department of Microbiology and Immunology, UCSF Diabetes Center, University of California, San Francisco, San Francisco, CA 94143, USA; 4) Departments of Medicine and of Microbiology & Immunology, the Rosalind Russell-Ephraim P. Engleman Medical Research Center for Arthritis, and the Howard Hughes Medical Institute, University of California, San Francisco, CA 94143; 5) These authors contributed equally.

   Functional genetic screens using CRISPR/Cas technology have become an invaluable tool to discover gene function in cell lines at a genome scale. However, it is still a nascent technology with complex and sensitive elements that remain unexplored. First, in order to obtain a cell line suitable for functional screens, a selection of a subclone with stable Cas9 expression is performed. This subclone is selected from an heterogeneous population of cells with varying levels of Cas9 expression that may introduce bias by responding differently to treatment. Second, screens can be performed using either Cas9 nuclease (CRISPRwt) for knockout mutations, or dCas9-KRAB (CRISPRi) for gene silencing. The comparison of the results of these two competing CRISPR systems has started but needs to be extended. Here, we performed a pooled genome-wide CRISPR screen for resistance to TRAIL-mediated apoptosis on Jurkat cell lines. A sgRNA library targeting most of the genes in the human genome by up to 12 sgRNAs was designed for the CRISPRwt and the CRISPRi system. The screen was run in each system on two subclones selected from the same starting population of cells. In this screen, we introduce a novel multi-level barcoding technology that enables the study of the screen at the subclonal level. The first level of barcoding allows to study the behavior of the four clonal lines across time, after they were mixed in a TRAIL-treated and an untreated vessel. We demonstrate that these clones have a heritable, but heterogeneous response to TRAIL: one sensitive and one resistant clonal cell. This phenomenon likely exists in other screens and is therefore both a source of power loss and bias. A second level of barcoding introduced during the sgRNA library PCR amplification allows us to distinguish between subclones carrying a same sgRNA. Our analysis of the pooled screen across time (cells were harvested at days 4, 9, and 14 after treatment) show that both CRISPR systems identify overlapping as well as mutually exclusive sets of gene hits. On the other hand, we observe that, within a same CRISPR system, results substantially differ between the two clonal populations. We demonstrate that the barcoding technology not only provides in-sample replication but also a means to explore the effect of sequencing depth or clonal mixture on power in a CRISPR screen. We show how heterogeneous clonal populations can impact the output of a pooled screen and lower the power of candidate detection.

3176T

Advanced applications for clinical research exomes. *M. Corioni, E. Lin, K. Jeong, F. Useche, A. Vadapalli, C. Pabon, M. Visitacion, G. Amparo, M. Ramaiah, M. Isaksson, D. Roberts.* Agilent Technologies, Santa Clara, CA.

Targeted re-sequencing enables highly sensitive and comprehensive detection of variants and provides insights into the biology behind a given phenotype. With recent major advances in this technology, combined with a better understanding of biological pathways, NGS is now extensively considered for use in clinical research. Whole exome sequencing provides deep coverage of genomic content from curated databases making it an efficient solution to characterize and catalogue variants. We describe several strategies that add additional value to whole exome analysis enabling more complete coverage and advanced applications such as detection of copy number changes and phasing. We share an augmented exome for clinical research that focuses on targets relevant to constitutional disease research with input from specific databases including Human Gene Mutation Database (HGMD®), ClinVar and Online Mendelian Inheritance in Man (OMIM™). We also describe the combination of exome with copy-number probes to extend target enrichment applications to the detection of genome-wide copy-number-changes (CNCs), and copy-neutral loss-of-heterozygosity (cnLOH). Finally, we demonstrate a phased exome coupled to 10x Genomics' linked read technology. The addition of "phasing" probes allows determination of long haplotype blocks. The separation of exonic reads into haplotypes further aids in structural variant and translocation determination, especially for disease causality in complex genotypes. We describe data analysis and performance attributes for each of these platforms, including SNP/INDEL, loss of heterozygosity, copy number variation, phasing, translocation, and resolution of complex compound heterozygote samples.

3177F

Target enrichment using a neurology panel for 12 barcoded genomic DNA samples on the PacBio SMRT Sequencing Platform. *K. Eng, W. Lee, T. Hon, A. Sethuraman, J. Gu, P. Baybayan, S. Kujawa.* Pacific Biosciences, Menlo Park, CA.

Target enrichment is a powerful tool for studies involved in understanding polymorphic SNPs with phasing, tandem repeats, and structural variations. With increasing availability of reference genomes, researchers can easily design a cost-effective targeted investigation with custom probes specific to regions of interest. Using PacBio long-read technology in conjunction with probe capture, we were able to sequence multi-kilobase enriched regions to fully investigate intronic and exonic regions, distinguish haplotypes, and characterize structural variations. Furthermore, we demonstrate this approach is advantageous for studying complex genomic regions previously inaccessible through other sequencing platforms. In the present work, 12 barcoded genomic DNA (gDNA) samples were sheared to 6 Kb for target enrichment analysis using the Neurology panel provided by Roche NimbleGen. Probe-captured DNA was used to make SMRTbell libraries for SMRT Sequencing on the PacBio RS II. Our results demonstrate the ability to multiplex 12 samples and achieve 1300x enrichment of targeted regions. In addition, we achieved an even representation of on-target rate of 70% across the 12 barcoded genomic DNA samples.   .

A comprehensive system for monitoring and analyzing human genome sequencing data. *S. Germer, J. Carter, J. Spencer, R. Musunuri, B.-J. Chen, H. Swaerdlow.* New York Genome Center, New York, NY.

The number of human genomes being sequenced has increased dramatically since the introduction of the Illumina HiSeq X instrument. In the past year, New York Genome Center has sequenced >12,000 whole human genomes at >30x. To ensure sustained production of high quality data generation across multiple library preparation protocols and versions of the sequencing chemistry, we have developed a comprehensive system for monitoring and analyzing the performance of the HiSeq sequencing instruments and the quality of raw and analyzed sequencing data. Instrument performance is monitored through a web-based display that emulates the Illumina Sequence Analysis Viewer software across all instruments, and allows both real-time and historical review of key quality metrics. A searchable browser interface displays flow-cell lane-level performance in terms of pass-filter (PF) clusters, the base quality (%>Q30, Reads 1 and 2), the percent of PhiX control template aligned, phasing and pre-phasing, as well as the error rate. Upon completion of a sequencing run, automated de-multiplexing generates a report for each flow-cell containing lane- and sample-level metrics, including percent PF reads identified and assigned to a sample, the read quality, as well as estimated duplication and adaptor contamination rates. This report flags metrics that fail to meet specified criteria, and holds the corresponding FastQ files from automatically progressing to downstream analysis until reviewed by a dedicated sequencing analyst. The data captured is organized in a database which allows us to track performance over time, by querying, for instance, PF rates, quality, or duplication rates by instrument, time period, library prep type, etc. Once a sample has progressed through the bioinformatics analysis pipeline, a separate web-based tool displays graphically or in a table format more than 25 per-sample metrics (related to alignment, coverage and coverage uniformity, contamination estimates, variant call quality, and more). The efficient and interactive interface allows analysts to quickly review project level data, to ascertain quality and identify QC failures, prior to data release for tertiary analysis. We will illustrate how the ability to track metrics at several levels and across all sequencing runs and samples allows us to identify outliers for further investigation, and to maintain consistently high quality performance across several large scale sequencing projects.

Whole genome mapping makes vital contributions to human reference assembly curation. *J.W. Torrance, W. Chow, K. Howe.* Wellcome Trust Sanger Institute, Wellcome Genome Campus, Hinxton, Cambridge, United Kingdom.

Whole Genome Mapping is a technology developed by BioNano Genomics for establishing the large-scale structure of a genome by visualising the spacing of fluorescently labelled sequence motifs on single molecules of DNA that are hundreds of kilobases in size. The resulting genome maps have been successfully employed for scaffolding high quality genome assemblies. The Genome Reference Consortium (GRC) are applying genome maps to a new purpose: the evaluation and improvement of the human reference genome assembly. The genome maps we have consulted include publicly available data generated by BioNano Genomics and the Genome in a Bottle Consortium, covering a trio from the CEPH Utah Reference Collection including NA12878, a trio of Ashkenazi Jewish ancestry, the YH genome, and a Han Chinese genome, as well as a CHM1 haploid hydatidiform mole genome map from BioNano. These genome maps have been vital in correcting the primary reference assembly by allowing more accurate estimation of the sizes of gaps and tandem repeat regions, and by aiding the identification of erroneous deletions. They have also helped to identify and confirm regions of haplotypic variation consisting of indels or copy number variation, providing valuable supporting evidence for the addition of alternate loci to the assembly. One of the examples where the genome maps confirmed the need for a sequence change to the primary assembly involved an erroneous deletion affecting two exons of *CDK11B*. In another case, the CHM1 map identified a 99 kb insertion relative to the primary assembly affecting the pseudogene *GUSBP1*, resulting in the addition of an alternate locus to the assembly. The GRC makes genome map alignments available via their gEVAL browser (geval.sanger.ac.uk), for both GRCh37 and GRCh38. To our knowledge, gEVAL is the only genome browser that provides genome map alignments for human reference assemblies. It thus constitutes a resource for discovering whether large-scale variation or RFLPs exist in a region of interest. These genome map alignments can be viewed in concert with the host of other data sources which gEVAL provides, including cDNA alignments, clone end-pair alignments, alignments with other human genome assemblies, and information on regions under review by the GRC.

Quality assessment of stranded mRNA libraries from low input RNA material using Illumina NeoPrep digital microfluidics automation. *C. Viollet[1,2], G. Sukumar[1,2], N. Lott[1,2], C.L. Dalgard[1,2].* 1) Uniformed Services University, Bethesda, MD, USA; 2) Collaborative Health Initiative Research Program, Bethesda, MD, USA.

Statement of purpose: Sequencing library preparation may be automated by digital microfluidics. The Illumina NeoPrep system utilizes electrowetting for liquid handling in a microfluidics card and offers complete workflows for amplification-based whole genome and transcriptome sequencing library preparation. For the stranded mRNA workflow, an input of 25–100 ng total RNA is specified. As the workflow utilizes a closed system with low reaction volumes, we aimed to determine the lower limit of input for library generation and assess metrics for yield, primer dimer fraction, and size distribution, as well as sequencing metrics for duplicate rate, alignment quality and concordance of transcript expression across starting inputs. The purpose of this study is to provide guidance for digital microfluidics library preparation of low or even below quantitation samples for mRNA-seq. **Methods:** We used two reference total RNA samples, a universal human reference (UHR) and control iPSC line, as input into the NeoPrep TruSeq Stranded mRNA Library Prep Kit at ranges between 0.3 to 210 ng. Library size distribution was assess using automated capillary electrophoresis (Fragment Analyzer) and yield was measured by qPCR (KAPA Quant on LightCycler 480). Libraries were pooled and sequenced on a NextSeq 500 with paired-end 75 bp reads. Quality filtered output was analysed using TopHat alignment and Cufflinks. **Summary of results:** All generated libraries were above 6 nM yield, homogeneous for ~320 bp peak size. Yields were associated with input and ranged from 6–370 nM. Recommended input of 25 ng yielded ~200 nM libraries with negligible (<0.5%) adapter dimer peak. In comparison, below specification input of 0.3 ng yielded ~6nM libraries with 7% adapter dimer peak. Pooled sequencing resulted in efficient multiplexing with no difference in %Q30 between libraries by input. A decrease in percentage of total reads aligned was observed with decreasing input RNA amounts. Most significantly, the duplicate rate increased as a function of decreased input, ranging from ~5% for high input to ~87% for the lowest input (0.3 ng). However, we observed that transcript expression values were highly correlated ($R^2 > 0.98$) between recommended and low input RNA libraries after normalization. Thus, we have defined a lower range of RNA input for acceptable NeoPrep workflow and how output metrics for library diversity, sequencing efficiency and transcript expression analysis are associated with low input.

3181W

GWAS data generation using heparinized red blood cells. *S. Hall[1], S. Paciga[1], C. Tow-Keogh[1], W. He[1], B. Zhang[2].* 1) WW Research & Dev, Pfizer, Groton, CT; 2) WW Research & Dev, Pfizer, Cambridge, MA.

The Pfizer BioBank manages collections that have been obtained from a subset of clinical trials where participants have consented to provide biospecimens for broad, exploratory research. Occasionally, suboptimal specimens are received and may be the only source available for experimental purposes. In this study, 123 heparinized red blood cells were received for a genome-wide association study (GWAS). Heparinized blood is not generally considered a viable source for DNA extraction and there was no supportive literature available to indicate its suitability for GWAS analysis. Agencourt®Genfind™ v2 magnetic bead DNA extraction chemistry was used to purify DNA from these specimens. The DNA concentration and yields were low due to the presence of heparin but quality measures were satisfactory. We were able to generate GWAS data from all of the specimens using Illumina's OmniExpressExome BeadChip array containing >950,000 SNP markers. Most of the specimens had a genotyping call rate >95% or better.

3182T

Ins and outs of current nucleic acid quantification and a solution towards standardization. *T. Martens, K. Plasman, T. Duthoit, T. Montoye.* R&D, Trinean, gentbrugge, east flanders, Belgium.

Failure of many molecular assays can be attributed to the quality of the nucleic acids used. Therefore, it is of utmost importance to thoroughly investigate both the quantity and purity of nucleic acids before proceeding to downstream assays. Most commonly-used technologies include UV/VIS droplet spectroscopy (i.e. Nanodrop) or fluorescence based assays (i.e. Qubit). These however suffer from some inherent drawbacks like labor-intensity and low accuracy. In an attempt to increase specificity while preserving ease of use and processing speed, UV/VIS droplet spectroscopy and an intelligent algorithm (DropSense16 + cDrop) were combined allowing more accurate nucleic acid quantification. Here, we use experimental data using different types of nucleic acids to demonstrate the advantages and shortcomings of each technology and propose ways to standardize nucleic acid QC ultimately resulting in a higher success-rate of downstream assays.

3183F

Unprecedented characterization of a human trio for new genomic reference materials. *J.M. Zook[1], J. McDaniel[1], M. Salit[2,3].* 1) Material Measurement Laboratory, National Institute of Standards and Technology, Gaithersburg, MD; 2) Material Measurement Laboratory, National Institute of Standards and Technology, Palo Alto, CA; 3) Department of Pathology, Stanford University, Stanford, CA.

The Genome in a Bottle Consortium (GIAB) has developed unprecedented data for a human trio, which is a candidate NIST Reference Material. These well-characterized genomes will underpin advances in genome sequencing and its applications in basic science, clinical medicine, and engineering of living matter. We are developing assemblies and phased variant calls of all sizes for as much of the genome as possible using 12 publicly available datasets from one trio, with no publication embargo and with publicly disclosed analyses. These data include BioNano Genomics, Complete Genomics paired-end and LFR, Ion Proton exome, Oxford Nanopore, Pacific Biosciences, SOLiD, 10X Genomics, and Illumina paired-end, mate-pair, exome, and synthetic long reads. We are using these data and developing new integrative methods to characterize increasingly difficult types of variants and regions of the genome. We have now expanded our high-confidence benchmark regions from 78% of the pilot genome NA12878 to 88-90% of this genome and a new genome. To further expand these benchmark regions, GIAB is collaboratively using these diverse data and integrating methods to create benchmark variant and homozygous reference calls in difficult-to-map regions and for larger, more challenging types of variation. 20 groups have contributed analyses of 12 different datasets for our trio. We have developed several de novo assemblies from long reads, resulting in a contig N50 >4 Mb and genome size >3 Gb. These assemblies have been used along with mapped short and long reads to generate structural variant calls using at least 20 algorithms. The resulting SV calls include deletions, novel and mobile element insertions, copy number variants, and inversions. High-confidence calls are being formed by integrating and evaluating the candidate calls from all methods. Preliminary integrated results for deletions in the son include 5300 deletions >50bp for which at least 2 different technologies have concordant size predictions and no other technology contradicts. This community effort is continuing to develop high-confidence benchmark calls for difficult variants in challenging regions of the genome - enabling optimization and development of technologies and algorithms and translation to clinical applications.

3184W

Genome-wide sequencing of STRs illuminates the haplotype structure of linked microsatellite-SNPs. *G. Shin[1], H. Lee[1], S. Grimes[2], B. Lau[2], H.P. Ji[1,2].* 1) Division of Oncology, Stanford University School of Medicine, Stanford, CA; 2) Stanford Genome Technology Center, Stanford University, Palo Alto, CA.

Microsatellites, also referred to as short tandem repeats (STRs) are multiallelic in terms of germline variation as a result of higher mutation rate than SNPs. As a result, STR genotyping is highly informative when characterizing genetic populations. However, the linkage disequilibrium structure of microsatellites and SNPs is largely unknown and there is little informative genetic analysis of the haplotype structure involving these variants. This knowledge gap mainly due to the absence of high-throughput genotyping technology for these loci. In this study, we used a novel targeted sequencing technology (STR-Seq), which can simultaneously genotype more than 2,000 microsatellite loci and their proximal SNPs. Particularly, STR-Seq uses paired-end sequencing reads to physically link STR and SNP genotypes. Unlike previous targeted sequencings, STR-Seq provides extraordinary efficiency in capturing the informative DNA molecules that span the entire repetition as well as the flanking sequences using targeted in vitro CRISPR/Cas9 fragmentation. Moreover, the technology eliminates PCR amplification and thus eliminates artifact insertions and deletions that obscure true genetic variation. We examined 2,191 microsatellite regions where a proximal SNP within 100bp has been reported. To increase the number of potential STR-SNP haplotypes, we considered the number of SNPs within the proximity to the microsatellite and genotype frequency of individual SNPs. In our initial analysis, we identified among a set of eight individuals, an average of STR-SNP haplotypes at 714. These haplotypes proved highly useful for a number of genetic application such as determining the composition of genetic mixtures. Currently, we are using this approach to define the microsatellite haplotype structure of over 1,000 individuals, by which allelic diversity, frequency spectra, and population differences of STR-SNP markers will be characterized.

3185T

Shining a light in the "dark matter" of the exome: Using linked reads and exome bait capture to map NGS short reads to genes and their paralogous segments. *L. Tian, C. Kao, F. Mafra, R. Pellegrino, H. Hakonarson.* The Children's Hospital of Philadelphia.

Mapping the repetitive regions of the genome remains challenging with current sequencing methods due to the reliance on short reads of ~200-400bp. About 10% (1,998 genes) of the exome contain repeat that is at least 250 bp in length and exhibits >98% identity to a paralogous segments located elsewhere in the genome. Of genes involved, 286 of them belong to the Medical Exome. It was further narrowed down to 73 genes that 1) have low coverage in ExAC, 2) are non-unique region by SiRen, and 3) are non-unique region by mappability files generated by GA4GH and the Genome in a Bottle Consortium. Here, we present a methodology to systematically resolve these repetitive regions using the 10x Genomics Chromium platform coupled with Agilent's SureSelect target enrichment with optimized baits. The optimized exome contains "bridging baits" that 1) are spaced within intronic and intergenic regions to preserve long-range info following capture, and 2) can capture uniquely mappable short reads to provide unambiguous reference genome location. The 10x's Lariat, a linked reads aware short reads aligner, was used to resolve the multi-reads in the repetitive regions. We show that 37 genes are completely resolvable (MAPQ≥20) when pre-processed via Chromium + optimized baits. Nine genes are partially resolvable, but can be fully resolved with improved bait design. 14 genes have paralogs that are too close (<50kb) that require improved bait design and lower MW DNA input. Nine genes have high G/C content that may improve by optimizing/increasing baits. Five genes have short repetitive sequences within the genes/exons and likely are not resolvable with linked reads, whereas the rest of them are upon optimization.

3186F

Untargeted metabolomics provides an unbiased approach to diagnosis of rare inborn errors of metabolism and further insight into rare disorders like transaldolase deficiency. *L. Hubert[1], L.H. Rodan[2], T. Donti[1], V.R. Sutton[1], G.T. Berry[2], Q. Sun[1], S. Elsea[1].* 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Division of Genetics and Genomics, Boston Children's Hospital, Harvard Medical School, Boston, MA.

Diagnosis of inborn errors of metabolism typically requires knowledge and experience with these rare disease entities and an understanding of the spectrum of the phenotype, such that targeted testing can be undertaken. Transaldolase deficiency is a rare inborn error of the pentose phosphate pathway caused by mutations in *TALDO1*. Clinical presentation includes coagulopathy, liver dysfunction, dysmorphic features, nephropathy, cutis laxa, splenomegaly, hemolytic anemia and genitourinary malformations. Biochemically, transaldolase deficiency results in the accumulation of erythritol, D-arabitol, ribitol and sedoheptulose in the body fluids of affected patients, and diagnosis is made when targeted analysis reveals elevations of these compounds, reduced/deficient *in vitro* TALDO activity, and/or molecular analysis of *TALDO1*. Despite these established methods of detection, diagnosis of transaldolase deficiency may be delayed due to its broad clinical spectrum, which can result in unfocused investigational efforts. To address the need for rapid and accurate testing for transaldolase deficiency and other inborn errors of metabolism, we developed a large scale analytical scheme capable of generating semi-quantitative z-score values for over 900 unique compounds from the analysis of a single specimen using untargeted metabolomic profiling. Applying this technique to analyze over 500 clinical samples, we were able to make an initial diagnosis in ~5% of cases, including transaldolase deficiency, where elevations of ribitol, erythronate, ribonate, arabitol were uniquely observed. Confirmation of this diagnosis was made by a GC/MS targeted analytical method, where elevated concentrations of several polyols and pentose phosphate pathway metabolites were detected. For example, plasma sedoheptulose was ~100-fold over normal in a previously published patient with homozygosity for the c.574C>T (p.Arg192Cys) *TALDO1* mutation (Rodan and Berry, JIMD Rep. 2016 Apr 30. [Epub ahead of print]). Compared to traditional methods which are time consuming and costly, the ability to identify a disorder with a single test in a large cohort of patients presenting with ambiguous clinical indications highlights the utility of untargeted metabolomic profiling. Thus, metabolomics may offer a route for more efficient diagnosis and earlier treatment of inborn errors of metabolism.

3187W

Combining enzymatic DNA fragmentation with NGS library construction results in high quality, high yield, libraries. *L. Apone, V. Panchapakesa, K. Duggan, T. Shtatland, B. Langhorst, J. Murdoch, C. Sumner, C. Rozzi, P. Liu, K. Krishnan, D. Rodriguez, J. Bybee, D. Rivizzigno, L. Mazzola, F. Stewart, E. Dimalanta, T. Davis.* New England Biolabs, Inc., Ipswich, MA.

The use of Next Generation Sequencing (NGS) data has been instrumental in advancing our understanding of human genetics and identifying the molecular events that contribute to human disease. Continued advancement relies on overcoming the limitations and bottlenecks associated with NGS. We have focused on NGS library preparation, where the requirement for numerous steps and expensive equipment, can lead to sample loss, errors, and limited throughput. More specifically, we have developed a library construction method that combines enzymatic DNA fragmentation with end repair and dA-tailing in a single step. Integrating these reactions eliminates the need for costly equipment to fragment DNA and reduces the number of sample transfers and losses. Adaptor ligation is carried out in the same tube, after which a single cleanup step is performed. For low input samples, PCR amplification is performed prior to sequencing. This method is compatible with a broad range of DNA inputs and insert sizes. Libraries generated using this streamlined method with inputs ranging from 0.5ng to 500ng of intact DNA show no significant difference in coverage uniformity or sequence quality metrics, compared to libraries generated with mechanically sheared DNA. Likewise, libraries generated to contain insert sizes that range from 150bp to 1kb, display no significant difference in sequence quality from each other or those generated with mechanically sheared DNA. Finally, this streamlined method generates libraries of substantially higher yields than those generated using mechanically fragmented DNA, allowing the use of lower DNA inputs. The ability to generate high quality NGS libraries from intact DNA without the need for costly equipment and numerous cleanup or liquid transfer steps substantially reduces the time, cost and errors associated with library construction. In addition, these advances permit greater use and adoption of NGS technologies.

3188T

Comparison of synthetic long read sequencing methods and optical mapping for *de novo* **genome assembly.** *D.W. Mohr[1], A.F. Scott[1], A. Naguib[2], N.I. Weisenfeld[3], V. Kumar[3], P. Shah[3], D. Church[3], D.B. Jaffe[3].* 1) McKusick Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore MD 21287; 2) BioNano Genomics, Inc. , 9640 Towne Centre Drive, Suite 100, San Diego, CA 92121; 3) 10X Genomics, Inc., 7068 Koll Center Pkwy #401, Pleasanton, CA 94566.

We have been studying methods for assembling high quality genomes from non-human mammals. Current short-read methods have come to dominate genome sequencing because they are cost-effective, rapid, and accurate. However, short reads are most applicable when data can be aligned to a known reference, generally assembled with more traditional methods. Because such methods are time-consuming, costly, and inefficient, we have explored approaches to *de novo* genome assembly using several novel approaches for sequencing and assembly. In particular, we evaluated the Illumina 384-index (aka, "Moleculo") method, the 250 bp paired-end DISCOVAR sequencing protocol, the 10X Genomics Chromium Linked-Read sequencing method with ~1M-indexes, together with the BioNanoGenomics (BNG) optical mapping and hybrid assembly approach. We show that the Chromium method, assembled with SuperNova, provided the longest sequence blocks and, when used for de novo assembly, produced scaffolds with an N50 (>10 kb) of ~15 Mb with the longest individual scaffold >60 Mb. When combined with BNG optical maps the scaffold N50 was >20 Mb and the longest individual scaffold was >70 Mb. Because both BNG and 10X technologies interrogate single DNA molecules they can also be used to construct haplotypes and to detect larger scale structural variants between parental chromatids. Combining the two orthogonal methods of Chromium Linked-reads with BNG optical maps is likely to make the assembly of high quality genomes routine and significantly improve our understanding of comparative genome biology.

3189F

Genome-wide poly(A) tail length profiling using novel Tail End Displacement sequencing (TEDi-seq). *Y. Woo, J.T. Lis, H. Kwak.* Molecular biology and genetics, Cornell University, Ithaca, NY.

Poly(A) tails play a critical role in mRNA stability and are closely involved in the regulation of gene expression in early development and cell cycle. Earlier biochemical studies of poly(A) tails showed that they can be synthesized up to the length of ~250 nucleotides (nt). Recently, sequencing-based techniques such as TAIL-seq and PAL-seq have provided genome-wide measurements of poly(A) tail lengths with the median of ~50 nt in mammalian cells. However, it was still difficult to identify the association between translation efficiency and poly(A) tail length from these results, and unclear why there was a discrepancy between observed poly(A) tail lengths (~50 nt) and early biochemical studies. Furthermore, both sequencing techniques require extensive repurposing of sequencing devices which may limit the feasibility of the assay and produce unexpected biases.Therefore, we developed a novel method for more accessible genome-wide profiling of poly(A) tail length named Tail End Displacement sequencing (TEDi-seq). Here, we applied a precise size selection of hydrolyzed 3' mRNA fragments including the poly(A) tail and sequenced the RNA fragments. In TEDi-seq, the 5' ends of the sequence reads displaced by the fragment size reflect the poly(A) tail length. As a result, we found a median poly(A) tail length of ~ 50 nt in human lymphoblastoid cell lines, and a possible portion of mRNAs with longer poly(A) tail length. Our data suggest that a subpopulation of mRNAs with longer poly(A) tail length exists and may be differentially regulated in mammalian cells. Finally, our novel system may be a potential tool to measure poly(A) tail efficiently and accurately, and contribute to elucidate the dynamic roles of mRNA stability and translational control dependent on poly(A) tail length.

3190W

Leapfrogging genome assemblies by sequencing single cells. *M. Hills[1], E. Falconer[1], K. O'Neil[2], A. Sanders[1,3], P.M. Lansdorp[1,4,5].* 1) Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada; 2) Genome Sciences Centre, BC Cancer Agency, Vancouver, BC, Canada; 3) Genome Biology Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany; 4) Division of Hematology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada; 5) European Research Institute for the Biology of Ageing, University of Groningen, The Netherlands.

   The mouse and human genome assemblies have revolutionized the way we conduct molecular research, rapidly expanding our understanding of the biology of these organisms and the diseases associated with them. These references are of high quality but still contain fragments which have not been localized to the genome and large regions that are incorrectly orientated with respect to the rest of the chromosome. Using Strand-seq, a single cell next-generation sequencing technique, we identified errors in the latest assemblies of mouse and humans with the goal of improving and refining these genomes. Strand-seq involves only sequencing parental DNA template strands in single daughter cells, preserving the directionality of DNA. Across multiple single cells, orientation errors and chimeric assembly fragments were readily detected as changes in the strand directionality across a chromosome, while unmapped fragments were located to specific regions. The reference assemblies of most other model organisms that are important for studies of human biology and disease are far less complete. For example, the ferret (*Mustela putorius furo*) is a model for the study of human respiratory diseases, including influenza infection and transmission, but the assembly is still in the draft stage, consisting of ~8,000 unplaced contigs. The pig (*Sus scrofa*) is important medically, representing a model for human pathologies and infectious diseases, and as a surrogate model for human wound healing and gastrointestinal tracts. In contrast to the ferret, the pig has scaffolds ordered into its 20 chromosomes, but still contains ~5,000 unplaced scaffolds and almost 75,000 gaps. More common model organisms also have important implications in human health, but still lack high-quality assemblies, with multiple gaps and unplaced fragments (for example *Danio rerio*), or are at earlier scaffold stages (for example *Xenopus tropicalis* and *Cavia pocellus*). We therefore used Strand-seq to rapidly and inexpensively create more complete genome assemblies for these five model organisms. We identified extensive orientation errors (for example, ~30% of the pig assembly was misoriented), and were able to cluster the thousands of fragments present in scaffold-stage assemblies into individual, ordered chromosomes. We demonstrate how Strand-seq allows us to create accurate reference assemblies rapidly and efficiently, which in turn aids research into human disease, pathologies and evolution.

3191T

Long range applications with short read sequencing. *S.T.K. Garcia, B.D. Galvin, H. Heaton, P. Hardenbol, C. Jabara, D.B. Jaffe, S. Kyriazopoulou-Panagiotopoulou, V. Kumar, P. Marks, H. Ordonez, M. Pratt, M. Schnall-Levin, P. Shah, M. Sooknah, A.W. Xu, N.I. Weisenfeld, I. Yousif, D.M. Church.* 10X Genomics Pleasanton, CA.

   High-throughput sequencing has revolutionized genome analysis. However, it is clear that traditional short read methods provide an incomplete view of the genome and result in an incomplete understanding of the clinical and biological complexity present. In particular, the lack of long-range information combined with inherent limitations in the mapping of short reads severely limits the robust identification of structural variants, haplotypes, and variants in difficult regions of the genome. To address these problems, we developed a technology that retains long-range information while maintaining the power, accuracy, and scalability of short read sequencing. At its core, haplotype-level dilution of long input molecules into >1 million barcoded partitions creates a novel data type referred to as 'Linked-Reads' that enables high-resolution genome analysis with minimal DNA input (~1 ng). Coupling Linked-Reads with novel algorithms that take advantage of these linkages allows for improved individual genotype reconstruction without sacrificing variant calling accuracy. We obtain 99% SNP sensitivity with greater than 99% PPV in confident regions for genome and exome on the NA12878 sample. We see phase blocks with an N50 of 4.1 Mb for genomes and 222 Kb for exome. We also show improved performance in regions of the genome typically inaccessible due to the presence of paralogous sequence/highly repetitive regions. Highly homologous sequences traditionally leading to ambiguous mapping can now be analyzed when associated with distinct barcodes. We estimate that we can rescue ~50 Mb of previously inaccessible sequence. We demonstrate that clinically-relevant variants can be identified in these previously inaccessible regions in genes including *CYP2D6*, *SMN1*, and *STRC*. Finally, retention of long range information facilitates the identification of copy number variants, copy neutral inversions, inter- and intra-chromosomal events, and more complex structural rearrangements. For a representative NA12878 genome 17 large SV calls were made, 16 of which had evidence from orthogonal methods, assembly, or raw reads. Importantly, 10 of the 17 events were fully or partially phased with single nucleotide variants. The utilization of Linked-Reads significantly improves our ability to reconstruct individual haplotypes and provides confidence in variant calls by providing an additional data type- phasing.

Ultra-sensitive mosaic mutation detection for clinical applications.
A. Hoischen[1], M. Steehouwer[1], M. Kwint[1], R. Acuna Hidalgo[1], E. Mersy[2], A. Paulussen[2], M. van de Vorst[1], L.E.L.M. Vissers[1], M. Nelen[1], C. Gilissen[1], J.A. Veltman[1,2], J. Shendure[3], A. Goriely[4]. 1) Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands; 2) Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, The Netherlands; 3) Department of Genome Sciences, University of Washington, Seattle, Washington, USA; 4) Weatherall Institute of Molecular Medicine, University of Oxford, UK.

Despite the great advances in the next generation sequencing field there is still room for improved targeted re-sequencing assays that combine high throughput with ultra-high sensitivity. We have now further optimized a single-molecule molecular inversion probe (smMIP) based targeted re-sequencing approach[1]. Single-molecule tracing is enabled using up to 4^{10} (1,048,576) molecular tags. Consensus calling of respective PCR-duplicates allows correction for PCR and sequencing errors. The improved assay allows low-frequency or sub-clonal variant detection with variant levels of <0.05%. This assay provides very robust genotyping accuracy, high throughput, fast turnaround and cost-effectiveness. We anticipate that this or similar assays allow novel applications in which mutations are present in very low relative abundance in any given DNA sample with important new applications beyond cancer genetics. Here we present first successful applications that include: 1.) Accurate determination of the fraction of mutated alleles for post-zygotic *de novo* mutations[2]. 2.) Detection of previously unrecognized mosaic disease causing mutations for rare clinical syndromes. 3.) Detection of known 'paternal age effect disorders' causing mutations as small clonal events in dissected testis material[3]. 4.) First evidence for presence or absence of parental alleles in cell free DNA from plasma of pregnant women.   References: 1) Hiatt JB, et al. 3193W

Challenges and opportunities in implementing pharmacogenomic clinical decision support tools within diverse Electronic Medical Record (EMR) systems. *J. Ross, D. Bailey, A. Solomon.* OneOme, LLC, Minneapolis, MN.

There is growing evidence that pharmacogenomic testing can significantly reduce a patient's overall healthcare costs and greatly improve their outcomes.[1,2] Recently, the cost of pharmacogenomic testing has fallen under $250 for multi-gene panels providing increased accessibility to a broader range of patients and providers. However, results are often returned as a static report. These reports are manually scanned into the EMR and reviewed initially but then are treated similarly as other temporal based results quickly relegated to the EMR's archives. This provides very limited value to the patients because the report is only used to address the patient's present situation and doesn't leverage the knowledge in a data build that can then be used to address future prescription complexities and changes. In addition, referencing the document within the EMR system can be challenging, often significantly reducing the utility of the test results for the patient and provider. In order to provide value and maximize effectiveness of pharmacogenomic testing, the tests should be easy to order and results must be integrated into the EMR system as structured data, readily available, thus allowing clinical decision support tools the ability to continually access the information which may be clinically relevant and potentially actionable for managing clinical care for the lifetime of the patient.We will demonstrate how structured pharmacogenomic information integrated with EMR systems such as EPIC and Cerner impact the utility and accessibility, and how OneOme's clinical decision support tools, co-developed and exclusively licensed from Mayo Clinic, can provide ongoing, relevant and actionable information designed to improve patient outcomes. Quantification of genome-wide nascent mRNA by click chemistry and RNA-seq. *W. Wang[1], R. Song[2,3], M. MacGibeny[2,3], J. Wiggins[1], J. Miller[1], L. Enquist[2,3].* 1) Institute for Integrative Genomics, Princeton University, Princeton, NJ; 2) Department of Molecular Biology, Princeton University, Princeton, NJ; 3) Princeton Neuroscience Institute, Princeton University, Princeton, NJ.

   RNA-seq has been widely used to quantify transcript abundance; however, in most cases it is applied directly on all RNA transcripts existing in the samples at certain time points to measure the steady-state transcript levels. Partitioning the whole RNA sample into newly synthesized RNA over a period of time and pre-existing RNA would enable characterization of the dynamics of the transcriptome. Such RNA partition can be achieved by incubating live cells with an alkyne-modified nucleoside 5-ethynyl uridine (EU) to label the nascent RNA, followed by click reaction with an azide-modified biotin to capture the EU-containing nascent RNA with streptavidin magnetic beads. In the current study, SMART-Seq2 method, originally developed to amplify and sequence poly-A containing RNA transcripts from single eukaryotic cells, was applied on the small amount of EU-labeled bead-captured RNA from primary cell culture to characterize the nascent mRNA synthesis.   Compared to the input RNA before capture, amplified cDNA from EU-labeled RNA demonstrated shorter fragment length, likely due to RNA degradation during the lengthy hybridization capture process. Linear correlation was clearly observed in the transcript abundance on log scale between EU-labeled RNA and input RNA, while the spread was wide. Control RNA captured from cells without EU treatment (unlabeled RNA) showed much lower cDNA amplification yield, which was barely detectable. However, its transcript abundance still demonstrated correlation to the input RNA, especially for genes with high expression levels, revealing the non-specific capture of unlabeled RNA by streptavidin beads. In conclusion, it is feasible to quantify genome-wide nascent mRNA abundance by combing Click chemistry with mRNA amplification and sequencing analysis. There is still room for improvement in the bead capture specificity and efficiency.

A highly efficient, low-bias and strand-specific RNA-seq library preparation method for transcriptome profiling. *E. Yigit, K. Karaca, K. Krishnan, B. Langhorst, T. Shtatland, D. Munafo, D. Rodriguez, P. Liu, L. Apone, V. Panchapakesa, K. Duggan, C. Sumner, C. Rozzi, F. Stewart, L. Mazzola, J. Bybee, D. Rivizzigno, E. Dimalanta, T. Davis*
. New England Biolabs, Ipswich, MA.

   RNA-seq (RNA sequencing) has undoubtedly become the most popular method for transcriptome analysis. It is widely used for gene expression analysis including detection of mutations, fusion transcripts, alternative splicing, and post-transcriptional modifications. Recent improvements in next generation sequencing technologies (NGS) and sample barcoding strategies allow analysis of multiple samples in parallel in a cost effective manner. As RNA-seq is increasingly adopted for molecular diagnostics, the quality and reproducibility of library preparation methods become more important. In addition, demand for library preparation methods that produce successful NGS libraries from low input RNA or precious clinical samples is increasing. To overcome these challenges, we have developed a strand-specific RNA-seq library preparation method that retains information about which strand of DNA is transcribed. Strand specificity is important for the correct annotation of genes, identification of antisense transcripts with potential regulatory roles, and for correct determination of gene expression levels in the presence of antisense transcripts. Our method can be used for a wide range of input RNA (10-1000 ng total RNA) without any modifications to the protocol, making it a convenient method for RNA-seq library preparation. More importantly, GC content analysis, gene body coverage and gene expression correlation show that there are no significant differences between libraries with varying inputs, even though input amounts varied by two orders of magnitudes. As a result, our method has increased sensitivity and specificity, especially for low-abundance transcripts, and reduced PCR duplicates and sequence bias, delivering high quality strand-specific data. Our method is compatible with both poly A-tail enriched and ribosomal RNA depleted samples, and is amenable to large-scale library construction and automation.

The Korean Biobank Array project. *Y. Kim, S. Moon, M. Hwang, B. Han, B. Kim.* Center for Genome Science, National Institute of Health, Heungdeok-gu, Chungcheongbuk-do, South Korea.

Recently, customized genotyping chips with low cost have gathered increasing attention to conduct a large-scale population based genomic study. Generally, customized chips are designed to contain variants for a specific research purpose or variants selected from the discovered variants of sequencing data. For example, biobank arrays such as a custom array for Kaiser permanente/UCSF genotyping project, UK biobank array, Japonica array, and China Kadoorie biobank array have been introduced to perform genome-wide association study on complex traits by genotyping more than tens of thousands of samples. In 2014, Korea National Institute of Health initiated the Korean biobank array(Korean chip) project. The Korean chip project aims to study hidden genetics of various diseases by genotyping more than 100,000 samples from three prospective cohorts. At the first phase of the Korean chip project(2014-2015), Korean chip was designed and genotyping of 35,000 samples using the Korean chip was completed in 2015. Korean chip contains about 833K markers including genome-wide taggers and about 200K of functional variants. In the preliminary analysis using about 7,000 samples, Korean chip showed better genomic coverage over widely used commercial arrays (95% for MAF ≥ 5%, 73% for MAF 1-5%). Also Korean chip discovered novel associations for liver enzymes and lipid traits and numerous nonsynonymous variants within the previously reported GWAS loci.

Universal sample preparation for omics–based applications in personalized medicine. *L. Poveda, J. Tracy, L. Opitz, N. Selevsek, R. Schlapbach.* Functional Genomics Center Zurich, ETH Zurich/University Zurich, Switzerland.

Combining "Omics" information from the analysis of diverse biomolecules, such as nucleic acids and proteins, opens up new opportunities in the field of personalized/precision medicine where patients can be monitored across multiple molecular readouts to improve disease diagnosis and treatment. Ideally, the data should be collected from the same sample using a universal sample preparation method, which enables the extraction of the different classes of biomolecules for sensitive analysis. Recently, the pressure cycling technology (PCT) has emerged as an efficient sample preparation strategy, enabling the extraction of proteins from a small amount of samples such as needle tissue biopsies. Here, we performed the lysis of small amounts of porcine tissue biopsies using the PCT approach, enabling the downstream analysis of proteins, RNA and DNA. In total, more than 300 molecular readouts were generated from 7 different tissue types (pig liver, heart, aorta, spleen, lung, aorta, brain) processed in four replicates and at four different tissue weights (0.2, 0.5, 1 and 3 mg) each. Estimated protein yields resulting from the PCT workflow were directly proportional to the tissue weights and demonstrated high reproducibility between replicates and organs. For nucleic acids, the PCT workflow was combined with standard DNA/RNA isolation kits enabling the purification of genomic DNA and total RNA from the samples. For both, high DIN and RIN numbers as measures for the integrity and quality of the nucleic acids were obtained across almost all tissue weights and organs, reflecting low degradation of the biomolecules during sample processing. After isolation, all tested samples were further processed for proteome and transcriptome profiling using mass spectrometry and Next Generation Sequencing analysis, respectively. As expected, a high correlation was identified between protein and transcript abundances for the same organ, but a lower correlation was measured across organs. Pathway enrichment analysis revealed several activated molecular pathways that were found to be expressed strictly organ and tissue-specific. The presented robust and sensitive method for the isolation of multiple molecular species from minimal samples provides the basis for an integration of complex data sets from proteomics and genomics for a comprehensive view on cells or organs under defined physiological states, a prerequisite in system biology and personalized medicine.

3198F

Comparison of polyA-selected, ribo-minus, and exon capture RNA-sequencing in splicing events detection. *S. Peng[1], M. Seiler[1], J. Wu[1], J. Zou[2], R. Darman[2], P. Kumar[2], C. MacKenzie[2], J. Palacino[2], L. Yu[1].* 1) Data Science and IT, H3 Biomedicine Inc., Cambridge, MA; 2) H3 Biomedicine Inc., Cambridge, MA.

Defects in pre-mRNA splicing cause or contribute to various human diseases. Large scale cancer genome projects also identified mutations in spliceosome components, e.g. SF3B1, U2AF1, or SRSF2, initially in myeloid-lineage malignancies and, more recently, in breast cancer and melanoma. These mutations result in frequent selective aberrant mRNA splicing events, including exon skipping / inclusion (SRSF2 & U2AF1) or alternative 3' splice site (SF3B1). RNA-seq is used to profile transcriptomes and identify novel transcripts and alternative splicing events. RNA-seq libraries can be prepared from total RNA using different protocols, such as polyA-selection, ribo-minus, and exon-capture. Current publications comparing different RNA-seq library preparation methods focus on the gene expression profiles, but neglected to compare detection power of different methods for splice junctions, which is critical when studying mutational or interventional splicing modulation.To compare splicing detection capacities of different RNA-seq protocols, we obtained data with polyA (pA), ribo-minus (RZ) and TruSeq RNA Access (ExCap) in K052 cells, which carries SRSF2.p.P95H mutation.

	pA(+)	RZ	ExCap
% Unique Reads	90.8	72.6	84.6
% Splice Junction Reads	32	18	35
# Unique Junctions	215000	198000	154000

The overlapping percentages of splice junctions detected when comparing between two methods range from 63 to 87%. When limiting the comparison to the exon-capture target regions, the overlapping percentages improve, and range from 79% to 90%. In ribo-minus sample, a large number of reads are mapped to non-polyA RNAs, such as histone mRNAs, lncRNAs and snoRNAs, which decrease the detection power of splice junctions. The conclusion holds true when we examined several reported aberrant splicing events associated with SRSF2.p.P95H. Overall, PolyA-selected RNA-seq offers the broadest splice junction coverage, including identification of novel junctions. Ribo-minus RNA-seq provides information on non-polyA transcripts, but needs higher sequencing coverage to reach similar detection power for splice junctions. Exon-capture based RNA-seq (RNAaccess) is not recommended for global splicing profiling and discovery, however, it can be a viable alternative to profile known splicing events.

RD-Connect (rd-connect.eu) is a platform connecting omics data, registries, biobanks and clinical bioinformatics for rare disease research (platform. rd-connect.eu). RD-Connect aims to contribute to the IRDiRC objectives for 2020 and to narrow the gaps in rare disease research, where patient populations, clinical expertise and research communities are small in number and highly fragmented. The RD-Connect platform securely integrates -omics data with biosample and clinical information, providing not only a centralised data repository but also a sophisticated and user-friendly online analysis system. Raw Whole Genome, Exome or gene panel NGS data are deposited at the European Genome-phenome archive and processed with RD-Connect's standardised analysis and annotation pipeline. The corresponding clinical information is recorded in a connected PhenoTips instance using the Human Phenotype Ontology, OMIM and Orpha codes. The results are made available to authorised users through the highly configurable and efficient platform, which runs on a Hadoop cluster and uses ElasticSearch. The user-friendly interface enables filtering and prioritization of variants using the most common quality, genomic location, effect, pathogenicity and population frequency annotations. Additional tools, such as Exomiser, DiseaseCard, Alamut Functional Annotation (ALFA), ePGA (epga.gr) and UMD Predictor (umd-predictor.eu) are integrated at several levels. To share data beyond the platform, RD-Connect has lit a GA4GH Beacon within the Beacon Network (beacon-network.org) and is actively involved in the development of the GA4GH/IRDiRC Matchmaker Exchange (matchmakerexchange.org, MME) 1-sided matching approach. The development of the MME API will enable more complex queries while still ensuring that no personal sensitive information is shared. There are over 2200 NGS samples already available in RD-Connect. The number is quickly increasing and we welcome new submissions.

Pan-microbial detection using Axiom® Microbiome Array. *P. Rack, M. Wu, L. Le, C. Sheppy, M. Mittmann, A. Pirani, M. Shapero.* Affymetrix, part of Thermo Fisher Scientific, Santa Clara, CA.

The human microbiome is defined by a diverse set of microbes, including eukaryotes, archaea, bacteria, and viruses, that can differ across body sites. These microbes play a key role in both human health and disease. As sequences of microbial genomes continue to expand, microarrays are well positioned to capitalize on this information content. Here we present an overview of Axiom® Microbiome Array, which enables researchers to detect all known microorganisms in a sample with a single assayAxiom Microbiome Array contains approximately 1.3 million probe sequences targeted towards more than 11,000 microbial organisms. The array design enables species- and strain-level resolution from individual samples and uses Axiom® assay biochemistry to interrogate non-polymorphic sequences in both family-conserved and target-specific regions from NCBI database sequences. Axiom™ Microbial Detection Analysis Software (MiDAS) powers the analysis workflow for Axiom Microbiome Array. Axiom™ MiDAS is built on a Composite Likelihood Maximization (CLiMax) algorithm developed at Lawrence Livermore National Laboratory, which is used to predict the identities of targets in an unknown sample.Array performance has been evaluated on both known complex mixtures and *bona fide* biological samples (stool) against stringent quality control metrics including positive predictive value (PPV), true positive rate (TPR), limit of detection (LOD), and reproducibility. TPR and PPV were evaluated on 222 samples of known composition with complexity varying from 1 to 22 strains per sample. LOD was determined using a broad log dilution series of known microbial genomes in the presence or absence of background human genomic DNA (gDNA). The results indicate a higher overall accuracy at the species level than 16S rRNA gene sequencing technology.In summary, Axiom Microbiome Array offers a solution for the identification and enumeration of microbial entities comprising complex biological samples. The scalable sample throughput enabled by 24- and 96-array formats, with the potential to expand to a 384-array format, coupled with laboratory automation allows processing of hundreds to thousands of samples per week with minimal manual intervention. This feature makes Axiom Microbiome Array a cost-effective means for detection and examination of microbiomes.

3201F

Saliva is a good alternative DNA source for whole genome and/or whole exome sequencing. *A. Thrasher[1], Z. Wang[1], H. Mulder[1], D. Hedges[1], T. Chang[1], C. Rosencrance[1], J. Easton[1], L. Robison[2], J. Zhang[1].* 1) Department of Computational Biology, St. Jude Children's Research Hospital, Memphis, TN; 2) Department of Epidemiology & Cancer Control, St. Jude Children's Research Hospital, Memphis, TN.

The increased accessibility and decreased cost of next generation sequencing (NGS) has enabled an increasing number of genomic studies. Blood is the preferred DNA source for germline studies using NGS. However, drawing blood is an invasive process requiring trained personnel to interact directly with the sample donor. DNA from saliva is a more convenient and cost-effective alternative. The primary concern with DNA isolated from saliva has been the quality and suitability of this DNA for the generation of high quality non-array data, such as that obtained by next generation sequencing. To address this, matching blood and saliva samples were collected from five healthy subjects (age range 36-64). A series of DNA isolation optimization experiments were performed on the saliva samples, with phenol/chloroform isolated DNA from blood serving as the reference. Whole genome (WGS) and whole exome (WES) sequencing was performed on samples from optimized saliva DNA isolation and DNA from blood. The average coverage for WGS and WES was 30X and 100X respectively with >70% of the coding exons at >20X in both data sets. Genetic variations, including single nucleotide variation (SNV), small insertion/deletion, copy number variation (CNV) and structural variation (SV) are highly concordant between the two source materials with only 1 saliva-specific coding SNV across the five pairs. Comparison of the somatic variants identified exclusively in one source detected *TCRA* and *TARP* rearrangements in blood, as expected. Further, we performed metagenomic analysis of unmapped reads from both blood and saliva samples. Blood samples had 5-6% unmapped reads compared to 7-18% in saliva. Evaluation of source of unmapped reads found that 0.54% mapped to viral species in both sample types. In contrast, 10.3% of unmapped reads from saliva samples mapped to bacterial species, compared with only 1% of unmapped reads from blood samples as expected[1]. This analysis represents, to our knowledge, the first comprehensive examination of WGS and WES data generated from blood compared to saliva. Our analysis shows a high level of concordance between the two sample sources, and as expected few somatic variants. This indicates that high quality sequencing data can be derived from saliva samples for germline genetic analyses. [1] C. James, R.M. Iwasiow, H.C. Birnboim (2011). Human genomic DNA content of saliva samples collected with the Oragene self-collection kit. DNA Genotek. PD-WP-011 Issue 4/2011-11.

3202W

A custom mapping and annotation workflow for array-based genotyping applied to a large biobank cohort. *E.A. Tsai[1,2,3], C.-F. Lin[1,2,3], A. Brown[1], S.S. Amr[1,3,4], M.S. Lebo[1,3,4].* 1) Personalized Medicine, Partners HealthCare, Cambridge, MA; 2) Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; 3) Department of Medicine, Harvard Medical School, Boston, MA; 4) Department of Pathology, Brigham and Women's Hospital, Boston, MA.

Background: In recent years, there is an increasing number of SNPs identified through next generation sequencing that are not typically included in genotyping arrays. Given the low cost of genotyping arrays and the clinical importance of these positions, it is valuable to include them on SNP arrays applied to large populations. However, as many of these SNPs are not currently present on the commercial array, they require novel design, additional quality control, and manual curation. There tends to be limited testing of the probe design and probe performance due to the sheer number of novel SNPs included, so this process requires careful quality control. Methods: 1) We created a workflow that remaps the probes from the Illumina manifest data to ensure that they optimally aligned to the targeted region. 2) We designed a custom, curated flat file that provides information about the variant not available in the traditional PED format, including variant level information such as the rsID, annotations to the nearest gene, and transcript-level consequences for coding variants. In addition, the normalized VCF nomenclature and observed call rates of each marker are also included. 3) We identified variants that would be potentially returnable in the ACMG incidental findings list of 56 genes using our annotated SNP file. Other components of the overall workflow include sample phasing, imputation, and easy access to subsets of the sample dataset. Results: We have implemented this workflow for Illumina Multi-Ethnic Genotyping Array (MEGA), Expanded Multi-Ethnic Genotyping Array (MEGA[EX]), and Multi-Ethnic Global (MEG) array. This family of biobank genotyping arrays have 1.8 to 2 million probes including custom-designed exome content (50,000+ loss of function variants) and an increased representation of SNPs present in non-Caucasian cohorts. Using the ACMG incidental findings gene list, we identified more than 1,500 variants genotyped that could potentially be a returnable finding if they were identified in an individual. Summary: We present a custom workflow for accurate mapping, strand determination, and annotation of genotyped data. This workflow is the standard mechanism for data processing and delivery for data generated via the Partners HealthCare Biobank Initiative. It was applied to genotyping results for 10,000 samples, and an additional 15,000 samples are in the queue. Further analysis will determine the number of returnable variants identified among this cohort.

3203T

Method for fetal fraction determination through INDEL targeted genotyping. *N.M. Kiesling, A. Kruger, J. Thompson, K.M. Klusman, B.M. Hanlon, T.P. Mann.* Progenity Inc, Ann Arbor, MI.

Noninvasive prenatal testing for fetal chromosome abnormalities relies on the presence of fetal DNA circulating in the mother's blood. The sensitivity of the test may be reduced in cases of low fetal fraction, the percentage of fetal DNA to maternal DNA, resulting in a false negative test outcome. The amount of fetal DNA present in the mother's blood is highly variable and dependent on factors such as gestational age, maternal BMI and smoking. NIPT results can be put into clearer context by accounting for the fetal fraction within the sample. The most widely accepted method for ascertaining the fetal contribution to the total DNA is through maternal and fetal genotyping, i.e. detection of paternally inherited alleles. The quantity of fetal DNA present in the sample has a direct relationship to the sensitivity and accuracy of the genotyping methodologies, thus enrichment techniques such as whole genome amplification (WGA) are often done to increase the quantity of DNA. However, genotyping amplified product can be complicated by several factors including the high probability of WGA and sequencing error to introduce point mutations into the product. These point mutations, when occurring in specific locations, can appear as alternate alleles and result in an erroneous genotype. Here we describe a method for fetal fraction determination through genotyping using WGA material that is designed expressly to eliminate sequence errors and reduce noise in allele ratios. This methodology begins by querying INDELs rather than SNPs for genotype determination as INDELs are much less likely to be affected by WGA and sequencing induced mutations than SNPs. Amplification and sequencing errors are further reduced through condensation of PCR duplicates into a consensus sequence. Finally, an accurate count of reference and alternate alleles is obtained through an alignment-free counting analysis, and fetal fraction is quantified by an expectation-maximization approach. We have demonstrated that INDEL targeted genotyping with an alignment-free analysis can accurately determine the proportion of fetal DNA in a pregnant plasma sample that has undergone WGA.

3204F

Size distribution, yield, and genomic mapping characteristics of cell-free DNA extracted from different donors, different body fluids, and at different time-points. *M. Toloue, M. Goldrick.* Bioo Scientific, Austin, TX.

Purpose: There has been a recent surge of interest in analysis of fragments of DNA recovered from cell-free biological fluids as they may allow non-invasive monitoring of malignant disease and other pathological conditions. Clinical studies have shown the feasibility of detecting genetic variants associated with recurrence of cancer after treatment, in cell-free DNA (cfDNA) extracted from blood plasma and urine, and there are many reported cases of earlier detection of metastatic disease by analysis of cfDNA, compared to conventional imaging tests. However, there have been relatively few cfDNA-based assays ("liquid biopsies") validated for clinical use, partly due to incomplete understanding of the biological processes that lead to release of DNA into biofluids. A substantial fraction of cfDNA is recovered as fragments of ~170 bp and multimers thereof, which is thought to reflect its association with the histone proteins that comprise nucleosomes. Larger fragments may also be recovered, even after removal of contaminating cells. To better define the characteristics of cfDNA, we carried out studies to compare size distribution, concentration, and genomic origin of cfDNA extracted from plasma and urine from a diverse group of healthy subjects. Methods: Platelet-poor plasma and clean-catch centrifuged urine samples were obtained from healthy donors representing different ages, genders, and ethnic groups. For some donors, multiple samples were obtained over a time-course. cfDNA was extracted using magnetic-bead-based kits (Bioo Scientific) and analyzed on an Agilent 2100 HS DNA chip to determine concentration and size distribution. A subset of samples was converted into whole-genome libraries and used for paired-end sequencing on an Illumina MiSeq. Sequencing reads were binned according to size of the cfDNA from which they originated, and mapping characteristics (genomic coverage and %GC) were determined for larger and smaller fragments. Results: Differences in yield and size distribution of cfDNA were observed for different biofluids, for different donors, and for sequential samples collected from the same donor. The proportion cfDNA larger than 500 bp could not be attributed to differences in sample collection or preanalytical processing. Variation in genomic mapping characteristics were seen in cfDNA extracted from different donors, from different size ranges of cfDNA, and from different samples from the same donor.

3205W

OneSeq phased exome for structural variant and compound heterozygote detection. *E. Lin[1], F. Useche[1], M. Isaksson[1], B. Galvin[2], H. Ordonez[2], J. Lee[2], A. Wei Xu[2], P. Marks[2], M. Schnall-Levin[2], D. Church[2], S. Garcia[2], M. Sooknah[2], M. Corioni[1], K. Jeong[1], A. Vadapalli[1], G. Amparo[1], M. Ramaiah[1], C. Pabon[1], D. Roberts[1].* 1) Genomics, Agilent Technologies, Santa Clara, CA; 2) 10x Genomics, Pleasanton, CA.

Massively parallel sequencing has been extremely successful in elucidating the genetic etiology of Mendelian disease and complex disorders such as cancer. Target enrichment applications such as whole exome captures have enabled higher sequencing depths to accurately determine single nucleotide variants (SNV), small insertions/deletions (INDEL), and chromosomal copy number changes. However, short-read sequencing provides only a few hundred nucleotides of uninterrupted sequence, preventing the assignment of successive variants along the chromosome to a specific allele. Moreover, structural variants can only be identified if reads are mapped across a breakpoint. This is difficult especially if the breakpoint occurs in repetitive regions. To address these limitations, we have developed the OneSeq Phased Exome Target Enrichment System for use with the Chromium™ linked-read technology from 10X Genomics. The phased exon capture is aided by selected probes targeting intronic regions. Multiple reads derived from a single long DNA molecule are linked together and aligned, providing a phased scaffold across the exons. This allows segmentation of variants into long haplotype blocks and the phasing of entire genes. Linked reads also reduce alignment ambiguities, thus improving coverage in regions that are traditionally difficult to map. Further, linked reads can identify breakpoints and chromosomal translocations. Herein we describe the wetlab, instrumentation, and informatics workflows for combined 10X library prep and exome capture. We describe phasing performance and demonstrate applicability for determining both structural variants and compound heterozygotes. The addition of phasing and structural variant determination to traditional exome analysis will aid in the elucidation of complex genotypes and drive research and understanding of disease causality.

Effect of coverage depth and haplotype phasing on structural variant detection in human genomes from PacBio long reads. *A.M. Wenger, S. Kujawa, L. Hickey, C.S. Chin, J. Korlach.* Pacific Biosciences, Menlo Park, CA.

Each human genome has thousands of structural variants compared to the reference assembly, up to 85% of which are difficult or impossible to detect with Illumina short reads and are only visible with long, multi-kilobase reads. The PacBio RS II and Sequel single molecule, real-time (SMRT) sequencing platforms have made it practical to generate long reads at high throughput. These platforms enable the discovery of structural variants just as short-read platforms did for single nucleotide variants. Numerous software algorithms call structural variants effectively from PacBio long reads, but algorithm sensitivity is lower for insertion variants and all heterozygous variants. Furthermore, the impact of coverage depth and read lengths on sensitivity is not fully characterized.   To quantify how zygosity, coverage depth, and read lengths impact the sensitivity of structural variant detection, we obtained high coverage PacBio sequences for three human samples: haploid CHM1, diploid NA12878, and diploid SK-BR-3. For each dataset, reads were randomly subsampled to titrate coverage from 0.5- to 50-fold. The structural variants detected at each coverage were compared to the set at "full" 50-fold coverage. For the diploid samples, additional titrations were performed with reads first partitioned by phase using single nucleotide variants for essentially haploid structural variant discovery.   Even at low coverages (1- to 5-fold), PacBio long reads reveal hundreds of structural variants that are not seen in deep 50-fold Illumina whole genome sequences. At moderate 10-fold PacBio coverage, a majority of structural variants are detected. Sensitivity begins to level off at around 40-fold coverage, though it does not fully saturate before 50-fold. Phasing improves sensitivity for all variant types, especially at moderate 10- to 20-fold coverage. Long reads are an effective tool to identify and phase structural variants in the human genome. The majority of variants are detected at moderate 10-fold coverage, and even extremely low long-read coverage (1- to 5-fold) reveals variants that are invisible to short-read sequencing. Performance will continue to improve with better software and longer reads, which will empower studies to connect structural variants to healthy and disease traits in the human population.

Rapid, high-throughput clinical sequencing and reporting for personalized medicine. *D. Muzny[1], K. Walker[1], J. Hu[1], V. Korchina[1], R. Raj[1], Y. Ding[1], H. Doddapaneni[1], Q. Wang[1], J. De La Cruz[1], Y. Yang[2,3], M. Leduc[2,3], C. Eng[2,3], D. Ames[4], A. Carroll[4], M. Murugan[1], C. Kovar[1], W. Salerno[1], E. Boerwinkle[1,5], E. Venner[1], R. Gibbs[1].* 1) Baylor College of Medicine, Human Genome Sequencing Center, Houston, TX 77030; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston TX 77030; 3) Baylor Miraca Genetics Laboratories, 2450 Holcombe Blvd, Houston TX 77021; 4) DNAnexus, Mountain View, CA 94040; 5) Human Genetics Center, University of Texas Health Science Center at Houston, Houston, TX 77225.

Advancement of NGS applications in the clinical diagnostic arena requires methods for rapid, robust delivery of high-quality sequencing data covering clinically relevant genes and HIPPA compliant cloud-based tools for sample accessioning and reporting along with robust analysis pipelines for clinical applications. These combined laboratory and analytical methods enable rapid data generation, variant annotation, diagnostic interpretation and generation of clinical reports for large studies (>10,000 patient samples) using capture panels (~500kb) within a CAP/CLIA environment.   Our pipeline utilizes a '*lightning capture*' process to deliver variant calls in 5-7 days after sample intake. The '*lighting capture*' process includes: quick enrichment library preparation, (5-6 hours) and capture enrichment (approximately 14 hours); rapid sequencing (Illumina HiSeq2500) and data analysis via the HGSC-developed clinical pipeline - Neptune. Methods employ a cost-effective 47plex co-capture format for regional capture hybridization followed by sequencing 94 samples (2 capture pools) per HiSeq 2500 lane for data generation. To ensure integrity of the end-to-end process, we have implemented the Fluidigm SNPTrace assay by Fluidigm to confirm sample identity and detect potential sample cross-contamination.   Application of this pipeline includes a capture panel (CAREseq, 535kb) of 109 genes and ~1500 unique single nucleotide variant positions with known common genetic variants of clinical relevance for the National Institutes of Health eMERGE network. This clinical capture design and process has been validated utilizing 647 control samples. High enrichment efficiency was observed (>79% reads on target and buffer) and superior coverage metrics (99.7% of target bases ≥20x coverage, and 347x average coverage). A detailed analysis of the design performance using 42 de-identified samples found that known mutations were correctly identified with high confidence (100%), including CNV mutations. Coverage analysis of the 647 validation test samples, found only 14 exons with low coverage using the criteria of ≥10% of samples with coverage <20X, demonstrating the high quality of the capture reagent and process. This pipeline, including secure cloud-based sample accessioning and automated clinical reports for review will be used to process >12,500 samples for the eMERGE program. .

MTTE: An innovative strategy for the evaluation of targeted/exome enrichment efficiency. *K. Klonowska, L. Handschuh, A. Swiercz, M. Figlerowicz, P. Kozlowski.* European Centre for Bioinformatics and Genomics, Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznan, Poland.

Recently, next-generation sequencing (NGS) has become the leading method for analyzing the architecture of human genomes. Although currently available strategies for the preparation of exome-enriched libraries are well established, a final validation of the libraries in terms of exome enrichment efficiency prior to the sequencing step is of considerable importance. Here, we present a strategy for the evaluation of exome enrichment, i.e., the Multipoint Test for Targeted-enrichment Efficiency (MTTE), based on the well-validated protocol of multiplex ligation-dependent probe amplification (MLPA) method. Our assay for post-capture exome enrichment validation is composed of 20 MLPA probes, including 10 probes located in targeted genomic regions (mostly exons of protein coding genes and one region overlapping miRNA sequence), 9 probes located in non-targeted genomic regions (introns and intergenic regions), and one probe located in flank of the targeted regions. The MLPA probe set was designed according to a strategy developed previously in our group, allowing easy design and generation of assay for the analysis of almost any region of interest. We used the MTTE assay for the evaluation of enrichment efficiency at five consecutive steps of the Illumina TruSeq Exome Enrichment procedure, including libraries after the first and second steps of enrichment. The calculated values of enrichment-associated parameters (i.e., relative enrichment, relative clearance, overall clearance, and fold enrichment) and the comparison of MTTE results with the actual enrichment calculated based on the fraction of NGS reads mapping to the targeted regions revealed the high reliability of our assay. Additionally, we took advantage of our MTTE results to determine the potential sequence-associated features that may confer bias in the enrichment of different capture targets. The identified features (e.g., content of purines R=0.70, p=0.02) add to the current knowledge regarding factors that influence exome enrichment efficiency. Importantly, the MTTE strategy can be easily adapted to the region of interest important for a particular project, e.g., if particular genes are sequenced, target-specific probes may be located in each exon of the gene. The additional advantage of MTTE is its low cost (~5 USD per sample). Thus, the MTTE strategy is attractive for post-capture validation in a variety of targeted/exome enrichment NGS projects. Advances in small RNA NGS: Low input samples and automation. *S. Shore[1], J.M. Henderson[1], J.F. Quintana[2], F.W.N Chow[2], K. Chhatbar[2], G. Zon[1], A.P. McCaffrey[1], A. Buck[2], R.I. Hogrefe[1].* 1) Research and Development, TriLink BioTechnologies, San Diego, CA; 2) Infection and Evolution, University of Edinburgh, Edinburgh, UK.

Next-generation sequencing (NGS) is revolutionizing nucleic acid analysis. To obtain high quality sequencing data it is vital to minimize undesired products such as adapter dimers. These can occupy valuable flow cell space and result in unproductive reads. Many biological samples contain limited genetic material, thus it is important to use a library preparation method that yields highly specific final products from low input amounts. One of the more challenging sample types to prepare for sequencing is small RNA (sRNA). sRNAs are non-coding short regulatory RNA sequences, such as miRNA. Due to the inherently short lengths, a sRNA library is difficult to size select away from an empty library (known as adapter dimer). Therefore we developed a technology specifically targeted to reduce adapter dimer formation during small RNA library preparation using chemically modified CleanTag™ adapters. We found that without adapter dimer formation during the NGS sample preparation, small RNA libraries can be purified by an automatable bead-based size selection process eliminating the need for gel purification. In addition, reduction of adapter dimer formation allows for successful NGS sample prep with significantly lower total RNA inputs. For example with CleanTag™ modified adapters, gel purified libraries generated from 10 and 1 nanogram (ng) total human brain RNA input libraries resulted in 86% of total reads mapped to miRNA and less than 1% of total reads attributed to adapter dimer. At 10 ng input gel purified libraries from a commercially available kit resulted in only 40% of total reads mapped to miRNA while 50% of total reads attributed to adapter dimer. While commercial kits do not produce usable data at 1 ng, replacing gel purification with magnetic bead purification at 1 ng input, CleanTag™ libraries resulted in sufficient miRNA reads and less than 10% adapter dimer. We have successfully sequenced low RNA input biological samples such as extracellular vesicles, plasma, urine, FACS sorted and immunoprecipitated samples that have previously proven difficult to sequence. Sequencing results at 10 picogram total human brain RNA input show the potential to sequence small RNA at the single cell level using modified adapters. These results demonstrate the necessity of adapter dimer suppression and utility of CleanTag™ technology for both low input and high throughput library preparation. Currently, we are adapting CleanTag™ for use in long RNA sequencing.

Monitoring guide RNA synthesis for CRISPR/Cas9 genome editing workflow using the Agilent 2100 Bioanalyzer System. *M. Liu[1], A. Padmanaban[2], I. Pechtl[3].* 1) Agilent Technologies, Inc., La Jolla, CA; 2) Agilent Technologies, Bangalore, India; 3) Agilent Technologies, Waldbronn, Germany.

Bacterial clustered regularly interspaced short palindromic repeats (CRISPR) - associated protein 9 (Cas9) system has increased in popularity as a genome editing tool for targeted mutations, insertions, deletions and gene knockout studies. CRISPR genome editing has also proved superior to Zinc-finger nucleases (ZFN) and transcription activator- like effector nucleases (TALENs) due to its simplicity and easy programmability. In CRISPR, a guide RNA (gRNA) is used to recognize and introduce a double standard break (DSB) in a target DNA. The DNA repair mechanism triggered after the break is then exploited to introduce an insertion/deletion (indel) in the case of non-homologous end joining (NHEJ), or precise genetic modification if a homology-directed repair (HDR) pathway is triggered.A critical part of the CRISPR/Cas9 tool is the design and synthesis of the gRNA that comprises T7 promoter sequence, target sequence, and protospacer adjacent motifs (PAM). Monitoring the transcription of the gRNA is critical to the workflow to ensure successful gene editing.Here we present an automated electrophoresis approach for monitoring the synthesis of gRNA. The study involves design and synthesis of gRNA against two candidate genes by PCR amplification. The resulting amplicon is expected to contain all necessary components in gRNA to induce DSB. The synthesized gRNA is then purified to remove contaminating DNA oligos and checked for size and purity using the electrophoresis system.

Automation of genome gel-bead and library preparation kit for 10X Genomics Chromium Controller workflow. *M. Benway[1], P. Kocjan[1], A. Price[2], B. Gerwe[1].* 1) PerkinElmer, Inc. Life Sciences & Technology, Hopkinton, MA. USA; 2) 10X Genomics, Inc., Pleasanton, CA. USA.

The field of genomics is shifting towards longer-read sequencing than those typically obtained by current next-generation sequencing (NGS) technologies, in order to capture the full complexity of genomes. Current short-read sequencing technologies keep costs relatively low but the short-reads miss critical information including phasing, structural variants and the ability to map highly repetitive regions. Without this information, only a partial structure of the genome is realized with many mutations and variants being missed.   10x Genomics' Chromium™ platform is able to preserve this information over distances >150kb by linking the short-reads to a larger DNA fragment by use of a barcode. In this process, ~1 ng of DNA is partitioned into millions of nanoliter droplets via a microfluidic chip, each containing a unique barcode introduced by a co-partitioned gel bead. The generated libraries are currently compatible with all short-read sequencers, enabling this hidden information to be accessed without the need to invest in a new sequencing infrastructure. The use of finely-tuned liquid-handling systems becomes advantageous and ensures optimal performance when manipulating the novel 10x Genomics gel bead and partitioning oil reagents, as well as, preserving the integrity of high-molecular weight input DNA during routine handling.   Here, we describe and demonstrate how the uniquely flexible capabilities of the PerkinElmer Sciclone® NGSx Workstation interface with the 10x Genomics chip to successfully handle these specific requirements. We show the preservation of intact genomic DNA during automated library preparation and demonstrate that the libraries made using the Sciclone are of comparable quality to manual preparation. Automation is critical to the reproducible scale-up of high-throughput projects by removing manual variability, increasing efficiency, and enabling LIMs tracking. Combining the Sciclone with 10x Genomics' unique partitioning technology has the potential to unlock the promise of NGS in these large-scale studies.

Automated, high-throughput NGS library preparation from low input FFPE and cell-free DNA sample material. *B. Gerwe[1], V. Vanessa Kelchner[2], L. Cook[3], C. Fronick[3], V. Magrini[3], M. Benway[1], J. Laliberte[2], S. Sandhu[2], C. Schumacher[2], L. Kurihara[2], V. Makarov[2], T. Harkins[2], R. Fulton[3].* 1) Perkin-Elmer, Inc. Life Sciences & Technology, Hopkinton, MA; 2) Swift Biosciences, Inc., Ann Arbor, MI; 3) McDonnell Genome Institute at Washington University School of Medicine, St. Louis, MO.

While technical advances in Next-Generation Sequencing (NGS) have facilitated lower input sample volumes and material, the challenges of library bias and library complexity affecting data quality remain. Accel-NGS® 2S DNA Library kits (Swift Biosciences) have been designed to overcome these challenges providing uniform and more complete coverage, resulting in improved sequencing efficiency and reduced costs. Additional cost and time savings can be found in automating library preparation, leading to increased throughput while maintaining high-quality data and reproducibility with little to no variation across wells. In this study, we describe and demonstrate high-throughput automated NGS library preparation for targeted capture and WGS from 10ng FFPE and 10ng cfDNA on the PerkinElmer Sciclone® NGSx with Accel-NGS 2S DNA Library kits. An Alu 247/115 repeat assay was used to assess contamination of high molecular weight DNA, quantity and integrity of cfDNA and FFPE prior to library preparation. Reproducibility and quality were determined by qPCR, LabChip® GX analysis and subsequent sequencing on the Illumina HiSeq X10. As DNA extracted from FFPE exhibits varying degrees of damage, the Alu repeat assay is an accurate way to assess and quantify usable DNA. Our results show a DNA integrity score (ratio of ng/µl Alu 247/115) of ≥0.4, improving as fixation time decreases. For cfDNA, the expected integrity score of ≥0.29 was achieved. DNA quantity was sufficient for 10ng input into the prep. Library yields were sufficient for sequencing, and LabChip analysis validated the targeted insert size of 350bp for FFPE and 165bp for cfDNA. Sequencing of manual versus automated library preparations yielded similar results: ultra-low duplication, no adapter dimer formation, median insert size in-line with the LabChip results and library complexity as expected for 10ng human gDNA. Accel-NGS 2S DNA Library kits on the Sciclone NGSx provide sequence-ready libraries, with equal or better reproducibility and quality to manually prepared libraries. Highly efficient library preparation driven by end repair of both 3' and 5' DNA termini delivers a more complex library requiring less sequencing, enabling comprehensive analysis of low input DNA samples such as FFPE and cfDNA. Significant cost savings and improvement in lab efficiencies were achieved combining the use of PerkinElmer automation for higher throughput library prep with Swift's highly efficient library preparation.

Single molecule targeted sequencing for cancer gene mutation detection. *J. He[1,2].* 1) Department of Biology, South University of Science and Technology of China, Shenzhen, Guangdong, China; 2) Direct Genomics Ltd. Shenzhen, Guangdong, China.

With the rapid decline in cost of sequencing, it is now affordable to examine multiple genes in a single disease-targeted clinical test using next generation sequencing. Current targeted sequencing methods require a separate step of targeted capture enrichment during sample preparation before sequencing. Although there are fast sample preparation methods available in market, the library preparation process is still relatively complicated for physicians to use routinely. Here, we introduced an amplification-free Single Molecule Targeted Sequencing (SMTS) technology, which combined targeted capture and sequencing in one step. We demonstrated that this technology can detect low-frequency mutations using artificially synthesized DNA sample. SMTS has several potential advantages, including simple sample preparation thus no biases and errors are introduced by PCR reaction. SMTS has the potential to be an easy and quick sequencing technology for clinical diagnosis such as cancer gene mutation detection, infectious disease detection, inherited condition screening and noninvasive prenatal diagnosis.

Improvements to chromatin immunoprecipitation applications through more robust library preparation methods. *A. Blattler[1], K. Cunningham[2], K. Chen[1], L. Kurihara[2], B. Egan[1], V. Makarov[2], T. Harkins[2], T. Kelly[1].* 1) Active Motif, Inc., Carlsbad, CA, USA; 2) Swift Biosciences, Inc., Ann Arbor, MI, USA.

Chromatin immunoprecipitation followed by Next Generation Sequencing (ChIP-seq) has allowed for the genome wide identification of transcription factor binding sites and histone modifications, providing insight into key mechanisms of gene regulation in human disease. One limitation in ChIP-seq is the requirement for millions of cells, making it difficult to perform the assay in primary cells and tissues. Recent advancements by Active Motif enabled high-quality ChIP from lower cell numbers and from difficult formalin-fixed, paraffin-embedded (FFPE) tissues. However, due to low-abundance or damaged DNA, standard library preparation methods limited the ability for these methods to be applied genome-wide. The Swift Accel-NGS 2S Plus DNA Library Kit dramatically improved the sequencing of these samples due to high efficiency library conversion at low input. By combining both 5' and 3' end repair with optimized ligation that requires no adapter titration at low input, libraries representing the target complexity of these samples could be generated. Here we present data demonstrating how the combination of Swift library technology and Active Motif's ChIP technology has enabled high quality sequencing of several ChIP-based applications. CTCF ChIP-Seq using 2S Plus from 50,000 cells resulted in peaks comparable to ENCODE data for CTCF from 20,000,000 cells. Additionally, Active Motif and Swift have enabled ChIP-seq from as little as 1,000 cells for histone modifications and increased resolution from FFPE ChIP-sequencing experiments.

3215T

CHDbase: A genomic variation data warehouse for congenital heart disease. *J. Fitch[1], D. Gordon[1], S. Fitzgerald-Butt[2], V. Garg[2], K. McBride[2], P. White[1].* 1) The Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH; 2) Center for Cardiovascular Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH.

In a simple case, the genetic cause of a disease can be determined by sequencing the DNA from an affected individual, comparing that sequence to a known reference, and then looking through the locations where the sequences differ for a variation that is known to cause the phenotype in question. However, since an average person has 4 - 5 million sites where their genome differs from the reference, it is impractical to manually evaluate them all. Many different techniques have been developed to automate the reduction of this list by assuming that some characteristics of a variant make it unlikely to cause a rare disease, such as a high frequency in non-diseased populations, being a synonymous change, or occurring in a region of the genome that is not highly conserved. When the straightforward approaches to finding causative genetic mutations fail, a larger cohort study can be performed that attempts to find association between variants that are found in many examples of diseased genomes while not being found in control genomes. One of the main challenges with this approach is that as cohort sizes are increased, to increase the statistical power of the study, computational complexity is increased as well. Further exacerbating the computational challenge is the realization that some of the simplifying assumptions are not valid. For example, causative variants may be non-coding, or caused by rare combinations of more common variants. These factors drive the requirement for a Big Data approach. Hadoop is a popular Big Data distributed storage and computation framework that has been widely used in many different data science fields. The goal of this project is to leverage this technology to facilitate the storage and analysis of genomic variation from large cohort studies in order to find causative mutations. To prove the effectiveness of this approach, we have loaded variant data for 800 whole exome and whole genome sequenced samples in a study to identify the genetic etiologies of congenital heart disease (CHD). The variant warehouse design allows integration of multiple data sources, including variant frequency, damaging prediction criteria, and phenotypic data. Writing applications to process CHD variant data stored in this variant warehouse provides a mechanism to rapidly perform complex data processing steps with a great deal of flexibility and enabling the development of the oligogenic functionality required to look beyond monogenic disease etiologies.

Accelerating discovery in the undiagnosed: Nationwide Children's Hospital's Research Genomics Strategic Initiative. *B. Kelly[1], T. Mihalic Mosher[1], D. Corsmeier[1], H. Kuck[1], J. Fitch[1], K.L. McBride[2], G.E. Herman[1], P. White[1].* 1) The Institute for Genomic Medicine at Nationwide Children's Hospital, Columbus, OH; 2) The Center for Cardiovascular Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH.

A key component of Nationwide Children's Hospital's strategic plan is to integrate genomics into the everyday practice of pediatrics. Following our participation in the CLARITY Undiagnosed Challenge, we set out to create an interdisciplinary research program to identify new disease genes for pediatric disorders through exome and whole genome sequencing, translational bioinformatics and functional genomics. CLARITY Undiagnosed, launched by Boston Children's and Harvard Medical School, was markedly more difficult than the original CLARITY challenge. Whole genome sequencing data was provided for families for whom extensive clinical and genetic testing had been previously performed with few to no answers. Competitors were asked to provide reports on their findings that could be interpreted by researchers, medical professionals and families. The key to our approach was the diversity of the team that we assembled, with clinical geneticists, genomic researchers, genetic counselors, clinicians with phenotypic expertise and bioinformaticians to review clinical results, assign phenotypes, discuss analyses and agree on results to report. Our team was specifically recognized for its ability to combine research and clinical expertise, "setting a high bar for clinical genomics." Building upon this success, we have established a new Research Genomics Program at Nationwide Children's Hospital with two main goals: 1) to educate clinical faculty on the use of genomics approaches in patient care, treatment, and precision medicine and 2) to discover novel, disease-causing variations in targeted clinical populations. To achieve these goals, we formed a Steering Committee to solicit cases from clinicians within the hospital and a Genomic Review Board to decide case qualification and play an active role in the analysis and review of cases. We are utilizing advanced techniques for sequencing, analysis and annotation, and applying a variety of computational approaches to prioritize candidate genes. To date, we have 20 rare disease families identified and/or enrolled, representing 7 hospital sections (Genetics, Rheumatology, Neonatology, Neurology, Hematology/Oncology, Gastroenterology and Endocrinology). Ten of these families have been consented, sequenced and analyzed with three pathogenic variants discovered in known genes, demonstrating the power of our approach for genomic diagnosis while leading to the discovery of new disease genes. An update on our efforts will be presented.

3217W

Variation in accuracy of genetically determined sex from genome-wide genotyping chip arrays according to low frequency SNP content. *S. Provost[1,2], G. Asselin[1,2], L-P. Lemieux Perreault[1,2], D. Valois[1,2], I. Fillion[1,2], V. Normand[1,2], L. Mailloux[1,2], I. Mongrain[1,2], J-C. Tardif[1,2,3], M-P. Dubé[1,2,3].* 1) Montreal Heart Institute, Montreal, Canada; 2) Université de Montréal Beaulieu-Saucier Pharmacogenomics Centre, Montreal, Canada; 3) Université de Montréal, Faculty of Medicine, Montreal, Canada.

At the Université de Montréal Beaulieu-Saucier Pharmacogenomic Centre, we have genotyped large numbers of samples from clinical and observational studies. As part of our regular procedures, we perform genomic quality control verification including the concordance between clinically reported sex and genetically determined sex. In the present study, we assessed genetically determined sex using: i) the PLINK F statistics, ii) heterozygosity of the X chromosome, iii) the number of genotype calls on the Y chromosome, and iv) by comparing mean intensities of X and Y chromosome probes using the log R ratio (LRR) and B allele frequency graphics (BAF). Genotype data was generated for over 44,000 DNA samples from 8 randomized clinical studies and 3 large observational studies tested with different Illumina genome-wide BeadChip arrays (Human610quad, ExomeChip, Omni2.5, Omni2.5-exome, HumanCore, and MEGA). Analyses were performed using the pyGenClean data clean up pipeline. We found that the rate of X-chromosome heterozygosity in females varied according to the array's low frequency SNPs content (minor allele frequencies <0.05) and that it had an impact on the performance of metrics to assess the concordance between clinically reported sex and genetically determined sex. In particular, X-chromosome heterozygosity was 30% for arrays with lower low frequency SNP content (610quad, HumanCore), 20% for arrays with intermediate low frequency SNP content (Omni2.5), 10% for arrays with high low frequency SNP content (Mega) and finally, 4% for chips with very high low frequency SNP content (ExomeChip). In order to optimize accuracy of genetically determined sex by GenomeStudio and Beeline, we report on array-specific expected parameters for quality metrics for the determination of sex. Across the different studies, sex discrepancies ranged from 0.12% to 0.97% and originated from different sources. Sex chromosome abnormalities represent a minority of the sex mismatches, and we report on the rates of putative XXX, XXY, partial loss of heterozygosity (LOH) and XO/XX mosaics detected based on to the tested quality metrics. This study highlights the importance of genomic quality control metrics calibration with evolving genotyping chip content.

Detection and depletion of bacteria contamination in saliva derived DNA samples for human whole genome sequencing. *M. Costello, N. Lennon, S. Gabriel, Broad Data Sciences and Data Engineering Group.* Genomics Platform, Broad Institute, Cambridge, MA.

Obtaining saliva from patients for downstream genomic analysis has become increasingly popular as collection kits are easy to use and are much less invasive than blood draws or biopsies. However, one major drawback of saliva samples is the presence of non-human DNA, mainly due to oral bacterial contamination. In reviewing data from the 2500 saliva samples processed over the past year through our whole genome sequencing (WGS) pipeline, the average non-human contamination in saliva derived WGS samples is about 10% but can range anywhere from just 1% to greater than 70%. This non-human contamination makes achieving the desired human genome coverage quite difficult, incurring extra sequencing costs and often requiring additional filtering steps during data analysis. Here, we present our two pronged approach for dealing with bacterial DNA contamination in human samples. First, we are developing a specific and sensitive QPCR assay to detect and quantify the amount of bacterial contamination in saliva derived DNA samples. Second, we are also developing methods to deplete bacteria DNA from human samples which allow separation of prokaryotic DNA from the CpG-methylated eukaryotic human DNA. Implementation of these methods will allow us to assess % contamination in a high throughput manner and provide methods for enriching for human DNA prior to library preparation and sequencing. Combined, these new methods will allow us to separate out samples with extremely high contamination, move forward with those with low contamination, and rescue samples with moderate contamination via the depletion protocol. Implementation of these processes will reduce sequencing costs, improve usable data yield, and simplify downstream analysis for saliva derived WGS samples.

Automated, low-cost and low-input RNA-Seq and DNAseq library preps. *S. Vaezeslami[1], S. Srinivasan[3], P. Malihi[2], P. De Hoff[3], T. Herrero[3], T. Cuong[3], J. Jenkins[1], L. Laurent[3], J. Hicks[2], P. Kuhn[2].* 1) TTP Labtech, Cambridge, Ma; 2) University of Southern California, Los Angeles, CA; 3) University of California at San Diego, San Diego, CA.

Significant decrease in sequencing costs, having access to genomics automation platforms, and recent increase of both research and clinical sequencing applications have led to a larger demand for high-throughput, low-cost and low-sample input NGS sample preps. Using low volume liquid handlers, with low dead volume and ability to work with difficult and viscose solutions at sub-microliter volumes offer many advantages in NGS sample prep processes, such as library construction, quantification and normalization/pooling. These advantages include lower cost, higher throughput, better reproducibility, less hands-on time, less sample input, and improved process control. In this poster we will discuss two applications in which the sample prep volumes were reduced to sub microliter volumes in order to significantly lower the cost and amount of sample input. Moreover we discuss a 384-well low-volume Ampure bead clean up performed in less than 1 hour. mosquito liquid handler, based on true-positive displacement technology, has been instrumental in these workflows to provide an accurate, precise and reliable walk-up solution. In the first example the volumes of NEBNext® Ultra™ II DNA Library Prep kit (E7645S) were reduced by 10 times and the amount of sample inputs were reduced to 5, 37 and 60 ng in 6.5 µL total volume, from 185 ng sample input in manual reaction set up at 65 µL. In the second example the reaction volumes and sample inputs of NEBNext® Small RNA Library Prep kit for Illumina® (E7580) were reduced by more than 5 times (down to 1 ng of input RNA). The results of miniaturized volumes sample preps were compared to those of manual set up at the same or larger volumes. Sequencing data show that the results are not affected by lowering the sample input or volumes. The most important factors are having an accurate and precise liquid handler to avoid sample to sample variation when miniaturizing the volumes and sample inputs. Finally, we discuss a magnetic bead clean up protocol in less than 5 uL total volume and in 384 well plate format. The challenges of low volume bead clean up in 384 format are the large tip dimensions and high dead volume of most large volume liquid handlers. By using mosquito HV liquid handler and doing the clean up in less than 5 µL the required sample input and the amount of magnetic beads used were dramatically reduced, which in turn will save on the cost, especially for high throughput applications.

Ligation-free small RNA sequencing libraries from clinical samples using SMART® technology. *A. Farmer[1], N. Bolduc[1], S. Lee[1], K. Tanriverdi[2], E. Malahias[2], E. Mikhalev[2], J. Freedman[2].* 1) Takara Bio USA, Inc., 1290 Terra Bella Ave, Mountain View, CA 94043, USA; 2) University of Massachusetts Medical School, Department of Medicine, Division of Cardiovascular Medicine, Worcester, MA 01605, USA.

Small non-coding RNAs regulate gene expression via diverse mechanisms and facilitate fundamental cellular processes such as transcript splicing and protein translation. Moreover, small RNAs may act at sites different from their original production via incorporation and transport in bodily fluids. Obtaining an accurate portrait of small RNA expression levels from small sample inputs carries potential both for the fulfillment of basic research objectives and the development of novel therapeutics and clinical diagnostic solutions. Towards this end, we have developed a novel, ligation-free approach for the preparation of small RNA sequencing libraries that leverages 3′ RNA polyadenylation followed by cDNA synthesis and template switching. This approach minimizes sample representation bias and is sensitive enough to accommodate inputs of as little as 1 ng of total RNA. Here we present data demonstrating the accuracy, sensitivity, and reproducibility afforded by the SMARTer® smRNA-Seq Kit for Illumina®. Using a library of synthetic miRNAs, we show that the SMARTer method generates a more accurate representation than the typical adapter ligation method. Furthermore, we successfully created high-quality libraries using 400 pg to 1 ng of RNA extracted from plasma and serum samples, demonstrating the suitability of the SMARTer approach for applications such as biomarker discovery.

3221T

Improved expression profiling and cellular localization of circRNA molecules in human samples. *A. Zaghlool[1], A. Ameur[1], C. Wu[2], J.O. Westholm[1], M. Manivannan[3], K. Bramlett[3], M. Nilsson[2], L. Feuk[1].* 1) Science for Life Laboratory, Department of Immunology, Genetics and Pathology, Uppsala University, Sweden; 2) Science for Life Laboratory, Department of Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden; 3) Clinical Sequencing Division, Life Science Solutions Group, Thermo Fisher Scientific, San Francisco, CA, USA.

There is strong evidence that circular RNAs (circRNAs) play an important role in gene regulation and may contribute to the development of various human disorders. However, the global properties of circRNAs such as accurate estimation of expression levels and cellular localization remain elusive. Here, we developed an Ion AmpliSeq™ target-enrichment sequencing panel to provide an accurate estimation of circRNAs expression levels and to increase the sensitivity for the detection of circRNAs expressed at low levels. Moreover, we adapted the previously published PadLock technology to visualize circRNA in situ at subcellular levels. To evaluate the circRNA panel, we performed sequencing on total, cytoplasmic and nuclear RNA extracted from human cell lines, brain, liver, heart, placenta and blood (total number of samples=30) using the Ion Torrent™ system. Our panel included 130 circRNA and 130 linear targets from the same genes and 15 negative controls (coding sequences lacking annotated circRNAs). The circRNA sequencing produced around 8 million reads per sample, of which 97% where mapped to the targets in the panel. CircRNA expression showed high correlation between technical replicates (R=0.98), highlighting the reproducibility of the panel. In agreement with previously published data, we show that the majority of circRNAs are located in the cytoplasm, and that circRNA expression levels vary between tissue types. Our results also show that circRNAs are detectable in human blood and we will further investigate other types of samples including serum and FFPE material. Our panel increased the sequence coverage for circRNA targets by several orders of magnitude as compared to expression levels obtained from total RNA sequencing, thereby providing increased sensitivity for detecting circRNAs expressed at low levels. Moreover, the unique design of the panel allows an accurate estimation of expression ratios between circRNA and their linear counterparts. These ratios were validated using qrtPCR. CircRNAs visualization using FISH has been challenging due to their short sequence length. By adapting the PadLock method on fixed SHSY-5y cells we also demonstrate an efficient visualization of circRNA localization in situ on a subcellular level. In summary, we describe a novel, cost effective and scalable sequencing panel to accurately estimate circRNA expression from various input materials, as wells as an efficient method to determine their subcellular localization.

Measuring warfarin resistance of every *VKOR* variant to guide dosing.
M.A. Chiasson[1], A.E. Rettie[2], D.M. Fowler[1]. 1) Genome Sciences, University of Washington, Seattle, WA; 2) Medicinal Chemistry, University of Washington, Seattle, WA.

Vitamin K epoxide reductase (VKOR) is the target of warfarin, a commonly prescribed anticoagulant with an extremely narrow therapeutic window. Warfarin-related hemorrhages result in an estimated 21,010 hospitalizations yearly. Approximately 30% of the variation in warfarin dose is driven by sequence variation in *VKOR*. Thus, knowing a patient's *VKOR* sequence before initiating treatment could allow for more precise dosing if we knew its warfarin resistance phenotype. However, only 28 of the 54 known missense variants in *VKOR* have been characterized for warfarin resistance. These 54 are only the tip of the iceberg: as more people are sequenced, additional variants will appear. To address this issue, I am measuring the warfarin resistance of all 3,260 VKOR missense variants using deep mutational scanning, a method that combines high throughput mutagenesis with deep sequencing. I created a reporter cell line with the endogenous *VKOR* gene knocked out and am engineering a library of these cells to contain all VKOR missense variants. I will use a flow cytometric assay to sort variants into bins according to VKOR activity across a range of warfarin doses. Deep sequencing of each bin will enable me to calculate an IC_{50} value for every variant. I will validate IC_{50} values for a subset of variants using traditional assays and clinical data. These IC_{50} data will comprise a *VKOR* sequence-resistance map that reveals how each singly mutated variant we could observe in a patient affects warfarin resistance. My ultimate goal is to develop a *VKOR* sequence-based dosing algorithm to help clinicians start patients on the appropriate dose of warfarin.

MinION nanopore sequencing of human leukocyte antigen-B region.
K.N.T. Ton, S. Cree, A.L. Miller, M.A. Kennedy. Department of Pathology, University of Otago, Christchurch, Canterbury, New Zealand.

The human leukocyte antigen (HLA) system is a gene family that encodes the human major histocompatibility complex (MHC). The HLA complex plays a key role in the human immune system by presenting peptide antigens to T-cells. *HLA-B* is the most polymorphic genes in MHC class I, leading to over 4000 *HLA-B* alleles (IPD-IMGT/HLA Database Release 3.24). Many *HLA-B* alleles have been associated with adverse drug reactions and disease risks. *HLA-B* alleles are routinely identified by PCR-sequence-based typing (PCR-SBT) but the use of Sanger sequence data and genotypes can lead to difficulties resolving allele ambiguities. MinION is a nanopore sequencing device developed by Oxford Nanopore Technologies (Oxford, UK). This pocket-sized device allows generation of long reads on single molecules. A fragment of 1,704 bp and a sub-region of 943 bp covering *HLA-B* exon 2 and 3 from six DNA samples were amplified by nested-PCR. Both PCR amplicons of each sample were tagged with sequencing adapters and two different barcodes. All 12 amplicons were pooled and purified using Genomic DNA Sequencing kit (ONT). The library was loaded into the R7.3 flow cell and run for 48 hours. Raw sequence data was uploaded for base-calling using Metrichor software (ONT) and followed marginAlign pipeline (Jain et al., 2015) for mapping and variant calling. Data were compared with sequences obtained from PCR-SBT method. Using the MinION, we have sequenced *HLA-B* gene for 6 samples with two different read lengths. A total of 1,090 reads were parsed using uniquely identifying barcode, of which 100% were correctly aligned to the reference sequence. The mean of read length was 1,357 bases and average of read depth was 80X. There was a high consistency of variant calls when comparing within each sample pairs indicating there was no difference in sequencing quality between two amplicon sizes. Comparing with data from Sanger sequencing, we found that the discordant call rate was high, but good quality data could still be discriminated. Our conclusion is that the MinION is capable of sequencing *HLA-B* amplicons of multiple barcoded samples, and variants can be detected. However, the fact that MinION reads from the R7.3 chemistry are relatively error-prone, combined with HLA complexity, make accurate interpretation of haplotypes difficult. We will shortly repeat these analyses with the new MinION R9 flow cells which should lead to increased accuracy and read depths.

3224T

A highly sensitive cDNA kit for single cell or low input RNA-seq workflow. *Y. Bei, N. Guan, T. Shtatland, B.W. Langhorst, E. Yigit, N.M. Nichols.* New England Biolabs, Ipswich, MA.

RNA sequencing (RNA-seq) based transcriptome studies have become an important tool for gene expression profiling from diverse tissues, cell types, developmental stages and diseases. Until recently, most of the RNA-seq studies have required relatively high sample inputs, which can limit the study of low abundance samples such as relied on input from bulk samples, which can pose challenges for the study of low abundance samples, such as stem cells, circulating tumor cells (CTCs) (CTCs) or other scarce clinical samples. More recently, single cell RNA-seq has emerged as a powerful approach to characterize the gene expression heterogeneity of gene expression within phenotypically identical cell populations. Findings from such single cell RNA-seqthese studies have important implications in both basic research and clinical settings, including the study of tumor microevolution to develop potential targeted therapies.   To address support the growing needs in the area of single-cell transcriptomics research, we have developed a simple and robust single cell or low input (10 pg to 200 ng) RNA-seq workflow in which full- length cDNAs are first generated directly from cell lysis in a single tube**.** that transcribes and amplifies full length cDNAs in a single tube from either single cells or low input total RNA ranging from 10pg to 200ng. The resulting cDNA libararies are subsequently converted into sequencing-ready Illumina libraries using the NEBNext® Ultra™ II DNA Library Prep Kit, or alternatively can be converted into libraries for other major NGS platforms. can be easily further converted into NGS libraries that are compatible with any major sequencing platforms. In this work,Using this method and other commercially available alternatives, we present collected RNA-seq data from single HEK 293 cells and low input Universal Human Reference RNA (UHR) with an ERCC reference RNA spike-in., Compared to other methods, we observed using our cDNA Kit in conjunction with NEBNext® Ultra™ II DNA Library Prep Kit. For comparison, we also prepared libraries using SMART-Seq v4 Ultra Low Input RNA Kit for Sequencing from Clontech. hHigher library yields and a reduction in bias against transcript 5' ends with our low-input cDNA synthesis approach. were observed in samples prepared with our method described in this work. In addition, In addition, our workflow identified significantly more transcripts from both samples examined in this study.

Post RNA-seq analysis GUI. *J. Chung[1,2], G. Jun[1,8], L.A. Farrer[1,2,3,4,5,6,7].* 1) Biomedical Genetics, Boston University Medical Campus, Boston, MA; 2) Bioinformatics Graduate Program, Boston University, Boston, MA; 3) Department of Medicine, Boston University Medical Campus, Boston, MA; 4) Department of Biostatistics, Boston University Medical Campus, Boston, MA; 5) Department of Neurology, Boston University Medical Campus, Boston, MA; 6) Department of Ophthalmology, Boston University Medical Campus, Boston, MA; 7) Department of Epidemiology, Boston University Medical Campus, Boston, MA; 8) Eisai Inc, Andover Product Creation Innovation System, Andover, MA.

Most current RNA-Seq data analysis tools were developed primarily for the purposes of differential expression gene (DEG) analysis and quality control (read mapping). We developed an interactive software program, *Post-RNA-Seq graphical user interface (GUI),* which facilitates exploration of the association of genetic variants with expression of individual transcripts and corresponding amino acids in protein structures. *Post-RNA-Seq GUI* software is designed to integrate 1) isoform-specific expression levels resulting from the RNA-Seq analysis tool, RSEM (*Li B et. al.* 2011) or MISOPY (*Katz Y et. al.* 2010); 2) genotype and DNA sequence data; and 3) protein structure data. Users can explore specific transcripts (or exons) of their interest in published genetic association studies (e.g. quickly determine whether any genetic loci been detected near the transcripts) and compare isoform expression levels between cases and controls and detect significant cis-acting eQTLs for the transcripts. Finally, users can view the amino acids encoded by specific variants in 3-dimensional (3D) protein structures of the transcripts. In summary, *Post-RNA-Seq GUI* allows exploration of diverse types of data resources to search for other important information related to RNA-Seq findings using a graphical interface. This software saves time and effort which might otherwise be expended on manually exploring many datasets.

RNASeq 2.0 @ Broad Genomics: Advances in RNA sequencing analysis.
C. Cibulskis, M. Shand, K. Bergin, A. McBeth, G. Vicente, Y. Farjoun, K. Tib-betts, N. Lennon. Broad Institute of MIT and Harvard, Cambridge, MA.

   RNA sequencing has the potential for broad reaching applications in clinical research and clinical diagnostics[1]. Approaches to the generation and analysis of RNA sequencing data has numerous potential endpoints including, but not limited to, the detection of variants, gene fusions, alternative splicing, and expression profiling. The ability to generate high quality RNA sequencing data and perform sensitive and efficient analyses is critical to realizing the full value of transcriptome data in clinical research and clinical practice. Broad Genomics and our collaborating research teams have a long history of generating and analyzing RNA sequencing data for both cancer[3,4] and germline applications[2]. Analytic tools currently available for RNA sequencing analysis are many and varied in terms of application, practicality and efficiency. To better enable our research teams to gain optimal utility from RNA based studies, we complete-ly reassessed the data and analyses that we are delivering. We then built and launched an updated RNASeq 2.0 pipeline that includes optimized read alignment, fusion, expression, and variant detection. Broad RNASeq 2.0 will be made available in our cloud-based analysis workbench (FireCloud) and will facilitate scalable and rapid analysis runs, RNA/DNA analysis integration and ease of data sharing. We will describe the details and merits of Broad RNASeq 2.0 as well as other important improvements in our laboratory processing.   1: Byron SA, Et al. Translating RNA sequencing into clinical diagnostics: oppor-tunities and challenges. Nat Rev Genet. 2016 May;17(5):257-71. doi:10.1038/nrg.2016.10. 2: GTEx Consortium. Human genomics. Sensitive capture of full-length transcript information with targeted RNA-seq. *S. Gandlur, R.N. Fish, S. Zhang, Y. Gindin, S. Taylor, A. Farmer.* Takara Bio USA, Mountain View, CA.

   While recent advances in technology have greatly improved research in whole transcriptome RNA-seq, several challenges still remain, stemming from the complexity inherent in such large-scale sequencing. The large dynamic range of the transcriptome often means that a few highly abundant transcripts account for the majority of sequencing reads while less-abundant transcripts (representing a majority of RNAs) account for only a small percentage of se-quencing reads. Targeted RNA-seq aims to overcome this problem by improv-ing sequence coverage of transcripts of interest that may be present in low amounts, saving costs, and simplifying analysis. Sensitive targeted enrichment of RNA enables the capture of information about transcripts that would other-wise be missed or would require a much greater number of sequencing reads to be detected, including chimeric gene fusions, transcript isoforms, and splice variants. We combined a streamlined method for direct capture of full-length transcripts from total RNA with the cDNA synthesis technology of the SMART-Seq® v4 Ultra® Low Input RNA Kit for Sequencing to develop a target-specific protocol with high sensitivity and low background. The resulting RNA capture method demonstrates consistent enrichment and coverage from 1 ng to 1 µg of a variety of total RNA inputs. By capturing full-length transcripts, the protocol enables the detection of structural variation in expressed RNAs. For example, we identified a gene fusion event present at a frequency lower than 0.5% in a sequencing library of fewer than 2 million reads while targeting only one partner of the gene fusion. Additionally, we were able to maintain relative expression levels for targeted genes post-enrichment, providing confidence in differential expression analysis of transcripts of interest. Furthermore, the substantial increase in coverage of only a subset of genes of interest results in a lower sequencing depth required, thereby reducing analysis time and experimental costs.

3228F

Parsing nature's modification strategies in defining new therapeutic targets for Marfan syndrome. *J.P. Habashi[1], E.G. MacFarland[2], N. Huso[2], R. Bagirzadeh[2], Y. Chen[2], D. Bedja[2], H.C. Dietz[2,3].* 1) Dept Pediatric Cardiology, Johns Hopkins Univ, Baltimore, MD; 2) Dept Genetics, Johns Hopkins Univ, Baltimore, MD; 3) Howard Hughes Medical Institute, Bethesda, MD.

Marfan syndrome (MFS) is an autosomal dominant disorder caused by mutations in FBN1. The leading cause of mortality is aortic root dilation and dissection. Women with MFS show an enhanced risk of accelerated aortic dilatation or tear late in pregnancy or in the early postpartum period. We previously identified oxytocin as a critical mediator in mice homozygous for a hypomorphic Fbn1 allele (mgR/mgR). 91% of mgR/mgR females die from aortic dissection in the immediate postpartum period; prevention of lactation or treatment with a highly specific oxytocin receptor antagonist diminished ascending aortic growth rate (0.54 ± 0.43 and 0.44 ± 0.49 vs. 1.02 ± 0.61mm/7weeks in placebo treated mice, respectively) and resulted in a dramatic decrease in death from dissection (26% and 7%, respectively). Curiously, the deleterious gene-by-environment interaction imposed by pregnancy closely mimicked that observed upon exposure of MFS mouse models to calcium channel blockers (CCBs); both showed acceleration of growth and a unique predisposition for tear in the distal ascending aorta (AscAo) – an aortic segment typically spared in both people and mice with MFS. Using a genetic modifier screen and a candidate-based approach, we previously showed that CCB-induced aortic disease in MFS relates to a PLC/IP3/MAP3K4/MEK/ERK axis of activation in aortic vascular smooth muscle cells. Based upon phenotypic concordance, we reasoned that this same pathway might be relevant to pregnancy-induced disease; this hypothesis was strengthened by the knowledge that oxytocin activates peripheral tissues such as the myometrium through PLC activation. We observed that hydralazine, an antihypertensive agent that is FDA-approved in pregnancy and inhibits IP3-mediated events, achieved a near-complete rescue from dissection (5%) and abrogation of pathologic growth of the AscAo (0.23 ± 0.32mm/7wks; $p \leq 0.0001$). Hydralazine clearly outperformed a hemodynamically equivalent dose of propranolol that lowers blood pressure but does not address aberrant signaling (43% dissection and 0.59 ± 0.28mm/7wks; $p \leq 0.05$). In keeping with hypothesis, we also found that the recently FDA-approved MEK antagonist trametinib reduced both postnatal death due to aortic dissection (15%, $p \leq 0.0001$) and AscAo growth (0.64 ± 0.55mm; $p \leq 0.05$) in MFS mice. All outcomes showed direct correlation with the extent of ERK phosphorylation in the aortic wall. These data illustrate the power of modifier studies in defining therapeutic opportunity.

3229W

What to expect when she's expecting: The development of multidisciplinary obstetrical and neonatal management guidelines for Long QT syndrome types 1 and 2 in British Columbia. *S.F. McIntosh[1], J. Hathaway[2], J. Grewal[3], V. Rychel[4], H. Bos[5], E. Sherwin[6], A. Krahn[3], L.T. Arbour[1].* 1) Department of Medical Genetics, University of British Columbia (Island Medical Program), Victoria, BC, Canada; 2) BC Inherited Arrhythmia Program, St. Paul's Hospital, Vancouver, BC, Canada; 3) Division of Cardiology, Department of Medicine, University of British Columbia, Vancouver, BC, Canada; 4) Department of Obstetrics and Gynaecology, St Paul's Hospital, Vancouver, BC, Canada; 5) Perinatology, Victoria General Hospital, Victoria, BC, Canada; 6) Division of Pediatrics, Department of Cardiology, University of British Columbia, Vancouver, BC, Canada.

Background: Although the majority of women with Long QT syndrome (LQTS) type 1 or 2 have uneventful pregnancies, extra monitoring of the mother, fetus and newborn from conception to the postpartum period is warranted to prevent adverse outcomes. Maternal issues include choice and titration of beta-blocker and monitoring for cardiac events, especially in the higher risk postpartum period. Fetal growth surveillance is required due to the association between beta-blockers and intrauterine growth restriction (IUGR). The newborn must be followed carefully due to the possibility of adverse effect of beta-blocker exposure in utero or through breast milk. To date, no comprehensive guidelines exist to guide clinicians on best practices for obstetrical and postpartum management of LQTS. Frequent clinical dilemmas prompted the BC Inherited Arrhythmia Program to form an expert group to develop Provincial consensus guidelines. The expert team, comprised of an obstetrician and cardiologist from a high-risk cardiac obstetric clinic, pediatric and adult electrophysiologists, geneticists, and a perinatologist, reviewed the literature and held meetings over a 2-year period to gather input, build consensus, and invite input from primary care providers. **Recommendations:** These consensus guidelines provide specific expert-level recommendations including: *Maternal-*Titrate beta-blocker up through the latter stages of pregnancy due to increasing blood volume and excretion, and back down to pre-pregnancy levels in the postpartum period -Schedule routine ECGs until 12 weeks postpartum to monitor/optimize beta-blockade -During labour, anaesthesia, and delivery: avoid potential triggers for ventricular arrhythmia such as QT-prolonging medications, electrolyte imbalance, excessive bleeding and prolonged 2nd stage pushing *Fetal-*Monitor fetal growth by ultrasound at 18, 28 and 36 weeks, with follow-up scan in two weeks and referral to obstetrician if any growth concerns identified *Neonatal-*Monitor for signs of beta-blockade (drowsiness, hypotension, and hypoglycemia) in the newborn and breastfeeding infant -Perform ECGs at 24 hrs and 3 weeks of age -Discuss genetic testing for LQTS (if known mutation in family) **Conclusion:** These multidisciplinary obstetrical and neonatal management guidelines for LQTS types 1 and 2 provide a foundation for further national and international practice guidelines. Evaluation from patient and provider perspectives will determine next steps.

3230T

Polymorphisms in CYP2C9 are associated with response to indomethacin among neonates with patent ductus arteriosus. *C.J. Smith[1], A.M. Momany[2], K.K. Ryckman[1,2], J.M. Dagle[2].* 1) Department of Epidemiology, University of Iowa, Iowa City, IA; 2) Department of Pediatrics, Division of Neonatology, University of Iowa, Iowa City, IA.

Background: Indomethacin is a non-steroidal anti-inflammatory drug (NSAID) used to treat patent ductus arteriosus (PDA). In general, approximately two-thirds of neonates experience closure of the PDA in response to indomethacin, while approximately one-third will require surgical ligation to close the ductus. Evidence suggests that response to indomethacin is highly heritable. We investigated the association between single nucleotide polymorphisms (SNPs) and PDA closure in response to indomethacin. **Methods**: Candidate SNPs were identified in the literature. A case-control analysis was performed among neonates who responded to indomethacin and neonates who required surgical ligation (56 cases, 104 controls). Independent transmission disequilibrium tests (TDT) were performed among parent-child trios of neonates who responded to indomethacin (102 probands) and neonates who required surgical ligation (50 probands). **Results**: rs2153628 was associated with response to indomethacin in the case-control analysis (OR: 0.521, 95% CI: 0.287, 0.947, p=0.0307). rs2153628 and rs1799853 were associated with response to indomethacin in the TDT analysis (OR: 2.357, 95% CI: 1.262, 4.404, p=0.00558 and OR: 2.50, 95% CI: 1.101, 5.676, p=0.0233, respectively). Haplotype analyses did not reveal any significant haplotype associations. **Conclusion**: We identified an association between two SNPs, rs2153628 and rs1799853, and response to indomethacin for the treatment of PDA. The G allele of rs2153628 conferred a protective effect against requiring surgery. The T allele of rs1799853 conferred a protective against requiring surgery. Both SNPs are located in *CYP2C9*, a member of the cytochrome P450 family of enzymes and a known metabolizer of NSAIDs. These findings suggest that response to indomethacin in the closure of PDA may in some cases be due to polymorphisms associated with less efficient metabolism of indomethacin.

3231F

Metabolomic study of amino acid, carnitine and acyl-carnitine profiles in Chinese preterm infants. *X. Zhao[1,2,3], X. Tao[1,2], P. Wang[1,2], Y. Tian[3], N. Zhong[1,2,4].* 1) Department of Medical Genetics, Peking University Health Science Center, Beijing, China; 2) Maternal & Children's Hospital of Lianyungang City, China; 3) Center of Translational Medicine, PLA General Hospital, China; 4) New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY, USA.

Objective: Preterm birth (PTB) was defined as the delivery of an infant of less than 37 complete weeks of gestation. Due to the immaturity of the neonatal liver, premature infants may have a higher rate of out-of-range results [1]. Distinct metabolic patterns have been shown to be associated with different classes of gestational age in population of preterm and term infants [2]. The current study is to determine the impact of gestational age to metabolic profiles. **Material and Methods:** A total of 10,087 neonatal dried blood spot samples, including 300 of preterm and 9,787 of full-term infants, were collected between the 4th and 7th day post-delivery in South-western China. None of the infants was diagnosed with an inborn error of metabolism. The samples were prepared and analyzed by LC-MS-MS that screens 11 amino acids (Ala, Arg, Cit, Gly, Leu, Ile, Pro, Orn, Phe, Tyr, Val) and 32 carnitines. The result was processed by SPSS 19.0. For comparison of two groups of samples, the 2-tailed Wilcoxon Signed Ranks or Mann–Whitney test was used in suitable circumstances. **Results:** Compared to the term group, the concentration of Ala, Leu+Ile+Pro-OH, Pro,Val, C4DC+C5OH, C14, C16, C16:1OH, C18, and C18:1 among the 11 tested amino acids and 32 carnitines were lower in the preterm group (p<0.01), but the serum concentrations of Arg, C5, and C18:2 were higher in preterm group (p<0.01). **Discussion:** We reported here that the preterm infants were low for various amino acids and acyl-carnitines. Contrary to the findings of Mandout et al., who found the serum concentrations of Tyr, Phe, Met, Leu and Ala were higher in Indian preterm infants comparing with local term infants [3]. The low serum amino acid concentration maybe due to the reduced digestive activity of preterm infant, as Henderson et al reported that pepsin activity and postprandial output are significantly lower for preterm infants[4]. Our results demonstrate the complexity of understanding the impact of immaturity on metabolic profiles, and may lead to the development of specific amino acid, carnitine supplement for Chinese premature infants. 1. Pediatr Res 2001; **49**:125-9. 2. Clin Chem 2005; **51**:745-52. 3. Indian J Pediatr 2013; **80**:736-44. 4. Pediatr Res, 1998; **43**(4 Pt 2):1A-420A. .

Peripheral blood vitamin D-related microRNAs and mRNAs in early pregnancy of women with preeclampsia. *H. Mirzakhani[1,2], S. Liu[1], M. Santolini[1,2], A. Litonjua[1,2], A. Sharma[1,2], S. Weiss[1,2].* 1) Channing Division, Brigham and Women's Hospital, Boston, MA; 2) Harvard Medical School.

Preeclampsia (PE) is a major cause of maternal and perinatal morbidity and mortality, complicating approximately 5% of pregnancies. Identification of circulating biomarkers could provide insight into the pathophysiology of PE and suggestion of preventive measures. Maternal vitamin D (25OHD) deficiency is associated with the development of PE. Using the data from Vitamin D Antenatal Asthma Reduction Trial (VDAART), we conducted a nested case control study of 157 pregnant women (47 with PE) to explore the integration of peripheral blood vitamin D-associated miRNA and mRNA expression profiles in association with PE at 10-18 weeks of gestation. We previously found 348 vitamin D-associated genes (158 up-regulated) demonstrating differential expression between the women who developed PE and controls (FDR < 0.05 in VDAART; p<0.05 in a replication OMEGA cohort). Functional enrichment analysis and interactome mapping of this gene set suggested several highly functional modules related to systematic inflammatory and immune responses including some known nodes with high degrees of connectivity (e.g. *IL8, MX1, HLA-DP1, HLA-DBQ1, MMP9, RPL31, ACTA2, IFII44L* and *SERPING1,* all previously reported in association with PE). Applying the same method for the mRNA expression profiling, we investigated the differently expressed miRNAs between the above 157 cases and controls. Furthermore, we used mirDip miRNA target prediction database (after filtering high confidence interactions with standardized scores >80, range 0-100) to investigate the potential regulatory miRNAs of the replicated PE gene signatures. Among a total of 602 expressed miRNAs (Ct<30), 467 miRNAs were analyzed. 68 differentially expressed miRNAs (41 downregulated) in women who developed PE compared to the controls were identified (FDR<0.05). Of these, 18 (14 downregulated) were vitamin D-associated miRNAs (FDR<0.05). Accordingly, miR-597 and miR-29a targets demonstrated significant enrichment in the gene set as potential regulators of the differentially expressed genes (p<0.05). miR-29a, a previously investigated miRNA in association with PE, was also among 18 vitamin D-associated miRNAs. Our data suggests expressed plasma miRNAs in early pregnancy might play a role in the regulation of distinctive genes involved in immunomodulatory responses and subsequent PE ocurrence, and might be potential biomarkers for diagnosis or prevention of PE. RT-PCR and functional validation of miR-597 and miR-29a are undergoing.

3233T

Clinical, pathologic, cytogenetic, and molecular profiling in self-identified Black women with uterine leiomyomata. *C. Gallagher[1,2], M. Hayden[3], Z. Ordulu[1,3], B. Quade[1,4], R. Anchan[1,3], N. Middleton[1,3], S. Srouji[1,3], E. Stewart[5], C. Morton[1,3,4,6,7].* 1) Harvard Medical School, Boston, MA; 2) Department of Genetics, Harvard Medical School, Boston, MA; 3) Department of Obstetrics, Gynecology and Reproductive Biology, Brigham and Women's Hospital, Boston, MA; 4) Department of Pathology, Brigham and Women's Hospital, Boston, MA; 5) Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN; 6) Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA; 7) University of Manchester, Manchester Academic Health Science Centre, Manchester, UK.

Uterine leiomyomata (UL), also known as fibroids, are the most common tumor of the female reproductive tract and are the primary indication for hysterectomy in the U.S. Black women are disproportionately affected by UL compared to other racial groups, having a greater lifetime incidence of developing fibroids and an earlier age of diagnosis. In order to elucidate molecular and genetic mechanisms responsible for the increased prevalence and morbidity associated with UL in black women, clinical, pathologic, cytogenetic, and select molecular profiling (*MED12* mutation analysis) of 75 self-reported black women undergoing surgical treatment for UL was performed. Mean age at time of surgical treatment was 39.5 years with 41 women undergoing myomectomy and 34 hysterectomy. The primary indication for medical or surgical intervention was menorrhagia with 53.3% of the cohort reporting this symptom. Our cohort demonstrated a more severe clinical presentation than previously conducted studies, specifically in regard to the number of fibroids per patient (18.2 vs. 9.9) and uterine weight (591.9 g vs 477 g) in the group undergoing hysterectomy. However, our cohort broadly resembles previous cytogenetic studies of UL tumors: Karyotypically abnormal tumors were detected in 30.7% of women and 17.9% of analyzed tumors. Therefore, data from our cohort are not supportive of an association between race and increased occurrence of cytogenetic abnormalities that may contribute to any population-specific morbidity or prevalence rate. In addition to the very complex cytogenetic abnormalities present in our cohort (24.1% of abnormal tumors), there is a notable decrease of t(12;14) (10.3% of abnormal tumors vs. expected 20%) and increased frequency of tumors with deletions of segments of chromosome 7 (51.7% of abnormal tumors vs. expected 17%). Our data on *MED12* mutation analyses (73.2% of tumors harbored a *MED12* mutation) provide additional support for a significant role of *MED12* in tumorigenesis. Although the effect of *MED12* tumorigenesis appears significant irrespective of race or ethnicity, downstream events such as karyotypic abnormalities appear different in black women. While more detailed analyses of individual cases and the inclusion of more comprehensively profiled cases are warranted, the case series presented herein demonstrates that certain genetic and molecular characteristics of UL alone do not explain the increased prevalence and morbidity of UL in black women.

Rare mutations in spermatogenesis genes underlie a significant fraction of idiopathic male infertility. *K.A. Fakhro[1], M. Arafa[2], H. El Bardisi[2], A. Robay[3], J.L. Rodriguez-Flores[4], J.G. Mezey[4], C. Abi Khalil[3], J. Malek[3], A. Al Ansari[2], S. Said[2], R.G. Crystal[4].* 1) Translational Medicine, Sidra Medical and Research Center, Doha, Qatar, Qatar; 2) Urology, Hamad Medical Corporation, Doha, Qatar; 3) Genetic Medicine, Weill Cornell Medical College - Qatar, Doha, Qatar; 4) Genetic Medicine, Weill Cornell Medical College, New York, NY USA.

Non-obstructive Azoospermia (NOA), the complete absence of sperm production, is the most severe form of male infertility, affecting up to 1% of the male population worldwide. Despite state-of-the-art clinical assessment, most NOA patients remain idiopathic and incur a significant socioeconomic burden between fertility treatments and surgical sperm retrieval procedures, both with limited success. The genetics of NOA are poorly understood primarily due to its sporadic nature coupled with the difficulty of isolating a genetic signal from a variety of environmental exposures in this adult-onset disease. To approach this challenge, we used whole exome sequencing (WES) to assess patients with idiopathic NOA. First, to increase the number of genes associated with causes for NOA, we identified 10 multiplex families and sequenced all available members (including fertile siblings). In all 10 families, we discovered rare mutations altering highly conserved residues segregating with disease. Seven of these occur in genes with previous evidence of having critical roles in spermatogenesis from mouse models and two are related to human infertility, but none were previously reported in isolated NOA. We combined our 10 new genes with 56 genes reported in the literature as associated with human spermatogenic failure to create an "NOA gene panel." Using WES, we assessed 66 additional unrelated subjects with "idiopathic" NOA and identified that 15 (23%) had 16 rare mutations altering highly evolutionarily conserved residues in 14 of these NOA panel genes. To determine if this was expected by chance, WES analysis was carried out on a population-matched group of 64 confirmed fathers. Of these, only 3 had mutations in the NOA gene panel, 2 of which were only heterozygous in recessive genes (p=0.0002 compared to the idiopathic NOA group). Altogether, our data indicates that for millions of idiopathic NOA men worldwide, WES could significantly improve the diagnostic yield if introduced as part of the routine patient work-up.

Amniotic fluid metagenomics in pregnancies affected with gastroschisis. *M.S. Patel[1], H. Wang[1], G.X. Yang[1], Y. Hu[2], A. Swenerton[1], D. Siciliano[1], K. Sangha[1], R.R. Miller[3], P. Tang[4].* 1) Dept. of Medical Genetics and Child and Family Research Institute, University of British Columbia, Vancouver, BC, Canada; 2) Department of Obstetrics and Gynaecology and Child and Family Research Institute, University of British Columbia, Vancouver, BC, Canada; 3) BC Centre for Disease Control and University of British Columbia, Vancouver, BC, Canada; 4) Department of Pathology, Sidra Medical and Research Center, Doha, Qatar.

We developed a method to use massively parallel sequencing followed by pathogen identification to ask the question - does gastroschisis more commonly affect pregnancies in younger mothers because they have more limited immunity to pathogens? That is, could some cases of gastroschisis be caused by a previously undetected infectious agent? To study this question, we obtained amniotic fluid at diagnostic amniocentesis from 12 pregnancies affected by gastroschisis and 24 maternal age matched, gestational age matched and season matched controls undergoing diagnostic amniocentesis for elevated maternal serum screen results. To start, we first determined which nucleic acid isolation column had the best performance using amniotic fluid spiked with different viruses and bacteria, with the QIAamp MinElute and PureLink columns found to work best, depending on the virus tested. We then optimized a metagenomics protocol to allow detection through massively parallel sequencing on an Illumina HiSeq 2500 instrument of RNA and DNA viruses regardless of size, with as little as 200 microliters of amniotic fluid or 15 pg starting material. Between 30 and 75 million reads were obtained from each sequencing library. Bioinformatics processing of the raw read files was performed to remove random primers, trim low quality bases, remove ribosomal sequences, remove duplicate reads and filter out human sequences, resulting in 4-8% of reads remaining. We assess the performance of this method by spiking control amniotic fluid with various infectious agents, performing sequencing and then using a variety of pathogen identification algorithms and a variety of taxonomic assignment algorithms as well as developing our own software. We describe the microbiome of midgestation human amniotic fluid from healthy pregnancies and also report our findings in pregnancies affected by gastroschisis.

A multi-stage genome-wide association study of uterine fibroids in African Americans. *J.N. Hellwege[1], J. Jeff[2], L.A. Wise[3], C.S. Gallagher[4], M. Wellons[1], K.E. Hartmann[1], S. Jones[1], E.S. Torstenson[1], S. Dickinson[5], E.A. Ruiz-Narváez[3], N. Rohland[4], A. Allen[4], D. Reich[4,6,7], B. Pasaniuc[8], N. Mancuso[8], H.K. Im[5], D.A. Hinds[9], J. Palmer[3], L. Rosenberg[3], J.C. Denny[1], D.M. Roden[1], E.A. Stewart[10], C.C. Morton[4,7,11], E. Kenny[2], T.L. Edwards[1], D.R. Velez Edwards[1].* 1) Vanderbilt University Medical Center, Nashville, TN; 2) Icahn School of Medicine at Mount Sinai, New York City, NY; 3) Boston University, Boston, MA; 4) Harvard Medical School, Boston, MA; 5) University of Chicago, Chicago, IL; 6) Howard Hughes Medical Institute, Chevy Chase, MD; 7) Broad Institute of Harvard and MIT, Cambridge, MA; 8) University of California at Los Angeles, Los Angeles, CA; 9) 23andMe, Inc., Mountain View, CA; 10) Mayo Clinic, Rochester, MN; 11) University of Manchester Academic Health Science Centre, Manchester, England.

Uterine fibroids (UF) are common, benign tumors of the uterus that affect 77% of women by menopause, are the leading indication for hysterectomy, and account for costs of up to $34 billion annually in the United States. African American (AA) race and increasing age up to menopause are the strongest known risk factors. AA women are more likely to suffer from UF than European American women, and on average have earlier onset as well as larger and more numerous fibroids. We conducted a multi-stage genome-wide association study (GWAS) of UF risk among AAs followed by *in silico* genetically predicted gene expression profiling of top hits. In Stage 1, UF AA cases and controls (1273 cases, 1379 controls) were confirmed by pelvic imaging, either from a validated algorithm applied to electronic health records (PPV 98%, NPV 96%) at eMERGE Network sites or study ultrasounds in the CARDIA Women's Study. Confirmation of UF status by imaging reduces rates of misclassification of cases with subclinical UFs. Stages 2 and 3 used *in silico* replication from the imputed 23andMe, Inc. survey-based data (1354 AA cases, 1419 AA controls) and low-pass sequencing data from the Black Women's Health Study (2511 AA self-reported cases, 2231 AA self-reported controls). Stage 1 was genotyped by GWAS arrays and was imputed to the 1KGP reference haplotypes. Genetic UF risk was modeled by logistic regression adjusted for principal components of ancestry, and was followed by a fixed effects meta-analysis of results from all three stages. We observed a genome-wide significant association among 5528 AA cases and 6513 AA controls at the African ancestry-specific SNP rs10939126 (minor allele frequency=0.07) in *TBC1D19* on chromosome 4 (OR=1.69, 95% CI 1.47–1.91, p-value=3.21×10^{-9}, p_{het}=0.46). *TBC1D19* (TBC1 domain family member 19) is most highly expressed in uterine tissue from GTEx, supporting its role in uterine biology. Evaluation of the genetic association results with MetaXcan identified nominally significant genetically predicted gene expression of *TBC1D19* in breast tissue (p-value=0.0087). This suggests tentative support for a mechanism underlying the genetic result, as both uterine and breast tissues are hormone-sensitive. Overall, we performed the first multi-stage GWAS for UF among AA women, and identified a novel African-specific locus within *TBC1D19* with potential biological relevance for UF through genetically predicted gene expression. .

3237F

Admixture mapping of uterine fibroid characteristics using African American women from BioVU. *M.J. Bray[1], T.L. Edwards[1,2,3,4], M.F. Wellons[2], K.E. Hartmann[2,3,5], D.R. Velez Edwards[1,3,4,5].* 1) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, TN; 2) Department of Medicine, Vanderbilt University, Nashville, TN; 3) Vanderbilt Epidemiology Center, Vanderbilt University, Nashville, TN; 4) Institute of Medicine and Public Health, Vanderbilt University, Nashville, TN; 5) Department of Obstetrics and Gynecology, Vanderbilt University, Nashville, TN.

Uterine fibroids are benign tumors affecting up to 77% of women by menopause and cost the US up to 9.4 billion dollars annually in healthcare expenditures. A strong risk factor for fibroids is African ancestry, where African Americans (AAs) have larger and more numerous fibroids than European Americans (EAs). It is possible that differences in fibroid characteristics between AAs and EAs are driven by genetic loci that differ in frequency between AAs and EAs. To address this, we performed admixture mapping (AM) analyses on fibroid tumor characteristics including volume, largest dimension, and number in AA women. Using BioVU, a clinical cohort within the Vanderbilt University Medical Center, we abstracted information regarding fibroid size and number from the medical records of 439 AA women. Using existing genome-wide association studies (GWAS) data, we conducted AM analyses using Local Ancestry in adMixed Populations-ancestral (LAMP-ANC) to call ancestry at each single nucleotide polymorphism (SNP) and subsequently performed regression analyses on $\log_{10}$ transformed volume of all fibroids, $\log_{10}$ transformed largest dimension of all fibroids, and number (1 vs >1). Afterwards, we conducted single SNP association analyses on imputed genetic data under the strongest mapping peaks. We limited all analyses to common SNPs (minor allele frequency >5%) and adjusted for age, body mass index, and five principal components for all analyses. After performing AM analyses, preliminary results highlight AM peaks on chromosomes 2p24.1 and 10q24.1 for volume, on chromosome 14q32.11 for largest dimension, and on chromosomes 7q21.11 and 14q24.3 for number. The strongest associations in the AM peak 10q24.1 for volume were in the gene slit guidance ligand 1 (*SLIT1*). After performing single SNP association analyses on suggestive AM peaks, single SNP association analyses for max dimension on chromosome 14q24.3 highlighted coiled-coil domain containing 88C (*CCDC88C*) (rs11160001, Beta = 0.18, 95% confidence interval (CI) 0.09-0.26, p = 5.79×10^{-5}). A recent study evaluating the associations of breast cancer risk variants in AA women from previous GWAS found that *CCDC88C* was associated with ER+ breast cancer in AA women. Future studies involve validating our AM study findings for tumor characteristics using an independent AA cohort. This work will lay the foundation for understanding the relationship between the genetic risk factors and phenotypic heterogeneity of fibroids.

3238W

The importance of clinical genetics during pregnancy via a hypophosphatasia family due to a novel mutation. *I. Boga[1], A. Bisgin[1], C. Cetin[2], S. Buyukkurt[2].* 1) Department of Medical Genetics, Balcali Clinics and Hospital,Cukurova University Faculty of Medicine, Adana, Turkey; 2) Department of Obstetrics And Gynecology, Perinatology Unit, Balcali Clinics and Hospital, Cukurova University Faculty of Medicine, Adana, Turkey.

   Objective: Hypophosphatasia is an autosomal recessive rare genetic disease with profound skeletal hypomineralization and respiratory compromise, caused by mutations in the Alkaline Phosphatase *(ALPL)* gene. We here report an infantile form of hypophosphatasia confirmed by mutational analysis and discuss the importance of diagnosing a rare disease for proper genetic counselling that include differential diagnosis, clinical genetics assessment and prenatal molecular testing. **Methods:** The pregnant women referred to the Medical Genetics Clinic due to having a child history with severe convulsions and rickets/osteomalacia. The genetic analysis performed in the *ALPL* gene by Sanger sequencing. Chorionic villus samples were obtained for prenatal diagnosis. **Results:** The history taking and clinical assessment revealed a possible diagnosis of hypophosphatasia. A novel p.I218S (c.653T>G) homozygous mutation was detected in a child. While the child had been found to have hypophosphatasia on the basis of both clinical genetic and molecular analysis, only the mother was carrier with the heterozygous mutation in the same position and the father does not have any mutation in the *ALPL* gene. We could not get the permission to the SNP array to confirm paternity. Obviously, the family was counselled to provide accurate information and possibilities. As a result, the family chose to undergo prenatal diagnosis that revealed no mutation in the foetus. **Conclusion:** Clinical genetic assessment and prenatal genetic counselling is thus considered an importance for confirming a diagnosis of rare disorders such as hypophosphatasia.

3239T

Validation of targeted next-generation sequencing for preimplantation genetic diagnosis of heritable connective tissue diseases. *S. Symoens[1], P. Van Acker[1], E. Van Holm[1], O. Vanakker[1], F. Malfait[1], C. Christodoulou[2], B. Heindryckx[2], P. De Sutter[2], E. Van den Abbeel[2], B. Callewaert[1], J. De Backer[1], A. De Paepe[1], S. Janssens[1], P. Coucke[1].* 1) Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Oost-Vlaanderen, Belgium; 2) Ghent Fertility and Stem Cell Team (G-FaST), Department of Reproductive Medicine, Ghent University Hospital, 9000 Ghent, Belgium.

   Preimplantation genetic diagnosis (PGD) is a diagnostic procedure that allows testing of preimplanted embryos for couples who are at-risk for a genetically defined monogenic disorder or a chromosomal abnormality. PGD for monogenic disorders has benefitted from the introduction of next-generation sequencing (NGS), as this technique enables the detection of a single mutation on a few (embryonic) cells in a more accurate manner. The Center for Medical Genetics Ghent functions as a national and international reference center for heritable connective tissue diseases (HCTD), including Marfan syndrome and other familial thoracic aortic aneurysm syndromes, osteogenesis imperfecta, and Ehlers-Danlos syndromes. These syndromes comprise a heterogeneous group of monogenic disorders that affect the normal development and homeostasis of the hard (bone, cartilage) and soft (skin, blood vessels, tendon and ligaments, ocular structures) connective tissues. Many of these conditions are associated with important morbidity and increased mortality, which justifies the use of prenatal diagnosis and PGD. We applied NGS to implement PGD for patients with these conditions in our center. Couples with a genetically defined HCTD and interested in PGD are counseled by a clinical geneticist and written informed consent is obtained. First, an optimization experiment is performed in order to validate the detection of the familial mutation on a limited number of cells. In total, for each proband 32 aliquots are isolated from an EDTA-blood sample each comprising 2-8 lymphocytes. Subsequently, lymphocyte aliquots are lysed and a PCR reaction encompassing the familial mutation is performed *in duplo* (PCR-A and PCR-B). Both PCR products are NGS sequenced on two separate MiSeq runs. Following this strategy, possible allele-drop-out and PCR performance on a minimal amount of DNA is evaluated. Hitherto, 3 *FBN1*, 2 *SMAD3* and one *TNNT2* at-risk couples have undergone this PGD validation phase, which has been successful for all. In a next step, trophectoderm cells are biopsied from day 5-6 embryos and the underlying familial mutation is examined by NGS. These results demonstrate that PGD through direct mutation detection by NGS is a powerful prenatal approach. Further optimization and validation for a larger cohort of HCTD patients followed by pre- and/or post-natal confirmation of the familial mutation is ongoing to calculate the success rate.

High-throughput screening for *SMN1* "2+0" copy number status by next-generation sequencing. *E.D. Boyden, K.A. Robinson, D.K. Neitzel, N.E. Faulkner, G.J. Porreca, M.A. Umbarger.* Good Start Genetics, Cambridge, MA.

Spinal muscular atrophy (SMA) is a lethal autosomal recessive neuromuscular disorder caused by functional loss of the *SMN1* gene, with a carrier rate of ~1 in 40. Most mutations involve *SMN1* copy number (CN) loss, produced by either deletion of part or all of *SMN1*, or more commonly by conversion of *SMN1* to *SMN2,* a linked paralog that encodes an identical protein but is poorly expressed due to a silent coding variant that disrupts proper splicing. We previously developed a protocol by which the CN status of *SMN1* and *SMN2* can be measured directly by next-generation sequencing (NGS). This method, which uses molecular inversion probes to capture loci specific to *SMN1* and *SMN2*, shows sensitivity and specificity for detection of *SMN1* CN loss similar to that of multiplex ligation-dependent probe amplification (MLPA), but has the advantage of being compatible with automated high-throughput screening. However, both methods typically determine CN status without the benefit of haplotype information, which renders them unable to identify "2+0" carriers. These individuals, who may represent between 4 and 27 percent of all SMA carriers depending on ethnicity, have 2 functional *SMN1* alleles on one chromosome and 0 on the other. Accordingly, they appear to be noncarriers by CN status, yet are in fact carriers as they may still transmit to offspring a chromosome that lacks a functional copy of *SMN1*. Recently, Luo et al. (Genet Med 2014) discovered markers that are commonly linked to *cis* duplications of *SMN1*; the presence of these markers in individuals with 2 copies of *SMN1* may indicate "2+0" carriers. Our NGS-based SMA screening method can reliably detect these markers, and so our protocol can be adapted to identify potential "2+0" carriers. Hence, this modification provides an avenue to improve the sensitivity of our method relative to that of other SMA carrier screening approaches.

3241W

Multigene molecular testing provides significant diagnostic yield for prenatal holoprosencephaly. *S. Duffer, J. Meck, L. Vincent, E. Kramer Dugan, V. Zvereff, G. Richard.* GeneDx, Gaithersburg, MD.

Holoprosencephaly (HPE), the most common malformation of the forebrain, occurs in 1/250 conceptuses and is readily detected by prenatal ultrasound. Karyotype abnormalities account for HPE in 40-50% of fetuses, but clinical sensitivity information for prenatal molecular testing of the four major HPE-associated genes *SHH, ZIC2, SIX3, TGIF* is limited. Here we report the detection rate for pathogenic and likely pathogenic variants (PV/LPV) identified by sequencing and copy number analysis in these genes in prenatal cases. **Method:** Data was reviewed for 176 fetuses with sonographic features of HPE referred for testing from 2003-2015. Of these cases, 55% reported negative karyotype and/or microarray results prior to molecular testing. Sanger sequencing analysis of *SHH, ZIC2, SIX3,* and *TGIF* was complemented by Multiple Ligation Probe Amplification (MLPA) for deletion/duplication analysis of these genes. **Results:** PV/LPV were identified in 41/176 (23%) prenatal HPE cases, including distinct variants in *ZIC2* (17), *SHH* (13), *SIX3* (8), and *TGIF* (3). More than half (51%; 20/39) of the PV/LPV sequencing variants resulted in loss of function. Only three copy number variants were detected, including whole gene deletions involving either *SHH* or *SIX3*, and a very rare, apparently *de novo* duplication of *SHH*. Additionally, three (1.7%) fetuses were heterozygous for a sequence variant of uncertain significance in the *SHH, ZIC2,* or *SIX3* gene, respectively. Parental testing in 24 families determined that nine variants (37%) occurred apparently *de novo* in the fetus, while twelve (63%) were inherited. Clinical parental information was available for nine of the inherited variants, with seven parents reporting mild clinical indications of HPE (e.g. hypotelorism) and/or a family history of previous pregnancies with HPE. **Conclusions:** In our large cohort, molecular testing of the major HPE genes determined the cause of HPE in 23% (41/176) of cases, validating results of a previous study (Bendavid et al., 2006). In both studies, *ZIC2* presented as the highest molecular contributor to prenatally detected HPE. The high frequency of inherited PV/LPV highlights the known intra-familial variability of symptoms, the importance of parental testing, and the need for careful clinical examination for minor features of HPE. We conclude that the combination of chromosome analysis and HPE panel testing will identify a causative genetic abnormality in over 70% of fetuses with prenatally detected HPE.

3242T

Research on maternal effects, maternal-fetal interactions and parent-of-origin effects (imprinting) in mothers and their children with schizophrenia. *K. Lee[1], J. Park[1,2], B. Lee[1,2], Y. Lee[1,2], E. Moon[1,2], H. Jeong[1].* 1) Department of Psychiatry, Pusan National University Hospital, Busan, Republic of Korea; 2) Medical Research Institute, Pusan National University Hospital, Busan, Republic of Korea.

   Background : Schizophrenia emerges during early stages of life and it has various effects such as causing considerable familial and social burden, as well as increasing health expenses. Also, it is disabling disease associated with heterogeneous psychiatric phenotypes. It is assumed that this disease is caused by a combination of genetic and/or environmental factors during critical periods of brain development increase the risk for this illness. **Introduction :** Various genetic effects like epigenetic effects might be operated by the inter-uterine environment mechanisms. The effects of parent-of-origin (imprinting), maternal genotype, and maternal-fetal genotype interactions could be investigated by collecting DNA from affected offspring and their mothers (case/mother duos) and comparing this with an appropriate control sample. Another method uses data from cases and both parents (case/parent trios) but does not require controls. In this study, we describe a novel implementation of a multinomial modeling approach that allows the estimation of such genetic effects using either case/mother duos or case/parent trios. We investigate the effects of estimation of maternal, imprinting and interaction effects using multimodal modeling using parents and their offspring with schizophrenia in Korean population. **Subjects and Methods:** We have recruited 27 probands(with schizophrenia) with their parents and siblings whenever possible. We analyzed 96 SNPs(Single Nucleotide Polymorphisms) of 17 functionally only relevant genes and 21 neuronal genes relevant to schizophrenia for DNA samples that was checked for the data quality and genotype error. We used EMIM analysis program for the estimation of maternal, imprinting and interaction effects using multimodal modeling.**Results:** Of analyzed 96 SNPs functionally and positionally relevant to schizophrenia, very significant SNP (rs 324420) was suggested in EMIM analysis for child genetics effects. (p= 1.5 □ 10⁻⁴) rs 324420 was also significant for child genetic effects allowing for maternal genetic effects (p = 5.3 □ 10⁻⁴) with very stringent multiple comparison Bonferroni correction. Additionally, no significant SNP was presented in the analysis results for maternal genetic effects allowing for child genetic effects.

3243F

Clinical consequences of whole-genome sequencing vs. SNP methods of noninvasive prenatal screening. *C.G. Artieri, C. Havery, K.A. Beauchamp, I.S. Haque, D. Muzzey.* Counsyl Inc., South San Francisco, CA.

   Noninvasive prenatal screening (NIPS) for aneuploidies via next-generation sequencing of cell-free DNA has gained wide clinical adoption due to its high accuracy. The most widely used NIPS offerings employ either whole-genome sequencing (WGS) or SNP-based methods to determine whether patterns deviate from those expected in a euploid pregnancy. Although published outcome studies and clinical guidelines indicate that both approaches have comparable performance [1], claims regarding the limitations of WGS methods persist, causing confusion among clinicians and patients. Here we directly and quantitatively compare the algorithmic requirements, performance, and clinical consequences of WGS vs. SNP-based NIPS. To enable fair comparison, we used published algorithms and assay parameters [3,4] to implement computational simulations for each method, allowing us to compare the methods in silico on a limitless number of euploid and aneuploid pregnancies. We show that the SNP-based method is sensitive to noise in sampling of allele frequencies, which is well represented by a beta-binomial distribution. In contrast, the depth-based WGS method is sensitive to the negative-binomial noise commonly observed in sequencing counts. By simulating data over a range of parameters congruent with published data, we show that WGS NIPS outperforms the SNP-based method in terms of both sensitivity and specificity, even when simulating the latter with less sampling noise than indicated by published data. Furthermore, we demonstrate that this sensitivity deficit results from the SNP-based method's dependence on the aneuploidy parent of origin: the deviation in allele frequencies produced by maternally inherited trisomies — up to 90% of Down Syndrome cases — is far less easily detectable as compared to rare paternal trisomies. In contrast, parental origin is irrelevant to WGS-based methodology, as it does not affect the depth signal. Finally, we evaluate the clinical consequences of how each NIPS strategy handles samples with low fetal fraction. Importantly, because only a subset of patients pursue an invasive test after receiving a "no-call" from noninvasive screening [4], clinics offering tests that routinely "no-call" low fetal fraction samples do not ultimately improve aggregate prenatal detection of aneuploidies in their patients. 1. ACOG/SMFM Committee Opinion #640 2015 2. Ryan et al. 2016. Fetal Diagn Ther 3. Lefkowitz et al. 2016. Am J Obstet Gynecol 4. Currier et al. 2012. Prenat Diagn.

De novo mtDNA point mutations are common and have a low recurrence risk. *C.E.M. de Die-Smulders[1,2], H.J.M. Smeets[1,2,3], A.T.M. Hendrickx[1], D.M.E.I. Hellebrekers[1], I.F.M. de Coo[4], C.L. Alston[5], C. Knowles[5], R.W. Taylor[5], R. McFarland[5], S.C.E.H. Sallevelt[1].* 1) Department of Clinical Genetics, Maastricht University Medical Center+ (MUMC+), Maastricht, The Netherlands; 2) Research School for Developmental Biology (GROW), Maastricht University, Maastricht, The Netherlands; 3) Research School for Cardiovascular Diseases in Maastricht, CARIM, Maastricht University, Maastricht, The Netherlands; 4) Department of Neurology, Erasmus MC-Sophia Children's Hospital Rotterdam, Rotterdam, The Netherlands; 5) Wellcome Trust Centre for Mitochondrial Research, Institute of Neuroscience, The Medical School, Newcastle University, Newcastle upon Tyne, United Kingdom.

   Background Severe, disease-causing germline mitochondrial (mt)DNA mutations are maternally-inherited, or arise *de novo*. Strategies to prevent transmission are generally available, but depend on recurrence risks, ranging from high/unpredictable for many familial mtDNA point mutations to very low for sporadic, large-scale single mtDNA deletions. Comprehensive data are lacking for *de novo* mtDNA point mutations, often leading to misconceptions and incorrect counseling regarding recurrence risk and reproductive options. We aim to study the relevance and recurrence risk of apparently *de novo* mtDNA point mutations. **Methods** Systematic study of prenatal diagnosis (PND) and recurrence of mtDNA point mutations in families with *de novo* cases, including new and published data. "*De novo*" based on the absence of the mutation in multiple (postmitotic) maternal tissues is preferred, but mutations absent in maternal blood only were also included. **Results** In our series of 105 index-patients (33 children and 72 adults) with (likely) pathogenic mtDNA point mutations, the *de novo* frequency was 24.6%, the majority being pediatric. PND was performed in subsequent pregnancies of mothers of 4 *de novo* cases. A fifth mother opted for Preimplantation Genetic Diagnosis (PGD) because of a coexisting Mendelian genetic disorder. The mtDNA mutation was absent in all 4 prenatal samples and all 11 oocytes/embryos tested. A literature survey revealed 137 *de novo* cases, but PND was only performed for 9 (including 1 unpublished) mothers. In one, recurrence occurred in 2 subsequent pregnancies, presumably due to germline mosaicism. **Conclusions** *De novo* mtDNA point mutations are a common cause of mtDNA disease. Recurrence risk is low. This is relevant for genetic counseling, particularly for reproductive options. PND can be offered for reassurance.

3245T

The role of the mitochondrial bottleneck in mtDNA disease risk and embryogenesis in zebrafish (non-)germline cells and human preimplantation embryos. *A. Otten[1], T. Theunissen[1], S. Sallevelt[1], J. Dreesen[1], M. Adriaens[2], J. Derhaag[3], M. Gerards[2], J. Vanoevelen[1], D. Samuels[4], A. Stassen[1], M. Muller[5], C. de Die[1], H. Smeets[1].* 1) Genetics and Cell Biology, GROW, Maastricht University, Maastricht, Limburg, Netherlands; 2) Maastricht Centre for Systems Biology (MACSBio), Maastricht University, Limburg, Netherlands; 3) Department of Obstetrics & Gynaecology, GROW, Maastricht University, Maastricht, Limburg, Netherlands; 4) Vanderbilt University School of Medicine, Nashville, USA; 5) GIGA, Université de Liège, Liège, Belgium.

   The mitochondrial DNA (mtDNA) inherits through a segregational bottleneck: a limited number of the mtDNA molecules from the oocytes pass to the offspring. We studied size, timing and mechanisms underlying this bottleneck in zebrafish embryos and in rest oocytes/embryos from preimplantation genetic diagnosis (PGD) for mtDNA disease. In zebrafish, the mtDNA content in maturing oocytes increases proportionally with the size of the cells and mature oocytes contain ~19.0×10^6 mtDNA molecules with high intra-individual variation (range: 3.3×10^6 – 42.2×10^6). During embryogenesis, the mtDNA copy number decreases to ~170 for FACS-isolated primordial germ cells (PGCs), a number similar to mammals, and to ~50 for non-PGCs. As the lowest mtDNA copy numbers occur at a fixed developmental stage, variation in the oocyte copy number dictates the mtDNA amount at the bottom of the bottleneck. To test whether a low copy number at the bottom of the bottleneck renders an oocyte vulnerable for *de novo* mtDNA mutations reaching significant heteroplasmy levels, we performed NGS of the mtDNA in 103 individual oocytes from eight zebrafish. Randomly scattered *de novo* mtDNA mutations were detected in ~20% of the oocytes with heteroplasmy levels above the detection limit of 1.5%. This is in line with our observation that ~20% of the germ cells have an mtDNA copy number ≤73 and would lead to detectable mutation loads. As the frequency of *de novo* mutations is close to reported error rate of the mitochondrial replication enzyme POLG, this seems to be the predominating factor. Moreover, this process could also explain the high frequency of *de novo* mtDNA mutations (~25%) observed in human patients. The mechanisms underlying the mtDNA bottleneck were further characterized from the mutation load distribution in human oocytes/embryos of m.3243A>G or m.8993T>G mutation carriers. In addition to genetic drift selection occurred on OXPHOS capacity and mitochondrial membrane potential, explaining the absence of m.3243A>G loads above 80% and the presence of m.8993T>G loads close to 100%. We calculated that proper embryonic development would require at least 50,000 copies of mtDNA, a figure similar to mice. In conclusion, complementary studies in zebrafish and human embryos have generated novel insights for the mtDNA bottleneck and for its role in mtDNA disease initiation and transmission and in fertility.

Prenatal diagnosis of non-viable anomalous fetuses by exome sequencing. *N. Vora[1], B. Powell[2], K. Foreman[2], E. Hardisty[1], K. Gilmore[1], A. Brandt[2], D. Marchuk[2], A. Lyerly[3], C. Rini[4], D. Skinner[5], C. Powell[2], K. Weck[2], J. Evans[2], J. Berg[2].* 1) Department of Obstetrics & Gynecology, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) Department of Social Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC; 4) Gillings School of Global Public Health; UNC Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; 5) FPG Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Our objective was to investigate the diagnostic performance of exome sequencing (ES) in non-viable fetuses with sonographic abnormalities who had normal microarray analysis. Given the complexities of analysis and return of results, we also sought to understand patient perspectives and knowledge of ES. ES was performed on DNA extracted from chorionic villi, amniocytes, or cord blood in 7 non-viable fetuses and from peripheral blood from their parents (12 additional trios are currently being sequenced). Trios were sequenced simultaneously. Prenatal-specific gene lists and bioinformatics pipelines specific to trio analysis were developed. Variant curation was performed manually and results were presented at a multidisciplinary meeting. Parents were consented for the return of 1) diagnostic results in the fetus; 2) medically actionable findings in the parents; 3) carrier status for significant autosomal recessive conditions in which both parents are carriers. Reported variants were confirmed by Sanger sequencing. A mixed-methods assessment using questionnaires and semi-structured interviews with 19 mother-father dyads was completed. In 4/7 (57%), ES provided a diagnosis or possible diagnosis of the following disorders: osteogenesis imperfecta type 3 (*COL1A1*), fetal akinesia sequence (*MUSK*), scalp-ear nipple syndrome (*KCTD1*), primordial microcephaly-dwarfism syndrome (*RTTN*). In two other cases, a single mutation in an autosomal recessive gene was identified. Incomplete sequencing coverage and the possibility of undetected deletions precluded exclusion of a second mutation. One medically actionable finding in a parent (familial hypercholesterolemia) was reported. None of the couples had significant carrier results to report. The average perceived likelihood (5.4/10) that this technique would explain the results was consistent with pre-test counseling. Most families (16/19) verbalized hope that sequencing would provide an answer. Women in the highest income levels scored highest on the pre-sequencing genetics literacy assessment. ES offers a useful technique to obtain a prenatal diagnosis in a cohort of non-viable fetuses with sonographic abnormalities and normal microarrays. Use of ES in this group may improve clinical care, reproductive decision-making, and refine phenotypes for known genes. Challenges related to genetics literacy, diagnostic capability, and variant interpretation must be addressed by highly tailored pre- and post-test genetic counseling.

3247W

Enhanced screening performance of a SNP-based NIPT for five clinically significant microdeletions in a large clinical cohort. *K. Martin, A. Kalyan, C. Lan, M. Stosic, K. Kobara, H. Ravi, T. Truong, S. Iyengar, A. Ryan, Z. Demko.* Natera, San Carlos, CA.

Objectives: To report on: (1) the clinical performance of a single-nucleotide polymorphism (SNP)-based noninvasive prenatal test (NIPT) for screening 5 clinically significant microdeletions [at the 22q11.2, 1p36, Cri-du-chat (CdCS), and Prader-Willi (PWS)/Angelman syndrome (AS) regions]; (2) the test's performance using an updated approach involving increasing the confidence threshold of the algorithm, and reflex sequencing of high-risk calls at a higher depth of read. **Method:** 58,501 consecutive clinical samples received for 22q11.2 del testing from Aug 2014–Feb 2015, and 42,318 samples received for 1p36, CdCS, PWS, and AS del testing from Feb 2014–Feb 2015, were analyzed at a CAP-accredited, CLIA-certified lab using a SNP-based NIPT. The same samples were retrospectively reviewed using the updated approach. Follow-up information from confirmatory diagnostic testing for the targeted regions and details of any ultrasound findings was collected for the high-risk cases to determine the positive predictive value (PPV) and false-positive rate (FPR) of the test. **Results:** The commercial test reported 403 cases as high-risk for a fetal microdeletion, approximately 80% of which became low-risk using the updated approach, primarily due to reduction in the number of FP calls. Follow-up information revealed PPVs ranging from 1.5%–20% with the original approach, depending on the condition screened, each of which increased 2.5–7x with the updated approach **(Table 1)**. For subcohorts with average *a priori* risk, the PPVs for selected microdeletions with the updated method were: 22q11.2, 12.5%; 1p36, 50.0%; and CdCS, 50.0%. **Conclusions:** An increased confidence threshold and reflexing at higher-depth led to marked improvements, with minimal loss in sensitivity, in the performance of a SNP-based NIPT for 5 clinically significant microdeletions, most notably due to a reduction in the FPR. Early intervention in children affected with these deletion syndromes can lead to improved outcomes and an enhanced quality of life. Population-wide implementation of this updated SNP-based NIPT for microdeletions has the potential to realize this outcome.

Table 1: Performance of the SNP-based NIPT

	22q11.2 del	1p36 del	CdCS del	PWS	AS
High-risk call-original approach, (N)	188	25	75	4	111
High risk calls-updated approach, (N)	54	7	7	4	17
PPV-original approach, (%)	14.1	20	8.9	-	1.5
PPV-updated approach, (%)	38.7	50	66.7	-	10
FPR-original approach, (%)	0.31	-	-	-	-
combined					0.58
FPR-updated approach, (%)	0.06	-	-	-	-
combined					0.09

3248T

Development of a novel targeted assay for non-invasive prenatal testing of fetal trisomies and sub-chromosomal abnormalities exhibits diagnostic level accuracy. *P.C. Patsalis[1,2], E. Kypri[1,2], K. Tsangaras[2], A. Achilleos[2], P. Mina[2], M. Neofytou[1], E.A. Papageorgiou[1,2], M. Ioannides[2], G. Koumbaris[1,2].* 1) The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus; 2) NIPD Genetics Ltd, Nicosia, Cyprus.

Purpose There is a great need for the development of highly accurate, cost effective technologies, which can facilitate the widespread adoption of Non Invasive Prenatal Testing (NIPT). We hereby present a novel cost effective assay of unparalleled accuracy which overcomes the limitations of current technologies. *Methods* This method enables the targeted analysis of selected genomic regions at very high sequencing depth and allows highly accurate fetal fraction determination to ensure extremely accurate aneuploidy detection. The analytical performance of the assay was evaluated using a proprietary bioinformatics pipeline that combines the results of four statistical models, including cell free DNA (cfDNA) fragment size information. A validation study, which included 611 samples derived from pregnancies of at least 10 weeks of gestation, was performed. Furthermore, in a proof of principle study, we applied this technology for the detection of microdeletion/microduplication syndromes using samples from normal pregnancies and spike-in samples simulating 5%, 10% and 20% fetal fraction. *Results* The validation study exhibited 100% sensitivity and specificity and correctly classified 52/52 (95% CI: 93.2-100%) cases of trisomy 21, 16/16 (95% CI: 79.4-100%) cases of trisomy 18, 5/5 (95% CI: 47.8-100%) cases of trisomy 13, and 538/538 (95% CI: 99.3-100%) normal cases. The test also correctly identified fetal sex in all cases (95% CI: 99.4-100%). In an additional proof of principle study, the test correctly detected the microdeletions and microduplications in all abnormal samples exhibiting 100% sensitivity and 100% specificity. *Conclusion* The clinical impact of cfDNA testing has been significant as indicated by its quick adoption in prenatal care. This novel technology overcomes limitations of current technologies and exhibits diagnostic level performance. This method enables accurate and cost-effective non-invasive fetal aneuploidy detection of trisomy 21, 18 and 13 as well as sub-chromosomal abnormalities which is critical for wide-spread adoption of NIPT.

3249F

Non-invasive prenatal testing for *de novo* **dominant monogenic diseases using maternal cell-free DNA.** *J. Zhang[1], J. Li[2], Y. Feng[2], H. Dai[2], G. Wang[2], X. Ge[1], X. Wang[1], A. Purgason[2], H. Mei[1], A. Breman[1], I. Van den Veyver[1,3], A. Beaudet[1], L. Wong[1].* 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Miraca Genetics Laboratories, Houston, TX; 3) Departments of Gynecology, Baylor College of Medicine, Houston, TX.

Background : It is estimated that *de novo* dominant mutations in ~500 genes cause severe intellectual disability in 3-5 per 1000 newborns which is 3-5 times more frequent than Down syndrome. Although prenatal non-invasive testing using maternal blood containing cell free fetal DNA (cffDNA) has been demonstrated to have better performance over conventional serum screening for women at increased risk of a pregnancy with aneuploidy for chromosome 21, 13 or 18, availability of non-invasive prenatal screening for severe fetal *de novo* Mendelian disease is currently limited. In this study, we aimed to develop a new non-invasive prenatal screening method using cffDNA to detect pathogenic variants in 43 genes associated with common dominant monogenic diseases. **Methods:** After molecular barcoding of ~ 6-10 ng input DNA by adaptor ligation and hybridization-based target enrichment, next-generation sequencing (NGS) on an Illumina platform was used to generate sequencing data with average read-depth of >2,000X in the targeted region. DNA fragments harboring the informative paternal alleles were counted after applying a mathematical algorithm involving a de-duplication step based on unique molecular barcodes and error correction for PCR, library construction and/or sequencing artefacts. Fragmented genomic DNAs with similar size to cffDNA from mother/child pairs, plasma cell free DNA admixture from female/male donors, Horizon cell free reference DNA as well as plasma cell free DNA from pregnant women at 10-18 week gestational age were used for the analytical and clinical validation. **Results:** Approximately >99% of the targeted region has a minimum coverage of 400X in order to call *de novo* mutations in the fetus. Among ~ 180 highly polymorphic loci included in this panel, all informative paternal alleles were evaluated and the analytical sensitivity was >97% in four cffDNA specimens with fetal fraction ranging 3.1-14%. The analytical specificity is > 98.5%. A pathogenic variant in *PTPN11* associated with Noonan syndrome was successfully identified in one spike-in control sample. **Conclusion:** We developed a highly sensitive and specific NIPT method to detect *de novo* mutations in the cffDNA. Clinical validation studies on larger numbers of samples from pregnant women are in progress to evaluate this new test which has a potential to be offered as a population-based prenatal screening for single gene Mendelian diseases.

3250W

Microarrays in prenatal diagnosis – some interesting cases during validation using the Affymetrix CytoScan 750K SNP chip. *L. Gole[1], S. Chan[1], C. Chua[1], S.P. Chua[1], L.L. Su[2], A. Biswas[2].* 1) Department of Laboratory Medicine, National University Hospital, Singapore; 2) Department of Obstetrics and Gynaecology, National University Hospital, Singapore.

Chromosomal microarray analysis has emerged as a primary diagnostic tool for the evaluation of developmental delay and structural malformations in children. For prenatal diagnosis, this technology has not been accepted very rapidly for fear of obtaining excessive information. We were apprehensive as we started our validations for this application, but were surprised by the results we obtained, which actually helped decision making for parents. We would like to share our experiences in this area by presenting a few cases. Only patients with high risk ultrasound findings were included in this study. DNA from cultured amniotic fluid was run on the Affymetrix CytoScan 750K SNP chip, with karyotyping being done simultaneously. Analysis was done using the Affymetrix ChAS software with the following cutoffs. DNA copy number loss of ≥ 1Mb or gain of ≥ 2Mb with UPD of ≥ 15Mb interstitially or ≥ 10Mb telomerically. Here we report 6 interesting cases where microarray provided additional and helpful information to the patients.

No	Clinical indication	Karyotype	Microarray karyotype	Results
1	Abnormal ultrasound findings A=18	46,XY,del(5)(p13p15.1).ish 5p15.2(D5S23,D5S721)x2	arr[hg19] 5p14.3p13.2(21,057,088-37,749,526)x1	Cri-du Chat not involved, but *NIPBL* deleted, known to cause Cornelia De Lange syndrome 1
2	Fetus with cardiac echogenic foci and echogenic bowels. A=22+6	47,XY,+mar. ish(15q11.2q13)(D15S11-,D15Z1-)	arr[hg19](1-22)x2,(XY)x1	Marker had no significant genomic content
3	Missed abortion	46,XX,add(6)(p24)	arr[hg19] 3p26.3p24.2 (61,891-24,670,223)x3,6p25.3p25.1 (222,200-5,277,366)x1	Microarray refined the abnormality as dup(3p) and del(6p)
4	Dandy Walker A=23+1	46,XX	arr[hg19] 4p16.3p16.1(2,931,120-6,494,394)x1	Del 4p results in Weyers acrofacial dysostosis or Ellis-van-Creveld syndrome
5	Fetus showed symmetrical IUGR A=21+3	46,XX,del(13)(q12q14)	arr[hg19] 13q12.3q14.13(29,116,876-47,290,217)x1	Does not involve *RB1*, but results in development delay and other significant developmental or morphological phenotypes. *BRCA2* also deleted
6	Twins. Lower fetus with IUGR, CVS,VSD A=19+3	46,XX,der(21) ins(21;?)(q11.2;?)	arr[hg19](1-22,X)x2	Surprisingly normal.

In conclusion, the microarray testing in prenatal samples of cultured amniotic fluid was very useful to parents in decision making. As long as genetic counselling is done clearly and clear guidelines are set with regards to whether the parents would like to know incidental findings involving (a) cancer genes e.g. *BRCA 1* and *2*, and (b) Infertility.

3251T

Frequency of prenatal diagnosis of most common chromosomal abnormalities in 289,076 births in Bogota and Cali, Colombia: 2011-2015. *P. Hurtado[1,2], S. Victoria Mojica[2], A. Puerto Niño[3], G. Gracia[4], I. Zarante[3].* 1) Ciencias Basicas de la Salud, Pontificia Univ Javeriana, Cali, Colombia; 2) Pontificia Universidad Javeriana Cali, Congenital Birth Defects Surveillance Programme of Cali; 3) Pontificia Universidad Javeriana Bogota, Congenital Malformations Surveillance Programme of Bogota; 4) Secretaria de Salud de Bogota, Congenital Malformations Surveillance Programme of Bogota.

Introduction: Chromosomal abnormalities (CA) have been reported in ~50% spontaneous abortion. CA is expected in ~10% of children. In Colombia, the CA rate per 10.000 births, for 1998 to 2000 years, was 3.52 for trisomy 18 (T18), 1.76 for trisomy 13 (T13) and 10.21 for trisomy 21 (T21). Nowadays exists primary, secondary and terciary prevention strategies for CA. Currently, the diagnosis based on ultrasound, biochemical and cytogenetic tests increases the likelihood of diagnosing CA during and after pregnancy. The gold standard, karyotyping, requires amniocentesis or chorionic villus sampling, which are invasive, and can cause abortions and anxiety in parents. Other new techniques, as non invasive prenatal diagnosis, are not are not available for the entire population.The aim of this study was to determine the frequency of prenatal diagnosis of most common CA (autosomal) in Bogota and Cali between 2011-2015.**Materials and Methods:** An observational study, based cohort 289,076 births in 9 hospitals from Bogota and Cali, Colombia, using Latin American Collaborative Study of Congenital Malformations ECLAMC methodology. Cases and controls were analysed looking at prenatal diagnosis of chromosomal abnormalities.**Results**: We found 409 patients with clinical syndromes of T21, T18 and T13. Suggestive ultrasound findings were found in 23.9% and confirmation of diagnosis with cytogenetic prenatal studies was done in 7.5%. Low birth weight was detected in 45.2% of patients. The diagnosis was most frequent in males with 54.2%. The frequency of T21 was 12.8 per 10,000 births (CI: 11.56-14.21), of whom suggestive prenatal ultrasound was 22% (n=83) and 5.9% cytogenetic prenatal studies (n=22). The frequency of T18 was 0.83 per 10,000 births (CI: 0.53-1.24), of whom sugestive prenatal ultrasound was 39.1% (n=9) and 30.4% cytogenetic prenatal studies (n=7). The frequency of T13 was 0.48 per 10,000 births (CI: 0.26-0.81), of whom sugestive prenatal ultrasound was 42.8% (n=6) and 14.2% cytogenetic prenatal studies (n=2).**Conclusions:** Prenatal diagnosis is essential to provide timely care and interdisciplinary approach to the patient and determine the level of care complexity for the delivery. Unfortunately, prenatal and cytogenetic diagnosis still is far below expectations and continues using the clinical diagnosis. The challenge is can use minimally invasive test with low morbidity and to make a timely diagnosis to improve the quality of life.

3252F

Diagnostic utility of chromosomal microarray analysis in neonates: A comprehensive multi-year study. *T. Sahoo, M.N. Strecker, S.B. Commander, M.K. Travis, N. Dzidic, K. Hovanes.* CombiMatrix, Irvine, CA.

   INTRODUCTION: Genomic imbalances are a frequent cause of congenital anomalies in neonates, and result in considerable morbidity and mortality. Although multiple, large studies have confirmed a major role for chromosomal microarray analysis (CMA) in pediatric evaluation, much less data exists specifically for the neonatal population. We undertook a comprehensive genotype-phenotype correlation analysis of all neonatal patients (≤29 days old) referred to our laboratory for CMA. **METHODS**: This study included 1351 patients over a 4 year period who were evaluated by oligonucleotide-aCGH (N=386) or single nucleotide polymorphism (N=965) array. The reasons for referral and any additional clinical data were codified into phenotypic categories and enumerated. **RESULTS**: Overall, clinically significant abnormalities were identified in 245/1351 patients (18%). Whole chromosome aneuploidy was identified in 80 cases (6%), segmental abnormalities in 163 cases (12%), and uniparental disomy (UPD) of an imprinted chromosome in 2 cases (0.1%). Variants of uncertain clinical significance (VOUS) were identified in 120 cases (9%), and multiple regions of homozygosity were reported in 46 cases (3%). In terms of genotype-phenotype correlations, 45% of aneuploidy cases were referred for a suspected chromosome abnormality, but only 20 cases (25%) correctly specified the aneuploidy of concern based on clinical features. Of the 165 abnormal cases (segmental abnormalities or UPD), the most frequent clinical indications included cardiac defects/suspected DiGeorge syndrome (N=50, 30%), suspected chromosome abnormality (N=39, 24%), central nervous system anomalies (N=32, 19%), multiple congenital anomalies (N=29, 18%) and dysmorphic features (N=26, 16%). Many patients had broader referral indications that overlapped two or more of the above categories. There were 13 cases in which the abnormality was mosaic (aneuploidy=6; segmental abnormality=6; UPD=1). We identified 74 cases with non-mosaic aneuploidies and 49 cases with segmental aneuploidies >10 Mb that may have been amenable to detection by karyotype. **CONCLUSIONS**: Our data identifies common referring indications for CMA in neonates and demonstrates the immense value of CMA in identifying the broad spectrum of associated genomic imbalances. Precise and rapid molecular diagnosis by CMA enables appropriate management, making CMA an optimal diagnostic tool for evaluating newborns with both syndromic and non-syndromic birth defects.

3253W

Pregnancy and neonatal outcome associated with genome-wide paternal uniparental disomy. *L. Wallace[1], E. McCready[2], M. Huggins[3], S. Winsor[4], S. McDonald[5], C. Li[6].* 1) Department of Obstetrics and Gynecology, Hamilton Health Sciences, Hamilton, Canada; 2) Department of Laboratory Medicine, McMaster University; 3) Obstetrics and Gynecology, Hamilton Health Sciences, Hamilton, Canada; 4) Obstetrics and Gynecology, McMaster University, Canada; 5) Department of Obstetrics and Gynecology, McMaster University, Canada; 6) Pediatrics, McMaster University, Canada.

   Mosaic genome-wide paternal uniparental disomy (GWpUPD) is rare, and associated clinical features are variable, presumably due to the proportion and tissue distribution of the normal and abnormal cells. We report a case that was referred to our center for an abnormally large and cystic placenta. Ultrasound at 14 weeks of gestation revealed a thick, multi-cystic, and ball-like placenta and an intact abdominal wall. The differential diagnosis included partial molar pregnancy, mosaic triploidy and mesenchymal dysplasia. Repeat scans at 16, 18 and 20 weeks showed persistently thick placenta with multiple small, non-vascular cysts throughout. Color-flow Doppler assessment was not consistent with a molar pregnancy. Uterine artery Doppler studies showed bilateral notching at 18 weeks. Amniotic fluid levels were high normal to borderline polyhydramnios. Fetal growth was appropriate for dates and gross structural fetal anomalies were not seen. Amniocentesis was done at 15 weeks of gestation. SNP oligonucleotide microarray revealed abnormal allele peak patterns, suggestive of two possibilities: mosaic GWpUPD (mos arr(1-22,X)X2 hmz pat) or mosaic triploidy (arr(1-22,X)X2~3). However QFPCR was consistent with a normal disomic complement for chromosomes 13, 18, and 21 in a female fetus, no triploid cells were seen. Testing for UPD 11p15 on cultured amniocytes was inconclusive. Paternal UPD of specific chromosomes or regions is known to be associated with a number of recognizable genetic conditions: paternal UPD6 with neonatal transient diabetes; UPD11 with Beckwith-Wiedemann syndrome; UPD 14 with Kagami-Ogata syndrome; UPD15 with Angelman syndrome; and UPD 20 with hypoparathyroidism. GWpUPD is associated with variable phenotypes presenting with complete or partial features of some or all of the above imprinting disorders, a combination of them or a normal outcome, presumably reflecting the proportion and tissue distribution of the abnormal cells. The pregnancy is ongoing at 28 weeks and we await to assess the baby postnatally. Our case offers a unique opportunity to gain further insight into the phenotypic spectrum of prenatally detected mosaic GWpUPD.

3254T

Genomic abnormalities in products of conception in the CMA era. *H. Yonath[1,3], D. Bar-Avin Dayan[2], J. Shamash[1], E. Guetta[1], H. Carp[2,3], D. Seidman[2,3], E. Pras[1,3], S. Reinstein[1].* 1) Inst Human Gen, Sheba Med Ctr, Ramat Gan, Israel; 2) Gynecology and Maternity Center, Sheba Med Ctr, Ramat Gan, Israel; 3) Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

BACKGROUD Approximately 15% of clinically confirmed pregnancies abort spontaneously in the first trimester and about 1.5% of pregnancies have severe malformations. About half of these early abortions can be explained by chromosomal abnormalities. Chromosomal microarray analysis (CMA) is transforming clinical cytogenetic practice and might have better success and detection rates. AIM: To demonstrate the usefulness and robustness of an array based method for the elucidation of genetic causes underlying pregnancy loss and termination of pregnancies for medical reasons. METHODS: 117 samples: from RPL (recurrent pregnancy loss) and TOP (termination of pregnancies) specimens underwent cytogenomic analysis and/or chromosomal microarray analysis. Chromosomal microarray analysis was performed using a oligonucleotide-based microarray platform. Results were evaluated at the cytogenetic and microscopic (greater than 10 Mb) and submicroscopic (between 3Mb to 10 Mb) levels. Maternal cell contamination was assessed in each fetal sample. RESULTS: Maternal cell contamination was identified in 5% of specimens. The remaining specimens were considered to be of true fetal origin. A result by CMA can be obtained from 6 weeks of gestation (range 6-35) A result was obtained in roughly 96% of RPL-CMA group, significantly higher than in the RPL-KARYOTYPE group (63%) (p=0.000173) Chromosomal aberrations were detected by CMA analysis in 28.8% of the RPL cases, and 38.5% of the TOP cases. Of these, 53% showed classical cytogenetic abnormalities (most of them in the RPL group) In 15.6% of cases considered normal at the cytogenetic level, chromosomal microarray analysis revealed a pathogenic copy number change (5.1% of the RPL cases and 26.3% of the TOP cases ,p=0.009221) . CONCLUSIONS: Chromosomal microarray analysis of products-of-conception specimens yields a high diagnostic rate. Moreover, compared with karyotyping, there appears to be an increased detection rate of chromosomal abnormalities when CMA is used to analyze the products of conception especially in the group of TOP. Identification of these abnormalities helps to estimate recurrence risks in future pregnancies.

3255F

Case Report: Prenatal diagnosis of X-linked Optiz G/BBB Syndrome by chromosomal microarray in a male fetus presenting with fetal hydrops, increased nuchal fold and absent nasal bone. *N. Martin[1], G. Nimmo[2], N. Watkins[3], J. Keunen[4], E. Kolomietz[3], M. Roifman[1,2].* 1) Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, Toronto, Ontario, Canada; 2) Division of Clinical & Metabolic Genetics, Hospital for Sick Children, Toronto, Ontario, Canada; 3) Department of Laboratory Medicine, Mount Sinai Hospital, Toronto, Ontario, Canada; 4) Department of Obstetrics and Gynecology, Mount Sinai Hospital, Toronto, Ontario, Canada.

X-linked Opitz G/BBB syndrome (XLOS) is a multiple congenital anomaly disorder typically characterized by ocular hypertelorism, laryngotracheoesophageal defects, and genitourinary abnormalities caused by mutations in the *MID1* gene. Prenatal presentations of XLOS are rare. We report a G4P1A2L1 29 year-old woman who presented at 19 weeks gestation with fetal ultrasound findings of bilateral pleural effusions requiring chest shunts in utero. The fetus also had an absent nasal bone, thickened nuchal fold and ascites, the latter of which resolved following fetal intervention. Amniocentesis was performed and microarray analysis revealed a novel likely pathogenic *de novo* 126 kb deletion encompassing the 3' region of the *MID1* gene in a male fetus. Deletions in this region have not been reported in the literature to be associated with XLOS. Postnatal examination of the newborn was consistent with multiple features of XLOS: severe hypertelorism, widow's peak, prominent forehead, and right cryptorchidism. One prior case of prenatal bilateral pleural effusion in a child with presumed XLOS has been reported; however, no molecular diagnosis was made. The current case confirms the finding of bilateral pleural effusions with or without hydrops as a presenting feature of XLOS and highlights the importance of considering a targeted fetal ultrasound for features of *MID1* and/ or *MID1* variant analysis if prenatal chromosome analysis is normal.

Prenatal CMA findings in urinary system malformations fetuses with normal karyotype. *H. Wang[1,2], Z. Dong[1,2], M. Chen[3], L. Xiong[4,5], Y. Song[3], J. Lou[6], Y. Kwok[1], K. Choy[1,2].* 1) Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong , Hong Kong, Hong Kong; 2) Shenzhen Research Institute, The Chinese University of Hong Kong; 3) Key Laboratory of Reproductive Medicine of Guangdong Province, Key Laboratory for Major Obstetric Diseases of Guangdong Province, Key Laboratory of Reproduction and Genetics of Guangdong Higher Education Institutes. The Third Affiliated Hospital of Guangz; 4) Bao An Maternal and Child health hospital, Shenzhen, Guangdong, China; 5) Shenzhen Key Laboratory of Birth Defects (Number:ZDSYS201504301707152); 6) Dong Guang Maternal and Child health hospital, DongGuan, Guangdong, China.

　Background: Fetal urinary system malformation, accounts for one third of all congenital malformations detected by routine fetal ultrasonography. Also known as congenital anomalies of kidney and urinary tract (CAKUT) are observed in 0.3 to 0.6% of live births and accounts for 40 to 50% of the etiology of chronic kidney disease in children. Chromosomal microarray analysis (CMA) has been proven to detect submicroscropic genomic imbalances prenatally because of its high-resolution and time-saving. However, prenatal studies on isolated or syndromic CAKUT and its advantage over traditional cytogenetics are limited. In this study, we aimed to investigate the diagnostic performance of CAKUT among prenatal cases with normal karyotype. **Methods:** This study recruited 108 prenatal samples, with detailed documented ultrasound findings and CMA results from four prenatal diagnosis centers. Pathogenic copy-number variants (CNVs) were identified based on the American College of Medical Genetics guideline. **Results:** The overall detection rate was 9.2% (10/108) for pathogenic CNVs by CMA. The extra diagnostic yield compared with karyotype was 1.7% (1/60) for the isolated CAKUT, and 18.7% (9/48) for the syndromic group. The incidence of pathogenic CNV is significantly different (p<0.05) between the isolated group and syndromic group. **Conclusion:** This study shows the improved diagnostic yield by CMA in prenatal CAKUT, compared with conventional karyotyping, with or without syndromic anomalies. Our data supports that CMA should be provided in prenatal diagnosis as a first-tier test for fetus with urinary system malformations. The pathogenic CNVs identified help to provide further understanding of the pathogenesis of the urinary system malformations and CNV spectrum.

3257T

Differentially expressed miRNAs in trisomy-21 placenta. *I. Svobodova[1], M. Korabecna[1], P. Calda[2], M. Brestak[3], E. Pazourkova[1], S. Pospisilova[1], M. Krkavcova[4], M. Novotna[2], A. Horinek[1].* 1) Institute of Biology and Medical Genetics, General University Hospital in Prague, Prague, Czech Republic; 2) Department of Obstetrics and Gynecology of the First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; 3) Screening center, Prague, Czech Republic; 4) GENVIA genetic laboratories, Prague, Czech Republic.

　Background: The Down syndrome (DS) etiology is still unknown. However, all data suggest that the mechanism is more complex than previously supposed. Epigenetic mechanisms, including miRNAs gene expression regulation, are one of potential influencing factors. The aim of this study was to compare miRNAs expressions in placentas with normal and trisomic karyotype and to associate differentially expressed miRNAs with concrete biological pathways.　Materials and Methods: In the pilot study, 754 miRNAs were profiled in 30 chorionic villi samples (CVS) - 14 normal and 16 DS, using real-time PCR technology and TaqMan Human miRNA Array Cards A and B. Twelve differently expressed miRNAs between compared groups of samples were validated on 50 independent samples (25 normal and 25 DS) using TaqMan miRNA Assays. The Mann-Whitney test with a cutoff p-value < 0.05 was used for results evaluation. Functional annotation and diseases association of selected miRNAs were performed using several web-based software tools (miRWalk, DAVID, WebGestalt).　Results: Seven miRNAs were verified as upregulated in DS placentas; three of these miRNAs are located on chromosome 21 (miR-99a, miR-125b and let-7c). Many essential biological processes, transcriptional regulation or apoptosis, were identified as being potentially influenced by altered miRNA levels. Moreover, miRNAs overexpressed in DS placenta potentially regulates genes involved in placenta development (GJA1, CDH11, EGF, ERVW-1, ERVFRD-1, LEP or INHA).　Conclusion: These findings suggest the possible participation of miRNAs in Down syndrome impaired placentation and connected pregnancy pathologies.　Supported by the Ministry of Health of the Czech Republic RVO VFN64165.

Molecular and functional characterization of a novel mouse mutant of the Planar Cell Polarity gene, *Vangl2. A.R. El-Hassan[1,2], F. Kharfallah[1,2], M.C. Guyot[2], Z. Kibar[1,2].* 1) University of Montreal, Montréal, Quebec, Canada; 2) Chu Saint-Justine, Montréal, Quebec, Canada.

Vangl2 is a core planar cell polarity (PCP) gene that acts in the non-canonical Wnt signaling pathway. The latter is known to be implicated in the regulation of morphogenetic processes of convergent extension during gastrulation and neural tube formation. Studies in mice and humans have demonstrated an important role of the PCP pathway in neural tube defects (NTDs). The mouse mutant of *Vangl2*, *Looptail* (*Lp*), has been used as a model for molecular studies of NTDs in humans. Homozygous *Lp/Lp* embryos suffer from a severe type of NTDs called craniorachischisis where the neural tube remains open along the entire body axis. They also show a PCP defect manifested by misorientation of hair cells in the cochlea of the inner ear. In the present study, we have identified a novel mutant allele of *Vangl2* called the curlybob mouse (Crb). A total of 40% of heterozygotes show a curly tail phenotype and 90% of homozygotes suffer from craniorachischisis. Around 17% of heterozygous females *Crb/+* have an imperforate vagina as compared to 50% in *Lp/+* females. Crb genetically interacts with Lp where 93% of double mutants *Crb/Lp* have craniorachischisis. The orientation of inner ear ciliated cells is more disturbed in *Crb/Lp* (double mutants) than in single Crb/+ or Lp/+ mutants. This novel mouse mutant represents another powerful model to dissect the role of *Vangl2* in PCP signaling in the inner ear and neural tube formation.

Implementation of non-invasive prenatal testing by semiconductor sequencing in a genetic laboratory. *A. Dheedene[1], T. Sante[1], M. De Smet[1], J.F. Vanbellinghen[2], B. Grisart[3], S. Vergult[1], S. Janssens[1], B. Menten[1].* 1) Center for Medical Genetics Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium; 2) Plateforme de Biologie Moléculaire, Département des Laboratoires, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium; 3) Centre de Génétique Humaine, Institut de Pathologie et Génétique, Charleroi, Belgium.

OBJECTIVES: To implement non-invasive prenatal testing (NIPT) for fetal aneuploidies with semiconductor sequencing in an academic cytogenomic laboratory and to evaluate the first 15 months experience on clinical samples. METHODS: We validated a NIPT protocol for cell-free fetal DNA sequencing from maternal plasma for the detection of trisomy 13, 18 and 21 on a semiconductor sequencing instrument. Fetal DNA fraction calculation for all samples and several quality parameters were implemented in the workflow. 1081 clinical NIPT samples were analyzed following the described protocol. RESULTS: NIPT was successfully implemented and validated on 201 normal and 74 aneuploid samples. For trisomy 21, 18 and 13 a specificity of 100%, and a sensitivity of respectively 98%, 94% and 100% was reached and accreditation for the NIPT workflow was obtained. From 1081 clinical samples, 17 samples showed an abnormal result: fourteen trisomy 21 samples, one trisomy 18 and one trisomy 16 were detected. Also a maternal CNV on chromosome 13 was observed, which could potentially lead to a false positive trisomy 13 result, but was reported as normal. One sex discordant result was reported, probably possibly attributable to a vanishing twin. No false-negative results have been reported to date. Moreover, our combined fetal fraction calculation enabled a more reliable risk estimate for trisomy 13, 18 and 21. CONCLUSIONS: NIPT for trisomy 21, 18 and 13 detection has a very high specificity and sensitivity. Due to several biological phenomena diagnostic invasive confirmation of abnormal results remains required.

3260T

Assessing the mutational spectrum of 7-dehydrocholesterol reductase and the toxicological effects of pharmacological inhibition during the prenatal period. *M.R. Boland[1,2,3,4], N.P. Tatonetti[1,2,3,4].* 1) Biomedical Informatics, Columbia University, New York, NY; 2) Systems Biology, Columbia University, New York, NY; 3) Medicine, Columbia University, New York, NY; 4) Observational Health Data Sciences and Informatics (OHDSI), Columbia University, New York, NY.

Seasonal factors occurring during the prenatal or perinatal period can affect long-term disease outcomes. Previously, we used clinical data from 1.7 million patients to identify 55 diseases correlated with birth season. However, this work did not reveal the environmental drivers underlying these associations. Vitamin D is a seasonally varying compound synthesized in the skin using 7-dehydrocholesterol and ultraviolet B radiation. A competing reaction occurs to convert 7-dehydrocholesterol to cholesterol via 7-dehydrocholesterol reductase (DHCR7). Deleterious mutations in *DHCR7* decrease the ability to produce cholesterol and enhance production of vitamin D. Thus making *DHCR7* mutations more evolutionarily favored in regions of the world with historically low sunlight access. Importantly, a rare Mendelian disease - Smith-Lemli-Opitz Syndrome (SLOS [MIM 270400]) is characterized by compound heterozygous mutations in *DHCR7*. SLOS results in severe fetal deformities and malformations. We discuss the toxicological information gleaned from a deep exploration of *DHCR7*. First, we present a compilation of SLOS-inducing *DHCR7* mutations and the geographic distribution (S. America, Europe, Australia, Asia) of those mutations among diseased populations. We describe several hypotheses for *DHCR7* mutations that would maximize vitamin D production via increased evolutionary pressure. Next, we looked at the mutational spectrum of *DHCR7* in an ethnically diverse, presumed healthy population from ExAC (http://exac.broadinstitute.org/). We observed that several mutations thought to be disease causing occur in healthy populations as well, sometimes with high frequencies, indicating an incomplete understanding of SLOS and highlighting new research opportunities. We also highlight several *DHCR7* variants found in ExAC that could represent SLOS carriers in under-represented ethnic groups. Our knowledge of the importance of vitamin D during the prenatal period coupled with our enhanced global understanding of the *DHCR7* mutational spectrum allowed us to hypothesize that exposure to DHCR7 inhibitors would result in deleterious effects similar to SLOS. We tested our hypothesis by investigating the fetal outcomes following prenatal exposure to DHCR7 modulators. First-trimester exposure to DHCR7 inhibitors resulted in outcomes similar to those of known teratogens (50% vs. 48% born-healthy). DHCR7 activity should be considered during drug development and prenatal toxicity assessment.

Dynamics of mitochondrial DNA heteroplasmy in human multi-generation pedigrees. *M. Su[1], N. Stoler[2], B. Rebolledo-Jaramillo[2], B. Dickins[3], D. Blankenberg[2], M. Madhava[1], F. Chiaromonte[5], R. Nielsen[4], I. Paul[6], A. Nekrutenko[2], K. Makova[1].* 1) Department of Biology, Pennsylvania State University, State College, PA; 2) Department of Biochemistry and Molecular Biology, Pennsylvania State University, University Park, PA; 3) School of Science and Technology, Nottingham Trent University, Nottingham NG1 4BU, United Kingdom; 4) Department of Integrative Biology, University of California, Berkeley, CA; 5) Department of Statistics, Pennsylvania State University, University Park, PA; 6) Department of Pediatrics, College of Medicine, Pennsylvania State University, Hershey, PA.

Mitochondrial DNA (mtDNA) accumulates de novo mutations causing heteroplasmy, the presence of more than one mtDNA variant within an individual. Studies of heteroplasmy in healthy individuals have shed light on understanding the dynamics of changes in heteroplasmy frequency from generation to generation. Such changes are governed by mtDNA bottleneck, a reduction in the number of mtDNAs during oogenesis. The variation of accumulated heteroplasmic mtDNA was found to correlate with the age of a mother at the time of fertilization in our previous study. To elucidate the dynamics of maternal transmission of human mtDNA and to further explore the effect of maternal age on mitochondrial mutations, we analyzed patterns of mtDNA heteroplasmic mutations in 85 two-generation human pedigrees with multiple siblings. We performed whole mtDNA genome sequencing on blood and buccal epithelial genomic DNA from two or more offspring from each pedigree and sequenced 613 mtDNA genomes in total. The focus of this study is on heteroplasmy changes between tissues, generations, pedigrees, and age groups. The association of mitochondrial heteroplasmy with mitochondrial haplogroups, the maternal age effect on the accumulation of mtDNA mutations, and the evolutionary mutation spectrum of human mtDNA in germline and somatic tissues will be discussed.

Interphase Chromosome Profiling (ICP) as a rapid, sensitive and cost-effective diagnostic tool for Amniotic Fluid (AF) and Products of Conception (POC) testing. *S.K. Bhattacharya[1], V.R. Babu[2], V. Lal[1].* 1) Cytogenetics, Dr. Lal Path Labs. Pvt. Ltd., Newdelhi, Delhi, India; 2) InteGen LLC, Orlando, FL 32819, USA.

Karyotype determination has an important role in the genetic work-up of POC specimens, since approximately one half of miscarriages are due to chromosomal imbalances. The three primary methods used to obtain karyotype are 1) Classical cytogenetics 2) Targeted FISH and 3) aCGH . Each of these methods has its advantages and disadvantages. While the classical approach covers the whole genome, the culture success rate is very low and as many as 30% of the cultures fail to produce results. Additionally, even in a successful culture, the TAT is significantly long. The targeted FISH, as the name indicates, only covers 5-7 chromosomes and therefore provides incomplete information. It also cannot detect any structural abnormalities. Microarray is highly sensitive in detecting most of the abnormalities, but the limitations associated with this technology are 1) inability to detect balanced translocations including Robertsonian translocations 2) inconsistent ploidy detection and 3) problem with low level mosaicism. Prenatal diagnosis by karyotype determination is done mostly to provide assurance, since majority of the pregnancies would have a normal karyotype. Therefore, fast and accurate information is highly critical for management of the pregnancy. However, the same limitations mentioned for POC also apply to prenatal diagnosis. To overcome these challenges, we recently validated and adapted a novel cytogenetic technology 'Interphase Chromosome Profiling (ICP) (InteGen LLC, USA) to assess the molecular karyotype of 200 miscarriage material and 80 amniotic fluid samples using interphase nuclei. Based on the clinical situation, ICP probes can be used to get high (550 band) or standard resolution. For POC and AF samples, using probes targeting sub-telomeres and centromeres, all numerical, most balanced and unbalanced structural aberrations, and all Robertsonian translocations can be detected. Using ICP, we obtained results from all (100%) samples and the TAT was significantly reduced to less than 7 days. However, with a proper workflow, results can be delivered in less than 48 hours.

Accurate detection of segmental aneuploidy in preimplantation genetic screening using targeted next-generation DNA sequencing. *M. Umbarger, K. Germain, A. Gore, B. Breton, E. Tsung, L. Walters-Sen, T. Mullen, N. Faulkner.* Good Start Genetics, Cambridge, MA.

Preimplantation genetic screening (PGS) aims to identify embryos that are chromosomally abnormal and thereby have limited reproductive potential. We have previously described a targeted next-generation DNA sequencing (NGS)-based method for PGS that has been validated for accurate detection of full chromosome aneuploidy, the most common form of chromosomal abnormality in preimplantation embryos. This method leverages FAST-SeqS technology to amplify and sequence tens of thousands of loci across the genome and therefore has the potential to detect sub-chromosomal or segmental aneuploidy. Here, we sought to characterize the performance of our targeted NGS PGS strategy with respect to segmental aneuploidy. First, we tested samples derived from 138 cell lines with previously reported segmental duplication/deletions ranging in size from 0.1 to ~80 Mb as well as 170 known normal samples and compared the resulting calls to the reported karyotypes, so as to assess the segmental calling sensitivity and specificity. We found that 112 of the 115 segmental copy number variants (CNVs) ≥10 Mb were called and that a total of 6 samples were falsely classified as aneuploid, yielding sensitivity and specificity estimates of 0.974 (0.926,0.991) and 0.965 (0.925,0.984), respectively. Next, to evaluate performance with respect to CNVs falling in parts of the genome for which samples were not available, we implemented a simulation strategy that enables genome-wide assessment of segmental calling sensitivity. Using data derived from trophectoderm biopsies from embryos that were classified as normal on our targeted NGS and microarray comparative genomic hybridization PGS platforms, we simulated segmental duplications of varying sizes across the genome and evaluated the frequency at which these duplications were called. These simulations revealed while there are positions in the genome where segmental calling sensitivity is reduced, these regions often coincide with heterochromatic and/or repetitive regions that are likely problematic with most PGS technologies. Collectively, the data suggest that our targeted NGS-based PGS approach is capable of detecting sub-chromosomal changes of ≥10 Mb with a sensitivity of >97% and a specificity that is comparable to that noted in our previous studies. In addition, our simulation methodology enables a level of comprehensiveness of sensitivity assessment that is difficult to achieve using samples.

Study the high incidence and mechanism of chromosome 22 aneuploidy in the embryos of male Robertsonian translocation carriers. *W. Wei, D. Chen Yue, S. Jian Dong, G. Chao, X. Jiazhi, L. Jiayin.* Reproductive Medicine, Jiangsu Provience Hosipital, Nanjing,Jiangsu,China, Jiangsu, China.

Background Approximately 2% to 3% of infertile patients are Robertsonian translocation carriers. Robertsonian translocation carriers are at high risk for infertility, spontaneous abortions, or offspring with unbalanced chromosome. **Objective** We try to find out the mechanism of the embryos from biparental robertsonian and reciprocal translocation carriers which emerge the aneuploidy. We will combine next generation sequencing with biological methods to discover the mechanism of genetics and better understand the influence of biparental translocation carriers on embryos. **Method** Analyzed the data from the PGD patients in reproductive center There were 30 maternal robertsonian translcation carriers, 49 paternal robertsonian translcation carriers,64 maternalbalanced translocation carriers, 104 paternal balanced translocation carriers, in total 247 patients. We choose two stages of embryos include blastomere and trophectoderm by sequencing. We use the two kinds of next generation sequencing machines to get the datas, Hiseq2000 and Ion torrent PGM. **Results** We analyzed the datas from PGD patients in reproductive center, the results show that the incidence of embryos from paternal robertsonian translocation carriers with chromosome 22 aneuploidy (70%) is higher than other three groups. The NGS results of chromosome 22 aneuploidy embryos from paternal translocation show that the mutation of gene CECR2, MED15 and POM121L4P may related to the high incidence of chromosome 22 aneuploidy of play a key role in it. **Conclusion** It is common that the embryos from robertsonian and reciprocal translocation carriers are aneuploidy. Our research firstly reports that the rate of chromosome 22 aneuploid embryos from paternal robertsonian translocation carriers is 70%, which is higher than other three groups. We found that CECR2, MED15 and POM121L4P are related to chromosome 22 aneuploidy. All of these supply a proof to deep understand the mechanism of aneuploid embryos.   .

Novel autosomal genes linked with male infertility. *D.V.S. Sudhakar[1], R. Phanindranath[1], N.J Gupta[2], M. Deenadayal[3], R. Singh[4], J. Reshma Devi[1], S. Yogendra[1], K. Thangaraj[1].* 1) Centre for Cellular and Molecular Biology, Hyderabad, India; 2) Institute of infertility and reproductive medicine, Kolkata, India; 3) Infertility institute and research center,Hyderabad, India; 4) Central drug research institute, Lucknow, India.

Introduction: Approximately 15% of the couples are infertile worldwide. Impaired fertility of male partner is causative in approximately 50% of all couples unable to conceive spontaneously. Earlier studies from our lab have shown that about 8.5% infertility among Indian men is due to the Y chromosome microdeletions. Further, analysis of several autosomal genes and mitochondrial genome accounted for additional 20.5% of the genetic factors responsible for infertility among Indian men. However, etiology of large proportion (74%) of infertile men still remained unknown. Our aim was to understand the role of novel autosomal genes in male infertility. **Materials and methods:** we sequenced exome of 44 idiopathic infertile men using Illumina Hiseq -2000 platform at 100X coverage. Raw data (.fastq files) were trimmed, mapped, aligned and further variants were called using GATK unified genotyper. Genotyping of the identified variants in more than 1400 samples (cases and controls) was carried out using iPLEX SNP Genotyping analysis on a Sequenom MassARRAY System. *CETN1* gene is one among the candidates identified from exome sequencing. We have sequenced the complete *CETN1* gene using peripheral blood DNA from 875 infertile men and 552 ethnically matched fertile controls. Functional studies were carried out using biophysical and cell biology techniques to understand the affect of *CETN1* variants on male infertility. **Results:** After extensive analysis of exome data we identified 32 novel and rare variants from 30 genes, that were mostly, stop gain and missense. In addition, CETN1 gene was selected from the exome data and the entire gene was sequenced; 5'UTR variant (rs 367716858) and missense (rs61734344) variant from CETN1 gene were found to be strongly associated with male infertility *(P_{Corr}<0.005)*, *(P_{Corr}=0.001)* respectively. Biophysical studies have shown that missense mutation (rs61734344) affects the calcium binding affinity, thermodynamic properties and surface hydrophobicity of the mutant (p. Met72Thr) CETN1 protein. Functional analysis of 5' UTR variant g580393C>T (rs367716858) has shown that mutation leads to increased expression of CETN1 protein. **Conclusion:** Our study has identified novel autosomal genes that are linked with male infertility.

3266T

Single cell testing versus amniocentesis and NIPT: Ultra-high resolution preimplantation genetic screening for microduplication-microdeletion syndromes. *G. Altarescu[1], T. Dror[1], E. Elinor Hakam-Spector[1], D. Kort[1], E. Farhi[1], M. Ben Shlomo[1], Z. Zeligson[1], R. Beeri[1], P. Renbaum[1], T. Eldar-Geva[2], E. Levy-Lahad[1], D.A. Zeevi[1].* 1) Preimplantation Genetic Unit, Medical Genetics , Shaare Zedek Medical Center, Jerusalem, Israel; 2) IVF Unit, Shaare Zedek Medical Center, Jerusalem, Israel.

   Introduction: Invasive prenatal testing and recent advances in noninvasive prenatal testing (NIPT) have afforded pregnant couples the ability to test for some pathogenic microdeletions during pregnancy. Nonetheless, due to the small size of these deletions (ranging from 1Mb-3Mb long), preimplantation screening for high-risk de-novo microdeletions remains too technically challenging for large-scale application. Aim: To assess whether moderately low coverage next generation sequencing can be utilized to screen clinically relevant microdeletion/microduplication syndromes in preimplantation embryos.   Materials and Methods: Structural chromosomal aberrations, resulting from parental balanced translocations, were tested in 96 different blastomere/blastocyst biopsies by array comparative genomic hybridization (aCGH) and moderately low coverage whole genome shotgun sequencing. For sequencing data analysis, custom in-house software was established for the determination of ultra-high resolution chromosomal copy number across the entire human genome. This same software was applied for the detection of pathogenic microdeletions in 12 polar body samples from the Hou et al (Cell.2013.155(7):1492-506) deep sequencing data set.   Results: Deep sequencing identified all 84 unbalanced and 12 balanced/euploid embryo samples that were detected by aCGH (100% of the cases). Strikingly, in the Hou et al. data even CNVs as small as 0.3Mb and 0.5Mb were detected with high confidence.   Conclusions: We have expanded the scope of preimplantation genetic screening (PGS) to include genetic disorders that are currently screened only by amniocentesis or NIPT. Indeed, our deep sequencing workflow offers the requisite high resolution CNV detection which is crucial for preimplantation diagnosis of common microdeletion disorders such as DiGeorge, and Prader-Willi/Angelman syndromes. Moreover, unlike aCGH our method is rapid, robust, and cost-effective.

3267F

Prospective analysis of maternal duplications improves positive predictive value in prenatal cell-free DNA screening. *M.D. Maxwell[1], C.M. Strom[2], B. Anderson[2], R. Owen[2], K. Zhang[3], F.L. Lacbawan[2].* 1) Medical Affairs, Quest Diagnostics, San Juan Capistrano, CA; 2) Research and Development, Quest Diagnostics, San Juan Capistrano, CA; 3) Research Support, Quest Diagnostics, San Juan Capistrano, CA.

   Introduction: For trisomy 21, the positive predictive value (PPV) is >90% for cell-free DNA (cfDNA) screening. However, the PPVs for trisomies 18 and 13 are substantially lower. Lower PPVs for trisomies 18 and 13 have been attributed to their low prevalence, vanishing twins, and confined placental mosaicism (CPM). However, maternal duplications can also contribute to lower PPV. Here, we determined if identification of maternal duplications can improve PPV for trisomies 21, 18, and 13. **Methods**: The cohort included 38,668 patients who elected prenatal cfDNA screening for advanced maternal age, abnormal ultrasound finding(s), abnormal maternal serum screening, or personal or family history of chromosomal abnormality. When elevated Z-scores for chromosomes 21, 18, or 13 were observed, a karyogram was generated to prospectively analyze for maternal duplications. When maternal duplications were identified, these cases were reported as negative for the corresponding fetal trisomy with the maternal duplication reported as an incidental finding. PPVs were calculated with and without prospective analysis and compared. **Results**: Prospective analysis of suspected maternal duplications improved PPV for trisomy 21 by 3.9%, trisomy 18 by 18.4%, and trisomy 13 by 12.1%, resulting in PPVs of 97%, 90%, and 72% respectively. For chromosome 21, 15 of 389 (3.9%) cases with elevated Z-scores had maternal duplications. For chromosome 18, 26 of 141 (18.4%) cases with elevated Z-scores had maternal duplications. For chromosome 13, 21 of 107 (12.1%) cases with elevated Z-scores had maternal duplications. Subsequent chromosomal microarray analysis on maternal blood confirmed the suspected maternal duplication in all 17 cases for which follow-up testing was ordered: 2/2 for chromosome 21, 4/4 for chromosome 18, and 11/11 for chromosome 13. **Conclusions**: Identification of maternal duplications in our large cohort has allowed us to improve our PPV for trisomies 21, 18, and 13. Prospective analysis of suspected maternal duplications improved the overall PPV by 12.9%, with the more dramatic improvement in PPV for trisomies 18 and 13.

3268W

Clinical utilization of NGS in Preimplantation Genetic Diagnosis (PGD)/ Screening (PGS) for chromosomal rearrangements. *S. Madjunkova[1], R. Antes[1], V. Kuznyetsov[1], C. Librach[2,3,4,5].* 1) Department for Preimplantation Genetics, Create Fertility Centre, Toronto, Ontario, Canada; 2) Create Fertility Centre, Toronto, Ontario, Canada; 3) Department of Obstetrics and Gynecology, University of Toronto, Toronto, Canada; 4) Department of Physiology, University of Toronto, Toronto, Canada; 5) Department of Gynecology, Women's College Hospital, Toronto, Canada.

   Introduction: Data from preimplantation genetic screening (PGS) of human embryos has confirmed that the incidence of structural and numerical chromosomal rearrangements increases significantly with maternal age. Selection of euploid embryos using aCGH has improved implantation and pregnancy outcome rates in assisted reproduction (ART) programs and has offered a non-invasive therapeutic option for carriers of balanced rearrangements. We have previously validated the next-generation sequencing (NGS) VeriSeq™ PGS kit and showed its accuracy, reliability and high level of consistency with aCGH. The aim of this study was to prospectively evaluate the performance of NGS PGS/PGD for chromosomal rearrangements in a clinical environment. **Material & Methods:** This study had institutional REB approval. Trophoectoderm biopsy (2-5 cells) of D5/6 blastocysts was performed for PGS/PGD on 315 embryos (121 IVF cycles) from February to May 2016. PGD for chromosomal rearrangements was performed on 10 embryos from 4 couples (2 carriers of reciprocal translocations, 1 with a Robertsonian translocation and 1 with a pericentric inversion). The same whole genome amplification product from each embryo was assessed with both the VeriSeq™ PGS kit on the MiSeq system (Illumina) and the 24Sure™/plus™ aCGH kit (BlueGnome). Results from the NGS were analyzed blindly and then compared to the aCGH results.   **Results:** Parallel analyses of the aCGH and NGS results revealed 100% concordance between the two platforms when the cut-off for reporting was ≥10Mb (del/dup) and mosaicism ≥50%. PGS analysis detected 69 single chromosome aneuploidies (22.3%), 71 complex (≥2) chromosome aneuploidies (22.9%) and 34 segmental aberrations (11%). Unlike aCGH, the NGS platform was able to identify aberrations in the presence of ≤50% mosaicism in 17% of the embryos. No embryos identified as euploid by aCGH were found to be abnormal by NGS. However, NGS gave less inconclusive results (1.3%) than aCGH (2.2%). PGD was successful in all analyzed embryos resulting in 3 euploid/balanced embryos. The hands-on time and cost per sample were lower with NGS when 24 samples were analyzed in a same run.   **CONCLUSION:** NGS is a reliable and robust high-throughput method for human embryo PGS/ PGD. In a clinical setting with high volume of analyses, NGS outperformed aCGH by reducing the hands on time and costs, and demonstrated a greater precision and accuracy. Considering the advantages of the NGS methodology we are now employing it routinely in our current clinical workflow.

3269T

A change in fetal risk after prenatal diagnosis: A case of HbS/City of Hope. *B. Clark[1], B. Pullon[2], T. Senior[1], A. Sajoo[3].* 1) Kings College Hospital, London, United Kingdom; 2) Waikato Hospital, Hamilton, New Zealand; 3) Guy's and St Thomas' NHS Foundation Trust, London, UK.

   A 33 year old woman of Nigerian background attended the genetics clinic to discuss the diagnosis of sickle cell anemia (SS) in her toddler, who was said to have had a mild course. The recessive nature of the condition, coping with her child's diagnosis and reproductive options including preimplantation genetic diagnosis were discussed. In a subsequent pregnancy, the patient requested prenatal diagnosis and was referred by her General Practitioner to the Fetal Medicine Unit. A maternal but not paternal sample was sent with the CVS sample to the laboratory. Results: DNA analysis showed that the fetus was heterozygous for the c.20A>T; p.Glu7Val sickle mutation and the c.208G>A; p.Gly70Ser City of Hope mutation in the HBB gene. A Consultant Haematologist saw the parents and affected child and obtained a paternal sample was obtained. HPLC analysis identified the father to be a sickle carrier, with normal hemoatology. Beta globin sequencing confirmed he was a compound heterozygote with HbS/City of Hope. Discussion: City of Hope is electrophoretically silent (Rahbar, 1984). Carriers are expected to be asymptomatic with normal hematology parameters. However, a case report (Paradisi, 2010) of a deceased child of African background with HbS/City of Hope genotype, severe anemia, bone marrow hypoplasia and an underlying congenital immunodeficiency was identified. Hb City of Hope in combination with beta-zero thalassemia has also been reported as clinically significant in a case report by Vinciguerra et al. (2014). The PND result, father's genotype and case reports were discussed with the patient by the Hematologist. The patient opted to end her pregnancy. Summary: This patient's reproductive risks for sickle cell-related disorders were altered after PND and fetal genotyping, which would not have been indicated if a paternal sample had sent initially with the CVS sample. Due to the potential risk of interaction between HbS and Hb City of Hope, the patient ended her pregnancy despite having a phenotypically normal partner heterozygous for the same genotype. The patient has subsequently had a child who is a carrier of the City of Hope variant.

3270F

Identification and characterization of rare hemoglobin variants: Experience at good start genetics. *J. Wilkinson, M. Zhu, M. Sardella, K. Robinson, N. Faulkner. Good Start Genetics, Cambridge, MA.*

Hemoglobin variants in the *HBB* and *HBA1/HBA2* genes are found with varying frequencies across ethnic groups. Individuals of African, Southeast Asian, and Mediterranean descent are at increased risk to be carriers for hemoglobinopathies and ACOG recommends that they be offered carrier screening. The appropriate screening tests include a complete blood count and hemoglobin electrophoresis. Several common *HBB* variants with known clinical consequences [Hb S, Hb C, Hb E, and Hb D-Los Angeles (Hb D-Punjab)] are easily identified by their electrophoretic profiles and confirmed with molecular sequencing. However, rarer variants in the *HBB* and *HBA1/HBA2* genes can be challenging to identify and interpret the potential clinical significance. Over the last 18 months at Good Start Genetics, 798 blood samples with variant peaks on hemoglobin electropherograms suggestive of an *HBB* or *HBA1/2* mutation were reflexed to targeted gene sequencing. As expected, the common *HBB* variants were most frequently identified (n=742; 93.2%). We also identified 31 rare or novel hemoglobin variants in the *HBB, HBA1* and *HBA2* genes, accounting for 6.4% (n=53) of all hemoglobin variants seen. Only 3 samples (0.4%) had variants that were still unidentified after using this testing approach. Many of the rare hemoglobin variants have little or no published information regarding the clinical consequences of inheriting the variant, alone or in combination with known pathogenic mutations. Publications are often single case reports with limited information about the clinical and hematological findings. We discuss rare variant interpretation in a well characterized disease. In the setting of a molecular testing laboratory, clinical information about the patient is often not available, and in the context of carrier screening, clinical findings in heterozygotes would not typically be expected. However, given the paucity of information known about these rare hemoglobin variants, more information is needed to accurately characterize these variants and how to counsel patients about their reproductive risks and diagnostic testing options.

Evaluating early pregnancy loss by whole exome sequencing. *H.M. Byers[1], A. LaCroix[2], T. Naluai-Cecchini[2], J.X. Chong[2], D.R. O'Day[2], M. Bamshad[2,3,4], I.A Glass[2,4], H.C. Mefford[2,4], University of Washington Center for Mendelian Genomics. 1) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA, USA; 2) Department of Pediatrics, Division of Genetic Medicine, University of Washington, Seattle, WA, USA; 3) Department of Genome Sciences, University of Washington, Seattle, WA, USA; 4) Division of Genetic Medicine, Seattle Children's Hospital, Seattle, WA, USA.*

Background: Pregnancy loss is a heterogeneous condition influenced by both genetic and environmental risk factors. One-percent of couples experience recurrent pregnancy loss (RPL), classically defined as three consecutive losses or, more recently, as ≥2 losses. For 50% of couples no etiology can be identified, denying couples an explanation and making it impossible to provide a precise risk of recurrence. Hypothesis: We hypothesized that that variants in genes critical to fetal development and/or intolerant of variation contribute to early pregnancy loss. Methods: The study is being conducted at a tertiary, academic medical center. Patients are recruited from this center, two private fertility clinics, a healthcare maintenance organization, or self-referral. Inclusion criteria are: ≥2 first trimester losses or ≥1 second or 3rd trimester loss and participation of the complete couple. Ectopic and molar pregnancies are not included. Exclusion criteria included: known cause for pregnancy loss; Mullerian anomaly; major maternal medical condition; losses at maternal age ≥40 or maternal BMI >40. Pedigrees suggestive of an autosomal dominant or recessive mode of inheritance (MOI) were prioritized for whole exome sequencing. Results: To date, 49 families, including 9 trios (male-female-1 loss) and 4 quads (couple + 2 losses), consented to participate were prioritized for whole exome sequencing. Analysis was focused on genes known to be highly conserved, underlie Mendelian conditions, or known to be critical for development as assessed in animal models. Conclusion: There are many challenges in studying genetic causes of pregnancy loss. Technological advances and declining costs of massive parallel sequencing have made it a more feasible area of study. There is enormous patient interest in this topic; identifying genetic causes and risk factors may ultimately benefit the millions of couples struggling with recurrent pregnancy loss.

A systematic evaluation of RNA quality of human conceptual tissue and its relationship to the post-mortem interval. *D. O'Day, M. Deng, K. Muggli, J. Corona, T. Naluai-Cecchini, T. Cox, I.A. Glass.* Department of Pediatrics, University of Washington, Seattle, WA.

To study tissue specific gene expression in early human prenatal development, high quality tissue samples are required. Quality assessment of starting material is vital for generating valid, accurate and reproducible data for a variety of biomedical research applications. Factors that may impact tissue quality include the post-mortem interval (PMI), tissue handling, and tissue storage prior to performing downstream experiments. Here, we systematically compare two tissue storage methods prior to Total RNA isolation from several human fetal tissues across a range of PMIs. RNA quality was evaluated using an Agilent Bioanalyzer 2100 to obtain the RNA integrity number (RIN). Tissue samples were divided in two and stored separately at -80°C dry and at 4°C in the RNA stabilization and storage solution, RNAlater, before processing the samples for RNA extraction. We determined that tissues stored in RNAlater, according to manufacturer guides, generated RIN scores consistently higher (mean RIN 9.5 ± 0.3 standard deviation; range 9.0 to 9.9) than those of tissues stored at ultra-low temperature (mean RIN 7.1 ± 1.5 standard deviation; range 4.9 to 9.7) prior to RNA extraction. Interestingly, only minimal RNA degradation is seen in cases with a PMI of up to 28 hours at 4°C. This data shows that proper handling and storage of samples can result in high quality RNA from several human fetal tissues including brain, heart, lung, kidney, muscle, and intestine within a PMI of 24 hours.

Preconception carrier testing using genome sequencing: What categories of results do patients want to receive? *P. Himes[1], K. Bergen[2], M.J. Gilmore[1], J.A. Reiss[2], T.L. Kauffman[2], C.K. McMullen[2], J.V. Davis[2], M.C. Leo[2], J.L. Schneider[2], G.P. Jarvik[3,4], L.M. Amendola[3], M.O. Dorschner[5], D.A. Nickerson[4], C.S. Richards[6], S. Punj[6], D.K. Simpson[1], A. Rope[1], K.M. Porter[7], K.A.B. Goddard[2], B. Wilfond[7].* 1) Department of Genetics, Kaiser Permanente Northwest, Portland, OR; 2) Center for Health Research, Kaiser Permanente Northwest, Portland, OR; 3) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 4) Department of Genome Sciences, University of Washington, Seattle, WA; 5) Department of Pathology, University of Washington, Seattle, WA; 6) Department of Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR; 7) Seattle Children's Research Institute, Treuman Katz Center for Pediatric Bioethics, Seattle, WA.

Background: As part of the Clinical Sequencing Exploratory Research (CSER) consortium, we investigated the use of genome sequencing (GS) for clinical preconception carrier screening. Compared with currently available clinical tests, single-gene panels, and multi-gene panels, GS can identify variants associated with hundreds to thousands of genetic conditions. However, the preferences of preconception couples regarding the types of carrier results returned through GS are not well studied. Methods: Women who had clinical carrier testing and were planning a pregnancy as well as the male partners of identified carriers were recruited, provided a taxonomy of genetic conditions, and asked to select return of results from broad categories (lifespan limiting, serious, mild, unpredictable, adult onset) rather than specific conditions. Participants could also choose whether to receive medically actionable incidental findings. We examined participants' selections and any differences between those choosing all versus fewer categories based on demographic characteristics and family history (Fisher's exact test, α=.05). Results: Most study participants (92% total; 91% of 279 females, 94% of 46 males) selected all categories. There were no statistically significant differences between non-Hispanic whites and nonwhites (92% vs. 85%; p=.07), participants with knowledge of a family with a genetic condition and those who did not (94% vs. 88%; p=.07), low or high income (91% vs. 90%; p=1.00), having a family history of a genetic condition or not (96% vs. 91%; p=.0.34) or having children or not (93% vs. 89%; p=0.17) on whether they chose all categories. Among the participants who decided against receiving return of results from all categories, 69% declined unpredictable findings, 52% adult-onset findings, 34% mild findings, 14% serious findings, and 10% incidental findings. Conclusions: In a setting with limited barriers to receiving additional information from genome sequencing, most participants elected to receive all possible information. The rate at which individuals selected all genetic results versus a subset of results did not differ by demographic factors. Additional work is needed to explore how participants understand, value, and use the information from each category.

3274W

Investigating *HOXA4 and HOXA11* **expression-affected implantation under the influence of N-acetyl cysteine.** *P. Afsharian[1], V. Mokhtari[1,2,3], M. Shahhoseini[1], S.M. Kalantar[2], A. Moini[3,4].* 1) Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran; 2) Department of molecular cytogenetics, Research and clinical center for infertility, Shahid Sadoughi University of Medical Sciences, Yazd, Iran; 3) Department of Endocrinology and Female Infertility, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran; 4) Department of Obstetrics and Gynecology, Faculty of Medicine, Tehran University of Medical Science, Tehran, Iran.

   Statement of purpose: N-acetyl cysteine (NAC) is a well-tolerated mucolytic drug that moderates clinging mucous secretions and enhances glutathione S-transferase activity. Various studies concluded that NAC can be effective on ovulation and pregnancy rate improvement in infertile patients when was co-administered with another drugs such as folic acid. Also, successful implantation rates under the effect of high expression of some genes especially in *HOXA* cluster have been reported in the literature. The main focus in this study is on the efficacy of NAC on implantation by effect on *HOX-A4* and *-A11* expression. As a new aspect of this study, we evaluated the expression of these genes in NAC supplementation during in vitro fertilization (IVF) cycle. **Methods used**: Thirty women aged 22 to 40 with a history of at least two recurrent implantation failure (RIF) who were undergoing IVF cycle were included in the study. The study was of the type a single center, double blinded, placebo controlled, randomized trial. Subjects received either NAC or placebo with both effervescent tablets having similar color, size and appearance. Expression of *HOX-A4* and *-A11* were assessed on the day of WOI (using Real Time PCR) biopsies from endometrium. The patients were randomly categorized in two groups (A/B) to receive NAC 1200 mg/day or placebo, for at-least 9 weeks before starting ovarian stimulation. Pipelled-based biopsy from endometrium was done on specific day (19-21) of their cycle. Then patients were undergone ovarian stimulation (using NAC) ended to IVF treatment. Total RNA-extraction and cDNA synthesis were performed from endometrium samples and evaluatied by RealTime PCR. **Summary of results**: Our obtained results have depicted that expression levels of *HOXA11* gene was significantly (*P* values= 0.046) different in comparing both A and B groups, however we have seen no expression of *HOXA4* in any groups on the day of WOI. As a remarkable finding, implantation rate was tailored in group B in comparison with that in group A. **Conclusion:** There is a significant difference in expression of *HOXA11* in comprising two NAC supplementation and placebo groups during IVF protocols for RIF patients unlike *HOXA4*.

3275T

Nelf **knockdown alters gene expression in GnRH neuron migration.** *E. Ko, L.P. Chorich, M.E. Sullivan, L.C. Layman.* Department of Neuroscience and Regenerative Medicine, Augusta University , Augusta, GA.

   Hypothalamic-pituitary-gonadal (H-P-G) axis function, which is regulated by gonadotropin releasing hormone (GnRH), is critical in pubertal development. Thus proper migration of GnRH neurons from the olfactory placode to the hypothalamus is important. Mutations in Nasal embryonic LHRH factor (NELF), which is also known as NMDA receptor synaptonuclear signaling and neuronal migration factor (NSMF), have been reported in normosomic hypogonadotrpic hypogonadism (nHH) and Kallmann syndrome (KS) patients. *Nelf* knockdown in NLT cells and *Nelf* knock out mice have shown disruption in GnRH neuron migration. However, the mechanism by which NELF regulates GnRH neuron migration is unclear. We reported that NELF is predominantly located in the nucleus and contains two atypical zinc finger domains. Jacob protein, the rat ortholog, is 98% identical to NELF, interacts with CREB after translocating to the nucleus by stimulating the NMDA receptor, and then affects other genes. We hypothesize that NELF could be involved in GnRH migration indirectly through regulation of other proteins (protein-protein interaction) and not by direct interaction (DNA–protein binding).   To determine what genes are potentially regulated by *Nelf*, cDNA arrays were performed following *Nelf* knockdown (KD) in mouse migratory neuronal NLT cells using *Nelf* shRNA Lentiviral particles. We selected 181 genes with at least 2 fold change either up or down-regulated and with P<0.028 in *Nelf* knockdown compared to a scrambled control. We found two known genes, *Cadm1* and *Grina,* which are involved in GnRH neuron migration, to be reduced in cDNA arrays by 52-54% with *Nelf* knockdown. To validate these genes, RT–qPCR was performed. In RT-qPCR, both of these genes were down-regulated, ranging from 58-94%. In addition, we validated 4 of the highest down-regulated genes, *Vnn1, Tmem176b, Rtp4* and *Efemp1,* ranging from 85-100 %, and 3 of the highest up-regulated genes, *Vcan, Hhip, Neot 2,* ranging from 99 -100%, by RT-qPCR. Confirmation of protein levels is ongoing. Findings from this study will further enhance our understanding of the function of *Nelf* in GnRH neuronal migration.

Finding genes for infertility: A balanced translocation in an oligospermic male uncovers *SYCP2* **overexpression.** *S.L.P. Schilit[1,2], T. Kammin[3], C. Hanscom[4], C. Redin[2,4,5], C.B. Gurumurthy[7], A.J. MacQueen[8], J.F. Gusella[2,4,5,6], M.E. Talkowski[2,4,5,6,9,10], C.C. Morton[2,3,6,11,12].* 1) Program in Genetics and Genomics, Biological and Biomedical Sciences Program, Graduate School of Arts and Sciences, Harvard University, Cambridge, MA, USA; 2) Harvard Medical School, Boston, MA, USA; 3) Department of Obstetrics, Gynecology and Reproductive Biology, Brigham and Women's Hospital, Boston, MA, USA; 4) Molecular Neurogenetics Unit, Center for Human Genetic Research, Massachusetts General Hospital, Boston, MA, USA; 5) Department of Neurology, Massachusetts General Hospital, Boston, MA, USA; 6) Medical and Population Genetics Program, Broad Institute of MIT and Harvard, Cambridge, MA, USA; 7) Developmental Neuroscience, Munroe Meyer Institute, Mouse Genome Engineering Core Facility, University of Nebraska Medical Center, Omaha, NE, USA; 8) Department of Molecular Biology and Biochemistry, Wesleyan University, Middletown, CT, USA; 9) Department of Psychiatry, Massachusetts General Hospital, Boston, MA, USA; 10) Department of Pathology, Massachusetts General Hospital, Boston, MA, USA; 11) Department of Pathology, Brigham and Women's Hospital, Boston, MA, USA; 12) Manchester Academic Health Centre, University of Manchester, Manchester, UK.

Infertility affects 10-15% of couples, making it one of the most common disorders for reproductive aged individuals. Over 20% of cases are idiopathic in nature, and it is commonly thought that many have an underlying genetic etiology. Identifying genes involved in unexplained infertility not only informs an understanding of the mechanisms regulating fertility, but also provides information to support diagnosis, genetic counseling and eventual therapeutic intervention. One approach to identifying genes involved in infertility is to examine the phenotype-genotype correlation in subjects with a clinical phenotype (*e.g.*, unexplained infertility) accompanied by a *de novo* balanced chromosomal anomaly (BCA), as is the foundation of gene discovery in the Developmental Genome Anatomy Project (DGAP, dgap.harvard.edu). One subject in this study, designated DGAP230, has oligospermia and 46,XY,t(20;22)(q13.3;q11.2). While it is generally thought that BCAs may reduce fertility due to production of unbalanced gametes, another possibility is that the chromosomal rearrangement disrupts or dysregulates genes important in fertility. By large-insert whole genome sequencing, we refined the location of chromosomal breakpoints in DGAP230. Through assessment of topological associated domains (TADs) at the sites of rearrangement, we have discovered overexpression of *SYCP2*, encoding synaptonemal complex 2 (MIM 604105), a structural protein involved in synapsis of homologous chromosomes in meiosis I. We hypothesize that *SYCP2* overexpression impairs proper spermatogenesis leading to oligospermia by meiotic nondisjunction. This effect could be mediated by either increased adherence between synapsed homologous chromosomes, or conversely, by poorly synapsed chromosomes that result from improper synaptonemal complex stoichiometry. To test causality and molecular mechanism we are modeling *SYCP2* overexpression in mice and *Saccharomyces cerevisiae*, respectively. In addition to pinpointing a putative genetic etiology for DGAP230's oligospermia, our study more generally demonstrates an alternative explanation for BCA-mediated infertility.

First day urine of discordant monozygotic twin reflected fetal metabolic programming in metabolomics study. *M.K. Thong[1], R.D. Muthukanoo[1], M.F. Loke[2], Y.M. Choo[1], A.A. Kamar[1], M.T. Ishak[1], J. Vadivelu[2].* 1) Department of Pediatrics, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia; 2) Department of Medical Microbiology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia.

Introduction: Metabolomics, is believed to be a promising new tool for clinical diagnosis. Refined clinical management of ill premature newborns may be achieved with knowledge available on neonatal development processes and their metabolomics profile. Objectives: The aim of this study is to investigate whether dynamic urinary metabolomics in a set of premature monozygotic twins reflects their metabolic status and its usefulness in predicting subsequent clinical conditions. Methodology: This is a longitudinal follow up study of a set of Malay female twin who developed multiple life-threatening conditions over the 6 week period of sample collection. A total of 57 urine samples were collected on 'day one' (i.e. within 24 hours of birth), "week two" and "week six" of life from neonates born premature (2 cases and 17 controls). Urinary metabolomics profiling was performed using liquid chromatography-mass spectrometry (LC/MS). Mass Profiler Professional (MPP) and statistic method including ANOVA and principal component analysis (PCA) in conjunction with pathway analysis were used for discovering discriminating metabolites. Results: PCA analysis revealed that urinary metabolomics profiles were significantly different among the twins on day 1, as well as compared to the control neonates, but were comparable on week 2 and week 6. Discussion: Metabolites in urine excreted at day one of life may predict differences in adaptation and alteration caused by the pathological conditions even though it is of discordant monozygotic twins. Pathways associated with vitamin B12, folate, selenium and tryptophan metabolism were significantly different between the twins. In addition, dopamine, melatonin and estrogen metabolites were significantly different among twins. Conclusion: Urinary metabolomics analysis may have a role in early identification of premature newborns with high risk of developing clinical complications and enable timely interventions and management.

3278T

Effects of paternal age on child's telomere length and number of *de novo* **mutations.** *S.W.W. Wong[1], B.D. Solomon[1,2,3], J.E. Niederhuber[1,4].* 1) Inova Translational Medicine Institute, Falls Church, VA; 2) Department of Pediatrics, Virginia Commonwealth University School of Medicine, 1201 E Marshall St, Richmond, VA; 3) Department of Pediatrics, Inova Children's Hospital, Inova Health System, Falls Church, VA; 4) Johns Hopkins University School of Medicine, 733 North Broadway Street, Baltimore, MD.

Telomeres play a vital role in maintaining genomic integrity and chromosomal stability in humans. Males tend to have shorter telomeric lengths (TLs) than females of the same age, which leads to the belief that females have less telomere attrition than males. Previous studies have shown that the child's TL is correlated with the father's age at conception, but have also provided contradictory results on whether the child's TL is correlated with either parents' TL. Most of these studies suffer from small sample sizes (number of families <100), as well as studying as an adult, where other intrinsic and extrinsic events during life introduce variance. In this study we estimate the TLs using the software telseq in 1315 whole genome sequenced (~40X) newborns and their parents. We also detected single nucleotide de novo mutations (DNMs) in the probands and were able to determine the parent of origin of over 40% of the DNMs using familial transmission and read haplotype assembly. This cohort is part of the "First 1,000 Days and Beyond Study" at the Inova Translational Medicine Institute, which represents a group unselected for health or disease. Using multiple linear regression, we find that the TL of the newborn child is positively correlated with both parents' TLs ($P<10^{-16}$) and father's age at conception ($P=2\times10^{-7}$), and is negatively correlated with gestational age ($P=6\times10^{-15}$) and male gender ($P=2\times10^{-3}$). The mother's age at conception, newborn's ancestry, and parents' BMI do not appear to be correlated with newborn's TL after controlling for the above factors. We performed separate multiple linear regressions for female and male newborns and found no statistical difference between the two genders in telomere attribution during gestation. Finally, we discovered that the number of DNMs in the newborn from the father is negatively correlated with father's TL ($P=9\times10^{-3}$), after controlling for father's age ($P<10^{-16}$) whereas the number of DNMs from the mother does not correlate with mother's TL, after controlling for mother's age. These observations present an interesting observation where an increase in paternal age may correlate with certain health risks in the child due to more do novo mutations, but at the same time may have a beneficial effect due to increased TL.

3279F

Performance evaluation and clinical implementation of a new paired-end MPSS approach for cfDNA based prenatal screening of common chromosome aneuploidies. *V. Cirigliano[1,2], E. Ordoñez[1,2], L. Rueda[1,2], I. Castilla[1], M. Grau[1], C. Fuster[2], M.P. Cañadas[1].* 1) Molecular Genetics, Labco Diagnostics/Synlab, Barcelona, Spain; 2) Biologia Celular, Universitat Autonoma de Barcelona, Bellaterra, Barcelona, Spain.

Objective: To assess the performance of a novel paired-end MPSS based cfDNA screening method on a large cohort of plasma samples from pregnancies of known outcome. Following the preliminary validation study, the efficiency of this approach was also evaluated on a large set of consecutive clinical samples from average risk pregnancies **Methods:** Retrospective blind study of 1730 1st trimester plasmas including 66 confirmed T21, 34 T18,13 T13 and 8 XY aneuploidies. The new NeoBona test was performed on cfDNA from 1 ml of plasma using Illumina paired-end MPSS and data analysis. An innovative algorithm was applied to generate a new Tscore reflecting the likelihood of aneuploidy based on fetal fraction, counting statistics, cfDNA sizes distribution and sequencing depth. Cut-offs at Tscore values were set to discriminate euploid/aneuploid cases and results compared with fetal karyotypes or neonatal outcomes. The NeoBona was than used to screen 6000 consecutive clinical samples from pregnancies above 10w of gestation (102 twins) regardless their risk category. **Results:** Results were obtained in 98.8% of cases from the validation cohort. All 21, 13 and XY aneuploidies were detected (100% sensitivity and specificity) as also 33/34 T18. Normal/aneuploid cases were correctly scored even at fetal fractions <1%. Results were obtained for 98% clinical samples, 96 trisomies 21, 17 trisomies 18 and 13 trisomies 13 were identified; 2 false positive results for T21 and one for T13 were observed (FPR 0.03% and 0.02% respectively). XY aneuploidy screening was also requested in 57% of clinical samples and 15 cases identified. Invasive procedures were performed in 9/15 cases and 1 false positive 45,X result was observed (FPR 0.05%). No follow up for normal results was available yet, the majority of which are still ongoing. Test failures occurred in 125 samples (2 twins), blood redraw provided valid results in 81% of cases. Thus, the NeoBona test showed overall success rate of 99.6% at redraw rate of 2%. **Conclusions**: Paired-end MPSS allowed simultaneous assessment of fetal fraction, cfDNA size distribution and counting which, combined with sequencing depth into a new analysis algorithm, allowed the NeoBona test to be successful even at fetal fractions <1% while reducing FPR. Setting cut-offs at the new multifactorial Tscore eliminates the lower limit at FF for reportable cases thus, potentially extending the benefits of cfDNA screening to a larger proportion of pregnancies. .

3280W

Computing confidence intervals on positive predictive value for non-invasive prenatal screening. *I.S. Haque, C. Haverty, J.D. Goldberg, E.A. Evans.* Counsyl, South San Francisco, CA.

While non-invasive prenatal screening (NIPS) for fetal aneuploidy has high sensitivity and specificity, prevalence varies significantly by maternal and gestational age. Variable prevalence affects the probability that a positive test indicates an affected fetus (positive predictive value, PPV). While ACOG and SMFM direct laboratories to report PPV individualized to the particular patient, no previous work has addressed how uncertain PPV calculations are or to what precision PPV can be estimated.We introduce a statistical framework to estimate the confidence interval (CI) around NIPS PPV. We estimate the uncertainty in NIPS analytical performance by fitting beta distributions to the 95% CIs on test sensitivity and specificity from large meta-analyses [1]. We sample the posterior distribution of aneuploidy prevalence by using original population data [2,3,4,5] to sample from beta distributions or bootstrap Kaplan-Meier curves as appropriate. We estimate the portion of the CI arising from each source by holding individual parameters fixed.With this method, we evaluate the 95% CI of NIPS PPV for trisomies 13, 18, and 21 (T13/18/21). Sampling all sources of uncertainty shows that CI breadth mostly varies by maternal age (MA): for example, the CI width for T21 is +/- 11% at age 20 down to +/- 4% at age 40. Low mean PPV for T13 and T18 leads to asymmetric CIs: the T13 PPV CI at MA=20yr and 12 weeks' gestation has a lower bound 13% below the mean of 20.8% but an upper bound 23% above the mean. All CIs are dominated by uncertainty in test specificity: at MA=20yr, the T21 CI is +/- 10.5% when sampling only over test specificity, +/-4% using only prevalence, and +/- 0.1% using only test sensitivity.Our results show that larger meta-analyses of NIPS specificity could narrow the PPV confidence interval two-fold for T21 or four-fold for T13 and T18 (motivating outcome data sharing among laboratories), but that additional gestational prevalence data will then be needed to further improve the precision of PPV estimates. The utility of providing PPV is well-justified even with the estimated CI. This work further demonstrates the need to use large meta-analyses to establish sensitivity and specificity rather than smaller individual studies.[1] Taylor-Phillips S et al. BMJ Open 2016 [2] Hecht CA and Hook HB. Prenat Diagn 1994 [3] Snijders RJM et al. Ultrasound Obstet Gynecol 1999 [4] Morris JK and Savva GM. Am J Med Genet A 2008 [5] Savva GM et al. Development of a national NIPT in Brazil. *C. Malcher[1], G.L. Yamamoto[1], P. Burnham[2], S.A.M. Ezquina[1], D.S. Marco Antonio[1], N.C.V. Lourenço[1], D. Bertola[1], I. De Vlaminck[2], M.R. Passos-Bueno[1].* 1) Human Genome Research Center, Institute of Biosciences, Universidade de São Paulo, São Paulo, Brazil; 2) Department of Biomedical Engineering, Cornell University, Ithaca, NY.

Background: Noninvasive prenatal tests (NIPT) performed in Brazil nowadays rely on outsourcing technology or the test itself. Our aim is to develop a national NIPT test at the Human Genome and Stem Cell Research Center using next generation sequencing **Method**: Libraries were prepared, indexed, multiplexed, captured for a gene panel and sequenced in MiSeq. We aligned the fastq files, removed duplicated reads, realigned based on known local indels and also removed reads with more than two mismatches. For trisomy detection (T21) we used 240 probes across chromosome 21, while for fetal sex determination we used 1 probe on the *SRY* gene on chromosome Y. We performed read count for these regions, followed by a Z-score test. For fetal fraction estimation we developed an in-house model to infer fetal fraction using SNPs (developed in R) detected from 6739 probes across 388 autosomal genes. **Results**: We used 68 samples (33 pregnant samples and 35 mock samples mimicking fetal fraction increase during pregnancy). Sequencing yielded a mean of 15.2 millions raw fastq reads (8.7-33.5 million) and mean coverage of bam files was 191.65 X (39.99 X-294.3X). Mean fitted fetal fraction for pregnant samples was 0.12 (0.02-0.3). Correlation analysis showed strong positive correlation between fetal fraction and gestational age (Pearson correlation r^2 =0.568, p-value = 5.5E-4). We did not find a significant association between fetal fraction and maternal weight (Pearson correlation r^2= -0.219; p-value=0.236). For fetal sex determination, we correctly classified all the samples, with a sensitivity of 100% (95% CI:87%-100%) and specificity of 100% (95% CI:87%-100%). Using a fetal fraction threshold of 0.06 for trisomy detection, we classified: 9/10 T21 pregnant samples with a Z-score above 3, 1/10 T21 pregnant samples with a Z-score below 3 (false negative) and 1/58 of the samples with a not-affected fetus presented a Z-score above 3 (false positive; Z-score=5.6, fetal fraction=0.18). Therefore, we have a sensitivity of 90% (95% CI:55.5%-99.75%) and a specificity of 98.28% (95% CI:90.76%-99.96%) for T21 detection. **Conclusion**: We are the first group in Brazil to develop a national noninvasive prenatal test of genetic disorders. We used high-coverage targeted next-generation sequencing in order to detect fetal genetic disorders, determine fetal sex (gender-independent) and estimate fetal fraction using only sequencing data, without any additional laboratory steps. Support: Fapesp/CNPq.

Impact of genetic disease, mode of transmission and mutation type on the outcome of preimplantation genetic diagnosis. *A.J. Hehr[1], B. Seifert[2], B. Paulmann[2], L. Eichhammer[1], C. Hofmann[1], D. Seifert[2], C. Gaßner[2], U. Hehr[1].* 1) Center for and Department of Human Genetics, Regensburg, Bayern, Germany; 2) KITZ, Regensburg, Bayern, Germany.

   Introduction: In the unique setting of the German Embryo Protection law preimplantation genetic diagnosis (PGD) for monogenic disorders in Germany could only be performed by polar body diagnosis (PBD) until 2015. With an average clinical pregnancy rate of 28% per PBD cycle the results are comparable to the PGD results obtained after blastomere biopsy on day 3. Preliminary data of our unique PBD cohort indicate an important impact of the underlying monogenic condition on PGD outcome. While a reproductive disadvantage during ART for female *FMR1* premutation carriers is well known, our data suggest reduced PGD success rates for further Repeat expansion disorders (RED) including Myotonic Dystrophy type 1 (MD1).   **Methods:** retrospective assessment of 208 PBD cycles for 100 families and 37 different monogenetic disorder including 30 female carriers for RED - Fragile X Syndrome (16), MD1 (11), Huntington disease (2) and SCA1 (1). **Results:** Transfer of 115 embryos in 67 PBD RED cycles resulted in 13 clinical pregnancies (19,1% per embryo transfer=ET), 6 missed abortions (46,2%) and 7 live births/ongoing pregnancies. In contrast, In 119 PBD cycles with ET for all other monogenic disorders (non-RED; 33) we obtained a clinical pregnancy rate of 32,1% per ET with 37 births/ongoing pregnancies and 15,9% missed abortions. In 26 PBD treatment cycles for 11 female MD1 carriers similar numbers of retrieved 12,9 vs. 14,1 non RED), mature (9,7 vs. 11,4) or fertilized oocytes (6,5 vs. 7,0) per PBD cycle were obtained at a median female age of 32,88 years (34,0 years non RED cohort). We did, however, observe a reduced implantation rate of 13,3% vs. 19,8% per transferred embryo and birth rate of 7,6% vs. 26,2% per PBD RED cycle compared to our non-RED cohort, correlated with decreased Anti-Mueller-Hormone levels. **Conclusion:** Assessment of our unique PBD cohort is indicating an important impact of the underlying genetic disorder and type of mutation on PGD outcome. We suggest, that female carriers of RED should be counseled about their reduced PGD success rates in order to allow informed reproductive decisions. In an ongoing study we currently address potential predictive biomarkers for favorable PGD outcome in order to improve individual pre-PGD counseling of female carriers interested in RED-PGD. Our preliminary RED data point towards impaired oocyte/embryo quality or endometrium receptivity and may guide further improvement of ART strategies for this PGD cohort.

A review of a 20-year experience with prenatal diagnosis records, 9,297 cases from Turkey. *H. Bolat[1], B. Durmaz[1], Z. Cengisiz[1], E. Karaca[1], A. Durmaz[1], A. Aykut[1], E. Pariltay[1], T. Sozen Turk[1], A. Rashnonejad[3], E. Arslan Ates[1], T. Atik[2], B. Erturk[1], H. Taslidere[1], N. Aliyeva[1], C. Gunduz[4], H. Onay[1], F. Ozkinay[1,2], H. Akin[1], O. Cogulu[1,2].* 1) Department of Medical Genetics, Ege University Faculty of Medicine, Izmir, Turkey; 2) Department of Pediatric Genetics, Ege University Faculty of Medicine, Izmir, Turkey; 3) Department of Biotechnology, Ege University Faculty of Medicine, Izmir, Turkey; 4) Department of Medical Biology, Ege University Faculty of Medicine, Izmir, Turkey.

   Introduction: Although novel procedures such as fetal DNA isolation from maternal blood are avaliable, invasive prenatal tests are still extensively being used for prenatal diagnosis in most countries. The aim of this study is to evaluate the demographic data, indications and cytogenetic results of prenatal samples. **Methods:** We conducted this study using records from 9297 patients that were referred to Ege University Hospital. The records of these referrals were retrospectively evaluated between 1995 and 2015. Chi-square and logistic regression analysis tests were performed for the statistical analysis of different events. **Results:** Analyses were carried out for the results of 8363 amniocentesis, 626 chorionic villus sampling and 308 cordocentesis samples. 50.80% of patients were ≥35 years of age. The number of referrals significantly decreased after 2009. Choromosome anomalies were determined in 538 (%5.8) cases (60.41% numerical, 39.59% structural). Autosomal trisomies were detected in 2.38%. Balanced structural anomalies were found in 0.9% whereas unbalanced structural anomalies were described in 0.1% of all samples. The demand for the prenatal testing of single gene disorders has increased throughout the years. Parental anxiety made up the 0.9% of the indications. The indications for prenatal diagnosis were advanced maternal age (48.2%), abnormal maternal screening tests (25.7%), abnormal ultrasound (USG) findings (11%). The indication of abnormal USG findings is found to be the most strongly associated with chromosomal abnormalities. Risk of having trisomy 21 significantly increased with advanced maternal age however trisomy 18 and 13 risk also increased but the difference was not statistically significant. The risk of having a trisomy 21 pregnancy was compared in different age groups. It was doubled in the 36-40 age group, 5 times and 10 times increased in the 36-40 and 41-45 age groups respectively compared to 21-25 age group. We found a cut-off value of 1/250 for trisomy 21, but we could not find a significant linear correlation between maternal serum screening test results higher than 1/250 with trisomy 21. **Conclusion:** Early diagnosis of genetic diseases has become very important in the health care system. We believe that, the review of these indications and their results might be helpful not only in gentic counseling before prenatal diagnosis but also in developing long term and effective strategies of genetic services.

Targeted gene set enrichment of placental transcriptome in preeclamp-sia. *J. Schuster[1], A. Uzun[1,2], J. Padbury[1,2,3].* 1) Pediatrics, Women and Infant's Hospital, Providence, RI; 2) Brown Alpert Medical School, Providence, RI; 3) Center for Computational Molecular Biology, Brown University, Providence, RI.

   Preeclampsia is a systemic and potentially life-threatening hypertensive disorder of pregnancy. Semantic data mining and natural language processing were used to curate published literature to identify genes associated to pre-eclampsia. We built a Database for Preeclampsia (dbPEC) consisting of these genes along with their associated clinical features, concurrent conditions, and published supporting literature. We previously aggregated the mined genes into gene sets associated with severity and timing of the phenotype, as well as tissue source and concurrent conditions (i.e., fetal growth restriction (FGR), gestational hypertension, or hemolysis, elevated liver enzymes, and low platelet count). Here we sought to identify enrichment of these gene sets in well phenotyped, published placental genome-wide expression data sets. The dbPEC gene sets associate to the corresponding phenotypic specifications in these expression data sets. One expression array compared severe early on-set preeclamptic patients (n=5) to normotensive patients (n=4) and we found significant enrichment for the gene set of fetal, early onset genes (p<0.0001). For a second expression array comparing severe preeclamptic patients (n=8) to normotensive patients (n=8) both the fetal, early onset gene set and the fetal, severe preeclamptic gene sets were nominally enriched (p<0.05). We also interrogated the networks of genes contributing the enrichment score for the most enriched gene set (*FLT1, CRH, PAPPA2, ABCA1, TGFB1, KDR, and NOV*) using GeneMania and Ingenuity Pathway Analysis. We assessed the biological functions, molecular functions and cellular components of these genes using the Gene Ontology Database and found the following signifi-cant GO terms: positive regulation of phosphate metabolic process, vascular endothelial growth factor-activated receptor activity, growth factor binding, and extracellular region. The approach is more successful than univariate analysis of genome-wide expression data because it leverages the genetic architecture of preeclampsia, by examining the combinatorial effect of genes using knowl-edge-based inferences.

3285F

A modified genotyping method to reliably identify single fetal cells in the maternal circulation. *X. Zhuo, Q. Wang, A. Breman, A. Beaudet.* Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

   Background: As part of an effort to develop fetal cell based noninvasive prenatal testing (CB-NIPT), we have sought a rapid, robust, and low cost method to genotype individual presumptive fetal cells especially to distinguish these from maternal cells in female pregnancies. We have chosen to modify a method described by others (Debeljak et al. PMID: 25132481) using haplotype counting by next-generation sequencing (NGS) for analysis of single cells. **Methods:** For cells from 12-16 weeks gestation pregnancies, both cytoker-atin (CK)-positive putative fetal cells and CK-negative maternal white blood cells were picked from slides from maternal blood using methods submitted for publication. The methods for recovering fetal cells involve fixation and permeabilization of all cells followed by staining for CK which is positive in fetal trophoblasts and for CD45 which is negative in fetal cells but positive in most maternal cells. Highly polymorphic genomic regions with 10-20 very informative SNPs within a 200-300 bp interval were amplified as described by Debeljak et al. A region of HLA-A was used primarily but other amplicons were also utilized including Y-specific regions. NGS was performed on the Ion Torrent platform. **Results:** This method allowed reliable differentiation of fetal and maternal cells. The HLA-A amplicon included >11 highly informative SNPs and was informative for distinguishing maternal and fetal cells in >90% of samples. Additional amplicons can be used to resolve uninformative cases, and a Y-specific amplicon is useful for male fetuses. Read depth per sample is usually >1000 reads of NGS data. Typically in fully informative cases, two haplotypes are found within the maternal reads, and fetal cells show reads with one but not the second maternal haplotype while also showing a novel paternal haplotype not present in the mother. A paternal DNA sample is not re-quired for use of this method to distinguish maternal and fetal cells in informa-tive cases. **Conclusion:** We found this method to be superior to SNP arrays, multiplex genotyping methods, and STR analysis considering cost, throughput, and reliable distinction of fetal from maternal cells. This method derives its power by providing a highly informative haplotype within individuals reads for single molecules. This method will facilitate genotyping of every single fetal cell within an overall platform for performing CB-NIPT.

3286W

Placental *MTHFR* 677C>T genotypes in pregnancy pathologies. *G.F. Del Gobbo[1,2], E.M. Price[1,2], C.W. Hanna[3,4], W.P. Robinson[1,2].* 1) University of British Columbia, Vancouver, Canada; 2) Child & Family Research Institute, Vancouver, Canada; 3) Babraham Institute, Cambridge, United Kingdom; 4) Cambridge University, Cambridge, United Kingdom.

Background: One-carbon metabolism is the biochemical pathway that activates and transfers one-carbon units for methylation reactions and nucleotide synthesis. A key step in this pathway is catalyzed by 5,10-methylenetetrahydrofolate reductase (MTHFR), which irreversibly commits one-carbon units to methylation reactions. A non-synonymous SNP in *MTHFR*, c.677C>T, produces a thermolabile enzyme with reduced function, which can be further exacerbated under folate-limited conditions. During pregnancy, the placenta extracts and concentrates folate from maternal circulation. Both maternal and placental/fetal *MTHFR* variants have been associated with pregnancy complications including miscarriage, neural tube defects (NTDs), and pre-eclampsia (PE). **Objectives:** To determine whether the placental *MTHFR* 677 T/T genotype is associated with NTDs, placental insufficiency (PI) (including PE and/or intrauterine growth restriction (IUGR)) and/or reduced birth weight/placental weight (BW/PW) ratio. **Methods:** Placental samples were acquired from pregnancies delivered at BC Women's Hospital in Vancouver, BC. Placentas from 195 healthy control, 55 NTD, and 65 PI pregnancies were genotyped by pyrosequencing at *MTHFR* 677. Fisher's exact tests were used to assess increased T/T genotype frequencies in pathology groups. ANOVA was used to compare BW/PW ratio between *MTHFR* 677 C/C + C/T genotype and T/T genotype placentas in a subset of N=173 healthy placentas. **Results:** Study population genotype frequencies were C/C: 0.498, T/C: 0.422, and T/T: 0.076, consistent with expectations for Hardy-Weinberg equilibrium and for a majority Caucasian and Asian population. NTD T/T frequency (0.091) was not significantly different from controls (T/T: 0.051), ($p = 0.214$), while the PI group had a marginally significant increase in the T/T genotype (T/T: 0.138), ($p = 0.024$) compared to controls. When the PI cases were subdivided by pathology, i.e. pre-eclampsia (both early- and late-onset) and normotensive IUGR, we found that no individual pathology drove the increased T/T frequency in the PI group. BW/PW ratio, a measure of placental efficiency, was not associated with placental *MTHFR* 677 T/T genotype ($p = 0.647$). **Conclusion:** Fetal *MTHFR* c.677C>T genotype does not contribute significantly to risk of pregnancy complications or altered BW/PW ratio in our folate-supplemented population. However, follow-up studies with larger sample sizes may be warranted for specific PI sub-pathologies.

3287T

Genome-wide analyses for age at menopause identify gene-environment interactions and causal relationships with other complex traits. *K.S. Ruth, The ReproGen Consortium (www.reprogen.org).* Genetics of Complex Traits, University of Exeter Medical School, Exeter, United Kingdom.

As more women delay childbearing, reproductive ageing has increasing relevance. Menopause timing has also been associated with adverse health outcomes such as breast cancer, heart disease, osteoporosis and type 2 diabetes. Previous GWAS meta-analysis by the ReproGen consortium focused on HapMap 2 imputed variants and in 70,000 women identified 56 mostly common genetic variants that together explain ~6% of population variance in age at natural menopause (ANM). We carried out a meta-analysis of 108,000 women imputed to the 1000 Genomes reference panel and thus including analysis of rarer variants. We used UK Biobank (35,000 menopausal women) to test a genetic-risk score for ANM for interactions with risk factors for ANM, and to perform Mendelian Randomization (MR) analyses. We identified 123 independent signals at 101 loci (MAF 1–49%; per allele effect -0.1 to -1.4yrs; smallest $P=1\times10^{-168}$) including 60 new signals, multiple independent signals at 14 loci and 4 signals on chr X. Non-synonymous variants were found in LD with 25 signals ($r^2>0.8$). As in previous analyses, DNA repair genes were enriched; new signals included variants in *FANCA* (per allele effect -0.1yrs; $P=2\times10^{-9}$) and *FANCM* (per allele effect -0.2yrs; $P=1\times10^{-10}$), two of which were non-synonymous. Other new signals included a non-synonymous variant in *CALCR* (per allele effect -0.1yrs; $P=8\times10^{-9}$) and an intronic variant in *FTO* (per allele effect -0.3 yrs; $P=3\times10^{-8}$), which was an eQTL for *FTO* ($P=2\times10^{-7}$) and was independent of the known BMI signal at this gene. Genetic risk for menopause appeared to be modified by maternal smoking during pregnancy, with both the combined SNP score and four individual variants exhibiting signs of significant G×E effects ($P<0.01$). MR analyses supported a causal role for later menopause on increased breast cancer risk, increased bone mineral density, decreased risk of osteoporosis and increased risk of uterine fibroids. By increasing the sample size and using a denser imputation we have more than doubled the number of known genetic signals for ANM and explained 8.5% of the population variance. Our results suggest a novel role for *FTO* in reproductive lifespan. MR analyses support the epidemiological relationship of ANM with osteoporosis. Finally, gene–maternal smoking interactions highlight the importance of the uterine environment during oocyte formation, and suggest that *in utero* exposures can affect reproductive lifespan.

3288F

A comprehensive strategy for exome-based preconception carrier screening. *S.C.E.H. Sallevelt, B. de Koning, R. Szklarczyk, A.D.C. Paulussen, C.E.M. de Die-Smulders, H.J.M. Smeets.* Department of Clinical Genetics, Maastricht University Medical Center+ (MUMC+), Maastricht, The Netherlands.

Whole exome sequencing (WES) provides the possibility of genome-wide preconception carrier screening (PCS). Here, we propose a filter strategy to rapidly identify the majority of relevant pathogenic mutations, which was developed on WES data from 8 consanguineous and 5 fictive non-consanguineous couples, and subsequently applied to 20 other fictive non-consanguineous couples. Presumably pathogenic variants based on frequency and 1) database annotations (HGMD/ClinVar) or 2) generic characteristics and mutation type (nonsense, frameshift and splice-site mutations), were selected in genes shared by the couple and in the female's X-chromosome. Unclassified variants, predominantly missense mutations and in-frame deletions/insertions not present in HGMD or annotated pathogenic in ClinVar, were not included. This yielded on average 29 [19-51] variants in genes shared by the consanguineous couples (n=8) and 15 [6-30] by the non-consanguineous (n=25). For X-linked variants the numbers per female were 3 [1-5] and 1 [0-3], respectively. Remaining variants were verified manually. The majority could be quickly discarded, effectively leaving true pathogenic variants. Dependent on the clinical consequences, reproductive choices can be offered to the couple. Addition of gene panels for filtering was not favorable, as it resulted in missing pathogenic variants. We conclude that WES is eligible for PCS, both for consanguineous and non-consanguineous couples, with the remaining number of variants being manageable in a clinical setting. It is important to develop and continuously curate databases with pathogenic mutations in order to further increase sensitivity of WES-based PCS.

3289W

Toll-like receptor 1 SNP markers (*TLR1* N248S, *TLR1* H305L) and preterm birth in a Wisconsin cohort. *T. Ranade[1], W. Luo[2], J. Eickhoff[2,3], B.R. Pattnaik[2,4], M. Baker[2,5,6], S.A. Tokarz[2], D.-A.M. Pillers[2,5,7].* 1) University of Wisconsin, Madison, WI; 2) Department of Pediatrics, University of Wisconsin, Madison, WI; 3) Department of Biostatistics, University of Wisconsin, Madison, WI; 4) Department of Ophthalmology and Vision Sciences, University of Wisconsin, Madison, WI; 5) Department of Medical Genetics, University of Wisconsin, Madison, WI; 6) Wisconsin State Laboratory of Hygiene (WSLH) Newborn Screening Laboratory, Madison, WI; 7) J.F. Crow Institute for the Study of Evolution, University of Wisconsin, Madison, WI.

Background: A subset of premature births occur in pregnancies complicated by infection. The first line of defense against infection is the innate immune system at the Toll-like receptor (TLR). TLRs are pattern-recognition receptors that recognize pathogen-associated molecular patterns (PAMPs). Activation of TLRs initiates an inflammation cascade of signaling moieties and cytokines. Genetic variation in these pathways is associated with diseases involving chronic and deregulated inflammation. Inflammation is associated with preterm birth, and TLR alterations are an area of investigation in prematurity research. We have previously reported results for SNPs in three TLR receptors (TLR1, 2, and 4). We found that TLR1 SNP rs4986791 (N248S) is associated with preterm birth in Wisconsin Black infants. Purpose: We sought to validate our association of TLR1 with preterm birth by studying a second TLR1 SNP in a discrete position within the gene. We hypothesized that TLR1 SNP rs3923647 (H305L) also marks an increased risk for preterm birth, and that the combined effects of TLR1 SNP (H305L) and (N248S) may enhance the association. Methods: We used DNA samples from residual newborn screening specimens from Wisconsin infants of gestational ages (GA), 23-42 wks. IRB approval was secured. 3040 samples were used for TLR1 SNP (N248S) analysis, and 1616 of these samples were adequate for subsequent TLR1 SNP (H305L) analysis. SNP genotype was determined using TaqMan® SNP Genotyping Assays (Lifetechnologies, CA). Results: The H305L minor allele T was associated with preterm GA< 34 wks with Odds Ratio (OR) 1.62 (P < 0.0003) and with GA< 28 wks with OR 1.56 (P < 0.0024). The combined effects minor alleles of TLR1 SNP 305 (T) and SNP 248 (C) also showed an association with prematurity (GA < 34 and <28 wks) (P < 0.00001), as well as low birth weight (< 1250g) (P < 0.0000015). The combined effects were most prominent in the Wisconsin Black cohort (GA<34 wks; OR for Whites is 1.81 vs. 3.27 for Blacks). SNP 305 heterozygotes were under-represented in our sample. This may reflect geographic population effects described in Wisconsin and is under ongoing investigation. Discussion: We found a significant association between TLR1 SNP (H305L) and preterm birth in a Wisconsin newborn cohort. The combination of minor alleles for both TLR1 SNP (H305L) and (N248S) was also associated with preterm birth. We recommend further study of TLR1 and its potential relationship to premature birth.

3290T

Genome-wide maternal uniparental disomy mosaicism identified in a products of conception sample tested via 24-chromosome single nucleotide polymorphism microarray with bioinformatics. *K. Merrion[1], M. Maisenbacher[1], D. Clark[1], M. Young[1], B. Levy[1,2].* 1) Natera, Inc., San Carlos, CA; 2) Columbia University Medical Center & the New York Presbyterian Hospital, New York, NY.

PURPOSE: Report a unique case of genome-wide maternal uniparental disomy (UPD) mosaicism in a products of conception (POC) sample. METHODS: POC testing was performed on a reported identical-twin loss at 16 weeks gestation. A fresh POC sample was sent to a reference lab with a maternal blood sample for analysis. Genotyping was performed using Illumina CytoSNP-12b microarrays with bioinformatics to confirm parental origin of abnormalities and rule out maternal cell contamination (MCC). RESULTS: A total of 5 dissections were performed: 2 were reported as MCC; 1 from the gestational sac showed an abnormal male result with triploidy of maternal origin; 2 taken from fetal skin showed a normal female result with all chromosomes being maternal in origin, consistent with genome-wide maternal heterodisomic UPD (rather than MCC, as the specimen was of clear fetal origin). Combined, the data reveal a complex case of mosaicism involving triploidy of maternal origin and a separate cell line with genome-wide maternal UPD. CONCLUSIONS: Although genome-wide paternal UPD, associated with complete molar pregnancy, is well documented in miscarriage, genome-wide maternal UPD has rarely been reported. In this case, an additional cell line with maternal triploidy, which has a known mechanism of either fertilization of a diploid egg, retention of a polar body, or fertilization of an ovulated primary oocyte,[1] was present. To our knowledge, there have been no prior reports of maternal triploidy/genome-wide maternal UPD mosaicism, and, the mechanism for this finding is unknown. There have been published reports of diploid/triploid mosaicism in a limited number of patients with intellectual disability and dysmorphic features,[2] and for cases in which parental origin of the extra set of chromosomes was determined, the majority were maternal in origin.[2] Several authors proposed a likely mechanism of digynic diploid/triploid mosaicism being inclusion of a second polar body into a diploid embryo early in development.[2,3] In this case, given the diploid cell line showed genome-wide maternal UPD, our proposed mechanism is a triploid conception followed by a postzygotic maldivision. Embryo to embryo hybridisation improves the quality and reduces the cost of preimplantation genetic diagnosis for chromosomal rearrangements using microarrays. *J.W. Ahn[1], A. Corrigan[2], A.R. Jones[1], S. Bint[2], A.F. Davies[2], H. Hewitson[2], P. Renwick[3], C. Mackie Ogilvie[3].* 1) Genome Informatics, Guy's and St Thomas' NHS Foundation Trust, London, UK; 2) Genetics Laboratories, Viapath, London, UK; 3) Genetics Laboratories, Guy's and St Thomas' NHS Foundation Trust, London, UK.

Preimplantation Genetic Diagnosis (PGD) is offered to couples that carry chromosome rearrangements and are therefore at risk of conceiving an abnormal child. Five to seven days following intracytoplasmic sperm injection, 5-10 cells from the embryonic trophectoderm are collected for testing. Whole genome amplification (WGA) is required due to the small amount of starting material; multiple displacement amplification of DNA is performed before oligonucleotide microarray comparative genomic hybridization. Standard protocols use commercial DNA derived from cell lines as control samples; this DNA is serially diluted to ~10 genomes before WGA. Amplification bias results in noise being introduced into the microarray data which can make detection of chromosome abnormalities challenging, especially with smaller segment imbalances. We hypothesized that this noise can be reduced by using control DNA extracted from a similar tissue type to the test sample. To evaluate this, we used as a control amplified DNA from another embryo biopsied at the same time as the test embryo. This reduced the mean derivative log ratio standard deviation (a measure of noise in array data) from 0.58 (n=46) to 0.31 (n=25), which was significant (p<0.01). Cases with known imbalances ranging 2.5-8.9 Mb were selected as test embryos; all imbalances were detected. We also developed software (EvE) to virtually hybridise embryos against each other. This allowed us to check that the two embryos that were physically hybridized together were not masking imbalances in each other. As a result of this work, we have improved the resolution of this test, and can now confidently detect 5Mb imbalances, down from our previous detection limit of 10Mb. Furthermore, the consumable costs associated with the test are reduced. This workflow therefore represents an advance in delivering PGD for chromosome imbalance.

3292W

Enhancing X-linked disease risk assessment with a non-invasive prenatal molecular assay. *M. Sekedat, L. Dohany, Y. Hong, J. Kim, H. Mueller, T. Reeder, J. Stoerker.* Progenity, Inc., Ann Arbor, MI.

   Cost-efficient sequencing technologies have enabled significant expansion of carrier screening panels for pregnant patients. Laboratories routinely perform expanded carrier screening for hundreds of genetic disorders, many of which are X-linked. For most mutations, parental carrier status only indicates the probability of giving birth to an affected child. Additional invasive testing is required for determining if the fetus is affected. However, there is an opportunity to refine the risk assessment for X-linked recessive disorders since children with two X chromosomes are very rarely affected. To address this, we developed a molecular assay that would accurately determine the presence or absence of Y chromosome material in maternal plasma as early as 10 weeks gestation. This high-throughput assay combines automated DNA extraction from maternal plasma, library preparation targeting sites on all chromosomes with emphasis on selection of the ChrY sites, and shallow-depth Illumina sequencing. A training set of 46 samples from pregnant patients carrying an XX fetus was used to generate a modified z-score for ChrY – referred to as the Y-score – for all samples. A second training set of 46 samples from pregnant patients carrying an XY fetus was used to determine the minimum Y-score for samples positive for ChrY material. The trained Y-score algorithm was tested on 433 samples having previously undergone cell-free DNA (cfDNA) testing (48.7% XX and 51.3% XY). The results were 100% concordant, indicating test accuracy equal to cfDNA testing for determining fetal ChrY status. **Conclusions:** The presence or absence of ChrY material can be used to enhance the risk assessment and guide management choices for pregnant patients who are carriers of X-linked disorders. This assay could be performed in addition to expanded carrier screening, offering valuable information to carriers of X-linked disorders, and may help reduce unnecessary invasive procedures for patients who are at low-risk of having an affected child.

3293T

Preimplantation genetic diagnosis leads to successful ongoing pregnancies in complex chromosomal rearrangements carriers. *B.C.F.K. Brunet, J.D. Shen, L.B. Cai, J.Z. Xie, J.Y. Liu, W. Wu.* The State Key Laboratory of Reproductive Medicine, Clinical Center of Reproductive Medicine, First Affiliated Hospital, Nanjing Medical University, Nanjing 210029, PR China.

   BRIEF BACKGROUND: Complex chromosome rearrangements (CCR) is a structural abnormality involving at least three break points on two or more chromosomes. It is a rare event and often related with spontaneous abortions, fetal malformations and infertility. Using next generation sequencing (NGS) for preimplantation genetic diagnosis (PGD) may increase the chance of achieving a balanced euploid pregnancy.   METHOD USED: Five CCR carriers were enrolled in this study: case A: 46, XY, t(1;4;11)(p31;p16;p22), case B: 46, XY, t(3;13;5)(p14;q21;p14), case C: 46, XX, inv(9)(p12;q13), t(13;15)(q14;q24), case D: 46, XX, inv(9)(p12q13), t(7;9)(q22;p22) and case E: 46, XX, t(2;7) (q21; q36), t(2;4) (p10;q10), t(2;4)(q15;q10). After 7 cycles, 85 oocytes were retrieved. Whole genome sequencing (WGS) was performed on 31 biopsied trophectoderm samples on day 5 or 6. Pregnancy was confirmed by fetal heartbeat using ultrasonography.   SUMMARY OF RESULTS: Five embryos were identified by WGS as balanced euploid. Of them, four were transferred resulting in three ongoing pregnancies and one miscarriage. The miscarriage is from case A, 40 days after her single embryo transfer in the first cycle. Chromosomal analysis of the abortus revealed normal karyotype. In the second cycle, the remaining embryos were transferred and her pregnancy is ongoing (over 50 days). There was no transferable embryo for case B after two cycles and for case E after one cycle. In the first cycle of case C, two embryos were identified as transferrable, a single embryo transfer was performed and her pregnancy is ongoing (over 50 days). Case D had a successful embryo transfer for only one euploid embryo, and showed a normal karyotype by amniocentesis at her eighth gestational week. In summary, the implantation rate per transfer is 100% (4 out of 4) and the ongoing pregnancy rate is 75% (3 out of 4). These results show that the use of NGS for CCR cases is promising for PGD.

3294F

An excess of chromosome 4 breakpoint in recurrent pregnancy loss. *R. Frikha, N. Bouayed, T. Rebai. Laboratory of histology, Sfax, Tunisia.*

Recurrent pregnancy loss, as at least more than 2 miscarriages, is a serious problem that affects couples who are trying to conceive. Many factors involved in reproductive process are far to being completely understood. Often, cytogenetic studies have an important role in the assesement of chromosomes abnormalities. For the search of potential loci, which might be revealed by clustering of chromosomal breakpoints, we report two reciprocal translocation involving chromosome 4 among couples with more than 2 early miscarriages and with a particular history of familial reproductive failure. These translocations were detected, among a total of six reciprocal translocations identified in 169 couples. Thus, this overrepresentation of chromosome 4 must reflect a real phenomenon. We suggest that chromosome 4 harbors a large chromosomal domain, the integrity of which is important for normal gametogenesis.

3295W

"They can't find anything wrong with him, yet": Mothers' experiences of parenting an infant with a prenatally diagnosed copy number variant (CNV). *B.A. Bernhardt, S.A. Walser, F.K. Barg, A. Werner-Lin. University of Pennsylvania, Philadelphia, PA.*

Chromosome microarray analysis (CMA) is used widely in prenatal settings. Some CNVs detected using CMA are associated with a variable or uncertain phenotype and/or possible neurocognitive involvement. Little is known about the experiences of parenting an infant following such findings. We conducted semi-structured interviews with 23 mothers of 6-12 month old infants diagnosed prenatally with a potentially pathogenic CNV. Questions elicited perspectives on the child's health and development, ongoing needs, and sharing results with others. Interviews were audiotaped, transcribed, and analyzed for common themes. Although most mothers reported that their infants were developing typically, the majority expressed concern about the child's future development given the CNV. They tried to reassure themselves that their child was unaffected by: comparing him/her to siblings, scrutinizing the child's appearance and behavior, or accepting provider reassurances. Even in the absence of developmental and neurological concerns, most remained vigilant about their child's development, and for some led to enrollment in early intervention or ongoing assessments by specialists. Maternal concern and vigilance were heightened if there was a positive family history of a neurodevelopmental disorder, the child had minor physical abnormalities, or a clinician expressed concern. Even mothers who were not overtly concerned stated they would likely attribute any abnormal behavior or development to the CNV. Half of the interviewees did not share the result with the child's pediatrician, relatives, or others due to fear of stigma, difficulty explaining the CNV, or presumptions that the child was unaffected. A few mothers regretted learning CMA results, yet most felt empowered to identify and address problems early. Interviewees recommended that clinicians provide regular updates about understanding of their child's CNV, access to families with a child with the same CNV, and referrals to psychological counseling as needed. These data reveal a gap between clinical involvement of a prenatally diagnosed CNV and parental interpretation and intervention to address problems that do not (yet) exist. Additional research is needed to address the long-term consequences of returning uncertain CMA results for parent-child bonding, and costs associated with ongoing assessment and/or unnecessary early intervention for typically developing children.

Profiling sncRNA expression through gestation by RNA sequencing. *E.M. Price[1,2], V. Martinez[3,4], D. Becker-Santos[3,4], I. Manokhina[1,2], W.L. Lam[3,5], W.P. Robinson[1,2].* 1) Medical Genetics, UBC, Vancouver, BC; 2) Child and Family Research Institute, Vancouver, BC; 3) BC Cancer Agency, Vancouver, BC; 4) Integrative Oncology, BCCA, Vancouver, BC; 5) Pathology and Laboratory Medicine, UBC, Vancouver, BC.

Small non-coding RNAs (sncRNA), including miRNAs (21-24 nucleotides long) and piRNAs (26-31 nucleotides long), have been recognized as important modifiers of gene expression. During pregnancy, active secretion and shedding of trophoblast releases placental sncRNAs into maternal blood circulation, which makes these placental sncRNAs attractive non-invasive biomarkers of health and disease. Though differential sncRNA expression has been described in maternal blood and placenta ascertained from complicated pregnancies, rarely are the same candidates reported by different studies. Understanding the biological and technical factors associated with sncRNA expression will be fundamental to developing robust and reproducible clinical tools. Thus in this study, the sncRNA transcriptome of 32 placentas, 6 first trimester (6-11 weeks gestation), 16 second trimester (14-24 weeks gestation) and 10 term (38-40 weeks gestation), was profiled using high-throughput small RNA sequencing. This approach allowed for detection of both piRNA and miRNA sequences by applying population-specific read-length filters. Expression levels were normalized by sequencing depth and transcript length (RPKM) and then log transformed for exploratory and differential expression analyses. Principal component analysis suggested sources of signal variation due to gestational age at delivery, total number of reads and processing time. Using samples with >1 million reads (n=30), 1446 of 2567 (56%) annotated miRNAs were expressed (RPKM >1) in more than one sample and 681 (26%) were expressed in more than 80% of samples of at least one trimester. Using this second set of expressed miRNAs, linear modelling identified 270 differentially expressed miRNAs (FDR <0.05) between trimesters, with most changes observed between the 1st and 3rd trimesters. There was a trend for change in miRNA expression with processing time, though this did not withstand correction for multiple comparisons. Our study suggests that both technical and biological factors should be considered in the study of sncRNAs.

Deciphering the impact of IL-10 gene polymorphism (-1082A/G, -592A/C and -819T/C) in preterm birth. *M. Pandey, S. Awasthi.* King George`s Medical University, Lucknow, India.

Background/ Objective: IL-10 is a key regulator for diminishing/weakening inflammatory response. Thus the objective of this study is to focus on the association of IL-10 gene and its polymorphisms with Preterm Birth(PTB). The process of spontaneous parturition in both preterm and term delivery is mediated by inflammation in the cervix, membranes, and myometrium. **Study Design:** A case-control study, conducted at Lucknow (India) included a total of 1118 subjects (559 cases and 559 controls). Cases were the mother`s who delivered preterm neonates(i.e. before 37 weeks of gestation) and controls includes mother`s with term delivery (i.e. after 37 weeks) .The demographic, clinical data was also obtained. Venous blood was used for DNA/RNA extraction. The genotyping of IL-10 (-819T/C, -1082G/A,-592C/A) was carried out and IL-10 mRNA levels was also checked in cases and controls. The polymorphisms were analyzed by polymerase chain reaction (PCR) restriction fragment length polymorphism (RFLP). The IL-10mRNA levels were analyzed according to genotype by quantitative real-time PCR (QRT-PCR) in both cases and controls Results: Significant association of IL-10 (-1082G/A) gene polymorphism was found (OR=1.727(1.70-2.5),p=0.006) in cases as compared to controls. The haplotypic analysis determined the association of IL-10 ATA (p=0.002)andATC(p=0.001) with PTB. The IL-10 mRNA levels were detected lower in preterm(mean±S.D.=3.08±2.22) as compared to term(mean±S.D.= 2.63±1.75) (p=0.05). Conclusion: IL-10 marks the protective impact in the inflammatory pathway of PTB. .

Comparing the clinical yield of carrier screening: Genotyping versus exon sequencing. *K.A. Beauchamp, G.A. Lazarin, H.P. Kang, K. Wong, E.A. Evans, J.D. Goldberg, I.S. Haque.* Counsyl, South San Francisco, CA.

Expanded carrier screening (ECS) identifies carriers of recessive diseases and may be performed using either targeted genotyping (TG) or next generation sequencing (NGS). TG typically provides genotype information on a fixed number of variants (typically below 3000), while NGS detects arbitrary variants within the region of interest, albeit at a somewhat higher cost. The relative efficacy of TG and NGS approaches is incompletely understood and depends on the choice of TG panel, the number of variants interrogated, and the ethnicity profile of the population being studied. Here we report on the de-identified, aggregated ECS results of 70,803 patients who were screened at Counsyl using NGS of up to 110 genes. Screening identified 27,850 individuals as carriers of 36,880 deleterious or likely deleterious mutations (some individuals were carriers for more than one variant). There were 3,760 unique deleterious mutations (many were present in more than one individual). A subset of these variants are detectable by the Counsyl TG panel, allowing direct comparison of the detection rates of NGS and TG approaches. Overall, the TG subset alone would have detected 63.1% of the pathogenic mutation calls identified by NGS, accounting for 69.4% of carrier individuals. However, in ethnicities that are underrepresented in typical TG panel designs (e.g. Asian populations), the TG test detects far fewer carriers (35.5% of mutations, 40.3% of carriers). As an additional comparator, we conceptualized the feasibility of a TG assay that achieves a high detection rate (DR). To achieve 90% DR in the pan-ethnic population requires a panel of 834 mutations. But reaching 95% DR more than doubles that panel size to 1,916 mutations. Even so, DR is not uniform across ethnicities: the 834-site panel only achieves 78% DR in Asian populations. Furthermore, evaluating this panel on patients not used during variant selection suggests additional benefits of NGS on the order of 3-5%. These data demonstrate superior sensitivities of NGS over TG for pan-ethnic ECS.

3299T

Cell based non-invasive prenatal testing using NGS-based copy number assessment of fetal cells. *A. Breman[1], L. Vossaert[1], E. Normand[1], J. Chow[3], L. U'Ren[3], R. Salman[1], S. Qdaisat[1], I. Van den Veyver[1,2], C. Shaw[1], Y. Yang[1], E. Chang[3], J. Stilwell[3], R. Seubert[3], E. Kaldjian[3], A. Beaudet[1].* 1) Molecular & Human Genetics, Baylor College of Medicine, Houston, TX; 2) Obstetrics and Gynecology, Baylor College of Medicine, Houston, TX; 3) RareCyte Inc., Seattle, WA.

Background: Detection of genomic copy number abnormalities from circulating single fetal cells using next generation sequencing (NGS) offers a promising non-invasive alternative for prenatal diagnosis. Towards this goal, we have established a method for performing fetal cell-based, non-invasive prenatal testing (CB-NIPT) during the first trimester. CB-NIPT for prenatal diagnosis has dramatic potential advantages over the currently available cell-free DNA-based tests because it enables analysis of pure fetal DNA. Here we show that we can successfully repeatedly recover individual fetal cells during the first trimester and perform NGS to detect clinically important copy number variants. **Methods:** Fetal cell enrichment was carried out using methods developed by the commercial author organization for blood preservation, density based enrichment, immunostaining, custom high-resolution scanning and analysis, and integrated single-cell picking. Whole genome amplification was performed on recovered single fetal cells and single nucleotide polymorphism-based genotyping studies were carried out for confirmation of fetal origin. NGS on an Illumina platform with approximately 5 million reads per cell (~0.1x haploid genome) was used to generate genome-wide copy number data. **Results:** Our data indicate that we can recover between 2 and 12 fetal cells with a trophoblast phenotype from 20-30 ml of maternal blood in most cases. NGS data from isolated single fetal cells has thus far shown concordance with diagnostic array CGH data from amniotic fluid or chorionic villus samplings in pregnancies affected with trisomy 21, trisomy 18, 47,XXY, and in one case a 2.7 Mb deletion on chromosome 15. **Conclusion:** CB-NIPT has dramatic potential advantages over cell-free DNA-based testing primarily because of the ability to analyze fetal DNA free of contamination by maternal DNA and avoid detecting maternal findings. CB-NIPT has the potential to detect most clinically significant cytogenetic abnormalities and even, in the future, *de novo* deleterious point mutations. Optimization of circulating fetal cell recovery and validation studies on larger numbers of samples from pregnant women are underway to evaluate the clinical validity of this test.

What Quebec pregnant women think about prenatal testing and their responsibility in the context of prenatal personalized medicine. *G. Lapointe[1], R. Drouin[2,3], C. Bouffard[1].* 1) Université de Sherbrooke, Sherbrooke, Québec, Canada; 2) Univeristé Laval, CHU de Québec, Québec, Canada; 3) Université du Québec à Montréal, Montréal, Canada.

The rapid developments in genomics portends to a future where it will be possible to predict and prevent diseases. The combination of new genomics tools and P4 medicine in the field of prenatal medicine – what we call "prenatal personalized medicine" (PPM) – will produce a large quantity of genomic information on the fetus. PPM encourages parents to actively participate in prenatal care and commits an unprecedented emphasis on the health of the fetus. This responsibility, combined with the explosion of genetic information, the advent of non-invasive prenatal tests (NIPT) and direct-to-consumer genetic testing, exposes PPM to several pitfalls. Our objective is to develop knowledge on the views and needs of pregnant women about current and new prenatal tests and on their responsibility regarding those tests. **METHODOLOGY**: Descriptive qualitative design and thematic analysis of 15 semi-structured interviews with pregnant women without a known risk of genetic disease, and previously briefed on available and forthcoming prenatal tests. **RESULTS**: At first, the majority of participants tended to choose NIPT with fetal cells, since it is a broad test, without risk. Several participants also wished to have an ultrasound, since they considered it important to see the baby. The possibility of undergoing NIPT early during pregnancy is seen as both an advantage and a disadvantage, and most agree that it should be accompanied by a doctor. Pregnant women want to actively become informed during pregnancy in order to increase their knowledge and reduce their concerns. They trust the expertise of their doctors, but find it important to become informed through a variety of other sources (e.g., the internet). They want to be responsible for what they can control during pregnancy (e.g., tobacco use), but feel that it is incorrect to require that pregnant women be responsible for what is beyond their control (e.g., genetic disease). **CONCLUSION:** Participants will opt for a new and safe technology that allows them to learn more about the health of their child. Although, these technological advances seem desirable, the majority of participants agree that these technologies should be used wisely, without putting too much responsibility on the shoulders of parents. .

Two cases of genetic counseling on additional chromosomes detected by karyotype analysis (G-banding) of amniotic fluid cells. *N. Takeshita, A. Takashima, T. Adachi, M. Nagaoka, M. Ishikawa, I. Sasaki, K. Yokokawa, M. Urita, A. Yokoyama, T. Kinoshita.* Obstetrics and Gynecology, Toho University Sakura Medical Center, Chiba, Japan.

[Introduction] Chromosomal karyotype analysis of amniotic fluid cells is a definitive prenatal genetic test. This report deals with points to be considered in conducting genetic counseling based on our experience in 2 cases in which additional chromosomes were detected by chromosomal karyotype analysis (G-banding) of amniotic fluid cells. **[Case 1]** A 32-year-old , became pregnant after receiving in vitro fertilisation and embryo transfer (IVF-ET) . Ultrasonography (US) examination performed at week 13 of gestation disclosed a fetal cystic hygroma on the neck. The patient was given genetic counseling by a clinical genetics specialist regarding potential causes of abnormalities including chromosomal aneuploidy and structural aberrations, and, at the request of the couple in part, amniocentesis was performed at week 16 of gestation. At week 18, results of the test showed the karyotype to be 46,XX,add(18)(p11.3). The patient gave birth to a female child weighing 3014 g . Based on the infant's countenance and features of her limbs, we suspected the possibility of 18 monosomy. The parents were offered an explanation again postnatally which included the possibility of clarifying the origin of the event, and they requested the newborn's karyotype analysis which was found to be 46,XX-,der(18)t(15;18)(q24;11.3). **[Case 2]** A 41-year-old . She underwent amniocentesis at week 16 of gestation on account of her pregnancy at an advanced maternal age. At week 18, results of the test showed the fetal karyotype to be 46,XY,add(9)(p24). Parental chromosomal analysis and detailed analysis with single nucleotide polymorphism (SNP) microarray procedure to locate the site of addition were also carried out at the parents' request. As a result, the aberrations were found to be arr Xp22p22.13(16,992,941-17,729,022)´2 and Xp21.3(28,791,782-28,903,443)´2, both being thought to be *de novo*. The mother was delivered of a male child weighing 2750 g . No anomaly was noted, nor did she request any postnatal chromosomal examination. **[Discussion]** In the case of an additional chromosome, it is not always easy to clearly evaluate its phenotype due to differences in the originating chromosome and the magnitude of the site of chromosomal addition. If an accurate explanation of the results of testing/observations is not provided to the parents, it may cause great anxiety. This underlines the vital importance of genetic counseling. .

The establishment of a new leaflet for prenatal diagnosis as an approach to prenatal genetic counseling. *T. Yamada[1,13], K. Sameshima[2,13], H. Sawai[3,13], A. Sekizawa[4,13], S. Nakagomi[5,13], K. Hayata[6,13], Y. Yamanouchi[7,13], Y. Fujii[8,13], H. Miyake[9,13], S. Yamada[10,13], Y. Fukushima[11,13], I. Konishi[12,13].* 1) Department of Obstetrics, Hokkaido University Graduate School of Medicine, Sapporo, Japan; 2) Department of Pediatrics, Minamikyusyu National Hospital, Aira, Japan; 3) Department of Obstetrics and Gynecology, Hyogo College of Medicine, Nishinomiya, Japan; 4) Department of Obstetrics and Gynecology, Showa University School of Medicine, Tokyo, Japan; 5) University of Yamanashi ;Graduate Faculty of Interdisciplinary Research, Chuo, Japan; 6) Department of Obstetrics and Gynecology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Okayama, Japan; 7) Department of Medical Welfare, Kawasaki University of Medical Welfare, Kurashiki, Japan; 8) Center for Genomic Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan; 9) Clinical Genetics Unit, Kyoto University Hospital, Kyoto, Japan; 10) Human Health Science, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 11) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 12) Department of Gynecology and Obstetrics, Kyoto University Graduate School of Medicine, Kyoto, Japan; 13) The Project of Health Research on Children, Youth and Families by Ministry of Health, Labour and Welfare, Japan (2014-2016).

[Background and Purpose] In Japan, "informed choice" has always been a controversial topic, as providing information is sometimes regarded as an act of misleading those with less knowledge. Many Japanese people believe that information on prenatal diagnosis (PD) pressures pregnant women into getting tested; therefore, it is difficult to speak openly about PD. Studies show that enough information is not reaching clients in primary obstetrics clinics because of this misconception. In an attempt to standardize genetic medicine in primary obstetrics clinics in Japan, we drafted a leaflet as a tool that provides balanced information of PD and directs clients to genetic counseling without pressuring them into prenatal testing. The objective of this study was to determine the impression of this leaflet on medical staff, pregnant women, and families of pregnant women and also to improve its contents. [Methods] A questionnaire was administered between November and December 2015 after using this leaflet at 5 institutions of study members throughout Japan. Data regarding the impression of the medical staff and pregnant women and/or family members were collected. This study was funded by Health and Labor Sciences Research Grant (MHLW14428175), and was approved by the institutional review board of each institution. [Results] A total of 51% of medical staff (n = 751) and 46% percent of pregnant women and family members (n = 366) responded to the questionnaire. When asked how they felt after reading the leaflets, 21.2% (119/382) of medical staff answered negatively and 34% (131/382) of them answered favorably. Furthermore, 24.1% (41/170) of pregnant women and family answered negatively and 44.7% (76/170) of them answered favorably. When pregnant women and family members were asked about the change in their feeling of happiness after reading the leaflet, 87.6% (149/170) indicated there was no change and 8.2% (14/170) answered negatively. When asked whether they felt the leaflets recommend PD, 32.5% (124/382) of medical staff and 12.9% (22/170) of pregnant women and family answered yes. [Conclusions] We conclude from this survey that this leaflet provides fair information to pregnant women and family, while medical staff tend to take a cautious attitude. There was a large variety of opinion on this leaflet because of the diversity of attitude and emotion towards PD. This leaflet should be used as a tool to direct pregnant women and family to genetic counseling. .

Next generation screening: TruSight One "clinical exome" for preconception screening in consanguineous couples. *E.P. Kirk[1,2,3], K. Barlow-Stewart[4], A. Selvanathan[5], S. Josephi-Taylor[6], L. Worgan[5], S. Rajagopalan[5], A. Bittles[7], L. Burnett[3], M. Buckley[3], A. Colley[5], T. Roscioli[1,8].* 1) Dept of Medical Genetics, Sydney Children's Hospital, Randwick, NSW, Australia; 2) School of Women's and Children's Health, University of New South Wales, Randwick, NSW, Australia; 3) SEALS Genetics Laboratory, Randwick, NSW, Australia; 4) Northern Clinical School and School of Public Health, University of Sydney, St Leonards, NSW, Australia; 5) Dept of Clinical Genetics, Liverpool Hospital, Liverpool, NSW, Australia; 6) Dept of Clinical Genetics, Royal North Shore Hospital, St Leonards, NSW, Australia; 7) Centre for Comparative Genomics, Murdoch University, Murdoch, WA, Australia; 8) Kinghorn Centre for Clinical Genomics, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia.

Background: Autosomal recessive (AR) disorders are a major cause of morbidity and mortality. Consanguineous couples are at increased risk for having a child with these disorders but to date, risk assessment based on family history and/or ethnicity often added little to that based on empiric observational data. Therefore exome (and in the future, whole genome) sequencing offers the prospect of "the screen for everything", providing information which can inform reproductive choice in this at-risk group. More broadly, it may provide a paradigm for assessment of the practicability and effectiveness of this screening approach in the general population. **Study design:** We used the TruSight One "clinical exome", which includes 4,813 genes linked to human disease, to pilot screen 15 consanguineous couples who were planning a pregnancy. **Results:** Three couples were found to be at risk of having children affected by AR disorders. In two couples, the risk was for disorders with neurodevelopmental phenotypes. Variants were identified in *C5ORF42* (Joubert syndrome/ Orofaciodigital syndrome type VI) and *LAMA1* (Poretti-Boltshauser syndrome). In the third couple, the risk was for glycogen synthase deficiency (*GYS2*) - a metabolic disorder which is treatable but can be difficult to diagnose, and can have severe consequences for an untreated child due to hypoglycemic episodes. Interviews conducted with the couples pre-test identified an intention to utilize any positive findings in their future pregnancy planning. **Conclusion:** Variant interpretation remains a challenge which will limit the sensitivity of this approach. Nonetheless, our results indicate that the benefits of screening are likely to be considerable, and a major advance over a targeted approach.

3304W

Implementing a strategy for massively parallel functional annotation of
HNF1A **missense variants.** *S. Althari[1,2], L.A. Najmi[3,4], A.J. Bennett[1], M. van de Bunt[1,2], P.R. Njolstad[4,5], A.R. Majithia[6,7,8,9], M.I. McCarthy[1,2,10], A.L. Gloyn[1,2,10].* 1) Oxford Centre for Diabetes, Endocrinology and Metabolism, University, of Oxford, Oxford, United Kingdom; 2) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; 3) Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway; 4) KG Jebsen Center for Diabetes Research, Department of Clinical Science, University of Bergen, Bergen, Norway; 5) Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 6) Programs in Metabolism and Medical & Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 7) Diabetes Research Center, Diabetes Unit, Department of Medicine, Massachusetts General Hospital, Boston, MA, USA; 8) Center for Human Genetic Research, Massachusetts General Hospital, Boston, MA, USA; 9) Department of Medicine, Harvard Medical School, Boston, MA, USA; 10) Oxford NIHR Biomedical Research Centre, Churchill Hospital, Oxford, United Kingdom.

Loss-of-function variants in *HNF1A* are the most common cause of maturity-onset diabetes of the young (MODY), a Mendelian form of hyperglycaemia where a molecular diagnosis influences treatment and prognosis. Recently, *HNF1A* missense variants have been associated with type 2 diabetes (T2D) predisposition and identified in the genomes of healthy individuals. Sensitive mapping of *HNF1A* alleles to clinical phenotype requires comprehensive understanding of the functional consequences of known and novel sequence variants. To address this clinical challenge, we are implementing a strategy for massively parallel functional screening of every possible missense variant in *HNF1A*. Successful implementation of the approach depends on having robust downstream HNF-1a targets to act as sensitive discriminators of molecular dysfunction. These have not been previously identified for the purpose of high-throughput allelic screening. Therefore, we have conducted a systematic search for HNF-1a regulated transcripts to identify potential markers of trans-activation in a physiologically relevant cell model. On the basis of cytogenetic, transcript and proteomic characterisation, the human liver cell line HepG2 was selected. HepG2 cells were infected with *HNF1A*-harboring lentivirus and exposed to a range of doxycycline (dox) doses (0- 5 μg/ml) over a 48-hr period. Having achieved dose dependent induction of *HNF1A*, with highest expression at 5 μg/ml dox, target identification was performed using qPCR and RNA-seq. The former involved probing of targets based on evidence in the literature of direct regulation by HNF-1a (11 genes), including *TMEM27* (dose-dependent upregulation)*, IGFBP1* (dose responsive downregulation), *SLC2A2* and *PAH* (unaffected). Transcriptome profiling revealed 22 transcripts showing significant differential expression (FDR corrected *P* value<0.01, 1-fold minimum induction) as a function of exogenous *HNF1A* (*P*=1.97e-09). The top two hits, *CUBN* (*P*=1.47e-07) and *CLDN2* (*P*=2.58e-06), have not been previously reported as HNF-1a targets. Preliminary motif analysis revealed several *HNF1A* binding sites 5-10 kb upstream *CUBN* and *CLDN2* (80% match score), with one site per gene overlapping DNase hypersensitivity regions in HepG2 cells. In summary, we have identified HNF-1a regulated transcripts in HepG2 cells including novel target transcripts which are currently being validated *in silico* and *in vitro* prior to their evaluation as markers for high-throughput variant screening.

Single-cell RNA-seq analysis of human pancreatic islets reveals novel gene signature for different cell types.
M. Garieri[1,2], C. Borel[1], T. Stoeger[3], F. Santoni[1], C. Howald[1,2], E. Falconnet[1], P. Ribaux[1], L. Pelkmans[3], P.A. Halban[1], S.E. Antonarakis[1,2], E.T. Dermitzakis[1,2]. 1) Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland; 2) Swiss Institute of Bioinformatics (SIB), Geneva, Switzerland; 3) Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland.

Pancreatic islets consist of several endocrine cell types. Single Cell (SC) transcriptome analyses provide an unprecedented opportunity to discover the heterogeneity of human pancreatic islets and as well the possibility to characterize gene signature for each cell population, which would be difficult to isolate with other methods. We investigate the heterogeneity of this tissue using SC RNA-seq. Dissociated islet cells of 3 donors (n=241, 183 after quality control) were analyzed. We also sequenced sorted-beta SCs (n=60, 44 after quality control) from the same individuals. Clustering analysis on islet SCs identified the following populations of cells: beta (mean *INS* expression 40777 RPKM, representing the 75% of all SCs), alpha (mean *GCG* expression 86443 RPKM, 12%), gamma (mean *PPY* expression 49928 RPKM, 3%), delta (mean *SST* expression 76061 RPKM, 2%) and a small population of exocrine. Out of these we identify 10 ductal and 2 acinar cell. In the sorted beta SCs we observed beta (INS 32708 RPKM, 93%) and delta SCs (SST 135327 RPKM, 7%). Interestingly we observed that insulin (*INS*) is expressed at appreciable levels in all the islets SCs and not just in the subpopulation of beta SCs described above. In addition *GCC* has expression in 93% of all islets SCs at appreciable levels. We controlled for the absence of transcript contamination of *INS* and *GCG* by sequencing 11 empty chambers. We verify the cellularity of the cell types using another technology (branched-DNA single-molecule FISH) allowing for quantification and cellular localization of transcripts. Standard differential expression approaches are not appropriate to identify gene markers for each cell population, while Fisher's exact test allow to identify known and novel genes and transcription factors. For the alpha SCs we identify 36 genes at 0.1% FDR: two transcription factors (*IRX2*, *ARX*), and other markers (i.e. *GC*, *SPOCK3*, *PAPPA2*, *FAP*, *LOXL4*). For the beta SCs we have 95 genes at 0.1% FDR: two transcription factors (*ZNF91*, *DDIT3*), four imprinted genes (*IGF2*, *MEG3*, *DLK1*, *CDKN1C*) and other markers (*HADH*, *RBP4*, *PCSK1*). At 0.1% FDR, we identify 80 genes for exocrine cells and 88 genes for endocrine cells with an enrichment in *SCG* gene family, precursors for biologically active peptides. We are using these gene signatures to further characterize what appears to be a continuity of cell identity among cells in the pancreatic islets. M.G and C.B. and the labs of SEA and ETD contributed equally to the work.

Modulation of gut microbiota by GLP-1 receptor agonist in the high-fat diet mice. *H. Li, Y. Ran, J. Jin, X. Yang, T. Zhou, Z. Deng.* Dept. Biotechnology, Jinan University, Guangzhou, Guangdong, China.

Accumulating evidence suggests that the gut microbiota is an important factor in mediating the development of obesity-related metabolic disorders, including type 2 diabetes. Glucagon-like peptide-1 (GLP-1) receptor agonists are indicated for treatment of type II diabetes since they mimic the actions of native GLP-1 on pancreatic islet cells, stimulating insulin release, while inhibiting glucagon release, in a glucose-dependent manner, as well as, involve communication with the central and peripheral nervous system, slowing gastric empty, reducing food intake, and producing weight loss. High-fat diet has been shown to cause shifts in the diversity of dominant gut bacteria. In this study, We measured shifts in cecal bacterial communities in mice fed high-fat (HF) diet+PBS or high-fat (HF) diet+ GLP-1receptor agonist for 8 weeks at the level of the diversity and taxa distribution by high-throughput 16S ribosomal RNA gene sequencing. The diversity of gut microbiota was significantly changed by GLP-1receptor agonist treatments. And the HF diet caused an increase in body weight over the 8-week-long feeding trial, whereas GLP-1receptor agonist slowed the increase in body weight.

3307W

The role of *CYP21A2* gene in Premature Pubarche (PP). *M. Soveizi[1,2], A. Rabbani[3,4], A. Setoodeh[3,4], F. Sayarifard[3,4], N. Mahdieh[2], B. Rabbani[2,4].* 1) Azad University, North Tehran Branch, Tehran, Iran, Tehran, Iran; 2) 2. Genetic Research Center, Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, Iran; 3) Children's Hospital Center, Tehran University of Medical Center; 4) Growth and Development Research, Tehran University of Medical Center.

AbstractPremature pubarche (PP) is considered to be a benign phenomenon; it follows the precocious appearance of pubic hair without other signs of puberty or virilization which diagnosed after exclusion of non-classical (NC) congenital adrenal hyperplasia (CAH). The aim of this study was to assess the relationship between the CYP21A2 genotype and children with sings of premature pubarche. Coding and non-coding regions of the CYP21A2 gene were directly sequenced. Our result showed that, in one of the case pathogenic mutation located in exon 7 at the position c.754G>T (Val252Leu) was observed. This means that only 10% of our patients showed CYP21A2 gene mutations. This indicates that there is relation to PP as discussed in literature. We are planning to sequence whole exome to find out the causal genes of PP phenotype. We need to expand the population for more accurate result and analyze other related genes.

3308T

Obesity in adults with 22q11.2 deletion syndrome. *A.S. Bassett[1,2,3,4,5], S. Voll[2], E. Boot[1,2,3], N. Butcher[2], S. Cooper[3], T. Heung[2], E.W.C. Chow[1,2], C. Silversides[3,5].* 1) Dept Psychiatry, CAMH, RS, University of Toronto, Toronto, ON, Canada; 2) Centre for Addiction and Mental Health, Toronto, Ontario, Canada; 3) The Dalglish Family 22q Clinic, Department of Psychiatry, University Health Network, Toronto, Ontario, Canada; 4) Toronto General Research Institute, University Health Network, Toronto, Ontario, Canada; 5) Division of Cardiology, Department of Medicine, University Health Network, Toronto, Ontario, Canada.

Purpose: To characterize the prevalence of and contributing factors to adult obesity in the most common recurrent copy number variation (CNV), 22q11.2 deletion, given that other rare CNVs are known to have obesity phenotypes. **Methods:** For 207 adults with 22q11.2 deletion syndrome (22q11.2DS), we used available height and weight measurements to calculate body mass index (BMI) and recorded associated factors that could play a role in obesity. We used maximum BMI per subject and logistic regression to test a model predicting obesity class. **Results:** The prevalence of obesity (BMI≥30) in 22q11.2DS (n=90, 43.5%; at median age 26.7 years) was significantly greater than for Canadian norms (OR 2.30, 95%CI=1.74-3.02, p<0.0001), even after excluding individuals with a history of antipsychotic use. The regression model was significant (*P*<0.0001). Psychotropic medication use and age, but not sex or presence of intellectual disability, were associated with higher obesity level. Ten (4.8%) individuals were diagnosed with type 2 diabetes at median age 39.5 years; prevalence was higher in those with obesity (*P*<0.01). **Conclusion:** The results suggest that adult obesity is related to the 22q11.2 deletion. The findings expand the potential genetic causes of obesity and have important implications for management of 22q11.2DS.

Mutation screen of *SLC35D3* in Chinese Han patients with metabolic syndrome. *Z. Zhang.* Qingdao University, Qingdao, China.

Metabolic syndrome (MetS) is a severe health problem that is characterized by Obesity, hyperglycemia,;hyperlipoidemia,;hypertension and other metabolic disorders. Studies suggest that large numbers of genes disorder cause MetS. We screened 363 Chinese Han patients with MetS and 217 unaffected individuals by sequencing the two exons and adjacent exon/intron boundaries together with 1 kb untranslated sequence upstream of the start codon of the *SLC35D3* gene. Two variants of SLC35D3 leading to the frame-shift of the coding sequence were found in two unrelated patients. In patient #1 (Male, Age: 55, BMI: 26.1, waist circumference: 109 cm, blood pressure: 135/85 mmHg, TG: 4.23 mmol/L, Chol: 5.28 mmol/L, Gluc: 4.4 mmol/L), a heterozygous ΔK404 was identified. In patient #2 (Male, Age: 51, BMI: 27.1, waist circumference: 100 cm, blood pressure: 120/80 mmHg, TG: 2.52 mmol/L, Chol: 5.94 mmol/L, Gluc: 5.2 mmol/L), a heterozygous insL201 was identified. In summary, we have identified 2 mutations of the *SLC35D3* genes in 363 MetS patients.

3310W

Chromosome 22 presents a higher density of CNVs among Brazilian patients with rare phenotypes. *C. Milani[1], J.G Damasceno[1], T.V.M.M Costa[1], F.A.R. Madia[1], E.A. Zanardo[1], A.T. Dias[1], M.M. Montenegro[1], G.M. Novo-Filho[1], F.B. Piazzon[1], D.C. Soares[3], A.M. Nascimento[1], M. Rocha[1,2], L.R.R.V Souza[1], M.S. Grassi[3], A.F.L. Carvalho[5], D. Bertola[3], M.I. Melaragno[4], C.A. Kim[3], M.M.S. Carneiro-Sampaio[3], L.D. Kulikowski[1,2].* 1) Laboratório de Citogenomica, Departamento de Patologia, Faculdade de Medicina da USP, São Paulo, Brasil; 2) Centro de Reprodução Humana e Genética, Departamento de Saúde Coletiva, Faculdade de Medicina do ABC, Santo André, Brasil; 3) Unidade de Genética, Departamento de Pediatria, Instituto da Criança, HC/FMUSP, São Paulo, Brasil; 4) Departamento de Morfologia e Genetica da Escola Paulista de Medicina, UNIFESP, São Paulo, Brasil; 5) Departamento de Biologia Geral, Laboratorio de Genetica Humana e Mutagenese, Universidade Federal da Bahia, Salvador Brasil.

A novel pattern of copy number variations was defined in a cohort of Brazilian patients from Cytogenomic Laboratory of FMUSP, identifying common CNVs and LOH correlated to rare phenotypes. **Materials and Methods:** A total of ninety eight (98) patients were analyzed using using SNP-array (Human-CytoSNP-12 BeadChip and CytoSNP-850K BeadChip) to map the presence of Copy Number Variations (CNVs) and Loss of Heterozygosity (LOH). We use bioinformatics techniques in order to construct a genomic profile of Brazilian patients. Thirty Brazilian patients with a spectrum of 22q11.2 phenotypic manifestations were further studied in order to stablish better chromosome breakpoint definition. **Results:** We identified 13 deletions, 14 duplications and nine regions with loss of heterozygosity. Also, our results showed atypical deletions with two hotspots: 22q11.21 and 22q13.32. Pathogenic CNVs associated with lupus erythematosus, polyarthritis, psoriasis, rheumatoid arthritis, sepsis, bronchitis and pneumonia and several different immunological features were found. The clinical evidence suggests that the immunodeficiency can be seen in most of the patients with chromosome 22q genomic alterations. Immunological phenotype may vary widely between the patients and the deletion size does not appear to be responsible for this variation. **Conclusion:** Cytogenomic investigation allowed a better chromosome breakpoint definition in a cohort of Brazilian patients suggesting that identification of deletion and duplication syndromes in 22q region enables a biological interpretation of the immunologic abnormalities. **Grants:** FAPESP 14/50489-9, CNPq 09/53105-9 and FINEP-CT INFRA 0160/12 SP8.

Genome-wide copy number variation analysis identifies leukocyte-specific protein 1 deletion vatiant for rheumatoid arthritis susceptibility. *S. Jung[1], S. Hwang[2], H. Jo[1], W. Kim[2], Y. Chung[1].* 1) Integrated Research Center for Genome Polymorphism, The Catholic University of Korea, Seoul, Korea; 2) POSTECH-Catholic Biomedical Engineering Institute, The Catholic University of Korea, Seoul, Korea.

Several copy number variations (CNVs) have been found to be associated with rheumatoid arthritis (RA). However, it remains unclear how they affect immune dysfunction and autoimmune diseases. We screened RA-associated CNVs across the whole genome and identified a novel leukocyte-specific protein 1 (LSP1) deletion variant for RA susceptibility located in 11p15.5. We replicated that the copy number of LSP1 gene is significantly lower in patients with RA, which correlates positively with LSP1 protein expression levels. Differentially expressed genes in Lsp1-deficient primary T cells represent cell motility and immune and cytokine responses. Functional assays revealed that LSP1, induced by T-cell receptor activation, negatively regulates T-cell migration by reducing ERK activation in vitro. Loss of Lsp1 promotes T-cell migration into antigen-instilled tissues and draining lymph nodes in mice with T-cell–dependent chronic inflammation. Moreover, patients with RA show diminished expression of LSP1 in peripheral T cells with increased migratory capacity, suggesting that the defect in LSP1 signaling lowers the threshold for T-cell activation. To our knowledge, our work is the first to demonstrate how CNVs result in immune dysfunction and a disease phenotype. Particularly, our data highlight the importance of LSP1 CNVs and LSP1 insufficiency in the pathogenesis of RA and provide previously unidentified insights into the mechanisms underlying T-cell migration toward the inflamed synovium in RA.

3312F

Accurate Rh blood-typing from next generation sequencing data. *M.M. Wheeler[1], H. Huston[2], K.W. Lannert[2], T. Shaffer[3], S. Fletcher[2], J.G. Underwood[1], M. Delaney[2,4], D.A. Nickerson[1], J.M. Johnsen[2,5].* 1) Department of Genome Sciences, University of Washington School of Medicine, Seattle, WA; 2) Bloodworks NW, Seattle WA; 3) Resolution Bioscience, 2023 120th Ave NE Bellevue, WA; 4) Laboratory Medicine, University of Washington School of Medicine,Seattle, WA; 5) Division of Hematology, University of Washington School of Medicine, Seattle, WA.

Antibody-based blood typing is one of the mainstays of precision medicine. However, newer genomic technologies have the potential to transform transfusion medicine by delivering high resolution DNA variants in clinically relevant blood group genes. Genetic variation is of particular importance in the highly immunogenic Rh blood group system, where genetic variants in the *RHD* and *RHCE* genes can alter blood group protein or antigen expression. Characterization of Rh remains challenging because the *RHD* and *RHCE* genes exhibit diverse types of genetic variation, including single nucleotide variants (SNVs), whole gene deletions, duplications, and complex rearrangements. Genotyping of the RH locus must accurately identify all forms of genetic variation in a systematic and unbiased manner. To achieve this, we developed a next generation sequencing (NGS) approach and applied this to 1135 blood donors, previously phenotyped by serology for Rh (D and C antigens). For analysis, we assessed SNVs using the GATK HaplotypeCaller pipeline and assessed structural variants (SVs) using a customized read-depth based approach. Overall, our analyses show high concordance between NGS Rh predicted antigens and serology (D antigen: 99.6% and C antigen: 99.0%). Moreover, SNV analysis detected 10 single nucleotide variants indicative of rare *RHD* alleles, as well as a novel frameshift *RHD* variant in an individual typed as D- by serology. All other D- individuals exhibited a known *RHD* whole gene deletion, while all serology C+ individuals contained a known *RHD*-to-*RHCE* gene conversion event. Finally, SV analyses identified 22 individuals with larger recombination events indicative of *RHD*-*RHCE* hybrid alleles; a subset of these hybrid alleles were validated by quantitative multiplex PCR of short fluorescent fragment analysis. Our results demonstrate that genotype-based, high resolution blood-typing of Rh is possible and can accurately detect known and novel clinically-relevant variation at the *RH* locus.

Clinical presentation and genotype-phenotype correlation analysis of *de novo* **large deletion including human long non-coding RNA** *TERC*. *G. Aubert[1,2], M. McKinnon[3,4], J. Davis[3,5], P. Eydoux[3,6], S. Vercauteren[2,3,6].* 1) Terry Fox Laroratory BC Cancer Agency , Vancouver, BC, Canada; 2) Repeat Diagnostics, North Vancouver, BC, Canada; 3) Child and Family Research Institute, Vancouver, Canada; 4) Department of Medical genetics, University of British Columbia, Vancouver, Canada; 5) Department of Hematology and Oncology University of British Columbia, Vancouver, Canada; 6) Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, Canada.

Dyskeratosis Congenita (DC) is a complex trait marrow failure syndrome characterized by pancytopenia and classically with skin and nail abnormalities and oral leukoplakia. The hallmark of this disease is very short telomere length in peripheral blood leukocytes. Telomere biology gene haploinsufficiency is one of the major disease mechanisms, directly implicating gene dosage in disease pathogenesis and severity. Abnormalities in 11 different genes have been shown to be causative in this rare disorder, including the long non-coding telomerase RNA *TERC*. Here we describe the clinical case of a patient who presented with abnormal bruising at 22 months. Review of clinical information revealed the patient displayed *in utero* growth restriction and was born premature with pancytopenia and macrocytosis. Peri-natal care included platelet transfusion but DC was not suspected at the time. Hemato-pathology investigation at 22 months revealed a hypocellular and fibrotic marrow with macrocytosis, abnormal megakaryocytes and elevated hemoglobin-F levels suggesting an inherited marrow failure syndrome. Peripheral blood leucocyte telomere length measurements were found to be very short, consistent with diagnostic findings in patients with DC. Cytogenetic studies included a positive chromosome breakage assay with detection of radial chromosomes suggestive of genomic instability. Karyotyping on peripheral blood lymphocytes revealed a large single copy deletion on chromosome 3q, however no chromosome fusion or translocation events were noted. Chromosomal array analysis confirmed the *de novo* 3.8Mb deletion includes the full *TERC* gene locus, as well as 30 other genes. Possible anticipation or inheritance of short telomeres were excluded as contributing factors since both parents had leucocyte telomere length within normal range for their age. Hematological symptoms were corrected by successful reduced intensity hematopoietic stem cell transplantation using a matched unrelated cord blood stem cell source. The patient is currently doing well more than 2 years later. Laboratory and genetic findings pertinent to this patient case of early telomere biology disease onset will be discussed in relation to genotype-phenotype and will be compared to other previously published cases with *TERC* haploinsufficiency. The importance of considering copy number variation analysis in the era of clinical next generation exome sequencing for the investigation of rare disorders will be highlighted.

3314T

Next generation sequencing for an asymptomatic case of Myelodysplastic syndromes (7qdel) from Pakistan. *S. Shahid, N. Irfan, S. Ahmed, M. Nadeem, T. Shamsi.* National Institute of blood diseases and bone marrow transplantation, Karachi , Sindh, Pakistan.

Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematologic malignancies characterized by impaired hematopoietic differentiation. Several studies on the molecular pathogenesis of MDS have identified disease causing alleles in patients but still their pathological contributions are not completely understood. Recent whole genome and targeted gene studies have found novel somatic mutations in MDS patients with pathological importance. The aim of this study was the mutational profiling of MDS patient to identify genetic marker in the genes involved in the regulation of histone function (*EZH2*, *ASXL1*, and *UTX*) and DNA methylation (*DNMT3A*, *IDH1/IDH2*, and *TET2*) that can be used in diseases prognosis and as well in deciding therapeutic options. Here we report a case of a 57 year old man referred to our institute, National Institute of Blood Diseases and Bone Marrow Transplantation (NIBD), Karachi, Pakistan. This patient was diagnosed as MDS and sub categorized as refractory cytopenia with multilineage dysplasia (RCMD) based on the morphological and cytogenetic analyses (46, XY, del (7q) (15). Patient was screened through next generation sequencing using myeloid sequencing panel of 54 genes comprising tumor suppressor genes and oncogenic hotspots. Data analysis was performed on instrument MiSeq reporter software. We identified a nonsense heterozygous mutation (c.3115C>T, p. Q1039X) in exon 13 of *ASXL1* gene. In addition, missense variant c.86 C>G, p.P29R (rs 12498609) in *TET2* gene was identified but this variant lies in non-conserved region and so not regarded as true missense mutation. Mutations in *ASXL1* gene is commonly found in advance stages of MDS and are associated with poor prognosis with overall inferior survival. But our study finds the better overall survival with good prognosis which is in contrast to reported cases. Hence screening of large number of patients is required to understand the mechanisms causing MDS pathogenesis. .

Deep targeted sequencing reveals potential causal alleles at SLE risk loci. *P. Raj[1], R. Song[1], B.E. Wakeland[1], K. Viswanathan[1], C. Arana[1], C. Liang[1], B. Zhang[1], F. Carr-Johnson[1], J.A. Kelly[2], B.R. Lauwerys[3], N. Olsen[4], C.K. Garcia[5], C. Wise[6], S.K. Nath[2], J.A. James[2], C.O. Jacobs[7], B.P. Tsao[8], D.R. Karp[9], Q.Z. Li[1], P.M. Gaffney[2], E.K. Wakeland[1].* 1) Immunology, UT Southwestern Medical Center, Dallas, TX; 2) Arthritis and Clinical Immunology Program, Oklahoma Medical Research Foundation, OK; 3) Pôle de pathologies rhumatismales, Institut de Recherche Expérimentale et Clinique,Brussels, Belgium; 4) Division of Rheumatology, Department of Medicine, Penn State Medical School, PA, USA; 5) Eugene McDermott Center for Human Growth & Development, Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX 75335 USA; 6) Eugene McDermott Center for Human Growth & Development, Department of Pediatrics, University of Texas Southwestern Medical Center, Dallas, TX 75335 USA; 7) Department of Medicine, University of Southern California, Los Angeles, CA; 8) Department of Medicine, Medical University of South Carolina; 9) Rheumatic Diseases Division, University of Texas Southwestern Medical Center.

Systemic lupus erythematosus (SLE) is an autoimmune disease caused by loss of humoral immune tolerance leading to the production of autoantibodies to a spectrum of self-antigens. Genetic predisposition is key for SLE susceptibility, however little is known about the magnitude and functional properties of causal genetic variants. We used targeted population sequencing approach to comprehensively characterize genetic variability at 28 risk loci for SLE in a panel of 1349 Caucasian SLE cases and controls. Overall, vast majority of SLE associated variants were discovered in non-coding region of genome. We analyzed 16 common risk loci in detail and formed haplotypes based on SLE associated potentially regulatory variants in strong LD with GWAS tag SNPs. We identified 88 potentially causal alleles embedded in these regulatory haplotypes. Based on ENCODE data these alleles are highly likely to impact binding of important transcription factors and regulate transcription of cis-genes (cis-eQTL) in human monocytes, dendritic cells (DCs) and macrophages. About 30 percent of these alleles were less common in population (MAF below 0.15), as a result, were rarely analyzed in SNP array based investigations in past. We developed a panel of over 100 normal human monocyte derived macrophages and dendritic cells to study the effect of these alleles on gene expression by RNAseq analysis. Such regulatory alleles at HLA locus upregulates transcription and cell surface level of HLA class II molecules in DCs. Similarly, at IRF5 locus, these alleles upregulates expression of IRF5 in Macrophages and LCLs. Based on the analysis of these regulatory alleles at risk loci, we identified transcriptional complexes that are most likely to be affected by these genetic changes which results in altered transcription of local genes and development of disease endophenotypes.

3316W

Shared and specific features of the individual transcriptomic response in sepsis due to faecal peritonitis. *K.L. Burnham[1], E.E. Davenport[1], J. Radhakrishnan[1], E. Svoren-Jabalera[2], P. Humburg[1], P. Hutton[3], A.C. Gordon[4], C. Garrard[3], A.V.S. Hill[1], C.J. Hinds[5], J.C. Knight[1].* 1) Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom; 2) Queen Mary University of London, Queen's Hospital University Hospital Trust, London, United Kingdom; 3) Adult Intensive Care Unit, John Radcliffe Hospital, Oxford, United Kingdom; 4) Section of Anaesthetics, Pain Medicine and Intensive Care, Imperial College, London, United Kingdom; 5) William Harvey Research Institute, Barts and the London School of Medicine, Queen Mary University, London, United Kingdom.

   Sepsis remains a major area of unmet clinical need, with mortality rates >30%. Although conventionally considered a unified disease with a common pathway to organ failure and death, substantial heterogeneity is seen, which has limited efforts to understand pathophysiology and improve therapeutic strategies. This study aimed to use transcriptomic profiling to investigate variation between and within patients with sepsis due to faecal peritonitis (FP). We present data for 147 samples from 117 adult FP patients recruited to the Genomic Advances in Sepsis study. Detailed phenotypic information was recorded and serial samples taken over five days following admission to intensive care units (ICUs). Genome-wide gene expression profiling of total leukocyte RNA purified using the Ambion LeukoLOCK Total RNA Isolation System was performed using Illumina HumanHT-12v4 Expression BeadChip arrays. An unsupervised clustering approach revealed sepsis response signature (SRS) subgroups within the dataset. The SRS1 group is associated with a higher 14 day mortality (p=0.0096) and shows enrichment of pathways relating to T cell exhaustion, cell death, and endotoxin tolerance. Serial sampling allowed resolution of the SRS groups over time, indicating that SRS1 occurs early and 54% of patients remain in the same SRS group over the study period. We additionally identified temporal changes in gene expression from onset of FP involving leukocyte activation, phagocytosis, and NK cell and IL-3 signalling. Comparisons with pneumonia patients (n=126) and non-septic controls (n=10) demonstrated a shared septic response across aetiologies, with EIF2 signalling the most enriched canonical pathway. We also validated differential gene expression relating to source of infection involving IFN signalling and viral infection, showing that while there is significant overlap in the sepsis transcriptomic response some specificity is seen. Our findings demonstrate that shared and specific processes modulate the individual transcriptomic response to sepsis. The presence of generic sepsis signatures informative for the underlying response state highlights the opportunity for patient stratification and precision medicine in sepsis.

3317T

Role of a long non-coding RNA in prednisolone resistance, cell proliferation and migration in childhood acute lymphoblastic leukemia. *M. Ouimet, M. Lajoie, C. Richer, R. Gioia, S. Drouin, D. Sinnett.* Division of Hematology-Oncology, CHU Sainte-Justine, Montreal, Quebec, Canada.

   Acute lymphoblastic leukemia (ALL) is the most common cancer among children. Survival rates of pediatric ALL have improved enormously over the past decades. However, 20% of B-cell precursor ALL (BCP-ALL) relapse during or shortly after completion of treatment and still constitute one of the main cause of disease-related death in pediatrics. We need to better understand the molecular determinants of treatment outcome. Long non-coding RNAs (lncRNAs) are important regulators of gene expression that play multiple roles in the life cycle of genes, from transcription to mRNA splicing, RNA decay, and translation. Defects in cell differentiation and uncontrolled proliferation are a hallmark of leukemia. Thus lncRNAs involved in gene expression control during hematopoiesis, if deregulated, might contribute to the development and the progression of leukemia. To test this hypothesis, we examined lncRNA expression in pre-B cell childhood ALL (cALL). We performed RNAseq analysis of 57 newly diagnosed cALL and 3 CD19+ control from human cord blood. We assessed whether lncRNAs overexpressed in cALL have an impact on cell proliferation, apoptosis and migration. We observed that silencing of one particular lncRNA (*RP11-137H2.4*) in pre-B ALL cell lines inhibited leukemic survival and abrogated cell migration. Furthermore, we showed that the silencing of *RP11-137H2.4* renders pre-B ALL cells more sensitive to prednisolone, one of the spearhead drug used in multi-drug treatment of pediatric ALL. This is an important finding considering that i*n vivo* and *in vitro* response to prednisolone predicts long-term clinical outcome. Moreover, a disproportionate number of relapsed ALL patients acquire prednisolone resistance as compared to other anti-leukemic agents. These findings suggest a role for the lncRNA *RP11-137H2.4* in the pre-B cell ALL survival, proliferation and migration and might constitute a new target to address prednisone resistance and increase current survival rates. .

3318F

Identification of copy number variations (CNVs) associated with congenital diaphragmatic hernia (CDH). *Q. Zhu[1], E. Cerveira[1], M. Romanovitch[1], J. Kwon[1], F.A. High[2], M. Longoni[2], C. Coletti[2], C. Zhang[1], C. Lee[1], P.K. Donahoe[2].* 1) The Jackson Laboratory for Genomic Medicine, Farmington, CT; 2) Pediatric Surgical Research Laboratories, Massachusetts General Hospital, Boston, MA.

   Objectives: CDH is a common and severe birth defect. The incidence of CDH is approximately 1 in 2,500 newborns. More than 80 percent of the CDH patients are not associated with any known genetic syndromes and the underlying molecular mechanisms remain largely unknown. Copy number variations (CNVs) have been suggested to play important roles in the evolution and the pathogenesis of a variety of human diseases. The objective of this study is to identify CNVs associated with CDH. **Methods:** Array comparative genomic hybridization (aCGH) was performed for detection of CNVs in this study. We designed a high-resolution custom microarray (Agilent 8x60K) consisting of 181 target regions representing CNVs or genomic regions generated from extensive transcriptome analyses of normal gene expression in mouse embryonic diaphragms, bio-informatics analysis of protein-protein interactions through key signaling pathways, genes within chromosome deletions detected by CNV analyses in our patient cohort, genes known to cause diaphragm defects in knockout mouse models and human patients, and targets identified from linkage analyses. We performed aCGH on 170 CDH patient samples including 36 trio samples and 590 normal control samples. A panel of CNV candidates were validated by droplet digital PCR (ddPCR). Fisher's exact test was used for statistical analysis.   **Results:** In this study, we identified 67 copy number gains and 207 losses from the 170 CDH patient samples, as well as 192 gains and 434 losses from the 590 normal control samples. Cumulatively, the number of observed CNV losses is highly significant (P=3.8x10^{-5}, OR 1.65, 95% CI 1.29-2.11, Fisher's exact test). Among these CNV calls, 22 gains and 28 losses were observed in the CDH patients only. We also identified several de novo CNV calls from the 36 trio samples. We selected a panel of CNV candidates (8 gains and losses) for validation. Importantly, the panel included one novel gain specifically detected in three of the CDH patient samples (P=0.01by Fisher's exact test) and validated by ddPCR.   **Conclusion:** We have successfully developed and utilized a high-resolution custom array for identification of CNVs from the CDH patient samples. In addition, we have developed a highly sensitive and quantitative ddPCR assay for validation of the CNV candidates. This study has identified novel CNVs associated with CDH and has the potential for further discovery.

3319W

***De novo* assembly and RNA-seq shows season-dependent expression and editing in black bear kidneys.** *A. Srivastava[1], V.K. Sarsani[1], S.M. Sheehan[1], R.L. Seger[2], M.E. Barter[1], C. Lindqvist[3], L.C. Brody[4], J.C. Mullikin[5], R. Korstanje[1].* 1) The Jackson Laboratory, Bar Harbor, Maine; 2) Department of Animal and Veterinary Sciences, University of Maine, Orono, Maine; 3) Department of Biological Sciences, University at Buffalo, Buffalo, New York; 4) Genome Technology Branch, National Human Genome Research Institute, NIH, Bethesda, Maryland; 5) Comparative Genomics Analysis Unit, National Human Genome Research Institute, NIH, Bethesda, Maryland.

  Kidney disease affects more than 26 million Americans. Several mammals have the ability of regenerating the kidney after damage, and although humans likely have the same genes as those species, this does not occur. Therefore, a logical approach is to study the kidney in mammals that have this ability and compare this with human, with the goal of identifying genes involved in the recovery of the damaged kidney. One of those species is the American black bear (*Ursus americanus*). Previous studies in bears suggest unique features in the kidney that allow them to endure lower functioning during and recovery soon after hibernation. These processes are likely in part instilled in the genome sequence and gene expression patterns unique to the bear. To understand the molecular mechanisms underlying these processes, we have performed the whole genome de novo assembly of the black bear with over 100x coverage using Illumina paired-end, Illumina mate-pair, and low-pass PacBio single molecule sequencing. Hybrid assembly of genome yielded 113,759 contigs/scaffolds with N50 size of 190KB and went under comprehensive annotation. Further, we have sequenced RNA from Maine Black Bear and perform the comparison of renal gene expression between spring and fall samples. Our work identified the genes that showed significant expression difference that might play important roles in changes in physiology during hibernation and recovery. Moreover, from the RNA-seq data, we also found evidence of season-dependent differences in RNA-editing.

3320T

Long interspersed nuclear element-1 (LINE1)-mediated 8q13 microdeletion detected in a Japanese case with mesomelia-synostoses syndrome. *I. Imoto, T. Naruto, T. Kohmoto, M. Watanabe, S. Ujiro, K. Masuda.* Tokushima University, Tokushima, Japan.

Mesomelia-synostoses syndrome (MSS, MIM #600383) is a rare autosomal-dominant a syndromal osteochondrodysplasia characterized by mesomelic limb shortening, acral synostoses, and multiple congenital malformations due to a microdeletion at 8q13. To date five unrelated patients have been reported worldwide, and the sizes of reported deletions vary from 582 kb to 738 kb but invariably emcompass two contiguous genes: *SULF1* and *SLCO5A1*. At least two cases, it was reported that deletions do not result from nonallelic homologous recombination (NAHR). Here, we report the first case with MSS caused by a long interspersed nuclear element-1 (LINE1, L1)-mediated 591 kb deletion at 8q13 containing those two genes. An 11-year-old undiagnosed Japanese girl was the second child of non-consanguineous Japanese parents. She had multiple congenital anoanomalies, such as blepharophimosis, blepharoptosis, micrognathia, low-set ear, hypoplastic calcaneus, bilateral ectopic ureters, and left hydronephrosis. Throughout childhood, the limited extension of elbow joints, the bowing and shortening of the forearms, and the ulnar deviation of the hands had not significantly progressed. Symmetrical deformity of the legs resulted in genua valga and proximal dislocation of tibiae and fibulae had not significantly worsened, although malformed ankle joint and toes adversely affected the patient's gait. Targeted exome sequence using next-generation sequencing detected heterozygous deletion of *SULF1*, and subsequently performed array-based copy-number analysis detected a novel 591 kb deletion at 8q13 containing *SULF1* and *SLCO5A1*. Clinical features of this patient were mostly matched with those of MSS, which was considered to be caused by 8q13 microdeletion. Based on the results of array-based analysis, we performed long range-PCR to identify the deletion junction, and sequencing of junctional fragments revealed fusion of the two retrotransposons, L1PA2 and L1PA5, suggesting that the deletion is caused by recombination between L1 elements. Our case highlights the importance of NAHR using L1 repetitive sequences as one of mechanisms causing the 8q13 microdeletion, enclosing *SULF1* and *SLCO5A1*.

3321F

Single nucleotide polymorphism -829C→T of *DHFR* gene in Mexican patients with rheumatoid arthritis. *M.R. Hernández-Preciado[1,3], M.C. Morán-Moguel.[2], I.P. Dávalos-Rodríguez.[2,3], M.A. Aceves-Aceves.[2], I.M. Salazar-Dávalos.[2], M. Romero-Morán.[2], J.P. Valdovinos-Maravilla.[4], C.M. Enríquez.[4], L. González-López.[1,4], J.I. Gámez-Nava.[1,4], M. Salazar-Páramo.[1,4].* 1) Doctorado en Farmacología, Universidad de Guadalajara , Guadalajara, Jalisco, Mexico; 2) Doctorado en Genética Humana, Instituto de Genética Humana, Departamento de Biología Molecular y Genómica, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara; Guadalajara, Jalisco, México; 3) Centro de Investigación Biomédica de Occidente, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, México; 4) Unidad Médica de Alta Especialidad, Hospital de Especialidades, Centro Médico Nacional de Occidente. Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, México.

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease with a prevalence of 1% worldwide. Therapy of RA is based on the use of disease-modifying antirheumatic drugs (DMARDs). Methotrexate (MTX) is recommended as the first DMARD for most patients with RA. MTX is a potent inhibitor of the dihydrofolate reductase enzyme (DHFR). Changes in the levels of DHFR and consequently in the sensitivity to MTX could be due to single nucleotide polymorphisms (SNPs), the SNP -829C→T located at 223 nucleotide downstream from the stop codon between the first and second polyadenylation sites in the 3'UTR of the *DHFR* gene, has been involved in the expression of the enzyme. **Aim:** The objective of this study was to determine the association between the presence of SNP -829CT with response to treatment with MTX among patients with RA. **Methods:** Genomic DNA was obtained from 34 Mexican patients with RA (ACR 1987). From these patients, 16 had a good response to treatment with MTX (responders: evaluated by DAS 28 ≤ 3.2); 18 were considered as a treatment failure with MTX (non responders: DAS 28> 3.2). *DHFR* gene was amplified by polymerase chain reaction (PCR). PCR products were subjected to electrophoresis and analyzed on polyacrylamide gels stained with silver nitrate. The amplified product (269 bp) was digested with the *TspRI* enzyme. The C allele showed three fragments (203, 45 and 21 bp), the T allele has two fragments (248 and 21 bp). The analysis statistic was for direct count of genotypes and alleles, X^2 was applied for comparing groups. Statistical significance was considered p<0.05. **Results:** The genotype frequencies (GF) of SNP -829C→T were for responders patients: 9 CC (0.5), 7 CT (0.39), and 2 TT (0.11), while for non responder patients were 3 CC (0.19), 11 CT (0.68) and 2 TT (0.13). Allelic frequencies (AF) were for responder patients: 17 C (0.53) and 15 T (0.47), while for non responder patients were: 25 C (0.69) and 11 T (0.31). No significant difference were observed when comparing GF and AF in responders vs non responder patients (p>0.05). **Conclusion:** In this preliminary approach we found no significant association between the SNP -829CT and the response to treatment with MTX.

Correction of *IKBKAP* exon 20 splicing by splice switching oligonucleotides. *G.H. Bruun[1], T.K. Doktor[1], A.R. Krainer[2], T. Bruun[1], B.S. Andresen[1].* 1) Biochemistry and Molecular Biology (BMB), University of Southern Denmark, Odense, Odense M, Denmark; 2) Cold Spring Harbor Laboratory, NY, USA.

Correct splicing of exons with weak splice sites depends on a tight balance between positive and negative splicing regulatory elements (SREs). A large fraction of disease-causing mutations disrupt mRNA splicing by decreasing splice site strength or disrupting/creating SREs. We used iCLIP (individual-nucleotide resolution crosslink and immunoprecipitation) to create an in vivo binding map for the splicing regulatory protein hnRNP A1, which usually binds negative SREs to inhibit exon inclusion. HeLa cells with inducible expression of T7-tagged hnRNP A1 were UV irradiated generating irreversible crosslinks between RNA and RNA binding proteins allowing stringent purification of the bound RNA. The iCLIP libraries were subject to next-generation sequencing. We correlated the hnRNP A1 binding map with the hnRNP A1-regulated exons identified by hnRNP A1 knockdown and RNA-seq, and observed that the region immediately downstream of 5' splice sites is important for hnRNP A1-mediated exon repression. We hypothesized that exons with weak splice sites, which are skipped due to a tipped balance between positive and negative SREs, could be reactivated by blocking iCLIP identified hnRNP A1 binding negative SREs using splice switching oligonucleotides (SSOs). We demonstrated the validity of this approach to activate a *MTRR* pseudoexon and the alternative exon 3 in *SKA2* by SSO-mediated blocking of iCLIP-identified hnRNPA1 binding sites located immediately downstream of the 5' splice sites. Interestingly, our iCLIP map revealed a hnRNP A1 binding site in intron 20 close to the 5' splice site of *IKBKAP* exon 20. Skipping of *IKBKAP* exon 20 causes familial dysautonomia (FD). FD is a recessive disease, affecting the sensory and autonomic nervous system and is frequent in Ashkenazi Jews. Almost all patients with FD are homozygous for a IVS20+6T>C mutation in *IKBKAP*, which decreases 5' splice site strength, causing exon 20 skipping. The iCLIP identified hnRNP A1 binding site was confirmed by in vitro studies. Thus, we designed an SSO blocking the hnRNP A1 binding site in intron 20. Transfection of this SSO into FD patient fibroblasts fully restores *IKBKAP* exon 20 splicing. This points to a future SSO-based therapeutic possibility in FD and illustrates that the iCLIP generated hnRNP A1 binding map can be used to identify potential targets for SSO-based therapy.

Alternative splicing in *FMR1* premutation carriers. *F. Tassone[1,2], R. Olaby[1], H. Tang[1], L. Hickey[3], E. Tseng[3].* 1) Biochemistry and Molecular Medicine, UC Davis, Sacramento, CA, 95817, USA; 2) MIND Institute, UC Davis, Sacramento, CA, 95817, USA; 3) Pacific Biosciences, Inc., Menlo Park, CA, 94025, USA.

Over 40% of males and ~16% of female carriers of a *FMR1* premutation allele (55-200 CGG repeats) are at risk for developing Fragile X-associated Tremor/Ataxia Syndrome (FXTAS), an adult onset neurodegenerative disorder while, about 20% of female carriers will develop Fragile X-associated Primary Ovarian Insufficiency (FXPOI), in addition to a number of adult-onset clinical problems (*FMR1* associated disorders). Marked elevation in *FMR1* mRNA levels have been observed with premutation alleles and the resulting RNA toxicity is believed to be the leading molecular mechanism proposed for these disorders. The *FMR1* gene, as many housekeeping genes, undergoes alternative splicing. Using long-read isoform sequencing (SMRT) and qRT-PCR we have recently reported that, although the relative abundance of all *FMR1* mRNA isoforms is significantly increased in the premutation group compared to controls, there is a disproportionate increase, relative to the overall increase in mRNA, in the abundance of isoforms spliced at both exons 12 and 14. In total, we confirmed the existence of 16 out of 24 predicted isoforms in our samples. However, it is unknown, which isoforms, when overexpressed, may contribute to the premutation pathology. To address this question we have further defined the transcriptional *FMR1* isoforms distribution pattern in different tissues, including heart, muscle, brain and testis derived from FXTAS premutation carriers and age-matched controls. Preliminary data indicates the presence of a transcriptional signature of the *FMR1* gene, which clusters more by individual than by tissue type. We identified additional isoforms than the 16 reported in our previous study, including a group with particular splice patterns that were observed only in premutations but not in controls. Our findings suggest that the characterization of expression levels of the different *FMR1* isoforms is fundamental for understanding the regulation of the *FMR1* gene as well as for elucidating the mechanism(s) by which "toxic gain of function" of the *FMR1* mRNA may play a role in FXTAS and/or in the other *FMR1*-associated conditions. In addition to the elevated levels of *FMR1* isoforms, the altered abundance/ratio of the corresponding FMRP isomers may affect the overall function of FMRP in premutations. .

Single Molecule, Real-Time (SMRT) Sequencing of expanded spinocerebellar ataxia type 10 (SCA10) pentanucleotide repeat alleles directly from genomic DNA. *T. Ashizawa[1,2,3], Y.C. Tsai[6], B. Schüle[7], T.A. Clark[6], W.G. Farmerie[4,5], K.N. McFarland[2,3].* 1) Department of Neurology, Houston Methodist Research Institute, Houston, TX; 2) Department of Neurology, College of Medicine, University of Florida, Gainesville, FL; 3) McKnight Brain Institute, University of Florida, Gainesville, FL; 4) Interdisciplinary Center for Biotechnology Research, University of Florida, Gainesville, FL; 5) Genetics Institute, University of Florida, Gainesville, FL; 6) Pacific Biosciences, Menlo Park, CA; 7) Parkinson's Institute and Clinical Center, Sunnyvale, CA.

   Background: SCA10 is an autosomal dominant cerebellar ataxia caused by a large (up to 21kb) expansion of an intronic ATTCT repeat in *ATXN10*. Using SMRT Sequencing technology, we have reported contiguous sequences of PCR-amplified expanded SCA10 alleles. However, many SCA10 expansion alleles are too large for PCR amplification, and *in vitro* amplification may introduce sequence artifacts. **Purpose:** To obtain contiguous sequences of SCA10 alleles directly from the genomic DNA by the SMRT Sequencing technology, without PCR- or cloning amplification. **Methods:** Native SMRTbell libraries were enriched using a novel CRISPR-Cas9 approach. DNA molecules were cleaved adjacent to the SCA10 repeat, followed by ligation of a capture adapter and subsequent hybridization to magbeads. The enriched DNA was subjected to SMRT Sequencing. **Results:** The enriched DNA from representative SCA10 patients showed three types of the expansion motifs: type A alleles are mostly pure $(ATTCT)_{n1}$ repeat, type B alleles consist of $(ATTCT)_{n2}$-$(ATTCC)_{n3}$, and type C alleles have $(ATTCT)_{n4}$-$(ATCCT)_{n5}$-$(ATCCC)_{n6}$, where each of n1-n6 varies between circular consensus sequencing (CCS) reads of single individuals and between different family members, while the allele type does not change within each SCA10 family. The 5' repeat structure of these samples are consistent with the corresponding repeat-primed PCR data. The presence of $(ATCCT)_{n5}$ has been highly correlated with epilepsy phenotype of SCA10. All expansion alleles share a rare haplotype (<3% in the general population) and are found exclusively in populations with the Native American or Han Chinese background. **Discussions:** Since each CCS read represents the SCA10 repeat sequence from a single cell, the SMRT Sequencing can serve as a powerful assay for studies of repeat instability. The sequence variations in the entire span of expanded alleles allow us to critically examine genotype-phenotype correlations and repeat-dependent pathogenicity. We will discuss applications in future studies, including (1) elucidating the mechanism of SCA10 repeat instability using cells differentiated from patient-derived iPS cells, (2) investigating the role of type A alleles in development of the epilepsy phenotype, and (3) studying evolution of SCA10 repeat expansion alleles during the human migration. **Conclusions:** The SMRT technology has a potential to sequence large repeat regions directly from the genomic DNA.

3325W

Characterization of NAHR-mediated type-1 *NF1* deletions with breakpoints not located within the known NAHR hotspots PRS1 and PRS2. *H. Kehrer-Sawatzki[1], M. Hillmer[1], V.-F. Mautner[2], L. Messiaen[3], D.N. Cooper[4], A. Summerer[1].* 1) University of Ulm, Institute of Human Genetics, Ulm, Germany; 2) University Hospital Hamburg Eppendorf, Department of Neurology, Hamburg, Germany; 3) University of Alabama at Birmingham, Medical Genomics Laboratory, Department of Genetics, Birmingham, AL, USA; 4) Cardiff University, Institute of Medical Genetics, School of Medicine, Cardiff, UK.

   Neurofibromatosis type 1 (NF1) is a hereditary cancer syndrome with an incidence of 1 in 3000. In 5 % of all NF1 patients, large deletions encompassing the *NF1* gene and its flanking regions at 17q11.2 are the cause of the disease. The majority (80%) of all large *NF1* deletions are of type-1, encompass 1.4-Mb and are caused by nonallelic homologous recombination (NAHR). The breakpoints of type-1 deletions are located in the low-copy repeats NF1-REPa and NF1-REPc which exhibit high sequence homology to one another. Previous studies indicated that type-1 deletion breakpoints cluster within the paralogous recombination sites PRS1 and PRS2. These NAHR hotspots harbour the strand exchange regions (SERs) of all the type-1 *NF1* deletions reported so far. The respective SERs are of different length, spanning from 20-bp to 700-bp. The extent of the SERs are determined according to the distance between the paralogous sequence variants (PSVs) that flank the SERs. Within the SERs, NF1-REPa and NF1-REPc exhibit sequence identity. The NAHR-associated crossover sites are located within the SERs. In our present study, we investigated 250 patients with type-1 *NF1* deletions by means of multiplex ligation-dependent probe amplification (MLPA) and long-range PCRs to detect breakpoints located within PRS1 and PRS2. According to these analyses, 10% of the type-1 deletions do not exhibit breakpoints located with the NAHR hotspots PRS1 and PRS2. To identify the breakpoint location of these 25 type-1 *NF1* deletions not mediated by NAHR within PRS1 or PRS2, we performed high density array CGH. Subsequently breakpoint-spanning PCRs were designed in order to identify the respective SERs. These analyses suggested that the majority of the deletion breakpoints are located within the 14-kb region that separates PRS1 from PRS2. In the next step of our analysis we investigated the breakpoint-flanking regions of all type-1 *NF1* deletions with regard to the presence of sequence motifs that have the capability to adopt non-B DNA sequence conformations. Our findings imply that non-B DNA forming sequence motifs are overrepresented in the breakpoint-flanking regions of all type-1 deletions, those mediated by NAHR within the known hotspots PRS1 and PRS2 as well as those with breakpoints located outside these hotspots. We hypothesize that non-B DNA sequence motifs contribute to the occurrence of DNA double strand breaks that initiate the NAHR events underlying type-1 *NF1* deletions.

Evaluation of the contribution of complex structural variation at the 17q21.31 locus to the risk of progressive supranuclear palsy. *A. Huang[1], J. Chen[1], A. Karydas[2], B. Miller[2], A. Boxer[2], G. Coppola[1].* 1) Departments of Psychiatry and Neurology, Semel Institute for Neuroscience and Human Behavior, David Geffen School of Medicine, University of California, Los Angeles, CA; 2) Department of Neurology, University of California San Francisco, San Francisco, CA.

Progressive supranuclear palsy (PSP) is a devastating neurodegenerative disorder that affects movement, gait, breathing, balance, and cognitive function. It is a rare disorder that affects approximately three in 100,000 people. Genome-wide association studies have confirmed that, similar to other neurodegenerative disorders, genetic variation at a common inversion polymorphism located on 17q21.31 are among the greatest known contributors to disease risk. This 900 kbp inversion is divided into two main haplotypes groups, deemed H1 and H2. The absence of recombination is a hallmark consequence of the inversion polymorphism that distinguishes these two haplotype clades, the latter of which is exclusive to European populations. This stratification has generated some distinctive consequences with regard to disease risk. While the H2 structural haplotype predisposes European populations to 17q21.31 microdeletion syndrome, it has also shown to be highly protective against PSP. With several types of genetic data from over 380 individuals affected with PSP and an additional 180 control individuals, we carried out a wide variety of analysis in order to better characterize the complex structural variation within 17q21.31 and evaluate its contribution to PSP. First, we used dense, single nucleotide polymorphism (SNP) microarrays (Illumina Omni 2.5) to genetically determine sample ethnicity and divide our sample by H1/H2 carrier status. Raw Intensity data from these SNP arrays was then used to roughly delineate highly copy-number variable regions (CNVRs) within the 17q21.31 locus. The precise breakpoints of these CNVRs were further refined with discordant read-pair analysis of deep (30X) whole-genome sequencing (WGS) data in all individuals. Finally, read-depth analysis was used to type these multi-allelic CNVRs. Although within this limited dataset, we find no significant association overall copy number to PSP among any of the CNVRs analyzed, we describe the utilization of our WGS data as a reference for the construction of an imputation panel for common structural diversity in the region. This deeply-sequenced dataset thus serves as an invaluable resource for further examination of this structurally complex region. Evaluation in an expanded sample, utilizing the imputation of CNVRs, rather than cost-prohibitive WGS, to dissect the genetic association of structural variation within 17q21.31 to disease risk, are currently underway.

3327F

Modeling ring chromosomes: Ring structure affects gene expression both from the ring and throughout the genome. *L. Conlin, R. Rajagopalan, D. McEldrew, J. Mills, N. Spinner.* Department of Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA.

Ring chromosomes 14 (r(14)) and 20 (r(20)) are associated with well-characterized clinical syndromes that include seizures. To understand the effect of the ring chromosomes on gene expression, we carried out RNA-sequencing. In patients with r(20) mosaicism, we previously showed that the rings have no deletions or duplications, allowing comparison of normal and ring containing cells with no additional abnormalities. For each r(20) patient cell line, normal (46,XX) and r(20) (46,XX,r(20)) fibroblast cell lines were generated. For r(14), mosaicism is atypical, so RNA-sequencing was performed on 7 r(14) patients and 9 control cell lines. Four hundred and thirty five genes were differentially expressed (DEG) between ring chromosome 20 and isogenic normal samples. Of these DEGs, 335 were upregulated and 100 were down-regulated in the r(20) samples. Sixteen of these genes were located on chromosome 20. Gene ontology enrichment analysis of DEGs indicated altered transcription for a number of cellular phenotypes including cell movement, morphology, structure and assembly, growth, proliferation and cell cycle processes, which were consistent with functional studies. Allele-specific expression analysis of the r(20) samples showed decreased expression from the ring. Our data shows that ring chromosomes affect cellular transcription and function, even in the absence of associated copy number alterations. Additionally, we set out to create iPS cells for r(14) and r(20) to develop an *in vitro* neural developmental model to study the seizures and other associated brain abnormalities. IPS cells were created from fibroblasts and characterized for pluripotency markers. Multiple samples were studied for both r(14) and r(20), and in all cases the cells lost the ring chromosomes with the appearance of 2 normal chromosomes. We carried out fluorescence *in situ* hybridization for polymorphic CNVs and genome-wide SNP arrays to characterize these "normal" cells. In all cases, iPSCs resulted in uniparental isodisomy (UPD) for chromosome 14 or 20, as has been previously reported for ring chromosomes 13 and 17. We are therefore pursuing alternate strategies to create cellular models for ring chromosomes focused on generation of neural cells through direct-conversion of fibroblasts to neural progenitor or post-mitotic neurons. These cells will be used to to study gene expression profiles in disease-specific cell types and compared to patient fibroblast expression data.

3328W

Expression and proteomic analyses of KIF1A/25B in hereditary sensory and autonomic neuropathies type II. *S. Mohtashami[1,2], J.F. Schmouth[1,2], P.A. Dion[1,2], G.A. Rouleau[1,2].* 1) Experimental Medicine, McGill University , Montreal, Quebec, Canada; 2) Montreal Neurological Institute and Hospital, Montreal, Quebec, Canada.

Expression and proteomic analyses of KIF1A/25B in hereditary sensory and autonomic neuropathies type II *S. Mohtashami[1,2], J. F. Schmouth[1,2], P. A. Dion[1,2], G. A. Rouleau[1,2]* 1) McGill University, Montreal, QC, Canada; 2) Montreal Neurological Institute and Hospital, Montreal, QC, Canada.   Hereditary sensory and autonomic neuropathies form a group of genetic disorders characterized by variable sensory and autonomic dysfunctions. HSAN type II (HSANII) is a debilitating subtype manifesting in early childhood with distal numbness and loss of pain, temperature and touch. Our laboratory has reported truncating mutations in a nervous-tissue-specific exon (*HSN2*) of the *WNK1* gene. The *WNK1* isoform containing the alternatively spliced exon (*HSN2*) is referred to as the *WNK1/HSN2* isoform. Interestingly the protein region encoded by the alternatively spliced exon was found to interact with a particular isoform of another HSANII causative gene, *KIF1A*. The HSANII-causing *KIF1A* isoform is referred to as *KIF1A/25B* since disease-causing mutations were exclusively found in the alternative exon "*25B*". The expression profile of KIF1A/25B across the nervous system is determined by performing WB immunodetection using tissues from wild-type mice and a rabbit antiserum. The function of the protein encoded by exon 25B is assessed through a profiling of its interacting partners by performing co-immunoprecipitation for both full-length KIF1A/25B protein and the protein that correspond to exon 25B. Positive interactions are confirmed using liquid chromatography–mass spectrometry. We hypothesize that KIF1A/25B is the transit system through which WNK1/HSN2 traffics within the cells and offers the two proteins an opportunity to interact with other cellular elements relevant to the sensory and nociceptive aspects of HSANII. This study answers fundamental questions regarding the molecular pathophysiology of HSANII, though our findings have an impact on the understanding of other neuropathies and of normal neuronal processing.

3329T

Urea concentration is increased in the brains of Huntington's disease patients and in the striatum of the prodromal OVT73 sheep model. *R.G. Snell[1,2], R.R Handley[1,2], S. Patassini[1,2,4], I. Fourie[1], C.S Bawden[3], S.R Rudiger[3], P. Verma[3], G.J Cooper[4], R.D Unwin[4], H.J Waldvogel[2], J.F Gusella[5], M.E MacDonald[5], R.L.M Faull[2], S.J Reid[1,2].* 1) School of Biological Sciences, The University of Auckland, Auckland, New Zealand; 2) Centre for Brain Research, The University of Auckland, Auckland; 3) Molecular Biology and Reproductive Technology Laboratories, South Australian Research and Development, Adelaide; 4) Centre for Advanced Discovery and Experimental Therapeutics (CADET), Central Manchester University Manchester; 5) Center for Human Genetic Research, Massachusetts General Hospital, Harvard Medical School, Boston.

  Huntington's disease (HD) is an autosomal dominant inherited neurodegenerative disorder with onset generally in mid life. The mutation that causes HD is an expanded CAG repeat coding for glutamine in exon 1 of the HTT gene (1). Despite the gene being isolated over 20 years ago there is still no clear understanding of the biochemical processes leading to cell dysfunction and cell loss, processes that are initiated well before the onset of symptoms. We have recently reported the observation of an increase in urea distributed throughout post-mortem HD brains (2). Disruption of the urea cycle through mutation or acute bacterial toxicity can result in neuronal cell death and is therefore a potential pathogenic mechanism in HD. In order to investigate this phenomena further we have extended our human post mortem brain studies and have measured urea concentrations in brain and peripheral tissues from our prodromal transgenic sheep model. Confirming our preliminary observation we have seen an increase (3-4 fold) increased in HD brain samples from a large cohort (30 cases, 18 controls). We have also seen this increase in a subset of pathological grade 0-1 HD cases where there is minimal cell loss. Importantly, we find an increase in urea specifically within striatum from our prodromal HD sheep model in which cell loss is not a feature. Taken together this suggests that the increase in urea is unlikely to be a direct consequence of secondary catabolism. These observations are mechanistically supported by our observation of an up-regulation of the urea transporter transcript (SLC14A1) transcript throughout the human and sheep brains possibly as a physiological process to clear the urea.   1. The Huntington's Disease Collaborative Research Group. A novel gene containing a trinucleotide repeat that is expanded and unstable on Huntington's-disease chromosomes. Cell 1993, 72 (6), 971-983. 2. 3330F

Role of the Prader-Willi Syndrome protein MAGEL2 in intracellular pathways regulating the leptin receptor. *T.M. Wijesuriya[1], K.V. Carias[1], K. Fagan[1], L. De Ceuninck[2], J. Tavernir[2], R. Wevrick[1].* 1) Department of Medical Genetics, University of Alberta, 8–16 Medical Sciences Building, Edmonton, AB, Canada T6G 2H7; 2) Department of Biochemistry, Faculty of Medicine and Health Sciences, Ghent University, Albert Baertsoenkaai 3, B-9000 Ghent, Belgium.

Background: Children with Prader-Willi syndrome have neonatal feeding difficulties, developmental delay and excessive appetite. Loss of MAGEL2 causes a neurodevelopmental disorder (Schaaf-Yang syndrome) and may contribute to obesity in children with Prader-Willi Syndrome who lack MAGEL2 and other genes. MAGEL2 is essential in neurons that sense levels of the adipose tissue-derived hormone leptin. The MAGEL2 protein is important for recycling or degradation of proteins in the brain and interacts with and modifies the activity of E3 ubiquitin ligases. RNF41 is a E3 ubiquitin ligase that associates with a ubiquitin-specific protease (USP8). Together with USP8, RNF41 regulates the recycling of the leptin receptor by targeting it either for degradation or for recycling to the cell membrane. We hypothesized that MAGEL2 normally regulates the interaction between RNF41 and USP8, and that loss of this regulation could impair leptin response pathways in the brain in children with PWS. Methods: Human U2OS cells were transfected with recombinant constructs encoding epitope tagged versions of MAGEL2 and wild type and mutant forms of RNF41. Immunofluorescence was used to visualize the co-localization of different forms of RNF41 with MAGEL2 in intracellular compartments. We expressed recombinant MAGEL2, RNF41 and USP8 in combinations in human U2OS cells and examined the relative abundance of each protein in the presence or absence of the other components of the complex. Results: We identified interactions among components of the RNF41-USP8 complex that depended either on the activity of the RING domain of RNF41 (RNF-SQ mutant form) or the binding domain of RNF41 (RNF-AE mutant form). Co-expression of MAGEL2 with components of the RNF41-USP8 complex modified the abundance of proteins in the complex. Preliminary results suggest that MAGEL2 modifies the ability of RNF41 to auto-ubiquitinate or to ubiquitinate MAGEL2. Co-expression of MAGEL2 also modified the intracellular localization of components of the RNF41-USP8 complex. We also measured levels of endogenous RNF41 and USP8 level in brain tissues from Magel2 knockout mice and compared these levels to those found in tissues from wild type littermates. Conclusion: Our results suggest that MAGEL2 could modify the activity of the RNF41-USP8 ubiquitination complex in leptin sensing neurons, providing a possible mechanism for dysregulation of leptin sensing in neurons in children with Prader-Willi syndrome.

Integrated gene co-expression network analysis reveals genotype-phenotype correlations in Williams syndrome. *R. Kimura[1], K. Tomiwa[2], T. Awaya[3], T. Kato[3], M. Nakata[1], Y. Funabiki[4], T. Heike[3], M. Hagiwara[1].* 1) Dept Anatomy and Developmental Biology, Kyoto University Graduate School of Medicine, Sakyo-ku Kyoto, Japan; 2) Todaiji Medical and Educational Center, Nara, Japan; 3) Dept Pediatrics, Kyoto University Graduate School of Medicine, Sakyo-ku Kyoto, Japan; 4) Dep Human Coexistence, Kyoto University Graduate School of Human and Environmental Studies, Sakyo-ku Kyoto, Japan.

Williams Syndrome (WS) is caused by a 7q11.23 heterozygous deletion containing 26-28 genes. WS is characterized by various symptoms including hyper sociability. However, it remains unclear a biologically relevant signature about global dysregulations caused by deletion at 7q11.23. In contrast, Autism Spectrum Disorder (ASD) is a characterized by impairments in social communication and presence of restricted/repetitive patterns of behavior. Therefore, WS and ASD have been described as "opposite" disorders in terms of their social behavior. A better understanding of the differences between these two disorders could provide insights into genotype-phenotype relationships. In this study, we performed integrated gene co-expression network analysis to identify genes and pathways related to neuropsychiatric phenotypes. A total of 154 subjects, including 94 discovery groups (32 WS, 32 ASD and 30 Controls) and 60 independent replication groups (26 WS, 17 ASD and 17 Controls) participated in this study. To evaluate behavioral problems, we used the Child Behavior Checklist (CBCL) or the Adult Behavior Checklist (ABCL) and the Social Responsiveness Scale-2 (SRS-2). In addition to standard differential expression analysis using peripheral blood, we applied weighted gene co-expression network analysis (WGCNA) to identify genes and pathways related to specific phenotypes in WS. We identified several differentially expressed genes in WS compared to both ASD and Controls. Using WGCNA, we identified 7 modules associated with WS and 1 module associated with ASD. Interestingly, 3 modules, which were up regulated in WS, were significantly associated with neuropsychiatric phenotypes. Our findings strongly support the hypothesis the dysregulated transcriptomic network at the genome-wide level is associated with the variety of neuropsychiatric phenotypes in WS.

3332T

Kctd13 deficiency in mice causes recognition memory and sociability deficits. *T. Arbogast[1], E. Oh[1], R. Rodriguiz[2], W. Wetsel[2], N. Katsanis[1], C. Golzio[1].* 1) 1Center for Human Disease Modeling, Duke University, 300N Duke Street, Durham NC 27701; 2) Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC 27710.

The 16p11.2 BP4-BP5 deletion and duplication syndromes are associated with developmental delay and autism spectrum disorders, with a reciprocal effect on head circumference (i.e. micro/macrocephaly) and body mass index (i.e. obesity/underweight). We and others have generated mouse models of the 16p11.2 CNV (copy number variant) and these models recapitulated some of the phenotypes observed in humans including activity and short-term memory alterations (Arbogast, et al. 2016). By performing functional testing of the 16p11.2 CNV in zebrafish, we also found that overexpression of the human *KCTD13* transcript in embryos induces microcephaly, whereas knockdown of endogenous *kctd13* leads to macrocephaly, recapitulating the mirrored phenotype seen in 16p11.2 CNV carriers (Golzio, et al. 2012). To evaluate further the candidacy of *Kctd13*, we generated a ubiquitous knockout of *Kctd13* in the mouse and asked whether loss of *Kctd13* leads to behavioral deficits. First, we observed normal weight and activity in *Kctd13* mutant mice in both homozygotes (Hom) and heterozygotes (Het) indicating that *Kctd13* is not the driver of the BMI defects associated with 16p11.2 CNV. Second, we subjected the *Kctd13* Hom and Het mice and wildtype littermates to a suite of behavioral tests. We observed a significant deficit in novel object recognition and social interaction for the Het and Hom mice. In parallel, MRI analysis is currently performed to determine whether loss of *Kctd13* also has an impact on brain anatomy including the cortex and hippocampus in the mouse. Taken together, our functional studies suggest that dosage imbalance of *Kctd13* contributes to the intellectual disability and social deficits observed in individuals with the 16p11.2 CNV syndromes. Arbogast, T., A. M. Ouagazzal, C. Chevalier, M. Kopanitsa, N. Afinowi, E. Migliavacca, B. S. Cowling, M. C. Birling, M. F. Champy, A. Reymond and Y. Herault (2016). Deep sequencing reveal variations in somatic cell mosaic mutations between monozygotic twins with discordant psychiatric disease. *Y. Morimoto[1], S. Ono[1], A. Imamura[1], Y. Okazaki[2], A. Kinoshita[3], H. Mishima[3], H. Nakane[4], H. Ozawa[1], K. Yoshiura[3], N. Kurotaki[1].* 1) Department of Neuropsychiatry, Unit of Translation Medicine Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; 2) Michino-o Hospital, Nagasaki, Japan; 3) Department of Human Genetics, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; 4) Department of Psychiatric Rehabilitation Science, Unit of Rehabilitation Science, University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Neurodevelopmental disorders including schizophrenia, autistic spectrum disorder (ASD), and gender dysphoria (GD) are thought to be common, multifactorial diseases. Genetic factors as well as environmental factors including life events are involved in their pathogenesis. A number of family and twin studies have shown that genetic factors play an important role in the onset of various neurodevelopmental disorders. Phenotypically discordant MZ twins are interesting resources for genetic studies in diseases with a high concordance rate, and can make twin studies helpful in identifying the causative genes for heritable diseases. Identifying the molecular genetic differences between discordant MZ twins can help to elucidate the molecular mechanisms that underlie phenotypic discordance. To date, only a few studies have successfully detected genetic differences such as repeat length, single nucleotide variants, and copy number variants between discordant MZ twins. A number of genetic studies for neurodevelopmental disorders have been reported; however, because of genetic heterogeneity, their pathogenesis is still unclear. To identify causative genes for neurodevelopmental disorders, we performed whole exome sequencing (WES) and deep sequencing in 5 pairs of MZ twins with discordant neurodevelopmental disorders and 1 healthy control MZ twin. As a result, we identified 3 discordant variants confirmed by deep sequencing after analysis by personalized next generation sequencing in GD discordant twin. Three mutations in FBXO38, SMOC2 and TDRP, were detected with low allele frequency of mutant alleles on deep sequencing, suggesting that these loci are mosaic due to somatic mutations in a developmental stage. In silico analysis showed that the effects of all 3 mutations were "damaging". Specifically, testis development-related protein (*TDRP*) gene was found to be important in spermatogenesis and male infertility and may be related to maleness. In this context, *TDRP* could be a GD-related gene. In conclusion, we analyzed discordant variants in MZ twin pairs and 1 healthy control MZ twin using WES, and detected 3 somatic cell mosaic mutations in the GD twins by deep sequencing.It might be important to consider the presence of somatic cell mosaic mutations when confirming data obtained from WES. .

Human endogenous retroviruses and schizophrenia. *F. Macciardi[1], G. Guffanti[2], J. Fallon[1].* 1) Dept of Psychiatry & Human Behavior, Univ California, Irvine, Irvine, CA; 2) McLean Hospital, Department of Psychiatry, Harvard Medical School.

The Human Endogenous Retroviruses (HERVs) are the most represented elements of the Long Terminal Repeat class (LTR) of Transposable Elements (TEs), and make up 8% of the nuclear DNA. Intact HERVs maintain the structure of a retrovirus, but the vast majority are truncated or just Solo-LTRs. Yet, HERVs can be functionally expressed, acting primarily as enhancers or promoters of neighboring genes, in various tissues, as in the brain, with a putative functional role in diseases, like schizophrenia. The majority of HERVs studies estimated the combined expression of all insertions of an element (eg all copies of HERVs belonging to -K family), rather than pinpointing the exact genomic instance of a specific HERV (eg HERVK-1), limiting our understanding of their functional role. ENCODE RNA-seq studies revealed a widespread pattern of expression of different HERVs families in twelve different cell lines, and through application of an *ad hoc* mapping pipeline, demonstrated the feasibility of profiling single HERVs at their specific chromosomal locations. These results suggest that expression of specific HERVs insertions can be uncovered and their regulatory effect on neighboring genes assessed. We combined existing and newly developed analytical strategies for transcriptome assembly and annotation into a pipeline for HERV detection from RNA-seq data, and applied it to > 20 billion RNA-seq reads from 20 individual DLPFC expression profiles. We used TETranscript to evaluate the amount of expression for the hg38 reported 516 endogenous retroviruses (HERVs; #=481) and Long Terminal Repeats (LTR; #=35) families, obtaining expression signals for 97.7% of them. Then, we further analyzed our data with Trinity to map the individual elements of each HERV and LTR locus. We unequivocally mapped 28,432 expressed HERVs / LTRs, considering those RNAseq transcripts that overlap with at least 80% with an annotated HERV/LTR, confirming the sequencing by blastn. For example, we easily mapped the HERVKC4-int element within intron 9 of the C4A locus with high specificity and sensitivity, i.e., the HERVKC4 transcript is independent from exons and isoforms of C4A itself. Our preliminary results show that (1) HERVs and LTRs are expressed at detectable levels in postmortem brains, (2) we can unequivocally map individual elements and (3) reliably estimate their differential expression between cases and controls.

With a detection frequency of 0.044% in newborns, small supernumerary marker chromosomes (sSMC) derived from every chromosome have been observed. However, little is known about the mechanisms underlying their formation. In a proband diagnosed with schizo-affective disorder, we identified a complex copy-number variant (CNV) at 9p24.1p23 by array comparative genomic hybridization (aCGH). Custom high-density aCGH further revealed the pattern of the CNV to be triplication-duplication-triplication-normal-duplication (TRP-DUP-TRP-NML-DUP). Chromosome analysis and fluorescence *in situ* hybridization (FISH) in leucocyte cells revealed that the CNV was due to the presence of a sSMC stably inherited from his mother, who has a diagnosis of bipolar disorder with psychotic features. SNP array results indicated that this *de novo* complex genomic rearrangement (CGR) in the mother was likely generated through a mitotic interchromosomal event in the proband's maternal grandmother. The proband and his mother showed different levels of mosaicism for the CNV in all tissues studied (leucocytes, skin fibroblasts, lymphoblastoid cell lines, and induced pluripotent stem cells). High-density aCGH and quantification of the CNV by droplet digital PCR (ddPCR) consistently demonstrated fewer cells carrying the CNV in the mother than her son in both fibroblasts (75% versus 89%) and lymphoblastoid cell lines (0% versus 90%), potentially influencing their distinct clinical phenotypes. By long-range PCR and Sanger sequencing of the PCR products, we fine-mapped two breakpoint junctions (Jct1 and Jct2) of this complex CNV to nucleotide resolution, revealing a templated insertion of 399bp in Jct1 copied from a more proximal region at 9p23. Surprisingly, quantification of Jct1 and Jct2 by ddPCR indicated the presence of two copies of Jct1 versus one copy of Jct2, consistent with a rolling circle mechanism underlying formation of the triplication event. In summary, we propose that replication-based mechanisms have a role in the formation of sSMC with the CGR pattern potentially generated through a rolling circle. In addition, distinct levels of mosaicism in individuals carrying the same sSMC may have pleiotropic effects on psychiatric phenotypes.

Multi-level integrated exome analyses converge to a coherent system of molecular mechanisms on autism. *W. Luo[1], C. Zhang[2], C. Brouwer[1].* 1) Department of Bioinformatics and Genomics, UNC Charlotte, Charlotte, NC; 2) Department of Systems Biology, Columbia University, New York, New York.

Autism spectrum disorder (ASD) is a range of complex genetic diseases. In recent years, multiple whole exome/genome sequencing studies identified thousands of rare mutations and firmly established their roles in ASD. Because these variants rarely recur, major challenges remain as to: 1) evaluate the disease association of individual variants; 2) replicate independent studies or verify the results systematically. A coherent and systematic understanding of autism biology has not been achieved. To address these challenges, we devised a novel integrated analysis across multiple levels, i.e. variant, gene and pathway levels. This multi-level approach has major advantages over the classical one-level approach. First, it produces more informative, systematic, holistic genetic understanding. Second, multiple-level/angle screenings of the same data reaches more robust conclusions. Third, it provides more sophisticated and relevant classification and prioritization of rare mutations, which makes powerful analyses possible with these rare events. We applied this approach to two large scale whole exome studies and identified hundreds of potential causal mutations. We quantified and identified substantial consistence both within and between studies (Table 1), revealing a sequential convergence from variant, gene to pathway level. We deeply dissected ASD genetic association, and built a novel and more inclusive gene+pathway dual-hit model which could be generalizable to CNV or GWAS data. We reconstructed novel, replicable, systematic and multiscale molecular mechanisms for ASD (Table 1, Fig. 1-2). They provide solid and actionable molecular roadmaps for the development of effective and personalized ASD diagnostics and therapeutics. Note this multi-level integrated analysis is generally useful for other complex diseases and genomic studies. Note the full detail of this work is described in our pre-print at: http://biorxiv.org/content/early/2016/05/11/052878.

Telomere length variation in preschool children: Its relatedness with exposure to chronic stress, maternal depression, and cortisol reactivity. *A. Thakur, M. Kleiber, H. Sheikh, E. Hayden, S.M. Singh.* Biology, The University of Western Ontario, London, Ontario, Canada.

Major depressive disorders (MDD) often co-occur with stress. A number of recent reports have implied that stress-associated depression may be related to telomere length (TL). Shorter TL has been reported in the never-depressed daughters of women with a history of depression (familial risk for depression). Further, shorter telomeres have been reported to be associated with greater cortisol reactivity to stress. Such observations have been used to argue that TL may represent a biomarker for the risk for developing depression (Gotlib et al 2015). Such results and conclusions are not without exception and the relationship between TL, stress and depression, although intriguing, remains to be adequately elucidated. This research represents a follow-up on this controversy with an improved experimental design. It uses a large sample size (N=384) of mostly Caucasian young children (3-4 years) from South-western Ontario. Lifetime history of depression of the mothers was assessed using Structured Clinical Interviews for the DSM-IV and the UCLA Life Stress interview was used to assess chronic stress. All children were subjected to a defined play stress followed by assessment of their salivary cortisol and telomere length by monochrome multiplex qPCR following Cawthon (2009). Relative TL was measured as a ratio of telomere product (T) relative to the single copy albumin (S) gene product for each sample. The mean TL in our cohort is 2.42 (SD=1.98). This variability in TL has allowed us to assess any association of TL with stress related parameters. We found that, there was no correlation between TL of children and the exposure to chronic stress (p=0.319) or maternal depression (p=0.40). These results follow a number of reports in the literature, some used in a recent meta-analysis (Ridout et al 2016). It argues that this effect if exists, is relatively small. Further, we found a positive correlation between TL and increase in cortisol reactivity to the play stress (r= 0.181, p=0.000) and ground cortisol reactivity levels (r= 0.166, p=0.001). These results do not support the observation by Gotlib et al. (2015), who found a negative relationship between TL and cortisol in 97, 10-14 year old girls. Also, they do not support the implication that TL is related to stressful environment in very young children. Longitudinal studies are required on these children to offer a better insight on the relationship between TL and stressful environment and children's responses to stress.

Single cell allele specific expression (ASE) in T21 and common triso-mies: A novel approach to understand Down syndrome and gene dosage effects in aneuploidies. *G. Stamoulis[1], F. Santoni[2], P. Makrythanasis[2], A. Letourneau[1], M. Guiponni[2], M. Garieri[1], N. Panousis[1], E. Falconnet[1], P. Ribaux[1], C. Borel[1], S.E. Antonarakis[1,2,3].* 1) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) Geneva University Hospitals-HUG, Service of Genetic Medicine, Geneva, Switzerland; 3) iGE3 Institute of Genetics and Genomics of Geneva, University of Geneva, Geneva, Switzerland.

Trisomy 21(T21), is a model disorder of altered gene expression. Previous studies on aneuploidies were conducted on cell-populations or tissues. In our lab, in order to reduce the interindividual genetic variability, we have previously used a pair of monozygotic-twins discordant for T21 to study the global dysregulation of gene expression, (*Nature:*508;345-350;2014). However studies on gene and allelic-expression of single-cells(SC) may provide a different perspective on the biological and cellular impact of aneuploidy and in particular on the understanding of the fundamental mechanisms of gene dosage imbalance. We estimated the allele-specific-expression(ASE) from RNAseq of ~1000 single-cells in different aneuploidies:352 SC fibroblasts (172 Normal-179 T21 cells) from the pair of monozygotic-twins discordant for T21, 166 from a mosaic-T21, 176 mosaic-T18, 151 mosaic-T8, and 146 SC-fibro-blasts from mosaic-T13.In the monozygotic-twins, a considerable number of heterozygous sites genomewide were monoallelically expressed on a single cell level (Normal:73.5%-564,668 sites, and T21:78.7%-549,799 sites). We detected an increased monoallelic expression for chr21 sites in T21 cells with respect to Normal (Normal:63,3%-5,009 observations,T21:72.8%-6,456 observations). We classified chr21 genes in three classes based on the level of the aggregate monoallelic-expression of their corresponding heterozygous sites (9-monoallelic,29-intermediate,2-biallelic). Notably,monoallelic genes do not present the expected gene dosage imbalance (1.5 fold change) at single cell level as measured in bulk whole tissue studies.Similar results were also observed in the other aneuploidies. Here we demonstrate that, for monoallelic genes, the altered gene dosage observed in whole tissue studies induced by the aneuploid chromosome,is partially due to the higher fraction of cells expressing the gene on the supernumerary chromosome. This difference in the fraction of expressing cells could perturb the spatial and temporal development of the embryo and contribute to the development and variability of phenotypes in aneuploidies. We show that there is a larger fraction of trisomic single cells, compared to normal single cells, expressing genes on the extra chromosome contributing to the gene dosage imbalance mechanism.This study provides a new fundamental understanding of gene dosage effects in aneuploidies by exploring the gene dosage imbalance mechanism on a single cell level.

3339F

Delineating the impact of rare copy number variations on cognition in schizophrenia. *C. Lowther[1], J. Wei[2], G. Costain[1], D.J. Stavropoulos[3], C.R. Marshall[2], A.C. Lionel[2], S.W. Scherer[4], A.S. Bassett[5].* 1) University of Toronto, Toronto, Ontario, Canada; 2) The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, Ontario, Canada; 3) Cytogenetics Laboratory, Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, Ontario, Canada; 4) McLaughlin Centre and Department of Molecular Genetics, University of Toronto, Toronto, Ontario, Canada; 5) Department of Psychiatry, University of Toronto, Toronto, Ontario, Canada.

Background: The risk for developing schizophrenia (SZ) is 3-5% higher in individuals with an intellectual disability (ID) than in the general population. Individuals with comorbid ID are often excluded from genetic studies of SZ, leaving a gap in our understanding of the underlying genetic architecture of SZ-ID. Objectives: The purpose of this study was to 1) determine the yield of rare copy number variations (CNVs) in a cohort of adults with SZ-ID and 2) determine if the prevalence of rare CNVs is higher in SZ-ID compared to SZ-only and controls. Methods: 482 adults of European ancestry with SZ were ascertained from four psychiatric outpatient clinics in Eastern Canada. We used a broad definition of premorbid ID (FSIQ <85) to assign individuals to the SZ group with impaired cognition (n=160; SZ-ID). Those with FSIQ ≥ 85 were assigned to the SZ-only group (n=322). Using rigorous methods to detect genome-wide CNVs from high resolution microarrays we examined the burden of rare (<0.1%) CNVs >25 kb between these two groups and n=319 population-based controls of European ancestry. Results: The prevalence of subjects with one or more rare autosomal CNVs in the SZ-ID group was significantly higher than in SZ-only and controls across three CNV size cut-offs: >25 kb, >100 kb and >500 kb. The largest effect size for SZ-ID vs. SZ-only, and SZ-ID vs. control, comparisons was for two or more rare deletions >100 kb overlapping an exon (OR=9.28, CI 95% 1.14-246.99, p=0.0084), and one or more deletions >500 kb overlapping a gene (OR=5.21, CI 95% 2.17-13.91, p<0.0001), respectively. Compiling all SZ cases together revealed a significant negative correlation between FSIQ and the number of genes overlapped by a rare CNV >25 kb (Pearson r = -0.25, p=0.004). Identification of genes overlapped by a rare CNV in two or more SZ-ID cases and no SZ-only cases or controls suggests transcriptional regulation (*ZNF804A*, *LBH*), cortical formation (*ARHGAP11B*), synaptic signaling (*NRXN1*) and microtubule formation (*TUBB2A*, *TUBB2B*, *KIF25*) may represent novel etiological mechanisms associated with SZ-ID. Conclusions: To our knowledge this is the first study to use high resolution microarrays to examine the genetic architecture of SZ-ID. These results suggest there is an overall increased burden of genic deletions in SZ-ID compared to SZ-only. Examination of the genes overlapped by these CNVs may help identify novel pathways that are more specific to SZ-ID.

Low-copy repeats mediate genomic rearrangements of chromosome 22q11.2 in five probands from Brazilian public health service. *L.B. Minasi[1,2], A.J.C. Leite[1,2], I.P. Pinto[1,3], D.M.C. Cunha[1], C.L. Ribeiro[1,3], C.C. da Silva[1,2,3,4,5], A.D. da Cruz[1,2,3,4].* 1) Pontifical Catholic University of Goias, Department of Biology, Replicon Research Group, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 2) Pontifical Catholic University of Goias, Genetics Master's Program, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 3) Federal University of Goias, Biotechnology and Biodiversity PhD Program, Rede Centro Oeste de Pós-Graduação, Pesquisa e Inovação, Campus Samambaia, Goiânia, GO, Brazil; 4) Human Cytogenetics and Molecular Genetics Laboratory, Secretary of Goias State for Public Health, Goiânia, GO, Brazil; 5) State University of Goias, UnU Eseffego, Brazil.

The instability of 22q11 has been demonstrated by the high frequency of pathological rearrangements of this region. This instability is attributed to the presence of several large paralogous low copy repeats (LCRs), each containing a complex modular structure and a high degree of sequence identity. Non-allelic homologous recombination between these LCRs causes a spectrum of recurrent rearrangements, including deletions and duplications. In total, the region contains eight LCRs, known as LCR22-A to LCR22-H. Herein, we performed an analysis of duplicated genomic sequences including known LCRs surrounding the proximal 22q11.2 locus identified in five probandos who carried deletions and duplication. Chromosomal Microarray Analysis using Affymetrix GeneChip® CytoScanHD™ array showed at 22q11.2 region two cases with *de novo* deletions of 2.88Mb and 0.27Mb, one case with paternal inherited deletion of 0.75Mb, and two cases with maternal inherited of 0.34Mb and 0.79Mb. Using the Segmental Duplication track of the Human Genome Build 36.1 comparing 3 times of the CNV size surrounding the proximal 22q11.2 locus (chr22: 18,640,000—25,080,000) against itself, we recognized LCR-A to LCR-D flanking 2.88Mb deletion and LCR-B to LCR-D flanking 0.75 Mb deletion. For the 0.27Mb deletion, 0.34Mb and 0.69Mb duplications breakpoints we only identified LCR-H within the 22q11.2 region. Deletion at 22q11.2 was usually sporadic and was reported to be inherited in 6 to 28% of patients with DiGeorge Syndrome. In general, duplications are more likely to be inherited than their reciprocal deletions, with approximately 93% of small duplications. The most common deletion occurs between the two largest blocks, LCR22-A to LCR22-D, and results in a 3Mb deletion. We identified two groups of LCR22 that are flanking the genomic rearrangements from in two probands. These finding suggest that the occurrence of genomic rearrangements might be mediated by NAHR between of the LCRs, increasing the susceptibility to the generation of CNVs. On the order hand, the three other cases showed LCRs within the reported deletion and duplications breakpoints, thus it is not possible to speculate the detailed mechanistic in relation to how this deletion and duplication initially appeared in these patients. The recognition of LCRs provides important insights related to the role of genomic architecture in chromosomal rearrangements, chromosome evolution, and in human disease. .

Acadian variant of Fanconi syndrome is caused by mitochondrial respiratory chain complex I deficiency due to a non-coding mutation in complex I assembly factor NDUFAF6. *L. Piherova[1], H. Hartmannova[1], K. Tauchmannova[2], K. Kidd[3], P.D. Acott[4], J.F.S. Crocker[4], Y. Oussedik[5], M. Mallet[6], K. Hodanova[1], V. Stranecky[1], A. Pristoupilova[1], V. Baresova[1], I. Jedlickova[1], M. Zivna[1], V. Robins[3], M. Vrbacky[2], P. Pecina[2], V. Kaplanova[2], J. Houstek[2], T. Mracek[2], Y. Thibeault[7], A. Bleyer[3], S. Kmoch[1].* 1) Institute for Inherited Metabolic Disorders, Charles University, Prague 2, Czech Republic; 2) Institute of Physiology of the Czech Academy of Sciences, Prague, Czech Republic; 3) Section on Nephrology, Wake Forest School of Medicine, Medical Center Blvd., Winston-Salem, NC, USA; 4) Section of Pediatric Nephrology, Department of Pediatrics, Dalhousie University, Halifax, Nova Scotia; IWK Health Center, Halifax, Nova Scotia, Canada; 5) Department of Pathology, Dr. Georges L. Dumont University Hospital Centre, Moncton, New Brunswick, Moncton, New Brunswick, Canada; 6) Section of Pulmonology, Dr. Georges L. Dumont University Hospital Centre, Moncton, New Brunswick, Canada; 7) Section of Nephrology, Dr. Georges L. Dumont University Hospital Centre, Moncton, New Brunswick, Canada.

The Acadian variant of Fanconi Syndrome refers to a specific condition characterized by generalized proximal tubular dysfunction from birth, slowly progressive chronic kidney disease and pulmonary interstitial fibrosis. This condition is found only in Acadians, a founder population in Nova Scotia, Canada. The genetic and molecular basis of this disease is unknown. We carried out whole exome and genome sequencing and found that nine affected individuals were homozygous for the ultra-rare noncoding variant chr8:96046914 T>C; rs575462405, whereas thirteen healthy siblings were either heterozygotes or lacked the mutant allele. This variant is located in intron 2 of *NDUFAF6* (NM_152416.3; c.298-768 T>C), 37 base pairs upstream from an alternative splicing variant in *NDUFAF6* (chr8:96046951 A>G (c.298-731 A>G); rs74395342. *NDUFAF6* encodes NADH:ubiquinone oxidoreductase complex assembly factor 6, also known as C8ORF38. We found that rs575462405 - either alone or in combination with rs74395342 - affects splicing and synthesis of NDUFAF6 isoforms. Affected kidney and lung showed specific loss of the mitochondria-located NDUFAF6 isoform and ultrastructural characteristics of mitochondrial dysfunction. Accordingly, affected tissues had defects in mitochondrial respiration and complex I biogenesis that were corrected with NDUFAF6 cDNA transfection. Our results demonstrate that the Acadian variant of Fanconi Syndrome results from mitochondrial respiratory chain complex I deficiency. This information may be used in the diagnosis and prevention of this disease in individuals and families of Acadian descent and broadens the spectrum of the clinical presentation of mitochondrial diseases, respiratory chain defects, and defects of complex I specifically.

3342F

CLEC16A constrains NK cell cytotoxicity and protects against auto-immune susceptibility by regulating mitophagy and immune-mediated cell destruction. *R. Pandey[1], M. Bakay[1], S. Yoeun[1], A. Yermakova[2], J.D. Roizen[3], J.K. Kushner[4], J.S. Orange[2], H. Hakonarson[1,5].* 1) Centre for Applied Genomics, Children's Hospital Of Philadelphia, Philadelphia, PA; 2) Section of Immunology, Allergy, and Rheumatology, Department of Pediatric Medicine, Texas Children's Hospital, Houston, TX; 3) Division of Endocrinology and Diabetes Children's Hospital of Philadelphia, Philadelphia, PA; 4) Section of Pediatric Diabetes and Endocrinology, Department of Pediatric Medicine, Endocrine-Metabolism, Texas Children's Hospital, Houston, TX; 5) Department of Pediatrics, the Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

The C-type lectin-like domain family 16A (CLEC16A) is implicated in a majority of known autoimmune diseases via a previously unknown mechanism. Genetic variants in the 16p13 locus harboring the CLEC16A gene are associated with the susceptibility to T1DM. However, the role of CLEC16A and of CLEC16A variations in the physiology and pathogenesis of T1DM remains poorly understood. We hypothesize that the molecular link between CLEC16A and autophagy/mitophagy is abnormal in T1DM, and that subjects with T1DM have accelerated mitophagy that a) increases autoimmunity and b) exhausts the energy sources of the insulin-producing β cells resulting in the expression of clinical diabetes. **Results:** We generated Clec16a inducible knockdown (KD) mice and CLEC16A overexpressing Natural Killer (NK) cell line to examine the mechanism underlying the link between NK CLEC16A expression alteration and autoimmune susceptibility. Clec16a KD mice showed increased NK cell cytotoxicity, increased expression of NK activating receptors and accelerated mitophagy in splenic immune cells. Treatment with autophagy inhibitors Bafilomycin and Wortmannin offset the effects of Clec16a knockdown. We show that CLEC16A/Nrdp1 pathway regulates mitochondria integrity and function and that uncontrolled loss of CLEC16A leads to increased mitophagy and intrinsic pathway of cell death. KD of CLEC16A in human NK cells doubled their cytotoxicity, whereas CLEC16A overexpression led to reductions in cytotoxicity, expression of NK cell activating receptors via autophagy, DC maturation and IFN-γ release. Our mechanistic studies reveal that CLEC16A restrains NK cell functions by modulating expression of NK receptors via C Vps-HOPS complex, CART and autophagy. Thus, owing to its role in autophagy, Clec16a impacts the function of NK cells and the risk of autoimmunity. **Conclusions:** Our results establish a functional link between CLEC16A and mitophagy/autophagy in the context of autoimmunity which explains the immune dysregulation in Clec16a KD mice and may explain the risk of autoimmunity in humans with specific CLEC16A risk variants. Thus, drugs modulating mitophagy/autophagy may be specifically effective as treatment in individuals with associated CLEC16A risk variants.

3343W

The combinative effect of copy number variation (CNV) in 47,XXY, a sex chromosome variation (SCV). *C. Keen[1], T. Sadeghin[1,2], C. Samango-Sprouse[3,4].* 1) The Focus Foundation, Davidsonville, MD; 2) Neurodevelopmental Diagnostic Center, Crofton, MD; 3) Pediatrics, George Washington University, Washington, DC; 4) Molecular Genetics, Florida International University, Miami, FL.

Introduction: 47,XXY is a SCV associated with low fertility, tall stature, and language-based learning disorders. The prevalence of CNV, and subsequent effects on phenotypic variation, is not clearly understood. We report the case of two male siblings (SL and SB) of the same maternal and paternal origin. SL presents with normal IQ, reading disorder and has 8q22.3 duplication (516kb) suggesting trisomy in this location. SB presents with the identical CNV, 47,XXY, severe speech delay and intact IQ. Statement of purpose: Investigate the neurodevelopmental profile of male siblings with the same CNV, and one sibling with 47,XXY additionally. Methods: Chromosomal Microarray (CMA) was completed on both siblings and mother. Father is deceased, therefore CMA could not be completed and origin of the CNV is unknown. Neurodevelopmental assessments probed domains of language, cognition, and motor. Results: SL developmental milestones were within normal limits and no parental concerns. At 9 years, SL demonstrated average IQ, severe reading disorder with above-average performance in mathematics. On the Woodcock Johnson Reading Mastery, he had standard scores (SS) in word identification (SS=67), attack (SS=73), and comprehension (SS=64). He had SS=55 in passage comprehension and SS=57 in reading comprehension. SB had delayed ambulation skills, short stature, and weak visual motor skills. 47,XXY was identified after chromosomal analysis ordered at 23 months because of developmental delay. At 31 months of age SB had increased head circumference (75th percentile) disproportionate to weight (5th percentile) or height (25th percentile). Bayley Scales of Infant Development showed composite scores of 88 in motor and 95 in cognition. Expressive language was severely delayed, and he had trouble imitating motor and speech actions. SB's profile was characteristic of Childhood Apraxia of Speech (CAS), with more intact auditory comprehension (SS=76) than expressive communication (SS=56) on the Preschool Language Scale-5. Discussion: SB & SL have neurodevelopmental profiles indicative of motor planning deficits with language-based disorders. SB had CAS, which is not characteristic of 47,XXY but may be evidence of further compromise by the CNV. SL has reading disorder which is language-based but no signs of CAS. The comparative complexity of SB's neurodevelopmental profile suggests possible combinative effects of CNV and SCV and variable effects neurodevelopmentally.

Gene dosage effects in Down syndrome revealed by proteome-wide expression and turnover analysis. *Y. Liu[1], C. Borel[2], L. Li[3], T. Mueller[1], P. Boersema[4], P. Germain[5], G. Testa[5], A. Beyer[3], S. Antonarakis[2], R. Aebersold[1,6].* 1) Department of Biology, Institute of Molecular Systems Biology, ETH Zurich, Zurich, Zurich, Switzerland, Switzerland; 2) Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva; 3) University of Cologne, Cologne, Germany; 4) Institute of Biochemistry, Department of Biology, ETH Zurich, Zurich, Switzerland; 5) Department of Experimental Oncology, European Institute of Oncology, Milan, Italy; 6) Faculty of Science, University of Zurich, 8057 Zurich, Switzerland.

   Statement of purpose Down Syndrome (DS) is caused by the whole or partial trisomy of chromosome 21 (Trisomy 21, T21). However, how T21 impacts human functional proteome remains unclear. Previous proteomic studies suggested the gene copy number alterations (CNAs) only weakly impact on protein expression. We herein hypothesize that proteome-wide turnover analysis would hold a special promise in revealing the gene dosage effects of T21.   **Methods** We investigated the effect of the extra Chr21 at the levels of transcript quantity, proteome quantity and protein turnover rate. We analyzed the primary fetal skin fibroblasts derived from a pair of monozygotic twins discordant for T21, which uniquely allowed us to characterize the proteome changes due to T21 without the noise of genomic variability. To validate, we also analyzed the fibroblasts from 11 unrelated T21 individuals and 11 controls. We applied the cutting-edge SWATH mass spectrometry to reproducibly and accurately measure the proteomes. We further quantified protein degradation rates through a pulse SILAC experiment (pSILAC) up to 24 hours.   **Results and Discussion** We quantified 4056 unique proteins for expression and ~2200 proteins by pSILAC experiment for protein turnover rates in both normal and T21 twins. The T21/normal fold-change correlation between transcript and protein levels was extremely low, indicating substantial post-transcriptional regulation and buffering effects in T21. Overall, the protein degradation was faster in trisomy cells than the controls. Remarkably, those Chr21 encoded proteins that are members of heteromeric protein complexes were largely exempt from responding to CNAs, primarily through accelerated protein degradation. Moreover, we found that both mitochondrial and cytosolic ribosomal proteomes were degraded heavily in T21, but different degree of translational regulation shaped their final, divergent expression levels. Combining twin samples and unrelated individuals, we found that organelle specific proteomic variation between individuals may contribute to some variable T21 phenotypes.   **Conclusion** Our data suggests that protein specific degradation presents a primary mechanism of proteome remodeling in response to T21 and thus reinforces the understanding of "gene dosage imbalance" in Down Syndrome.

Chromosome therapy: Correction of chromosomal aberrations by inducing ring chromosomes in induced pluripotent stem cells (iPSCs). *T. Kim, K. Plona, S. Carney, A. Wynshaw-Boris.* Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH.

   Approximately 1 in 500 newborns are born with chromosomal abnormalities that include trisomies, translocations, large deletions and duplications. There is currently no therapeutic approach for correcting such chromosomal aberrations *in vivo* or *in vitro*. We have attempted to utilize a novel pathway for aberrant ring chromosome rescue that we recently uncovered to correct large-scale chromosomal aberrations. When we produced induced pluripotent stem cell (iPSC) models from patients with either a ring chromosome 17 or 13, we found that the ring chromosomes were eliminated and replaced by a duplicated normal copy of chromosome 17 or 13 via uniparental isodisomy (Bershteyn *et al.*, 2014, Nature 507:99). We hypothesized that a chromosome with a large aberration could be corrected by inducing the aberrant chromosome into a ring chromosome in iPSCs, which would then be eliminated and replaced by a normal chromosome which we termed "Chromosome Therapy." To test this, we induced chromosome 17 ring formation in control iPSC lines via a Cre/loxP approach. LoxP sites were inserted by gene editing at sites near each end of chromosome 17 in iPSC clones containing a terminal deletion of 17p. We used different color fluorescent proteins (Cyan and Venus) to confirm proper insertion of the sites into the 17p and 17q arms of chromosome 17 with the combination of antibiotic selection. Once this was accomplished, we infected these cells with Cre recombinase to induce ring formation of chromosome 17. We designed fluorescence *in situ* hybridization (FISH) probes to segregate the clones containing the specific targeted-chromosome 17 from the non-specifically targeted clones. To visualize cells that form a ring chromosome, we designed and cloned the partial tandem dimer Tomato (tdTomato) along with the loxP sites such that the cell will express tdTomato upon formation of a ring chromosome due to Cre-mediated recombination. Individual tdTomato-positive clones were identified, and we are isolating sufficient numbers of cells for karyotype and molecular analysis. Loss of tdTomato from these ring-containing clones will suggest the loss of the ring and duplication of the normal chromosome 17 by uniparental isodisomy. A similar approach is being tested in iPSCs from patients with Down syndrome (trisomy 21). Therefore, we have created a specialized system to test whether "chromosome therapy" for correcting large chromosomal aberrations by the induction of ring chromosomes is possible.

3346W

Chromatin looping and endogenous L1-endonucleases may drive local shattering during chromothripsis. *L. Nazaryan-Petersen[1], B. Bertelsen[2], M. Bak[1], L. Jønson[3], N. Tommerup[1], D.C. Hancks[4], Z. Tümer[2].* 1) Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Copenhagen N, Denmark; 2) Kennedy Center, Department of Clinical Genetics, Copenhagen University Hospital, Rigshospitalet, Glostrup 2600, Denmark; 3) Center for Genomic Medicine, Copenhagen University Hospital, Rigshospitalet, Copenhagen O. 2100, Denmark; 4) Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT 84112, USA.

Chromothripsis is a phenomenon where multiple localized double-stranded DNA breaks result in complex genomic rearrangements. Although the DNA-repair mechanisms involved in chromothripsis have been described, the mechanisms driving the localized "shattering" process remain unclear. High-throughput sequence analysis of a familial germline chromothripsis revealed an inserted SVA$_E$ retrotransposon associated with a 110 kb deletion displaying hallmarks of L1-mediated retrotransposition. Our analysis suggests that the SVA$_E$ insertion did not occur prior to or after, but concurrent with the chromothripsis event. We also observed L1-endonuclease potential target-sites in other breakpoints. In addition, we found four *Alu* elements flanking the 110 kb deletion and associated with an inversion. We suggest that chromatin looping mediated by homologous *Alu* elements may have brought distal DNA regions into close proximity facilitating DNA cleavage by catalytically active L1-endonuclease. Our data provide the first evidence that active and inactive human retrotransposons can serve as endogenous mutagens driving chromothripsis in the germline.

3347T

Complex *cis*-interaction is responsible for the craniofacial and neuroanatomical defects of the 4p16.1 copy number variant. *C. Golzio, G. Hayot, C. Bonnet, N. Katsanis.* Center for Human Disease Modeling, Duke Univ Medical Center, Durham, NC.

Copy number variants (CNVs) are frequent lesions involved in both rare and complex disorders that often involve the dosage misregulation of numerous genes. We have shown previously how the use of structural surrogate phenotypes in zebrafish embryos and genomic studies can dissect a single contributory locus to these phenotypes, which raised the possibility that this approach might be useful in dissecting systematically CNVs. Here we demonstrate the utility of this paradigm by dissecting a CNV on 4p16.1 CNV, deletions and duplications of which causes a syndromic form of autism with associated macrocephaly and facial dysmorphia. The CNV encompasses 5 genes: *DRD5*, *WDR1*, *ZNF518B*, *CLNK*, and *SLC2A9*. Analysis of existing cases in Decipher indicated that the 4p16.1 deletion was associated with micrognathia (small jaw) and microcephaly whereas the duplication was associated with an abnormal facial shape and macrocephaly. We thus sought to determine the contribution of these five genes to brain and face development. To mimic the duplication, we expressed each of the five human transcripts in zebrafish embryos. We found discrete drivers for the two major anatomical features tested. First, overexpression of either *SLC2A9* and *ZNF518B* were sufficient to induce macrocephaly. However, scoring for the possible drivers of the craniofacial defect neither gene induced appreciable pathology. In contrast, expression of either of two other genes, *CLNK* and *WDR1,* led to macrognatia (*CLNK*) and abnormal U-shaped of the Meckel's cartilage (*WDR1*). Finally, we asked whether the same transcripts might be relevant to the deletion by inducing deletions in each of *WDR1* and *CLNK* orthologs by CRISPR/Cas9; in contrast to the duplication experiment, only the loss of *Wdr1* led to micrognatia. Taken together these data suggest that the craniofacial and neuroanatomical phenotypes are due to the dose imbalance of several genes present in the 4p16.1 following a *cis*-interaction complex model rather than the effect of a major gene driver. Moreover, our data intimate that the phenotypes of deletion and duplication carriers might be caused by the combinatorial dosage imbalance of different genes, as opposed to a simper reciprocal model.

3348F

***De novo* sequence and assembly of the human primary cell line WI-38 genome.** *M. Roy[1], P. Peluso[2], C.S. Chin[2], G. Concepcion[2], A. Hastie[3], I. Soifer[1], J. Lee[3], N. Fong[1], M. Chan[1], A. Ireland[1], A. Levinson[1], D. Botstein[1].* 1) Calico Life Sciences LLC, South San Francisco, Ca; 2) Pacific Biosciences, 1380 Willow Rd., Menlo Park, CA 94025; 3) BioNano Genomics, 9640 Towne Centre Drive, Ste. 100, San Diego, CA 92121.

A robust method for *de novo* sequencing and assembly of individual human genomes is an important prerequisite for achieving truly personalized medicine. Currently most whole genome sequencing projects rely on technology that produces "short reads." Attempts at *de novo* assembly of short reads result in highly fragmented assemblies, so short reads are aligned to a standard reference genome that itself still contains gaps and misassemblies. Complex genomic structural variants (SVs) can affect human health (e.g., autism, MHC regions) but alignment of short reads against a reference genome introduces bias towards the reference genome's SVs, and obscures SV differences between haplotypes. Here we illustrate how long reads enable the determination of reference-unbiased sequence using long scaffolds of sufficient contiguity to determine haplotypes. We describe sequencing and *de novo* genome assembly of WI-38. This diploid untransformed human fibroblast line is of considerable medical and scientific importance; it is used in the production of human vaccines (e.g. MMR, varicella, etc.) and in 1965 it was used to demonstrate the Hayflick limit of cell division. **Collapsed Assembly:** WI-38 was sequenced to a depth of 80X on the PacBio RSII using P6-C4 chemistry. *De novo* assembly was accomplished with the Falcon assembler, yielding 2.92 Gb on 2,910 contigs. Assembly contigs had an N50 of 24.9 Mb, with the longest covering 109.1 Mb. Assembled contigs were scaffolded by optical mapping on the BioNano Genomics Irys platform using Nt.BspQI and Nb.BssSI nickases. Assembly statistics improved significantly with the mapping data, producing a genome of only 119 scaffolds with an N50 of 84.9 Mb. The longest scaffold appears to cover completely Chr8 with 143.9 Mb, spanning the centromere. Other large scaffolds included 138.9 Mb on Chr4, 133.6 Mb on Chr2, 110.7 Mb on Chr6, 108.6 Mb on Chr5, and 101.7 Mb on Chr3. **Phased Assembly:** PacBio contigs were unzipped with a diploid-aware FALCON assembler, and haplotype-resolved with FALCON-Unzip. After unzipping, the assembly had fewer contigs (1,952) and a longer N50 (26.4 Mb). Phasing produced 1.94 Gb of haplotigs (phased contigs), indicating 33% of the genome occurs in regions of limited heterozygosity. Haplotigs had an N50 of 0.37 Mb with the longest haplotig covering 2.52 Mb. Further haplotyping efforts will include adding the mapping data and refining the assembly via improved haplotype-aware Falcon and optical mapping algorithms.

Somatic mutations accumulate in stem cells of human skeletal muscle with aging. *I. Franco[1], K. Olsson[2], A. Johansson[3], P. Lundin[4], C. Bosia[5], T. Gustafsson[2], H. Fischer[2], M. Eriksson[1].* 1) Biosciences and nutrition, Center for Innovative Medicine, Karolinska Institute, Huddinge, Sweden; 2) Dept of Laboratory Medicine, Div of Clinical Physiology, Karolinska Institute, Sweden; 3) Science for Life Laboratories, Dept of Cell and Molecular Biology, Uppsala University, Uppsala, Sweden; 4) Science for Life Laboratories, Dept of Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden; 5) Human Genetics Foundation, Torino, Italy.

Tissue aging is characterized by progressive loss of function and renewal. In skeletal muscle, progressive decline in mass, activity and repair are related to the functional impairment of the resident stem cell population, the satellite cells. Aged satellite cells show reduced proliferative capacity and high levels of senescence. One trigger for senescence is DNA damage, which suggests that mutations might accumulate in the genome of aged satellite cells and compromise their function. In this study, we have analyzed the occurrence of somatic mutations in single satellite cells from young (age 21 and 24, n=2) and old (age 64-78, n=3) healthy individuals. Cells isolated from fresh *m. vastus lateralis* biopsies were selected for expression of the satellite cell marker CD56 and single-cell plated via fluorescence activated cell sorting (FACS). Single cells were clonally expanded to amplify DNA and tested for myogenic commitment by staining for desmin. Five clones/individual were whole genome sequenced obtaining a 15x coverage of 86.6%-90% of the genome. For each clone, comparison to muscle and blood sequences of the same individual was used to call somatic variants. To allow for the identification of variants present in the single cell originally isolated from the tissue, only variants displaying 0.35-0.65 alternate allele frequency were included. On average, 652±41 somatic single nucleotide variants (SNVs) and 38.6±3.4 somatic indels/genome were identified in young individuals. Old individuals showed a two-fold higher number of somatic variants/genome (1314±93 SNVs and 87.3±16 indels, young vs old SNVs p=5.2x10[-6], indels p=1.8x10[-8]), indicating that adult satellite cells accumulate 15 somatic mutations/year. 1.1% of mutations were located in exons and deleteriously impacted protein coding genes known to be expressed in satellite cells at a rate of 5 genes/aged cell. Our results provide the first evidence of an age-related increase in somatic mutations in human satellite cells and suggest that higher mutation burden in the stem cell compartment can contribute to muscle aging.

3350T

A novel high throughput pooled multiplex assay for relative telomere length measurement. *F. Jasmine, J. Shinkle, M. Sabarinathan, H. Ahsan, B.L. Pierce, M.G. Kibriya.* Public Health Sciences, University of Chicago, Chicago, IL.

   Background: Relative Telomere Length (RTL) is a potential biomarker of aging and cancer. We recently developed a non-PCR, probe based RTL assay using QuantiGene plex chemistry on Luminex platform, where probes for Telomere (T) and reference gene (R) for a given DNA sample were tested in a single well (multiplexing T and R). Here we describe, for the first time, a method of pooling multiple samples in the same well to increase the throughput and cost-effectiveness. **Material and Methods**: We used four different micro-beads (T1, T2, T3 and T4) for the same T probe and four different micro-beads (R1, R2, R3 and R4) for the same R probe. Each pair of probe set (T1R1, T2R2, T3R3 and T4R4) was used for a single plate to hybridize on to DNA. Corresponding wells of four such plates were pooled in a single plate for all the subsequent steps for signal amplification, attaching detection dye, wash and final detection of signal intensity on a Luminex 200. Quantification of the signal intensity was done by 8-point standard curve generated from 5-PL algorithm. RTL was calculated as T/R. We used blood DNA samples from 60 independent individuals and repeated in multiple batches to test the precision. Coefficient of variation (CV) for each sample was calculated from the replicates as standard deviation/mean and expressed as percentage. **Results:** By using four different bead sets, we could process a total of 256 independent samples (four 96-well plates each containing 64 samples including controls) at a time in one run. The precision of the assay was checked by the CV. The geometric mean of CV for all samples was 8.04%, arithmetic mean of CV was 8.41% and the median CV was 8.3%. There was no statistical significant difference of RTL between batches (p=0.09). More than 64% of the variation in the RTL data could be explained by sample-to-sample variation; only 0.02% variation was due to batch-to-batch variation and 1.2% variation was explained by bead-to-bead variation. Previously we have validated the Luminex results by comparing to TRF by Southern blot. Our data provides proof of principle for effectively increasing the throughput of RTL Luminex assay. Theoretically, we can further increase the throughput to 1280 samples per run by pooling up to 20 bead sets. **Conclusion:** We describe a novel pooled multiplex assay with currently known highest throughput for average RTL. The assay has reasonable precision and can be used cost-effectively for large-scale studies.

3351F

High throughput single-molecule mapping links subtelomeric variants and long-range haplotypes with high-resolution telomere length analysis. *H. Riethman[1], E. Young[2], S. Pastor[2], K. Lassahn[1], R. Rajagopalan[2], J. McCaffrey[2], J. Sibert[2], A. Mak[3], P-Y. Kwok[3], M. Xiao[2,4].* 1) Medical Diagnostic and Translational Sciences, Old Dominion University, Norfolk, VA; 2) Drexel University, School of Biomedical Engineering, Philadelphia, PA; 3) Cardiovascular Research Institute, University of California, San Francisco; 4) Institute of Molecular Medicine and Infectious Disease, School of Medicine, Drexel University, Philadelphia, PA.

   Accurate maps and DNA sequences for human subtelomere regions, along with detailed knowledge of subtelomere variation and long-range telomere-terminal haplotypes in individuals, are critical for understanding telomere function and its roles in human biology. Here, we use a highly automated whole genome mapping technology in nano-channel arrays to analyze large terminal human chromosome segments extending from chromosome-specific subtelomere sequences through subtelomeric repeat regions to terminal (TTAGGG)n repeat tracts. We establish detailed maps for subtelomere gap regions in the human reference sequence, detect many new large subtelomeric variants, and demonstrate the feasibility of long-range haplotyping through segmentally duplicated subtelomere regions. These features make the method a uniquely valuable new tool for improving the quality of genome assemblies in complex DNA regions. Based on single molecule mapping of telomere-terminal DNA fragments combined with quantitative analysis of physically linked (TTAGGG)n tracts specifically labeled in vitro using CRISPR-Cas9 directed methods, we estimate individual telomere lengths linked to distinguishable telomeric haplotypes; this single-telomere genotyping method opens the door to new high-resolution analyses of telomere length regulation and function in human health and disease.

Analysis of chitinases from nonpathogenic bacterium *Listeria innocua* .
S. Honda, S. Wakita, Y. Sugahara, F. Oyama, M. Sakaguchi. Department of Chemistry and Life Science, kogakuin University, Hachioji, Tokyo, Japan.

Listeria monocytogenes is causes a human listeriosis, a disease that affects immunosusceptible population such as pregnant women and the elderly. *L. monocytogenes* has two chitinase genes *(lmo0105* and *lmo1883)*, whose genes product have been identified as an important virulence factor associated with enhanced pathogenicity, and enhances the virulence of *L. monocytogenes* through suppression of the host innate immunity. *Listeria innocua* is a nonhemolytic and nonpathogenic bacterium. It is proposed that *L. innocua* and *L. monocytogenes* have evolved from a common ancestor, and the differential pathogenicity is due predominantly to the loss of virulence genes in *L. innocua*. *L. innocua* has putative chitinase genes *(lin0153* and *lin1996)* similar to *L. monocytgenes*. To identify the functional property of the putative chitinase genes, we expressed the putative chitinase genes *(lin0153* and *lin1996)* in *Escherichia coli*. The purified recombinant gene products (LIN0153 and LIN1996) exhibited chitinolytic activity for artificial and natural substrates. LIN0153 and LIN1996 showed optimum catalytic activity under neutral and acidic conditions at 50 °C, respectively, and were stable over broad pH (4-11) and temperature (4-40 °C) ranges. Both enzymes produced mainly dimers from colloidal chitin as a substrate. However, LIN0153 and LIN1996 could hydrolyze oligomeric substrates with processive exo- and nonprocessive endo-manner, respectively, and showed different reactivity toward oligomeric substrates. Thus, we identified two genes *(lin0153* and *lin1996)* encoding functional chitinases in *L. innocua*.

3353T

Protein A-mouse Chit1-V5-His expressed in *Escherichia coli* **possesses chitinase functions comparable to CHO-expressed protein.**
M. Kimura[1], S. Wakita[1], K. Ishikawa[1], K. Sekine[1], S. Yoshikawa[1], A. Sato[1], K. Okawa[1], A. Kashimura[1], D. Yamanaka[2], N. Ohno[2], M. Sakaguchi[1], Y. Sugahara[1], F. Oyama[1]. 1) Department of Chemistry and Life Science, Kogakuin University, Hachioji, Tokyo, Japan; 2) Laboratory for Immunopharmacology of Microbial Products, School of Pharmacy, Tokyo University of Pharmacy and Life Sciences, Hachioji, Tokyo, Japan.

Chitinases hydrolyze the β-1-4 glycosidic bonds of chitin, which is a major structural component of fungi, crustaceans and insects. Although mammals do not produce chitin, they express two active chitinases, chitotriosidase (Chit1) and acidic mammalian chitinase (AMCase). Chit1 levels are 1000-fold-elevated in the plasma of patients with Gaucher disease, an autosomal recessive lysosomal storage disorder. Chit1 have been shown to be closely associated with another diseases such as chronic obstructive pulmonary disease, Alzheimer disease and cystic fibrosis. However, the contribution of Chit1 to the pathophysiology of these diseases and pathophysiological conditions remains to be determined. In this study, we first expressed mouse mature Chit1 fused with V5 and (His)6 tags at the C-terminus (Chit1-V5-His) in the cytoplasm of *Escherichia coli* and found that most of the expressed protein was insoluble. In contrast, Chit1 tagged with Protein A at the N-terminus and V5-His at the C-terminus, was expressed in the periplasmic space of *E. coli* as a soluble protein and successfully purified. We produced mouse Chit1 as a recombinant fusion of Protein A-Chit1-V5-His, which was comparable to CHO cells-expressed Chit1. By our technique, it is possible to produce large amounts of active recombinant enzyme to study its pathophysiological roles as well as for potential therapeutic testing.

3354F

Loss and recovery of chitinolytic activity by amino acid substitutions in human acidic mammalian chitinase. *K. Okawa, M. Ohno, A. Kashimura, Y. Kobayashi, M. Sakaguchi, Y. Sugahara, F. Oyama.* Department of Chemistry and Life Science, Kogakuin University, Hachioji, tokyo, Japan.

Acidic mammalian chitinase (CHIA,;AMCase) is implicated in asthma and other allergic inflammations. Human and mouse AMCase share 82% sequence identity and 86% sequence similarity. Despite these structural similarities, these two homologues significantly differ with respect to their enzymatic characters at enzymatic activities. Multiple AMCase variants have been identified based on single nucleotide polymorphisms (SNPs) in humans and associations of certain AMCase polymorphisms and haplotypes with bronchial asthma have been reported. We reported the chitinolytic activity of the recombinant human AMCase was significantly lower than that of the mouse counterpart. By creating mouse-human chimeric AMCase protein we found that the presence of the N-terminal region of human AMCase containing conserved active site residues reduced the enzymatic activity of the molecule. Knowledge on genetic regulation of chitinolytic activity of AMCase is very limited. Here we report that the AMCase activity can be manipulated by naturally occurring amino acid substitution encoded by SNPs in human AMCase. Amino acid substitutions encoded by SNPs at the N-terminal region in human AMCase had distinct effects on the chitinolytic activity and we were able to reactivate the human AMCase, which were conserved in the mouse homologue.

3355W

Inactivation of mouse AMCase by introducing amino acid substitutions encoded by single-nucleotide polymorphisms in human AMCase gene. *F. Oyama, K. Okawa, M. Ohno, A. Kashimura, Y. Kobayashi, M. Sakaguchi, Y. Sugahara.* Dept Chemistry and Life Science, Kogakuin Univ, Hachioji, Tokyo, Japan.

Acidic mammalian chitinase (AMCase) has attracted considerable attention due to its increased expression under specific pathological conditions. Elevated or reduced AMCase levels have been reported in numerous diseases such as asthma, allergic inflammation, ocular allergy, dry eye syndrome, stomach cancer, adenoid hypertrophy, conjunctivitis, neuromyelitis, gastritis or nasal polyp formation. However, the contribution of AMCase to the pathophysiology of these diseases remains to be determined. We have shown that the chitinolytic activity of the recombinant human AMCase was significantly lower than that of the mouse counterpart. It has been known that AMCase activity is altered by naturally occurring amino acid substitutions encoded by single-nucleotide polymorphisms (SNPs). In this study, we attempted to dissect the effect of amino acid substitutions on the chitinolytic activity of mouse AMCase. For abolition of the mouse AMCase activity, introduction of amino acid substitution associated with human SNPs was sufficient, indicating that the residue is essential for chitinolytic activity of the enzyme.

3356T

Gene expression analysis of mammalian chitinase transcripts in pig tissues. *E. Tabata, M. Ohno, M. Sakaguchi, F. Oyama.* Department of Chemistry and Life Science, Kogakuin University, Hachioji, Tokyo 192-0015, Japan.

Chitin is the second abundant polysaccharide in nature. It is an integral component of the fungal cell walls, the exoskeletons of crustaceans and insects, and the microfilarial sheaths of parasites. Although mammals do not produce chitin and its synthase, genes encoding chitotriosidase (Chit1) and acidic mammalian chitinase (AMCase) and their translation products have been found in both human and mouse. Chit1 levels are elevated in the plasma of Gaucher disease and the bronchoalveolar lavage fluid of smokers with chronic obstructive pulmonary disease (COPD). AMCase expression and activity is upregulated in allergic airway responses in mouse models of asthma. However, the expression levels of chitinases in the other mammals have remained unknown. Pig has been known as a biomedical model due to its similarities to human in physiologically and anatomically which can bridge the gaps between mouse and human. Here, we quantified expression levels of the chitinases and reference genes in pig tissues on the same scale using quantitative real-time RT-PCR system. Both chitinases were expressed in all pig tissues. AMCase mRNA was predominantly expressed in stomach. Chit1 mRNA was also highly expressed in eyes and liver, but their expression levels were lower than the levels of AMCase. Our study suggests that AMCase functions as a digestive enzyme that breaks down chitin and as a part of the host defense against chitin-containing pathogens in pig stomach tissues.

3357F

Functional analysis of acidic mammalian chitinase under physiological conditions. *S. Wakita, M. Kimura, A. Kashimura, M. Sakaguchi, Y. Sugahara, F. Oyama.* Department of Chemistry and Life Science, Kogakuin University, Hachioji, Tokyo, Japan.

Chitin is the second abundant polysaccharide in nature. It is an integral component of the fungal cell walls, the exoskeletons of crustaceans and insects, and the microfilarial sheaths of parasites. Chitinases are glycosidases that break down glycosidic bonds in chitin. Although mammals do not produce chitin, mice and humans express two active chitinases, chitotriosidase and acidic mammalian chitinase (AMCase). AMCase has attracted considerable attention due to its increased expression under certain pathological conditions related to immune response, for example in an induced asthma mouse model and antigen-induced mouse models of allergic lung inflammation. Furthermore, AMCase has been shown to be involved in eye and stomach diseases. Recently, we reported that AMCase mRNA is synthesized in the mouse stomach at exceptionally high levels, comparable to pepsinogen, suggesting a digestive role of AMCase. Here we performed an extensive analysis of chitin degradation by AMCase not only in strong acidic, but also weak acidic to neutral conditions followed by fluorophore-assisted carbohydrate electrophoresis (FACE), a method based on labeling the reducing ends of oligosaccharides with a fluorophore. We found that AMCase generates $(GlcNAc)_2$ at broad pH range of 2.0~8.0 as well as increasing amount of $(GlcNAc)_3$ with higher pH.

3358W

Systematic characterization of VNTR polymorphisms using deep whole genomes and comprehensive phenotype profiles of 2,255 Estonians. *T. Esko[1,2], M. Kals[3], T. Puurand[4], Estonian Biobank[1].* 1) Estonian Genome Center, University of Tartu, Estonia; 2) Broad Institute, Cambridge, US; 3) Institute of Mathematics and Statistics, University of Tartu, Estonia; 4) Institute of Molecular and Cell Biology, University of Tartu.

Human genome has been systematically characterized since early 2000s but the focus has mainly been on single nucleotide variation (SNV) while the structural variation (like copy number variation) have been less studied. Last year a comprehensive characterization of 1000 Genomes sample for tens of millions of structural variants, but so far systematic studies on tandem repeats, like STRs (short tandem repeats) and VNTRs (variable number tandem repeats), have not yet performed. While VNTRs where one of the first DNA variants to perform locus mapping and they are still widely used in forensics, their role in health and disease is still unknown due to the availability of deep sequenced whole genomes. We have used deep whole-genome sequences (coverage of 30x, Illumina X10PCRfree technology) of 2,255 individuals from Estonian Biobank cohort to systematically study VNTRs. We called the structural variants by k-mer methodology, where the BAM files are indexed for a list of sequence combination for oligomer of 25 nucleotides. We next downloaded all known tandem repeat sequences (N:230,306) from *Tandem Repeat Finder database*. After that we systematically inquired our indexed BAM files and counted the total number sequence combinations for each individual, while estimating the approximate copy number form from the average sequencing depth (enabled by *PCRfree* highly even coverage across the genome). In summary, we identified 68,318 VNTRs which had a repeating element longer than 24bp. On average, the number of repeats per VNTR was 15, while maximum was 3,500 repeats. We validated our approach through Sanger sequencing for several VNTR classes (repeat count accuracy above 75%). Next, we used our Estonian Biobank WGS cohort, which has available comprehensively set of omics profiles (including RNAseq, methylation, MS-LC and NMR metabolomics and a wide set of clinical labs, like example blood cell counts) to systematically estimate the downstream effects of long VNTR polymorphisms on biological processes and cellular pathways. As an example, we identified 240 robust cis-eQTLs for 110 genes from RNAseq from blood (N:566), the strongest eQTL explaining up to 36% of phenotypic variation (*DDT* gene). Further analysis where conducted using electronic health records. In conclusion, we have developed a novel computational framework to call VNTR polymorphisms and through systematic analysis within a phenotypically rich sample have demonstrated a wide range of phenotypic consequences.

3359T

Analysis of nonsense-mediated mRNA decay (NMD) using genomic and transcriptomic data. *K. Inui[1,2], M. Suyama[1].* 1) Division of Bioinformatics, Medical Institute of Bioregulation, Kyushu University, Japan; 2) Division of Bioinformatics, Systems Life Sciences, Kyushu University, Japan.

;Nonsense-mediated mRNA decay (NMD) is a surveillance mechanism that degrades mRNAs with premature stop codon to avoid production and accumulation of truncated proteins. Although the mechanism is mainly studied in detail for each gene under specific experimental conditions, there is little analysis focusing on how it works in genome-wide scale in normal individuals. With the progress of personal genomics and the associated transcriptome analysis, now it is possible to analyze NMD in genome-wide scale. ;In this study, we used the data from genomic and the corresponding transcriptomic data from the same individuals (n = 445). First, we counted how many heterozygous stop-gain mutations are occurred in these individuals. On average, a person has about 4 such mutations. The number is comparable to the frequency of nonsense mutations in other studies, such as those reported in many exome analyses. Then we analyzed the corresponding transcriptomic data for the peripheral blood of the same individuals to see if NMD could be observed as allelic imbalance in gene expression, because the transcript from the allele with premature stop codon must be selectively degraded by NMD. Indeed, we observed such allelic imbalance in the expression of the transcripts at the loci with heterozygous stop-gain mutations comparing to those with heterozygous synonymous mutations as a control. We further analyzed positional effect of the premature stop codons on the strength of NMD. As expected, transcripts with premature stop codons in the same exon as the original stop codon and those located close to the last exon junction escape from NMD, which is already reported in many cases. This supports that the observed allelic imbalance can be a real signal for NMD. Interestingly, we found that the transcripts with premature stop codons in the same exon as the translation initiation codon also escape from NMD. These and some additional results obtained from the genome-wide studies of NMD will be presented.

A systematic analysis of mobile elements' contribution to human transcriptomes. *P. Liang, A. Joshi, W. Tang.* Department of Biological Sciences, Brock University, St. Catharines, Ontario, Canada.

Mobile element insertions (MEIs) are a major component of the genome for most higher eukaryotic organisms. In the human genome, MEIs, consist of mainly LINE 1 elements (L1), Alus, SVAs, and endogenous retrovirus (ERVs), and together all MEIs contribute to more than 50% of the genome sequences with over four million copies. MEIs are known to play important roles in genome evolution and gene function through a plethora of mechanisms. In particular, MEIs are known to participate and regulate the transcriptomes via alternation of gene expression and RNA splicing, as well as direct participation in transcriptome. In this study, we performed a systematic analysis of the MEI's participation in human transcriptomes by utilizing the most updated genome sequences and annotation data. Overall, a total of 2,090,354 MEIs (42.8% of all MEIs) locate inside or in the proximity of 44,455 genes/transcripts. While most locate in the introns, 128,761 directly participated in the exons 12,493 protein-coding genes, and 80,070 contributed to 26,984 non-coding transcripts. These MEIs cover all major types of MEIs with Alu/MIR, L1/L2, ERV, hAT-Charlie/TcMar-Tigger/hAT-Tip100/TcMar-Mariner being the major contributors. MEIs also contributed to miRNA target sites for 1,921 miRNAs in 7,183 genes. Among the above, 6,800 MEIs participated in the coding regions (CDS) for 4,768 genes. While Alu and L1 are also the major contributors as in the case for all exons, SVAs seems to have a much higher ratio (at least 5 times higher than other MEI types) for participating in CDS, but not in the untranslated regions. Seven of these MEI-CDS are contributed by MEIs uniquely found in humans, limited only to members from SVA and L1HS and all contributing to rare alternative splice forms, perhaps also gene splitting in two cases. Six of these 7 genes have variations associated with various diseases.   In summary, our results demonstrate that mobile elements have made significant contributions to human transcriptomes via participation in protein coding, alternative splicing, mRNA regulation, and non-coding regulatory RNAs. With most of these events occurring in a lineage- and species-specific fashion, they are partially responsible for primate- and human-specific phenotypes.

Potential use of *de novo* **CNVs as biomarkers for parental exposure to low doses of ionizing radiation.** *E.O.A. Costa[1,2,6], I.P. Pinto[2,3], M.W. Gonçalves[2], A.S. da Cruz[1,2], C.C. da Silva[1,2,3,4,5], R.W. Pereira[6], A.D. da Cruz[1,2,3,4].* 1) Pontifical Catholic University of Goias, Genetics Master's Program, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 2) Pontifical Catholic University of Goias, Department of Biology, Replicon Research Group, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 3) Federal University of Goias, Biotechnology and Biodiversity PhD Program, Rede Centro Oeste de Pós-Graduação, Pesquisa e Inovação, Campus Samambaia, Goiânia, GO, Brazil; 4) Human Cytogenetics and Molecular Genetics Laboratory, Secretary of Goias State for Public Health, Goiânia, GO, Brazil; 5) State University of Goias, UnU Goiania Eseffego, Goiânia, Goiás, Brazil; 6) Catholic University of Brasilia, Genomic Sciences and Biotechnology PhD Program, SGAN, 916 Norte, Módulo B, Avenida W5, Bloco C, Sala 205, Brasília, DF, Brazil.

The radiological accident in Goiania in 1987 caused a trail of human contamination, animal, plant and environmental by a radionuclide. The mutagenic effects of ionizing radiation (IR) on the germ cell line are of particular concern because it can persist for generations, leading to the accumulation of additional mutations in the progeny of exposed parents. Recently it was established that Chromosomal Microarray Analysis (CMA) is an important tool for detecting wide spectra of deletions or duplications in the human genome. Using CMA is possible to detect genetic changes in critical regions of the chromosomes, usually not detected with traditional cytogenetic markers. The aim of this study was to establish the frequency of *de novo* CNVs to be used as a germline mutation marker, which could be applied to increase the knowledge on the biological effects of human exposure to ionizing radiation. The exposed group consisted of 12 families with at least one parent directly exposed to ionizing radiation of Caesium-137. A total of 40 subjects were included in this study: 12 parents and 16 offspring that were conceived and born after the accident. All exposed parents had an absorbed dose of ≤0,2 Gy. A group of 8 non-exposed families from Goiânia population was used as controls. The statistical test applied was the Mann-Whitney U. The analysis were performed using the statistical software SPSS 21.0 with a significance level of 5% (p <0.05). The frequencies of CNVs were estimated for loss/generation, gain/generation, and burden/generation, representing 2.2×10^{-5}, 1.0×10^{-5}, and 3.2×10^{-5}, respectively, for the exposed group. For the control population, the frequencies were 1.5×10^{-5}, 6.2×10^{-5}, and 2.2×10^{-5}, respectively. Thus, the frequencies of CNVs showed statistically significant differences between the exposed and control groups for microdeletions ($p < 10^{-3}$, Mann-Whitney U). For microduplications there was no statistically significant difference (p=0,76). Thus, our preliminary data showed that CNVs are induced by low-dose of IR exposure in a human population, while losses were more frequent than gains within the exposed group. Moreover, the progeny of a population accidentally exposed to very low-doses of IR showed ~1.5x more *de novo* CNVs than non-exposed controls. In conclusion, the frequency of germline mutation/generation in CNV is useful to retrospectively study human populations exposed to IR.

3362T

Lower human germline mutation rate in a proband born to accidentally exposed parents. *A.D. da Cruz[1,2,3,4,6], E.O.A Costa[1,2,6], I.P. Pinto[2,3], M.W. Gonçalves[2], A.S. da Cruz[1,2], C.C. da Silva[1,2,3,4,5], R.W. Pereira[6].* 1) Pontifical Catholic University of Goias, Genetics Master's Program, Rua 235, n. 40, Bloco L, Área IV Setor Universitário, Goiânia, GO, Brazil; 2) Pontifical Catholic University of Goiás, Department of Biology, Replicon Research Group; 3) Federal University of Goias, Biotechnology and Biodiversity PhD Program, Rede Centro Oeste de Pós-Graduação, Pesquisa e Inovação, Campus Samambaia, Goiânia, GO, Brazil; 4) Human Cytogenetics and Molecular Genetics Laboratory, Secretary of Goiás State for Public Health, Goiânia, GO, Brazil; 5) State University of Goiás, UnU Goiania-Esefego, Goiânia, Goiás, Brazil; 6) Catholic University of Brasilia, Genomic Sciences and Biotechnology Graduate Program.

In Goiânia-Brazil, an accident caused human and environmental contamination by Cesium-137. Exposure to IR results in DNA damage, from modified nucleotides to DSB. In this study, we report the results of Chromosomal Microarray (CMA) of a 20yo born to parents accidentally exposed to IR, with absorbed doses (AD) of ≤0,2Gy. The proband's findings were compared to a control group of 8 children from Goiânia whose parents had no history of exposure. At the conception, mother's age was 26yo and father's 24yo. Conception occurred one month after parental exposure. CMA was performed using CytoScan HD. Filters for gain and loss were set at 15 and 8 SNP markers, respectively. *de novo* CNVs were considered if the average marker distance was ≤2.000 kb and size of ³1kb. We identified 10 CNVs, ranging from 1 to 15kb, including 9 deletions and 1 duplication in the proband. In the control population, we observed 238 CNVs, 14 duplications and 224 deletions, with an average of ~30 CNVs/child ranging from 1 to 140 kb. In both proband and controls, deletions were more frequent than duplications. Germline mutation rate of CNVs in the proband was 3.5×10^{-6} while the control group was 2.2×10^{-5}; in the proband, mutation burden showed 6.3x lower than controls. As the parents incurred whole-body exposure, it's possible that germline cells suffered severe DNA damage. It has been estimated that for every 1Gy, 1000 SSB and 40 DSB are produced. DNA damage may have triggered *in vivo* adaptive response, which is known to remains effective *in vivo* for 3 cell cycles in human lymphocytes. DNA repair in gonadal tissues, within the month prior to conception, could be the reason behind the generation of gametes with lower *de novo* mutations, lowering the rate in F1. Human genomic instability (GI) following RI exposure depends on AD, type of irradiated tissue, and cellular genotype. Our results suggest caution in reaching generalized conclusions related with human exposure to low doses of IR. Whether there is a linear or exponential dose response and whether there is a discrete threshold, below which biological consequences are uncommon, remain unanswered. Similarly, we are uncertain of the extent to which factors as LET, dose rate and bystander effect affect the outcome of exposure. Essentially, the extent of human germline mutations arising from exposure to ionizing radiation remains a critical scientific issue and the mechanisms underlying the phenomenon of transgenerational GI remain unresolved.

3363F

Spatial organization of topologically associated domains in individual chromosomes. *S. Wang[1,2], J. Su[1,3], B. Beliveau[4], B. Bintu[1,5], J. Moffitt[1,2], C. Wu[4], X. Zhuang[1,2,5].* 1) Howard Hughes Medical Institute, Cambridge, MA; 2) Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA; 3) Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA; 4) Department of Genetics, Harvard Medical School, Boston, MA; 5) Department of Physics, Harvard University, Cambridge MA.

The spatial organization of chromatin critically impacts genome function. Recent high-throughput chromosome-conformation-capture studies have revealed topologically associated domains (TADs) as a conserved feature of chromatin organization. How TADs are spatially organized in individual chromosomes remains, however, largely unknown. Here we developed an imaging method to directly map the spatial positions of numerous genomic regions along individual chromosomes inside the nucleus and used this method to trace the positions of TADs in four human interphase chromosomes. We observed that chromosome folding deviated from the ideal fractal-globule model at large length scales. Our single-chromosome images revealed that TADs were spatially organized into two physical compartments that were positioned in a highly polarized fashion in individual chromosomes. Moreover, we observed that active and inactive X chromosomes differed from each other and from autosomes in terms of folding and compartmentalization, suggesting that the spatial organization of TADs can be changed in response to regulation.

Discovery of widespread inherited fusion genes in human populations.
C. Bandlamudi[1,2], V.K. Dhiman[1], B.E. Stranger[1,3], K.P. White[1,2,4,5]. 1) Institute for Genomics & Systems Biology; 2) Committee on Genetics, Genomics & Systems Biology; 3) Department of Medicine; 4) Department of Human Genetics; 5) Department of Ecology and Evolution, University of Chicago, Chicago, IL.

   Recent studies have highlighted the extensive genetic diversity contributed by structural variation (SV) in the human genome. However, the prevalence and contribution of fusion genes, a consequence of SVs, to the genetic variation among humans remains largely unknown. Here, we analyzed more than 9,000 transcriptomes from 524 individuals in the Genotype Tissue Expression project (GTEx) to identify fusion genes in healthy individuals. A median of 15 tissue transcriptomes per individual allowed us to control for various splicing artifacts that typically confound fusion discovery from RNA-seq. We identified 64 fusion genes (59 novel) segregating at overall frequencies ranging from 0.2% (singleton) to 42%. Using whole genome sequencing (WGS) based SV analysis and genomic PCR we show a validation rate of at least 88%. We show that 70% of the fusion genes identified in GTEx are also detected in at least one individual in the TCGA (n=9,360) and HapMap (n=451) cohorts suggesting that substantial proportion of them are inherited rather than de novo. 7/12 fusion genes recurrent in GTEx showed statistically significant difference is fusion frequencies between different populations within multiple cohorts. We are currently investigating if these regions show signals of recent selection. Functional consequences of these events are hard to elucidate. However, using gene expression quantifications, we identified twenty fusion genes that resulted in ectopic expression of the downstream partner gene in at least a median of 3.5 tissues in which the downstream partner gene is typically not expressed. For example, the fusion, TFG-GPR128 (2.4% frequency), resulted in ubiquitous expression of the G-protein coupled receptor domain of highly tissue-specific GPR128 gene. In another example, in one individual, we find the UTR-5 of CASP4 (Caspase 4) fused to the entire protein coding region of CARD18 (Caspase-1 inhibitor) resulting in potential deregulation of caspase pathways due to the production of caspase-1 inhibitor instead of caspase-4. Our findings, for the first time, demonstrate the pervasiveness of fusion genes in human populations and highlight their potential contribution to phenotypic variation.

3365T

Effect of natural variation in copy number on epigenetic patterning and gene expression.
J. Yu, C. Li, S. Iyengar. Department of Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, OH.

   Purpose. Copy number variation (CNV), the most common type of structural variation, has been associated with many human diseases, but its role in disease pathogenesis is unclear. We hypothesized that CNVs alter gene expression through differences in histone modification patterning and performed a systematic evaluation of *cis* relationships between CNVs and histone marks in two embryonic cell lines, H1 and H9. **Methods**. CNV calls for H1 and H9 were obtained either from ENCODE or with PennCNV on SNP array data from GEO. Only CNV calls confirmed from others sources are kept for analysis. Profiles of 26 consolidated histone marks were obtained from the Roadmap Epigenomics Project for the two cell lines. RNAseq data were obtained from GEO. To evaluate the effect of CNV presence/absence on histone modification, we **1)** compared histone mark intensity between H1 vs. H9 at CNV regions while adjusting for DNase intensity and peak region GC content; **2)** compared the number of histone mark peaks in specific CNV regions in H1 vs. H9, in relation to the rest of the genome; **3)** evaluated the effect of CNVs on the expression of genes that overlap with a CNV region. **Results. 1)** For 13 out of 26 marks, CNVs were significantly associated with the number of peaks after Bonferroni correction. Three of the marks, H2BK120ac (shown to be enriched in transcription start sites and gene bodies), H2BK20ac (shown to be enriched in transcription start sites and gene bodies), and H3K18ac, had decreased number of peaks in duplication regions, while the other 10 had increased number of peaks. Interestingly, among these significantly associated marks, H2BK120ac, H2BK20ac, H3K18ac, H3K14ac, H3K14ac, H3K4me1, and H4K20me1 were significantly associated with decreased peak intensity, suggesting a balancing act to counter duplication. **2)** No significant effect of CNVs on gene expression was identified. **3)** We observed that expression of some gene families was completely shut down, including the olfactory receptor family and defensins. Olfactory receptors are known to be epigenetically regulated. The duplication CNV straddled defensins on chromosome 20 is also a known copy variation region. **Conclusion.** Our study suggested that histone marks significantly associated with CNVs might influence gene expression through changing the number and/or intensity of histone mark peaks, and help counter-balance any effect of CNVs on gene expression.

3366F

Temporal analysis of hippocampal gene networks identifies transcriptional modules related to epileptogenesis in a rat model of febrile seizures. *H. Azevedo, N. Khaled, P. Santos, F.B. Bertonha, C.A. Moreira-Filho.* Pediatrics, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil.

   The incidence of febrile seizures (FS) during childhood constitutes as a relevant risk factor for the onset of epilepsy, although the molecular alterations induced by FS in the brain remain largely unknown. Experimental hyperthermia-induced seizures have been used in animal models to investigate the consequences of FS, as these animals show histological, behavioral and brain hyperexcitability changes after the initial seizures. The present study aimed at investigating temporal changes in hippocampal gene co-expression networks during the development of rats submitted to hyperthermia-induced seizures. Total RNA was obtained from the ventral hippocampal CA3 region of Wistar rats at four time points after hyperthermic-induced seizures and then subjected to oligonucleotide microarray profiling. A weighted gene co-expression network analysis was applied to investigate modules of co-expressed genes, since these genes may be associated to common biological functions. This analysis consisted of constructing gene co-expression networks, identifying network modules and hubs, performing gene-trait correlations and examining intramodular connectivity changes. The most relevant co-expression modules were then functionally enriched to identify molecular pathways and functions associated to hyperthermic seizures. The results overall showed that after experimental FS the brain undergoes molecular changes linked to developmental pathways, such as those regulated by Wnt, Notch, Hippo and MAP kinases. Interestingly, modules of co-expressed genes related to neurogenesis, neuronal differentiation, axonogenesis and synaptic transmission were activated as early as one day after the hyperthermia episode. Moreover, the appearance of immune-related modules indicates that pro-convulsant events can lead glial cells to release pro-inflammatory mediators, initiating a cascade of events that contribute to the development of seizures. In line with these evidences, gene expression alterations in ion channels and solute carrier transporters suggest that ion imbalance in the neural tissue may also play a role for neuronal hyperexcitability. Therefore, it is possible conclude that hyperthermic seizures induce an intense tissue and synaptic remodeling process that could turn the brain prone to epileptic activity.

3367W

***ATM* heterozygous mutations underlying individual differences in radiosensitivity in human populations.** *S. Matsuura[1], E. Royba[1], T. Miyamoto[1], S.N. Akutsu[1], T. Yamamoto[2], Y. Kudo[3], S. Tashiro[4].* 1) Genetics and Cell Biology, RIRBM, Hiroshima University, Hiroshima, Japan; 2) Department of Mathematics and Life Science, Graduate School of Science, Hiroshima University, Higashi-Hiroshima 739-8530, Japan; 3) Department of Obstetrics and Gynecology, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima 734-8551, Japan; 4) Department of Cellular Biology, Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima 734-8553, Japan.

   Ionizing radiation (IR) induces DNA double strand breaks (DSBs), which are an initial step for chromosomal aberrations and cell death to cause acute and/or chronic radiation syndrome. In human cells, DNA repair system recognizes and rejoins DSBs to maintain genomic stability and protect against IR-induced carcinogenesis. It has been suggested that the individual differences in radiosensitivity exist in human populations, and that the nucleotide variants on DNA repair genes might be the genetic determinant for the individual differences. Germline mutations of the *ATM* gene, which encodes a master kinase in DNA damage response, cause a radiation hypersensitive autosomal-recessive disorder Ataxia-Telangiectasia (A-T [MIM 607585]) characterized by neurodegeneration and cancer predisposition. A-T heterozygous carriers exist at around 1 % in human populations and have been suggested to show a high risk of cancer. It is therefore important for radiological protection whether A-T heterozygous carriers are indeed radiosensitive or not. Here we used CRIS-ObRiGaRe (Obligate Ligation-Gated Recombination) method combined CRISPR/Cas9 system with non-homologous end joining (NHEJ)-mediated knock-in technique to generate *ATM* +/- human cultured cell clones in order to evaluate the effect of *ATM* heterozygous mutations on radiosensitivity, independently of the diverse genetic background and confounding factors such as smoking. We also demonstrated that IR-induced micronucleus formation, which is derived from unrepaired DSB-induced chromosomal fragments, in *ATM* +/- cells is enhanced more than that in *ATM* +/+ cells. Taken together, *ATM* gene variants are indeed involved in individual differences in radiosensitivity in human populations.

3368T

Conserved and tissue-specific effects of natural genetic variation on transcript and protein abundance. *S. Munger[1], J. Chick[2], P. Simecek[1], K. Choi[1], E. Huttlin[2], D. Gatti[1], S. Gygi[2], R. Korstanje[1], G. Churchill[1].* 1) The Jackson Laboratory, Bar Harbor, ME; 2) Harvard Medical School, Boston, MA.

Genetic variation can influence protein expression through transcriptional and post-transcriptional mechanisms, and these effects may be conserved across tissues or specific to one. To characterize the shared and tissue-specific effects of natural genetic diversity on the proteome, we combined RNA-seq and multiplexed, quantitative mass spectrometry with a genetically diverse mouse population, the Diversity Outbred (DO) heterogeneous stock. We measured genome-wide transcript and protein abundance in livers and kidneys from 192 DO mice, and mapped quantitative trait loci that influenced transcript (eQTL) and protein (pQTL) expression. We identified nearly 3,000 pQTL in each of the liver and kidney, divided equally between local and distant variants. Local pQTL generally had larger effects on protein abundance, these effects were conferred primarily through transcriptional mechanisms, and half showed conserved protein responses in both tissues. In contrast, distant pQTL influenced protein abundance nearly exclusively through post-transcriptional mechanisms and most were specific to the liver or kidney. We applied mediation analysis and identified a second protein or transcript as the causal mediator for half of the significant distant pQTL. Furthermore, we identified groups of proteins within known pathways that shared coincident subthreshold distant pQTL for which we could identify a single causal protein intermediate from the same pathway, demonstrating the power of integrating ontology and mediation analyses to tease out subtle but real genetic effects from mapping populations with modest sample sizes. Overall, our analysis revealed extensive tissue-specific networks of direct protein-to-protein interactions that act to achieve stoichiometric balance of functionally related enzymes and subunits of multimeric complexes.

Improved mate-pair sequencing for enhancement of re-sequencing pipeline for improve detection of structural variations in genomes. *S. Lok, S. Walker, S.W. Scherer.* The Hospital for Sick Children, Toronto, Canada.

Whole genome sequencing as it is commonly practiced is actually "re-sequencing", in which next generation DNA sequence reads from a query genome are mapped onto a reference genome and the differences tabulated. Reads unique to the sample, including many variants such as insertions, deletions, translocations, and copy number alterations are typically discarded because they cannot be mapped due to significant differences from the reference genome. To capture a more complete repertoire of genomic variants contributing to disease, there must a greater reliance on personalized genome sequencing (also known as *de novo* sequencing), in which the individual's genome is reconstructed from their own data alone. Currently, the cost of *de novo* sequencing for large patient cohorts is prohibitively expensive and will likely remain so for the foreseeable future. Here we describe the development, use and performance metrics of a new improved chimera-free mate-pair sequencing technology that can be easily integrated into the present re-sequencing pipelines in a cost effective manner. This offers an interim solution to enhance the detection of structural variations until the advent of *de novo* assembly methods appropriate for use in large cohorts. Unique DNA barcode identifiers attached to the ends of individual size-selected target DNAs enable the unambiguous discrimination of true mate-pairs created by intra-molecular ligation from unwanted chimeric mate-pairs created by random inter-molecular ligation during library construction. This simple but powerful step eliminates the major impediment of previous generations of mate-pair sequencing. Using HuRef DNA, we provide sensitivity and specificity benchmarks for INDEL detection, particularly in the 100 to 10,000 bp size range that are under-reported using standard re-sequencing methods. We are also applying this approach in families with autism spectrum disorder presumed to carry mutations, which are still yet to be identified.   .

3370W

Homolog paring: Some speculations and some super-resolution imaging. *T. Wu[1], R.B. McCole[1], J. Erceg[1], G. Nir[1], J. AlHaj Abed[1], B.J. Beliveau[2], H. Sasaki[2], M. Hannan[1], P. Yin[2,3], E.F. Joyce[1,4].* 1) Genetics, Harvard Medical School, Boston, MA; 2) Wyss Institute for Biologically Inspired Engineering, Harvard University, Boston, MA; 3) Department of Systems Biology, Harvard Medical School, Boston, MA; 4) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Homolog paring: Some speculations and some super-resolution imaging Conventional wisdom argues that organisms are diploid because "two is better than one": should a chromosome or gene suffer damage, then the homolog of that chromosome or gene will compensate for the loss. The situation with diploidy may be more complex, however. We suspect this because genomes have evolved elaborate mechanisms by which they address homology and, in contradiction to the purported "two is better than one", several such mechanisms cause one of the homologs to be silenced. The silencing can be predetermined, such as in imprinting, or random, such as with random monoallelism and X-inactivation. Either way, it seems that homologs may coordinate their decisions. One way in which somatic homologs communicate may be through direct contact via homolog pairing. Although once thought to be the exclusive property of Drosophila, somatic pairing is now considered a potential feature of many organisms, including humans. Here, we pull from observations of a wide variety of phenomena, including published studies of mutation rates as well as our own work on sequence ultraconservation and homolog pairing and speculate that the state of inter-homolog interactions may reflect a balance of pairing and anti-pairing forces and that the function of pairing may extend far beyond the adage of "an heir and a spare". This presentation will also summarize our most recent work exploring homolog pairing and nuclear organization, in general, using Oligopaints and two methods we have developed for single-molecule super-resolution imaging, called OligoSTORM and OligoDNA-PAINT. This work was supported by awards from the NIH (to CtW, PY, EFJ), NSF (PY), Wyss Institute (PY), W,R. Hearst Fund (RBM), EMBO (JE), and Damon Runyon Foundation (BJB).

Validation of mutations in iPS cells using droplet digital PCR. *T. Takahashi, M. Nomura, F. Kitaoka, J. Kuwahara, S. Yamanaka, N. Takasu, N. Amano.* Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan.

In order to ensure safety of induced pluripotent stem (iPS) cells and differentiated cells, it is important to check mutations such as single nucleotide variations (SNVs), insertion-deletions (Indels) and copy number variations (CNVs). In our pipeline, SNV/Indels and CNVs are detected using whole genome sequencing, exome sequencing and SNP array. To validate mutation candidates, we use amplicon sequencing. To validate the results of amplicon sequencings further, we used ddPCR in the following two cases. Firstly, once mutations were detected in iPS cells, we want to check whether the same mutations are also in original cells (e.g., fibroblast, peripheral blood mononuclear cell, and cord blood) or not. When we use amplicon sequencing, it is difficult to fix a threshold to remove false positives. To use ddPCR, we designed FAM fluorescent probe on the alternative genome and HEX fluorescent probe on the reference genome. Genomic DNA molecules were partitioned into 15,000 droplets and mutations were detected by the FAM fluorescent signals of each droplet. We successfully detected SNV/Indels (<0.1%) and CNVs in original cells. Secondly, we used ddPCR to distinguish homogeneous iPS cell clones having a specific mutation that were cultured from single cells in one well, and found that it worked well. In this study, one SNV on the X chromosome was checked in 5 clones. These clones were classified into two cases having a specific mutation or not. The ddPCR is a useful tool for validating SNV/Indels and CNVs in iPS cells and differentiated cells. In near future, we will apply ddPCR to validate the inversions and translocations.

Genome-wide context-dependent conservation in humans at nucleotide resolution. *J. di Iulio, E. Wong, I. Bartha, M. Hicks, J. Yu, J.C. Venter, A. Telenti.* Human Longevity Inc., San Diego, CA.

Two key challenges in the interpretation of human genome sequencing are (i) the large numbers of rare variants and (ii) the fact that the largest proportion of variation occurs in the non-protein coding regions of the genome. We used data from 10,545 deep-sequenced human genomes (mean 30X coverage) to define the probability of variation at any nucleotide position in the human genome before it is observed. This is achieved through the massive alignment of genomic elements from the pool of genomes in order to gain precision and power (number of elements x number of genomes) to estimate human variation probability with nucleotide resolution genome-wide. The model uses all possible heptamers and their variation rates to define regional conservation and diversity on the basis of departure from expectation (context-dependent conservation, CDC). CDC requires no a priori knowledge (such as genomic annotation, variation pathogenicity, etc) and is based solely on observed human variation. It complements other metrics (f.ex. CADD, eigen, DEAPsea) used for the identification of functional elements in the genome. The best prediction is achieved by combining all metrics (median AUC ROC=0.77); however it outperforms other metrics when used alone (median AUC ROC=0.74). We further tested whether non-coding functional loci would be identified on the basis of CDC scores. We describe a >30 fold enrichment in the 1st percentile of CDC scores for pathogenic ClinVar and HGMD variants annotated in non-protein coding regions. As proof of concept, the assessment of manually curated Mendelian-associated trait variants in non-protein coding regions (N=64) confirmed a strong enrichment in the first percentiles of the CDC scores (42% within the 1st percentile; 53% within 5th percentile). These results indicate that CDC scores used alone or in combination with the other existing metrics can reveal functional parts of the genome and support prediction of the pathogenicity of novel variants.

Assessing the concordance in the prediction of potential cis-regulatory loci from DNAse-seq and ATAC-seq data. *J. Peralta[1], J. Charlesworth[2], J. Blangero[1].* 1) South Texas Diabetes and Obesity Institute, University of Texas at the Rio Grande Valley; 2) Menzies Institute for Medical Research University of Tasmania, Tasmania, AU.

The relevance of non-coding variation for gene expression is difficult to assess. For coding variation the mechanisms of transcription and translation provide a clear path to the interpretation of its biological meaning. In the case of non-coding variation, the elements and mechanisms involved, such as promoters, enhancers, the local chromatin organization or transcription factor binding accessibility and affinity, are more diverse. This diversity increases the complexity of the problem and makes it difficult to establish a conceptual leap from non-coding variation to its biological relevance. One approach that we have been exploring to prioritize non-coding variation is to use a measure of the allele-specific open chromatin accessibility of non-coding heterozygous loci as a proxy of their potential for cis-regulating neighboring genes. Specifically, we use DNAse-I hypersensitivity sites (DHSs) as indicators of open chromatin to assess, within a variance component framework, the contribution to the variance in gene expression phenotypes of a covariance kernel derived from loci at allele-specific DHSs. We have previously applied this approach using DHSs from publicly available GM12878 lymphoblastoid cell line DNAse-seq data from the ENCODE Project, and found signals of potential cis-regulation for ten transcripts in our San Antonio Family Study (SAFS) cohort. Recently an improved method to detect open chromatin, ATAC-seq, has been developed. ATAC-seq is a faster protocol, requires significantly fewer cells, and takes a different approach to the detection of regions of open chromatin: it uses an engineered transposase that inserts the sequencing adapters directly into exposed DNA. We are now applying our method to the publicly available GM12878 ATAC-seq data to evaluate the concordance with our previous DNAse-seq based results.

3374T

Discovery of *de novo* **and rare Alu elements using mobile element scanning.** *J. Feusier, D.J. Witherspoon, W.S. Watkins, L.B. Jorde.* Human Genetics, University of Utah, Salt Lake City, UT.

   Alu elements compose 11% of the human genome, and they influence gene expression, chromosomal recombination, and disease pathogenesis. Identifying rare, polymorphic *Alu* elements will provide additional markers for human population analyses and forensic testing. Furthermore, determining the per-generation *Alu* retrotransposition rate is essential for understanding genomic evolution and as a baseline for somatic retrotransposition rates. However, rare, polymorphic *Alu* elements are difficult to analyze due to the large genomic copy number (~1.1 million elements), the repetitive sequence of the element, and the large sample sizes needed for detection of novel, low-frequency or *de novo* insertions. *Alu*Yb8/9 elements are young subfamilies that contribute ~30% of the recent polymorphic *Alu* retrotransposition events and contain a unique 7bp insertion that is absent in other *Alu* elements. Mobile element scanning (ME-Scan), developed by the authors, is a targeted, high-throughput method that pulls down *Alu* elements with the 7bp insertion prior to sequencing. Because there are only several thousand Yb8/9 copies, 24-sample libraries can be run on a single Illumina lane, making ME-Scan a cost-effective method for studying specific mobile elements in large cohorts of individuals. To identify novel *Alu*Yb8/9 elements, 41 CEPH pedigrees were sequenced using ME-Scan along with 216 individuals from various populations around the world ("population sample"). In the pedigrees, we performed PCR validation of 33 candidate *de novo Alu* insertions and discovered a single *de novo* element. This element was an exact match to the *Alu*Yb8 sequence and was located in an intronic region. Because Yb8/9 is only one active *Alu* subfamily, further sequencing of these pedigrees is required before we can accurately estimate the per-generation *Alu* retrotransposition rate. In the population sample, we discovered and validated 68 rare, polymorphic *Alu* elements by PCR and Sanger sequencing. Interestingly, we identified an *Alu*Yb8 sequence with 3 substitutions shared among 5 elements that has all of the hallmarks of an *Alu* subfamily, which we name *Alu*Yb8c3. We also found an additional ~600 novel, candidate *Alu* elements in the dataset. In conclusion, we identified the first non-disease causing *de novo Alu* insertion event, a new *Alu* subfamily, and identified novel polymorphic *Alu* elements for population analyses.

Widespread splicing of repetitive elements into mRNA coding regions. *S. Sabunciyan, M.M. Darby, J.T. Leek, B. Langmead, R.H. Yolken.* Johns Hopkins University, Baltimore, US.

   We characterized expression from individual repetitive element loci in the human brain using directional RNA sequencing data. Considering only sequencing reads that map uniquely onto the human genome, we discovered that the overwhelming majority of intronic and exonic repetitive element loci are expressed in the same orientation as the gene in which they reside. Further analysis revealed that repetitive element loci are extensively spliced into coding regions of gene transcripts yielding thousands of novel mRNA variants with altered coding potential. Lower frequency splicing of repetitive element loci into untranslated regions of gene transcripts was also observed. The same pattern of repetitive element loci splicing was detected in the brain tissue of all seven species we examined, ranging from humans to the fruit fly, and was also found in human blood. Repetitive element loci splicing with exons occurs largely at the canonical GT-AG splice junctions and is not restricted to a particular repetitive element class. This type of splicing usually gives rise to a minor splice variant and *in silico* analysis suggests that in certain cases repetitive element loci splicing may introduce a novel open reading frame. Reanalysis of sequencing data performed on polysome associated RNAs in the mouse cerebellum revealed that many repetitive element loci splice variants might be translated into proteins. Our results demonstrate that repetitive element loci expression is more complex than previously envisioned and raise the possibility that repetitive element loci splicing might generate functional protein isoforms.

Functional somatic mutations are negatively selected during reprogramming of induced pluripotent stem cells but positively selected during subsequent passaging. *M. D'Antonio[1], D.A. Jakubosky[2,3], W.W. Greenwald[4], M. Donovan[3], C. DeBoever[4], E.N. Smith[5], H. Matsui[6], A. Arias[1], H. Li[6], A. D'Antonio-Chronowska[1], K.A. Frazer[1,5,6].* 1) Division of Genome Information Sciences, University of California, San Diego, LA JOLLA, CA; 2) Biomedical Sciences Graduate Program, University of California, San Diego, LA JOLLA, CA; 3) Department of Biomedical Informatics, University of California, San Diego, La Jolla, CA; 4) Bioinformatics and Systems Biology, University of California San Diego, La Jolla, CA; 5) Department of Pediatrics and Rady Children's Hospital, University of California San Diego, La Jolla, CA; 6) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA.

To examine the functional effects of somatic mutations in iPSCs we conducted whole genome sequencing of 18 skin fibroblast-derived iPSCs and their matched blood DNA. We detected 46,612 somatic single nucleotide variants (SNVs), 2,776 small indels and 563 copy number variants (CNVs), ranging from 1 kb to 48 Mb. The number of SNVs and indels per sample is highly heterogeneous, ranging from 913 to 7,570 and is likely due to the presence of different numbers of somatic mutations in the cell of origin. Indeed, the eight samples with the highest number of mutations all harbor many CC-TT substitutions, which are known to be caused by UV damage and have been linked with melanoma. To investigate if CC-TT substitutions were under selection during iPSC reprogramming, we analyzed additional 255 blood and 19 skin fibroblast WGSs. These variants are strongly enriched in fibroblasts (335 CC-TT per sample, p-value = 8.7×10^{-11}) and iPSCs derived from fibroblasts (49, p = 4.8×10^{-11}), compared to blood (0.7), suggesting that the CC-TT substitution signature originates in skin fibroblasts. The fact that fibroblasts harbor more mutations than the iPSCs reprogrammed from fibroblasts indicates that fibroblasts with many CC-TT substitutions may be less likely to be successfully reprogrammed into iPSCs. To address functional differences between clonal (present in all cells in an iPSC line) and subclonal (present only in a fraction of the cells) SNVs, we investigated their associations with chromatin organization. By permuting the position of SNVs across the genome, we found that clonal SNVs are strongly enriched in quiescent chromatin (regions not associated with any ChIP-seq or DHS peaks, Z-score = 9.9) and heterochromatin (Z = 9.4), and depleted in enhancers (Z = -2.9), promoters (Z = -4.3) and transcribed regions (Z = -9.2). Conversely, subclonal SNVs are more likely to occur in promoters (Z = 0.5) and less likely in quiescent chromatin (Z = -2.6). These results show that clonal variants, which are likely derived from the cell of origin, tend to occur outside of functional regions, while subclonal mutations, which occur during passaging after reprogramming, are more likely to be present in active chromatin regions. Our data suggest that source tissue cells with high mutational burdens or with mutations that have phenotypic effects are less likely to be successfully reprogrammed; while mutations that arise shortly after reprogramming are likely to have functional effects.

3377T

Impact of 3D chromatin structure on cell type-specific gene expression in iPSC and iPSC-derived cardiomyocytes. *H. Li[1], A. Schmitt[2], P. Benaglio[3], E. Smith[3], N. Nariai[1], M. D'Antonio[1], H. Matsui[1], C. DeBoever[4], B. Ren[1,2], K. Frazer[1,3].* 1) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA; 2) Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA; 3) Department of Pediatrics, University of California, San Diego, La Jolla, CA; 4) Bioinformatics and Systems Biology, University of California, San Diego, La Jolla, CA.

The human genome is organized into 3D chromatin domains that play important regulatory roles in gene expression through long-range interactions. Recent studies have shown that large-scale topological structures are highly conserved across cell types; however, distinct chromatin contacts may exist between different cell types and drive cell type-specific gene expression. This has not yet been investigated due to the resolution of contact maps analyzed to date. In this study, we used high-depth Hi-C data to identify cell type-specific chromatin contacts in induced pluripotent stem cells (iPSCs) and iPSC-derived cardiomyocytes (iPSC-CMs), and determined if they are associated with cell type-specific gene expression. We assessed genome-wide chromatin interactions by performing high-depth Hi-C experiments using iPSC and iPSC-CM lines from 7 individuals. A total of 5.9 billion and 5.5 billion paired-end reads were generated for iPSCs and iPSC-CMs, respectively. Reads were aligned against human reference genome hg19 using BOWTIE2, followed by a stringent filtering process to remove abnormal chimeric pairs, self-ligations, and re-ligations. We built Hi-C contact maps at 10kb resolution, and assessed genome-wide differential contacts (DCs) using diffHic. We also conducted RNA-seq experiments on the same cell lines. A total of 16,217 genes passed quality control and were subjected to differential gene expression analysis using edgeR. We identified 3,762 DCs ($q<0.05$) and 6,101 differentially expressed (DE) genes ($q<0.01$, fold change>2) between iPSC and iPSC-CM. Of the 3,762 DCs, 1,277 (34%) had at least one anchor overlapping the transcription start site (TSS) of one of the 16,217 genes, and 792 (62% of 1,277) overlapped the TSS of one or more DE gene (in total 1,484 DE genes). By permuting the differential state of all 16,217 genes while maintaining the number of genes that were differentially expressed (6,101), we found that the TSS of DE genes were significantly enriched in the DCs ($p<1e-3$). Gene-set enrichment analysis showed that the 1,484 DE genes overlapping DC anchors share general gene ontology terms in common with the 4,617 DE genes that do not overlap DCs; but they are also uniquely enriched for cell-type specific terms including stem cell differentiation, embryonic morphogenesis, and cardiac septum development. These findings suggest higher-order chromatin structure plays an important role in the regulation of cell-type specific gene expression.

3378F

Insights into gene function and tolerance of homozygous variation in a highly endogamous population. *H.C. Martin[1], V.M. Narasimhan[1], K.A. Hunt[2], D. Mason[3], K.J. Karczewski[4], E.R. Maher[5], R.C. Trembath[6], D.G. MacArthur[4], J. Wright[3], J.C. Barrett[1], D.A. van Heel[2], R. Durbin[1].* 1) Wellcome Trust Sanger Institute, Hinxton, Cambridge, CB10 1SA, UK; 2) Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London E1 2AT, UK; 3) Bradford Institute for Health Research, Bradford Teaching Hospitals NHS Foundation Trust, Bradford BD9 6RJ, UK; 4) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA 02114, USA; 5) Department of Medical Genetics, University of Cambridge and NIHR Cambridge Biomedical Research Centre, Box 238, Cambridge Biomedical Campus, Cambridge CB2 0QQ, UK; 6) Faculty of Life Sciences and Medicine, King's College London, London SE1 1UL, UK.

   Individuals from populations with a high rate of consanguineous marriage are enriched for rare, homozygous loss-of-function (rhLOF) mutations that can be informative about gene function. We sequenced the exomes of 3222 healthy British Pakistanis from Birmingham and the Born in Bradford cohort, and discovered rhLOF mutations in 781 genes, a substantial enrichment compared to discovery rates in outbred populations. We observed a 13.7% depletion of homozygous knockout genotypes, implying selection against deleterious recessive variants. We also observed a smaller but significant depletion of homozygous missense variants predicted to be highly deleterious by CADD. These data allow us to look at the tolerance of particular gene sets to homozygous variation, in a way that is not possible in large outbred cohorts. For example, in known developmental disorder genes that typically act in a dominant loss-of-function manner, we see a significant depletion of missense variation in autozygous regions (p = 0.0002), suggesting an alternative mode of pathogenicity. We found individual gene knockouts significantly associated with lipid and glycaemic traits, which we are currently seeking to replicate in a larger cohort. If validated, these associations could point to potential new drug targets. Finally, we are expanding this study as part of the East London Genes and Health project. We aim ultimately to exome-sequence 25,000 healthy British South Asian adults (enriched for consanguinity) with linked electronic health records. Pilot data on 535 individuals reveals a mean autozygosity of 4.5%, which we expect to increase in future sample selection. Additionally, we are identifying individuals with high autozygosity in the UK Biobank for sequencing. Analysis of the existing Biobank data suggests we should expect a total of ~1,200/500,000 samples with at least 5% autozygosity. We will present preliminary results from these projects, which are expected to greatly expand the catalogue of human knockouts, shedding light on gene essentiality and function, and well as lending greater power to investigate the tolerance of specific gene sets and genic regions to particular types of homozygous variation.

3379W

Population survey of copy number variation in over 85,000 exomes and associations with serum lipids from electronic health records. *E.K. Maxwell[1], C. O'Dushlaine[1], J.S. Packer[1], S.E. McCarthy[1], C. Gonzaga-Jaregui[1], J. Staples[1], W.A. Faucett[2], J.B. Leader[2], I.B. Borecki[1], F.E. Dewey[1], Y.I. Chen[3], J.I. Rotter[3], J.C. Cohen[4], W.K. Chung[5], A.M. Muise[6], E.G. Baras[1], O. Gottesman[1], L. Habegger[1], J.G. Reid[1].* 1) Regeneron Genetics Center, Regeneron Pharmaceuticals, Tarrytown, NY; 2) Geisinger Health System, Danville, PA; 3) Los Angeles Biomedical Research Institute, Torrance, CA; 4) University of Texas Southwestern Medical Center, Dallas, TX; 5) Columbia University Medical Center, New York, NY; 6) Hospital for Sick Children, Toronto, Ontario; 7) The Clinic for Special Children, Strasburg, PA; 8) University of Connecticut Health Center, Farmington, CT; 9) ECOGENE-21, Chicoutimi, Québec.

   Copy-number variants (CNVs), a class of structural variation, are relatively underrepresented in genomic catalogs due to difficulties in their ascertainment. We recently developed CLAMMS - a versatile and scalable method that produces high quality exome CNV calls across the allele frequency spectrum and as small as a single exon. We applied CLAMMS to over 85,000 exomes sequenced at the Regeneron Genetics Center (RGC) from multiple collaborations. First, we present a survey of exonic CNVs in 50,726 exomes from the DiscovEHR Study and report associations between both common and rare CNVs and serum lipid traits, demonstrating the feasibility of integrating exome CNVs with EHRs to gain insights into disease. We highlight a novel familial hypercholesterolemia-causing tandem duplication in *LDLR* identified in 29 individuals associated with high LDL cholesterol and coronary artery disease, report on a rare complex structural variant surrounding *HMGCR* (a ~1.5 Mb tandem duplication with a nested ~600 Kb deletion), and show a common *LILRA3* microdeletion that associates with increases in HDL cholesterol and is linked to a previously identified upstream intergenic GWAS hit. We also survey the prevalence of known CNVs in our population, showing that *PMP22* duplications and deletions occur at relatively equal rates, suggesting the deletion is under-diagnosed. Second, we expand our CNV survey to a diverse set of over 85,000 samples, providing a broad view of CNV allele frequencies across populations. We highlight CNVs that show differences in prevalence among populations of distinct ancestry, including *LILRA3* microdeletions in East Asians and duplications in the keratin gene *KRT34* in Africans. We demonstrate that CNV-based principal components analysis can stratify individuals by ancestry concordantly with SNP-based analyses.

3380T

Features of *Alu/Alu* mediated genomic rearrangement. *X. Song[1], C. Beck[1], I. Campbell[1], Z. Coban-Akdemir[1], S. Gu[1], P. Boone[1], C. Shaw[1], J. Lupski[1,2,3].* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 3) Texas Children's Hospital, Houston, TX.

Alu elements belong to a subfamily of short interspersed nuclear elements (SINEs), comprise ~11% of the human genome, and are often found at the breakpoints of genomic rearrangements. Previously, the involvement of repetitive elements in genomic rearrangements was proposed to be due to DNA recombination, because of their large copy number and high level of sequence identity. However, recent studies of copy number variants (CNVs) and complex genomic rearrangements (CGRs) mediated by *Alu* pairs indicate that these events may preferentially utilize replication-based mechanisms with the *Alu* elements facilitating template switching. *Alu/Alu* CNVs can cause Mendelian diseases such as spastic paraplegia, Fanconi anemia, and Von Hippel-Lindau syndrome. To date, however, only a fairly small number of cases (< 200) detailing these events at the molecular level have been published. Many studies are limited by the sequence coverage and mapping difficulty due to the relatively short read length of most genomic sequencing technologies. Therefore, a bioinformatics study on reported *Alu/Alu* rearrangements can potentially illuminate the underlying mechanism(s), further characterize regions prone to genomic instability in the human genome, and may eventually improve molecular diagnosis and clinical treatment. In this study, 187 CNV-*Alu* pairs with experimental evidence supporting their role in deletion formation have been collated from published data; these experimentally determined *Alu/Alu* events were used as positive control to examine molecular features common to the mechanism. For each CNV-*Alu* pair, 1000 non CNV-*Alu* pairs within each generated region were randomly picked as a negative control dataset. Individual features were analyzed for all *Alu* elements and differences between positive and negative control datasets were tested. Statistically, when compared to non CNV-*Alu*s, CNV-*Alu*s tend to be longer in length, have higher GC content, a longer poly-A tail, and higher identity of A box and B box motifs.

3381F

Constructing a map of dispersed duplications in the human genome using whole genome sequencing data from families. *C.W. Whelan[1,2,3], R.E. Handsaker[1,2,3], G. Genovese[1,2,3], M. Lek[1,4], F. Zhao[1,4], J. McElwee[5], M.C. O'Donovan[6,7], D.G. MacArthur[1,4], S.A. McCarroll[1,2,3].* 1) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA; 2) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA; 3) Department of Genetics, Harvard Medical School, Boston, MA 02115, USA; 4) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston 02114, MA, USA; 5) Merck Research Laboratories, Merck & Co, Boston, MA, USA; 6) MRC Centre for Neuropsychiatric Genetics and Genomics, Institute of Psychological Medicine and Clinical Neurosciences, School of Medicine, Cardiff University, Cardiff, UK; 7) National Centre for Mental Health, Cardiff University, Cardiff, UK.

A longstanding challenge in the analysis of copy number variations (CNVs) has been to identify duplications that are dispersed – those in which the duplicated segment has inserted at a different genomic locus than its source (as opposed to tandem duplications, in which duplicate copies reside next to one another). Dispersed duplications can hide paralogous gene variants, distort linkage disequilibrium patterns, and make functional analysis of variants difficult, so a map of common dispersed duplications would be useful in many areas of genomics. We developed a way to utilize whole genome sequencing data from quartets (in which both parents and two offspring have been sequenced) to identify and map dispersed duplications. First, we develop an HMM-based method to determine the identity-by-descent (IBD) state of every locus in the genome in sibling pairs from each quartet. We then identify CNVs for which the copy numbers of the duplicated segment in the four family members is incompatible with the inheritance pattern determined by the IBD state between the siblings at that locus. By searching for CNVs that violate IBD inheritance patterns in multiple families, we can identify dispersed duplications. We then use the computed IBD states across the entire genome in every sibling pair in our data set to map the location of the dispersed segments to regions where every quartet's copy numbers and IBD states are compatible. We applied this method to over 200 quartets, identifying and mapping an initial set of over forty common dispersed duplications. We verify predicted dispersed duplications using linked-read data generated with the 10X Genomics technology, finding that the predictions of our approach were correct in 88% (15/17) of currently evaluable examples. By expanding this approach to more than 700 quartets, we are now building a comprehensive map of dispersed duplication polymorphisms that can be used to improve read alignment and variant calling in the affected genomic loci, remove confounding signals from association studies, and increase our understanding of genetic diversity.

3382W

Genome-wide copy number variation analysis and association with facial shape variation in a large cohort of Bantu Africans. *F. Yilmaz[1,2], M. Sorenson[3], D. Astling[2,4], H-C. Yu[2], J. Cole[2,5], S.A. Santorico[3,5,6], R.A. Spritz[2,5], A.E. Hendricks[3,5,6], T.H. Shaikh[2,5].* 1) Integrative and Systems Biology Program; 2) School of Medicine; 3) Mathematical and Statistical Sciences; 4) Department of Biochemistry and Molecular Genetics; 5) Human Medical Genetics and Genomics Program University of Colorado Denver; 6) Biostatistics and Informatics, Colorado School of Public Health.

The face is one of the most distinguishable characteristics of the human body. Family-based analyses of facial measurements have provided evidence that facial shape and morphology have a strong genetic component. However, the specific genetic factors underlying normal facial shape appearance remain largely unknown. Copy number variations (CNVs) are a significant source of normal genetic variation as well as the genetic burden associated with human disease. CNVs have been implicated in the etiology of numerous disorders resulting in multiple birth defects, including craniofacial abnormalities. We hypothesized that some variability in normal facial appearance results from CNVs which affect dosage of genes that modulate normal facial development. To test this hypothesis, we used genotype and phenotype data from ≈3700 Bantu Africans analyzed as part of the FaceBase I initiative. These individuals have been genotyped using high-density SNP-based microarrays and photographed using 3D morphometric cameras, which enable quantification of facial distances and shapes that explain the majority of facial shape variance. CNV data were generated from the raw data files obtained after genotyping with Illumina SNP arrays, using three CNV calling algorithms: PennCNV, DNAcopy and VanillaICE. CNVs were required to be concordant between two or more of the algorithms with an overlap of ≥50%, in order to reduce the number of false-positive calls. Further filtering for probe content, genomic size and segment logRatio was applied to obtain a set of high confidence CNVs. Our preliminary results detected CNVs in several genes previously implicated in craniofacial development and disorders, including *SHH, PAX3, FGFR1, FGFR2* and *IRF6*. We will present association analysis of single variants at a frequency ≥1% and gene-region based variants at frequency ≤5% to 34 quantitative facial phenotypes including 25 linear distance measures between facial landmarks, landmark derived centroid size and allometry (a measure of growth rate), head circumference, the first five Principal Components (PCs) from PCA of the whole face and the first PC from PCA of the midface. In addition to providing a comprehensive analysis of the relationship between CNVs and facial morphology, our study also provides a unique source of information about CNVs in a large African sample.

3383T

Zygotes segregate entire parental genomes in distinct blastomere lineages causing cleavage-stage chimerism and mixoploidy. *M. Zamani Esteki[1,7], A. Destouni[1,7], M. Catteeuw[2], O. Tšuiko[1,3], E. Dimitriadou[1], K. Smits[2], A. Kurg[3], A. Salumets[4,5], A. Van Soom[2], T. Voet[1,6,8], J. Vermeesch[1,8].* 1) Centre for Human Genetics, University Hospital Leuven, Department of Human Genetics, KU Leuven, 3000 Leuven, Belgium; 2) Department of Obstetrics, Reproduction and Herd Health, Ghent University, Ghent, 9820, Belgium; 3) Institute of Molecular and Cell Biology, Tartu University, Tartu, 51010, Estonia; 4) Competence Centre on Health Technologies, Tartu, 50410, Estonia; 5) Department of Obstetrics and Gynecology, University of Tartu, Tartu, 51014, Estonia; 6) Sanger-EBI Single Cell Genomics Centre, Wellcome Trust Sanger Institute, Hinxton, Cambridge, CB10 1SA, United Kingdom; 7) These authors are joint first authors and contributed equally to this work; 8) Co-senior authors.

Dramatic genome dynamics, such as chromosome instability, contribute to the remarkable genomic heterogeneity among the blastomeres comprising a single embryo during human preimplantation development. This heterogeneity, when compatible with life, manifests as constitutional mosaicism, chimerism, and mixoploidy in live-born individuals. Chimerism and mixoploidy are defined by the presence of cell lineages with different parental genomes or different ploidy states in a single individual, respectively. Our knowledge of their mechanistic origin results from indirect observations, often when the cell lineages have been subject to rigorous selective pressure during development. Here, we applied haplarithmisis to infer the haplotypes and the copy number of parental genomes in 116 single blastomeres comprising entire preimplantation bovine embryos (n = 23) following in vitro fertilization. We not only demonstrate that chromosome instability is conserved between bovine and human cleavage embryos, but we also discovered that zygotes can spontaneously segregate entire parental genomes into different cell lineages during the first post-zygotic cleavage division. Parental genome segregation was not exclusively triggered by abnormal fertilizations leading to triploid zygotes, but also normally fertilized zygotes can spontaneously segregate entire parental genomes into different cell lineages during cleavage of the zygote. We coin the term "heterogoneic division" to indicate the events leading to noncanonical zygotic cytokinesis, segregating the parental genomes into distinct cell lineages. Persistence of those cell lines during development is a likely cause of chimerism and mixoploidy in mammals.

Discovery and annotation of duplicate genes using long-read capture and transcript assembly. *M.L. Dougherty[1], J.G. Underwood[1,2], E. Tseng[2], B.J. Nelson[1], O. Penn[1], L. Harshman[1], M.Y. Dennis[3], E.E. Eichler[1,4].* 1) Department of Genome Sciences, University of Washington, Seattle, WA; 2) Pacific Biosciences, Menlo Park, CA; 3) University of California, Davis, CA; 4) Howard Hughes Medical Institute, University of Washington, Seattle, WA.

High-quality sequence assembly and accurate gene annotation are key to understanding genetic variation, but are often frustrated by segmental duplications (SDs). SDs comprise 5% of the human genome and contain approximately 1,000 genes in whole or in part. They are an important source of genetic instability associated with both rare and common disease and provide templates for evolutionary innovation. However, our understanding of these genes still lags behind the rest of the genome. Fundamental knowledge, such as gene models, which describe exonic structure and protein-coding potential, are still incomplete, incorrect, or even lacking for many duplicate genes. We developed a method that would yield full-length transcript information while also being able to distinguish between nearly identical gene copies. Our approach uses complementary biotinylated oligonucleotide probes to enrich for duplicate genes from first-strand cDNA. Targeted cDNA is amplified, size fractionated, and sequenced using single-molecule, long-read (PacBio) technology. Long-read sequencing permits us to distinguish between highly identical transcripts and can probe complex splicing patterns. We designed 516 probes to 20 gene families that underwent duplications specifically on the human lineage since divergence from chimpanzee. Sequence analysis of captured cDNA from fetal and adult brain reveals a 251-fold enrichment in the abundance of our targeted genes over non-enriched control. Mean transcript sizes ranged from 1200-2300 bp with transcripts up to 4 kbp identified with high confidence, while we are continuing to target larger size bins. Among the human-specific duplications, we observe new isoforms including novel sites of transcription initiation and termination as well as fusion transcripts with neighboring genes. We also observe previously unannotated open-reading frames (ORFs), indicating potential novel genes that have previously been missed. Our method provides a powerful approach to accurately define full-length transcripts, isoforms, and ORFs for new genes mapping to duplicate regions and will be more broadly applicable to other structurally complex regions of genomes.

Somatic mutation profiles from blood cells of healthy individuals reveals strong replication-associated mutational asymmetry. *W. Chen, Y. Hong, D. Zhang, C. Zeng.* Laboratory of Genomic and Precision Medicine, Beijing Institute of Genomics, Chinese Academy of Sciences, Beijing, Beijing, China.

Somatic mutations rather than inherited from germ cells, usually occur due to unrepaired DNA damages and DNA replication errors. This type of mutations may contribute to genotypic and phenotypic heterogeneity, and even jeopardize the human health. Most studies on somatic mutations focused on their association with pathogenesis of diverse diseases. According to current disease development models, somatic mutations take place continually and accumulate prior to disease occurrence. However, the process of the mutation accumulation remains poorly understood. To well characterize somatic mutations, we set up an optimized library preparation protocol and probability based variation calling method, and analyzed blood samples from four healthy individuals and their parents. By sequencing a mutation-free control DNA, we first obtained a priori trinucleotide-specific sequencing error rate, ranging from 0.0001 to 0.017. And the probability of a call as to be a mutation or an error was then calculated accordingly. In all, 493 mutations including 3 de novo germline mutations were detected across the 4 samples with an average of 123 mutations per sample, and the lowest allele fraction was 0.4%. Furthermore, we also generated a simulated mutation profile assuming a consistent mutation rate among different generations during cell division. The allele fraction distribution for real muations showed a bias toward low allele fraction ones comparing to this simulation. One possibility for this phenomenon is the change in mutation rate during the process of cell development. Subsequently, we summarized the percentages for all mutations at each of the 96 mutated trinucleotides for each individual, a significant enrichment of C>T was observed among all individuals, especially the mutated cytosine adjacent to guanine (namely CpG). Additionally, we also found that most of the C>T mutations occurred in the earlier time during replication in comparison with tumor somatic mutations. Meanwhile, C>T mutations was more frequently observed in the lagging-strand template than in the leading-strand template, showing the strand asymmetry for somatic mutations in normal cells. One possible explanation is that the lagging-strand templet may experience a longer exposure as single-stranded DNA which consequently result in a higher rate of cytosine deamination than that occurred in double-stranded DNA.

Genome-wide effects of engineered chromosomal translocations on transcription and genome architecture. *S. Kim[1], V. Ramani[1], C. Disteche[2], J. Shendure[1,3].* 1) Department of Genome Sciences, University of Washington, Seattle, WA; 2) Department of Pathology, University of Washington, Seattle, WA; 3) Howard Hughes Medical Institute, Seattle, WA.

The spatial organization of the genome within the nucleus is closely inter-twined with gene expression at multiple levels, ranging from chromosome localization to positioning of chromatin loops. However, it remains unclear to what extent each level of spatial organization drives changes in gene expression. Chromosomal translocations have previously been shown to perturb both the spatial organization of the genome and global gene expression, but a more complete understanding of these changes requires examining the effects of translocations in mammalian cells in isolation from other genetic or epigenetic differences. To address this challenge, we used CRISPR/Cas9 to induce translocations between an intron of the gene *HPRT1* and an intergenic region on either chromosome 8 or 21, and then selected for loss of functional HPRT1 to enrich for cells carrying translocations. Using this approach, we generated monoclonal cell lines derived from the near-haploid cell line HAP1, carrying t(X;8)(q26;q23), t(X;8)(q26;q24), or t(X;21)(q26;q21). Existing models of how chromosomal translocations impact gene expression suggest that expression changes would be primarily on the derived chromosomes, which might be localized in a novel region of the nucleus or have a novel chromatin structure near the breakpoints. We tested this hypothesis by both profiling the transcriptional changes in our translocation cell lines using RNA-seq and their changes in genome conformation using Hi-C. We find changes in gene expression spread throughout the genome, but only minimal changes in genome conformation at ~1 Mb resolution. Further, we find that even unmodified monoclonal cell lines derived from the same HAP1 population exhibit high variability in gene expression, suggesting that the variable effects of cell culture on gene expression can exceed those of engineered translocations.

Characterizing extreme structural rearrangement complexity in the human germline using whole-genome sequencing. *C. Redin[1,2,3], R.L. Collins[1,4], H. Brand[1,2,3], C. Hanscom[1], F. Quintero-Rivera[5], M. Devito[6], M. Talucci[6], R.J. Wapner[6], W.P. Kloosterman[7], M.E. Talkowski[1,2,3].* 1) Center for Human Genetic Research, Massachusets General Hospital, Boston, MA; 2) Department of Neurology, Massachusetts General Hospital, Boston, MA; 3) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; 4) Program in Bioinformatics and Integrative Genomics, Harvard University, Boston, MA; 5) Department of Pathology & Laboratory Medicine, UCLA Clinical Genomic Center, UCLA David Geffen School of Medicine, Los Angeles, CA; 6) Division of Maternal-Fetal Medicine, Department of Obstetrics and Gynecology, Columbia University Medical Center, New York, NY; 7) Department of Genetics, Division of Biomedical Genetics, University Medical Center Utrecht, 3508 AB Utrecht, The Netherlands.

Structural variation (SV) dynamically shapes the content and organization of an individual genome. A fraction of the SV landscape is non-canonical, or complex, involving multiple SV signatures compounded into a single variant. These complex SV (cxSV) range in intricacy from CNV-flanked inversions to extraordinarily complex rearrangements originating from chromosome shattering and random reassembly. The latter phenomenon, referred to as chromothripsis, was first reported in cancer but has also been observed in the viable human germline, albeit frequently co-occurring with disease phenotypes. We have performed long-insert whole-genome sequencing (liWGS) on >1000 human genomes from both control individuals and those with neurodevelopmental disorders or congenital anomalies. Throughout those studies, we have observed a diverse landscape of cxSV in the human germline, including extreme forms of largely balanced chromothripsis. To date, we have characterized 14 distinct recurrent subclasses of cxSV that are relatively large (>5 kb), demonstrating that: 1) >85% of all large cxSV involved at least one inverted segment; 2) collectively, cxSV were larger than canonical SV; and 3) complex duplications were over 2X larger but 3X less common than complex deletions. Importantly, the vast majority of cxSV were stably inherited from unaffected parents, and 22.1% of all cxSV appeared in >5% of subjects, evincing that cxSV is a standing class of variation in all human genomes. In three cases we have resolved extreme forms of chromothripsis involving up to 65 breakpoints across four chromosomes and disrupting up to 29 genes in a single individual. While two of these rearrangements were relatively balanced, the third one reported in a subject with developmental delay involved substantial genomic imbalance (>19Mb), a hallmark of chromothripsis in cancer but not previously observed in the germline. We further revealed this rearrangement to be mosaic (mosaicism of 55-58% by liWGS, ~60% by microarray), further suggesting that massively unbalanced chromothriptic rearrangements are unlikely to be tolerated in the human germline. Collectively, these analyses revealed an unprecedented diversity of large and relatively frequent cxSV in the human germline, and extreme examples of chromothripsis. These data suggest that such cxSV are tolerated in the human germline and are preferentially accessible to methods providing long-range information on genome structure.

High confidence phasing of rare variants over long distances using RNA-sequencing and phASER improves medical and functional genomic studies. *S.E. Castel[1,2], P. Mohammadi[1,2], W.K. Chung[3], Y. Shen[2,4], T. Lappalainen[1,2].* 1) New York Genome Center, New York, NY; 2) Department of Systems Biology, Columbia University, New York, NY; 3) Departments of Pediatrics and Medicine, Columbia University, New York, NY; 4) Department of Biomedical Informatics, Columbia University, New York, NY.

Haplotype phasing of genetic variants is important for clinical interpretation of the genome, population genetic analysis, and functional genomic analysis of allelic activity. Here we present phASER, a read-backed approach for phasing variants using RNA-seq reads, which often span multiple exons due to splicing, allowing for phasing of rare and *de novo* variants over long distances. Using data from both population-scale functional genomic and medical genetic studies we show that the inclusion of RNA-seq provides significant advantages over DNA-seq or population based phasing alone. We extensively benchmarked the characteristics of phASER read-backed phasing, including total variants phased, accuracy, and distance using GTEx data from across sequencing assays and tissue types, and found that up to 15% of rare coding variants could be phased using RNA-seq from a single tissue, at distances up to hundreds of kilobases. The incorporation of RNA-seq increased the number of rare coding variants phased by 1.5x for whole exome sequencing (WES) and 2.4x for whole genome sequencing (WGS). Next, we investigated the advantages of read-backed phasing with several types of sequencing reads in resolving potential compound heterozygosity for protein-disrupting variants. In 1000 Genomes individuals the inclusion of Geuvadis RNA-seq from LCLs increased power by 30%, and in a medical genetics study of congenital diaphragmatic hernia, RNA-seq in a tissue of disease relevance increased the number of expressed compound heterozygote alleles identified by 2.6x over WES alone. In addition to phasing, our method allows for the quantification of allelic expression at the haplotypic level as opposed to the variant level. When applied to Geuvadis data, phASER reduced false positive signals of allelic imbalance at 56% of genes tested, while uncovering false negatives at 7%. Finally, using GTEx v7 data, we combined read-back phased 30x WGS genotype calls with RNA-seq data from dozens of tissues to produce the largest panel of high confidence rare variant haplotypes to date. Using this panel we were able to uncover evidence of epistatic interaction between coding variants in the form of the accumulation of rare, putatively deleterious alleles on the same haplotype. Our work demonstrates that phasing using RNA-seq reads and phASER significantly improves haplotype-based analyses by incorporating a widely available data type that has become trivial to produce at population scale.

Building complete chromosomal haplotypes using single-cell sequencing. *D. Porubsky[1], A.D. Sanders[2], N. van Wietmarschen[1], E. Falconer[2], M. Hills[2], M.R. Bevova[1], D. Spierings[1], V. Guryev[1], P.M. Lansdorp[1,2,3].* 1) ERIBA, University Medical Center Groningen, Groningen, Netherlands; 2) Terry Fox Laboratory, BC Cancer Agency, Vancouver, Canada; 3) Division of Hematology, Department of Medicine, University of British Columbia, Vancouver, Canada.

Haplotypes are fundamental to fully characterize the diploid genome of an individual, yet phasing of genetic variants along the whole length of homologous chromosomes remains challenging. Here we introduce single cell DNA template strand sequencing (Strand-seq) as a novel approach able to phase diploid genomes along the entire length of all chromosomes. Strand-seq (Falconer et al., 2012) is a single cell sequencing technique with a unique ability to retain directionality of sequencing reads, based on the DNA template strand inheritance. This allows us to map every read to a single parental chromosome in a single cell. We demonstrate the power of haplotyping using Strand-Seq by phasing a HapMap individual (NA12878) at high accuracy (concordance 99.3%) without using generational information or statistical inference. With this approach, we mapped all meiotic recombination events in a family trio with high resolution (median range ~14kb). In addition our method allows phasing of larger structural variants like deletions, insertions as well as homologue specific estimate of copy number of segmental duplications. Moreover, balanced rearrangements like inversions which are difficult to detect with current technologies can be reliably phased using Strand-seq (Sanders et al., accepted Genome Research). To our knowledge this is the only sequencing technique able to map and phase heterozygous inversions. Lastly, the single cell resolution of our approach allowed us to observe loss of heterozygosity regions in small number of cells, a significant advantage for studies of heterogeneous cell populations, such as cancer cells. We conclude that Strand-seq is a unique and powerful approach to completely phase individual genomes and map inheritance patterns in families as well as detect haplotype differences in single cells. Falconer, E. et al. DNA template strand sequencing of single-cells maps genomic rearrangements at high resolution. Nat. Methods 9, 1107–12 (2012)Sanders, A.D., Hills, M., Porubsky, D., Guryev, V., Falconer, E., Lansdorp. P.M. Characterizing polymorphic inversions in human genomes by single cell sequencing. Accepted, Genome Research; submission number: GENOME2015/201160.

3390F

Impact of rare variants on gene expression. *X. Li[1], Y. Kim[2], J. Davis[3], E. Tsang[3], Z. Zappala[3], F. Damani[2], C. Chiang[4], . GTEx Consortium , I. Hall[4], A. Battle[2], S. Montgomery[1,3].* 1) Department of Pathology, Stanford University, Stanford, CA; 2) Department of Computer Science, Johns Hopkins University, Baltimore, MD; 3) Department of Genetics, Stanford University, Stanford, CA; 4) Genome institute, Washington University, St. Louis, MO.

Due to less selective process, rare variants have generally larger effect sizes than common variants among human population. However their exact functional impact remains largely unexplored hurdled by the requirement of extra-large sample sizes and deep whole genome sequencing. GTEx human tissue RNA-seq samples paired with genome sequencing samples (over 5000 RNA-Seq samples of 44 tissues of 449 donors, 148 individuals also with sequenced genome) provide us with the unique opportunity to unveil a comprehensive landscape of the functional impact of rare variants. In this study we set out to discover expression outliers among different tissues and characterize the roles of many types of rare variants behind those effects. For each of the 44 tissues, we identify 400~1400 outliers in each tissue (at FDR 2~6%).There are significant sharing of outliers among tissues, ranging from 5 to 17% depending on closeness of tissues. Investigating all categories of variants: SNP, indels and structural variants behind those outliers, we estimate that ~50% of the under-expression and ~20% of the over-expression outliers can be explained by rare variants in the genic region (TSS -10kb to TES + 10kb). Severe impact is found at multiple loss-of-function variants, structural variants and indels. For non-coding variants, most striking effect is seen at promoters but no evidence of enrichment is observed at enhancers. Looking at finer scale allele frequencies in 4000 UK10k individuals, we found that rare variants at our outliers are at even lower frequencies than rare variants detected with similar annotation in non-outliers, evidencing the presence of selective pressure on their potentially deleterious effects. Outlier expression is further validated by widespread allele specific expression (ASE) at those genes. We observe much larger ASE effect sizes at outliers than non-outliers, which is further confirmed by excluding mapping biases and blacklisted low-mappability regions. Our outlier findings also have substantial intersections with known GWAS, OMIM, OrphaNet, cancer and cardio gold standard genes, indicates that outlier expression can have functional impacts for various rare and common diseases. In summary, our study builds a detailed catalog of all types of rare variants and their regulatory effects, which forms the basis for prioritizing rare variants for further phenotypic characterization.

3391W

Copy number variation in human embryonic stem cell lines. *R. Handsaker[1,2], F. Merkle[3,4], G. Genovese[1,2], S. Ghosh[1,2,5,6], S. Kashin[1,2], M. Pato[7], C. Pato[7], K. Eggan[2,5,6], S. McCarroll[1,2].* 1) Department of Genetics, Harvard Medical School, Boston, MA, USA; 2) Stanley Center for Psychiatric Research, Broad Institute, Cambridge, MA, USA; 3) Metabolic Research Laboratories and Medical Research Council Metabolic Diseases Unit, Wellcome Trust - MRC Institute of Metabolic Sciences, Cambridge, UK; 4) Wellcome Trust – MRC Cambridge Stem Cell Institute, University of Cambridge, Cambridge, UK; 5) Harvard Stem Cell Institute, Department of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, USA; 6) The Howard Hughes Medical Institute, Harvard University, Cambridge, MA, USA; 7) SUNY Downstate Medical Center, Brooklyn, NY, USA.

Human stem cells are an important tool for biomedical research with many potential therapeutic and clinical applications. Previous studies have demonstrated that human stem cell lines can harbor significant genetic abnormalities and that these genetic variations can arise in culture, accumulate in the cell line, and undergo positive selection for growth advantage. Most studies of the genetic variation in human stem cells have used karyotyping or SNP arrays to characterize stem cell genomes, limiting the sizes of copy number variants that could be ascertained and the dynamic range of the copy numbers changes that could be inferred, or have investigated only a small number of cell lines. We performed deep (25x) whole genome sequencing on 130 human embryonic stem cell (hESC) lines, 99 lymphoblastoid cell lines (LCL) and 401 human DNA samples derived from whole blood. These data were used to analyze copy number variation, including both germline variation and variation that may have arisen in culture. We ascertained both fixed copy number mutations and mosaic copy number mutations that are present in a subset of the cultured cell population. We find that hESCs exhibit a high burden of large copy number mutations compared to LCLs, although the majority of the hESC lines surveyed are free of large copy number mutations. We identify several apparent hotspots of copy number mutation in hESCs, including further evidence for a previously reported hotspot on chromosome 20q. We find that certain mutational processes appear more than expected in hESCs, including the apparent formation of isochromosomes. These findings will inform both clinical and research applications that rely on the genomic stability and phenotypic readout from stem cell lines.

3392T

Analysis of the human subtelomeric regions to elucidate the real structure and pathogenesis of the related diseases. *Y. Kuroki[1], A. Toyoda[2], H. Noguchi[2], K. Yanagi[1], A. Fujiyama[2], T. Kaname[1].* 1) Genome Medicine, National Center for Child Health and Development, Setagaya-ku, Tokyo, Japan; 2) Center for Information Biology, and Advanced Genomics Center, National Institute of Genetics, Mishima, Shizuoka, Japan.

Human subtelomeres have unique structure of the genome, which form the transitions between chromosome-specific sequence and arrays of telomere repetitive sequence on the vicinity of chromosomal ends. Such regions show a complex genomic structure. The regions consist of variable mosaics of multi-chromosomal blocks of the nucleotide sequences. The subtelomere-specific repeats are identified as duplicated structures among the most of human subtelomeres. Abnormalities (e.g. deletions) of the subtelomeric region are associated with human diseases such as intellectual impairment and malformation syndrome (known as subteleomere deletion syndrome). Cause of subtelomeric abnormalities and precise relationship between their variations and clinical phenotypes are not fully elucidated. It is known that the latest reference data of human genome (GRCh38/hg38) are the most complete genome assembly in mammalian. However, there are still euchromatic gaps in several subtelomeric regions, due to their complex genomic structures. In fact, gene contents, constitution of the DNA elements, and variation of the copy number of the duplicated sequences in the subtelomeric regions have not been fully analyzed. Precise analyses in the subtelomeric regions are important to understand the subtelomere deletion syndrome. To clarify the precise and exact structure of the human subtelomeres, we isolated Fosmid/Cosmid clones covering the human subtelomeric region and started to analyze their complete structures by NGS analysis. In addition, we also performed the comparative analysis of subtelomeric sequences, which derived from Chimpanzee, Gorilla and Orangutan, for understanding the genome diversity and the evolutionary aspects in Primates. We present an overview of our project and show the current status at the meeting.

3393F

Stochastic gene activity in whole blood highlights more complex tissue identity. *L. Fresard[1], S.B. Montgomery[1,2].* 1) Department of Pathology, Stanford University, Stanford, CA; 2) Department of Genetics, Stanford University, Stanford, CA.

In transcriptome analysis, the number and repertoire of genes that are expressed often defines a tissue's identity. However, it is also well known that such expression can vary between individuals. We sought to quantify this variability and its impact on our understanding of tissue specificity by taking advantage of the availability of a large number of blood transcriptomes from the Depression Genes and Networks cohort. We analyzed blood expression of 909 individuals in order to precisely characterize and categorize gene expression in this tissue. We observe that 8,834 of all annotated protein coding genes (GENCODE v19) are always expressed in blood (43%), with 4,452 never expressed (22%) and 5,063 variably expressed (25%) among individuals. This variable gene activity can have several sources, but are in majority caused by environmental perturbations, genetics or their interaction. Most of the variable genes have expression levels comparable to those of constitutively active blood genes but may not be canonically described as a blood gene because not detected in a sufficient number of samples. We compared our results with standard resources describing tissue specific expression and we show that some of our variably expressed genes are conventionally described as not-expressed in blood. When exploring genes that are described as specific to tissues other than blood, we also see that a part of them are variably expressed in blood. To better describe the variable genes expression in other tissues, we used GTEx data and studied the proportion that is expressed in most individuals in different tissues. As many of the variably expressed genes in blood are constitutively active in other tissues, large studies of blood provide the opportunity to detect additional eQTLs that may be conventionally thought of as tissue-specific. These results highlight the need to refine our definition of tissue specific expression. Further, this work allowed us to assess expression of conventionally non-blood, tissue specific genes that are detectable in blood with numerous samples demonstrating the opportunities of large transcriptome genetic studies in blood.

3394W

Biased and coherent expression patterns of human Y chromosome genes. *A.K. Godfrey[1,2], D.C. Page[1,2,3].* 1) Whitehead Institute, Cambridge, MA; 2) Department of Biology, Massachusetts Institute of Technology, Cambridge, MA; 3) Howard Hughes Medical Institute, Whitehead Institute, Cambridge, MA.

The gonadal functions of human Y chromosome genes have long been a focal point of Y-chromosome research, despite the existence of widely transcribed genes in its male-specific region (MSY). To gain a broad and unbiased view of how MSY genes are expressed throuhgout the body, we measured their expression levels in 33 human tissues collected from 158 adult men, using a publicly available RNA-Seq dataset. We deployed methods to accurately estimate the expression levels of genes present in the MSY's abundant repetitive regions, as these were systematically underestimated in previous analyses. MSY genes cluster into two classes based on their expression profiles. Genes of one class demonstrate a high degree of specificity for the testis, with all but one (*SRY*) expressed predominantly in testicular germ cells. Genes of the second class, which include Y-specific regulators of gene activity, exhibit wide but biased expression across the body. These widely expressed MSY genes have correlated expression levels across both tissues and individuals, suggesting that they might function in similar biological processes. They are expressed similarly to their homologs on the X chromosome, yet they show relatively higher expression in the prostate and key endocrine glands, and more depleted expression throughout the brain. The biased and coherent expression patterns of human MSY genes motivate an expanded consideration of the Y chromosome's impact beyond the gonad and in differences between the sexes.

3395T

Genome assembly and full-length transcript profiling of stem cells from great apes. *J.G. Underwood[1,2], M.L. Dougherty[2], E. Tseng[1], O. Penn[2], C.M. Hill[2], D. Gordon[2,3], J. Huddleston[2,3], M.J.P. Chaisson[2], Z.N. Kronenberg[2], K.M. Munson[2], M. Malig[2], A. Raja[2,3], I. Fiddes[4], L.W. Hillier[5], C. Dunn[1], C. Baker[2], J. Armstrong[4], M. Diekhans[4], B. Paten[4], J. Shendure[2,3], R.K. Wilson[5], D. Haussler[4], C.S. Chin[1], A.M. Denli[6], F.H. Gage[6], E.E. Eichler[6].* 1) Pacific Biosciences of California, Menlo Park, CA; 2) Dept. of Genome Sciences, University of Washington, Seattle, WA; 3) Howard Hughes Medical Institute, University of Washington, Seattle, WA; 4) Genomics Institute, University of California Santa Cruz and Howard Hughes Medical Institute, Santa Cruz, CA; 5) McDonnell Genome Institute, Department of Medicine, Department of Genetics, Washington University School of Medicine, St. Louis, MO; 6) Laboratory of Genetics, Salk Institute for Biological Studies, La Jolla, CA.

Single-molecule, real-time (SMRT) sequencing technology has shown considerable promise in improving human genome assemblies as well as our understanding of genetic variation. Existing great ape genome assemblies contain hundreds of thousands of gaps, concealing genetic differences that separate the great ape species. We previously presented an accurate assembly of the Western lowland gorilla and now we add to that the common chimpanzee genome generated from SMRT sequence data and application of a string-graph *de novo* assembly algorithm (Falcon). The new reference genomes of gorilla and chimpanzee represent a more than 200-fold improvement in contiguity with contig N50s of 9.6 Mbp and 12.7 Mbp, respectively. Incomplete gene annotation of non-human primate genomes is a major impediment to understanding functional differences between humans and closely related primate species, especially during early development. Transcriptome profiling studies of human embryonic stem (ES) cells and induced pluripotent stem (iPS) cells are advantageous because a large number of protein-coding genes are expressed prior to lineage specification and differentiation. Moreover, large genes, genes embedded within duplications, and genes associated with repeats such as LINE and HERVH-associated pluripotency transcripts are difficult to study by short read expression profiling and assembly. To improve annotation and gain fundamental insights into pluripotency differences between humans and other primates, we generated PacBio full-length cDNA data to reflect the polyadenylated RNAs expressed in iPS cells from human, chimpanzee, and gorilla along with rhesus macaque as an outgroup. From each species, we are generating ~ 100,000 transcripts based on long-read sequencing of size-fractionated cDNA from 1 to 8kb. In addition to providing a higher quality annotation of transcriptomes for the great ape genomes, the data are providing novel insights into alternative promoters, non-coding RNA and fixed differences with respect to RNA processing, and novel ORF annotations between humans and great apes. With full-length transcript and gene models in hand, we are reassessing short read RNAseq data in order to quantify the abundance and expression patterns of these new gene models more accurately in other tissues. The full-length transcript data will provide a more complete understanding of genic differences between humans and our nearest phylogenetic neighbors.

3396F

Repeat elements expression profile across different tissues in GTEx samples. *H. Yang[1], S. Mangul[1,2], N. Zaitlen[3], S. Shifman[4].* 1) Department of Comptuer Science, University of California Los Angeles, Los Angeles, CA; 2) Institute for Quantitative and Computational Biosciences, University of California Los Angeles, Los Angeles,CA; 3) Department of Medicine, University of California, San Francisco, CA; 4) Department of Genetics, The Institute of Life Sciences, The Hebrew University of Jeruslam, Jerusalem, Israel.

Next Generation RNA Sequencing technology enabled researchers to investigate transcriptomics, which is directly correlated to protein expressions, as well as other activities within cells. However, some of the transcribed RNAs are not translated into proteins but rather reincorporated into the genome through a process called retrotranscription, and those sequences that are re-incorporated into the genome through this process is called retrotransposons. Retrotransposons occupy a significant portion of the human genome and are believed to have significant roles in certain diseases, such as Rett's disease or Schizophrenia. We investigated the differential expression of non-long terminal repeat retrotransposons: short and long interspersed elements, denoted as SINE and LINE, respectively, as well as Alu elements. The differential expression of non-LTR retrotransposons is investigated on 3000 RNA-Seq samples across 32 tissues types in Genotype-Tissue Expression (GTEx) dataset. The repeat profile was extracted by mapping reads to the reference of repeat elements on human genome. On average, 7.47% of total RNA-Seq reads are mapped to repeat elements. Of the reads mapped to repeat elements, 32% of repeat element reads are mapped to LINE, while 41% of repeat element reads are mapped to SINE. Of the tissue types, testes showed significantly higher expression of SINE-VNTR-*Alu* (SVA) subclass F compared with the mean expression of SVA-F throughout the samples (p = 2.46 * 10^{-33}), suggesting that there are important biological mechanism that upregulates the SVA element expression. Furthermore, high co-expression of *Alu* elements and LINE L1 elements is detected across tissues (R^2 = 0.7615), signifying that *Alu* expression may depend on the expression of L1 elements.

3397W

Identification and characterization of structural sequence variants in French Canadians. *K.S. Lo[1], C. Low-Kam[1], D. Rhainds[1], M.-P. Dubé[1,2], J.-C. Tardif[1,2], G. Lettre[1,2].* 1) Montreal Heart Institute, Montreal, Quebec, Canada; 2) Department of Medicine, Université de Montréal, Montreal, Quebec, Canada.

Structural DNA sequence variants (SV) include deletions, duplications, copy-number variants (CNV), insertions, inversions and translocations that affect 1 kb–3 Mb of DNA sequence. Recent discoveries have highlighted the importance of accurately genotyping complex SV in order to test their role in human diseases. In this project, we applied the Genome STRiP 2.0 (GS2) software (Handsaker et *al*., Nature Genet., 2015) to detect SV in 1,970 French Canadians from Quebec using data from low-pass whole-genome DNA sequencing (~5.6X coverage/participant). In comparison with other available tools, GS2 integrates information from multiple samples to increase confidence in SV genotyping calls.GS2 is computationally intensive, requiring the use of high-performance computing resources (>625 core-days for our dataset). After initial filtering of poor quality variants, 22,001 distinct autosomal CNV were identified, with an average of 701 CNV per individual and a mean minor allele(s) frequency (MAF) of ~1.2%. To assess the quality of the CNV identified, we compared our results with CNV from the 1000 Genomes Project (1000GP) phase 3 dataset identified with GS2. Approximately 60% of the CNV identified in 1000GP are also found in the French-Canadian dataset. About 39% of the CNV identified (mean length of 15kb) overlap with a gene, including 1,236 genes that are completely covered by a CNV. Of specific clinical interest, we found 165 genes annotated in the Online Inheritance in Man (OMIM) database that are completely encompassed within a CNV in French Canadians.To begin the exploration of the role of SV in the French-Canadian population, we tested the association between CNV genotypes and LDL-cholesterol (LDL-C) levels using an additive model in a linear regression framework. Interestingly, the most significant CNV is a multi-allelic variant with MAF=0.9% that overlaps with the first exon of the LDL-C receptor gene *LDLR* (*P*=$2.4x10^{-7}$). This CNV is absent from the 1000GP dataset, and corresponds to the previously described French-Canadian *LDLR* founder mutation identified in patients with familial hypercholesterolemia (Hobbs et *al*., NEJM, 1987). The CNV explained ~1% of the variation in LDL-C and conditional analyses indicate, as expected, that it is independent from the known *LDLR* SNPs previously identified by GWAS. Although association tests with other heart disease risk factors are ongoing, this example already illustrates the importance to assess SV in populations of interest.
