Background Obesity is a leading cause of non-communicable diseases such as diabetes, hypertension, hyperlipidemia, metabolic syndrome, cancer, and cardiovascular diseases. Prediction and prevention of obesity are important in terms of the increased prevalence of obesity and the social costs. In this study, we developed polygenic risk score (PRS) for obesity and conducted a phenome-wide association study (PheWAS) to investigate the trait-related consequences of obesity.

Methods This study used epidemiological genetic data from 58,690 participants of the Korean Genome and Epidemiology Study_Health EXAminee (KoGES_HEXA) study. We considered 92 phenotypes of potential trait-related consequences obtained by survey-based questionnaires and health examination. The genetic data were generated by the Korea Biobank Array and imputed using Korean Reference Genome. To develop PRS of obesity, we used 10 single-nucleotide polymorphisms (SNPs), including rs506589, rs11675198, rs3755804, rs792361, rs9348441, rs2076308, rs6265, rs8050136, rs6567160, and rs35560038, associated with obesity from the genome-wide association study (GWAS, $P<5.00\times10^{-8}$). The PheWAS is analyzed by a logistic or linear regression model for binary or continuous traits, respectively, with adjustment for sex and age.

Results The mean of PRS was 0.333 (SD=0.09) in obesity group and 0.319 (SD=0.09) in non-obesity group with significant difference ($P<5.16\times10^{-64}$). Each 0.1 increase in the obesity-PRS was associated with a 1.18 higher risk of obesity. In PheWAS, the eight phenotypes had an association with obesity-PRS; The most associated phenotype was hypertension (OR=1.60, $P=6.51\times10^{-5}$) and followed by arthritis (OR=1.86, $P=1.61\times10^{-4}$), intestinal polyp (OR=1.71, P=6.28×10-3), family history of hypertension(OR=1.30, P=0.007), breast cancer (OR=0.23, P=0.008), Hemoglobin(Beta=0.12, P=0.03), and family history of fatty liver (OR=1.47, P=0.05). Although not all phenome-wide associations were statistically significant, most diseases (61%) tended to show a positive direction with obesity-PRS.

Conclusion This study found that obesity-PRS was associated with increased risk of various diseases, especially hypertension supporting the potential causal relationship between obesity and chronic diseases. Obesity-related genetic data could attribute to identifying individuals at risk prevent obesity-related diseases.

PB1706 Phenome-wide genetic associations of educational attainment with mental and behavioral disorders

Authors:

A. Ayer, R. Wang, N. Banerjee, A. J. Averitt, A. Moscati, N. Lin, DiscovEHR-RGC, Mayo Clinic Project Generation, Regeneron Genetics Center, M. Cantor, A. Baras, E. Stahl, G. Coppola, V. M. Rajagopal; Regeneron Genetics Ctr., Tarrytown, NY

Background Many mental and behavioral disorders have strong genetic relationships with educational attainment (EA), and causality may be bidirectional and mediated via socioeconomic factors. Understanding these relationships can help interpret gene discoveries made by large-scale rare variant studies for such phenotypes. Here, we use common variants to investigate causal associations of EA with mental and behavioral disorders and bring insight into related rare variant associations. **Methods** We used the latest EA GWAS results to calculate a polygenic score (EA-PGS) for 350,475 individuals of European ancestry from five electronic health record-based cohorts. We then performed a phenome-wide association study using 83 mental and behavioral disorders based on ICD10 codes (Chapter V: F00-F99). Next, we used Mendelian Randomization (MR) to refine results and interpret direction of causality of significant associations. EA-PGS was calculated using LDpred, and PGS associations were computed using logistic regression in unrelated Europeans adjusted for appropriate covariates. Common variant associations were calculated using REGENIE and summary statistics were analyzed by MR, using the 'TwoSampleMR' R package. Statistical significance was determined using an FDR of 0.05. **Results** We identified 24 phenotypes significantly ($p < 5.7 \times 10^{-3}$) associated with EA-PGS, predominantly belonging to three groups: substance use, neurotic & stress-related, and mood disorders. MR results supported these findings and elucidated direction of causality. We found evidence for bidirectional causal associations between EA and all three disorder groups, but effects were relatively stronger in the direction of EA to disorders than disorders to EA (which could be partly due to a lack of strong disorder-specific instruments for the disorders). Substance use disorders, particularly tobacco use, showed the strongest associations. One standard deviation (SD) decrease in EA was associated with a 2.16 odds ratio of having a tobacco use disorder (95% CI = 1.90-2.45; $p = 3.7 \times 10^{-32}$), while one SD increase in genetic risk for tobacco use was associated with 0.14 SD decrease in EA ($\beta = 0.14$; SE = 0.013; $p = 1.6 \times 10^{-28}$). **Discussion** Our findings highlight strong genetic links between substance use disorders and EA, which is likely primarily mediated by socioeconomic factors. The results have helped interpret our recent findings on the links between rare variants in neurodevelopmental genes (which have strong negative effects on cognitive function and thereby on educational and socioeconomic outcomes) and tobacco use, which we believe is mediated by EA and related socioeconomic factors.

PB1707 Phenotype-driven filtering of whole-exome data from English-speaking individuals with specific language impairment (SLI) exhibiting precise grammar impairment reveals novel rare variants associated with SLI.

Authors:

M. Raza[1], E. M. Andres[2], K. K. Earnest[1], H. Xuan[1], C. Zhong[1], M. L. Rice[1]; [1]The Univ. of Kansas, Lawrence, KS, [2]Univ. of Missouri, Columbia, MO

Individuals with specific language impairment (SLI) are delayed in language acquisition and show persistent deficits in language despite average non-verbal intelligence and otherwise typical development, providing a test case for the specificity of language. There are two main SLI accounts; one focused on grammar acquisition and another implicating more domain-general mechanisms related to working memory. The current study focuses on the grammar acquisition account. In English-speaking children with SLI (ages 3;0-8;11 years), grammar impairment can be measured through performance on a grammar assessment, the Test of Early Grammatical Impairment (TEGI). The TEGI is highly sensitive and specific, consistently shows high heritability estimates (up to .92) and was used in only one prior molecular genetic study. Twin and family aggregation studies consistently indicate genetic factors are involved in language and SLI, but precise genetic mechanisms have not been revealed. Therefore, we set out to identify rare variants associated with TEGI performance. We performed whole exome sequencing (WES) in eight families with SLI (n = 74 total; n = 34 with TEGI score) and follow-up Sanger sequencing of identified co-segregating variants in additional unrelated probands who completed the TEGI (n = 146). We prioritized rare exonic variants shared by members of at least two families who performed below average on the TEGI under two filtering workflows: 1) novel and 2) previously reported candidate genes. We observed candidate variants on six new genes (*PDHA2*, *PCDHB3*, *FURIN*, *NOL6*, *IQGAP3*, and *BAHCC1*), and two genes previously reported for overall language ability (*GLI3* and *FLNB*). In at least one unrelated proband, we observed the same variants as those identified in the WES family members on *PDHA2*, *PCDHB3*, *NOL6*, and *IQGAP3*. Support from other studies suggests *PCDHB3*, a protocadherin gene, and *NOL6*, critical for ribosome synthesis, are possible important targets of future SLI investigation. Identifying the same variants associated with TEGI performance in multiple families emphasizes the utility of precise phenotyping and family-based genetic study.

Introduction: Aortic stenosis (AS) is the most common valvular heart disease with a prevalence of 10%-15% among individuals over 75 years. Currently, aortic valve replacement is the only available treatment. Understanding the genetic etiology of AS could help identify potential therapeutic targets. Large-scale plasma protein measurements can be integrated with genomic data to define protein quantitative trait loci (pQTL). Mendelian randomization (MR) of pQTLs with AS could identify actionable, causal protein biomarkers for the disease. **Methods:** We employed a two-sample MR approach to identify causal contributors to AS among plasma proteins. Publicly available pQTL results from the Atherosclerosis Risk in Communities (ARIC) study were analyzed with our recently published meta-analysis of ten AS GWAS (Meta-AS). Results were replicated using GWAS summary data from the Million Veteran Program (MVP). **Results:** Using 2,004 cis-pQTLs identified in ARIC Europeans, we generated 1,238 MR results with the inverse variance weighted method using multiple SNPs as instrumental variables. We found that the most significant proteins were ITPA (OR 1.05, 95% CI 1.03-1.08; $p = 3.79 \times 10^{-5}$; FDR < 0.05), ACE (OR 1.04, 95% CI 1.02-1.06; $p = 1.73 \times 10^{-4}$), and PCSK9 (OR 1.20, 95% CI 1.09-1.32; $p = 1.88 \times 10^{-4}$). Additionally, the results of the weighted median analysis confirmed the significance of these three exposures (ITPA $p = 1.49 \times 10^{-3}$; ACE $p = 6.04 \times 10^{-3}$; PCSK9 $p = 8.59 \times 10^{-4}$). The egger intercepts were also found to be insignificant. In the MVP replication, all three of these proteins were significant: ITPA (OR 1.03, 95% CI 1.01-1.06; $p = 1.04 \times 10^{-3}$), ACE (OR 1.03, 95% CI 1.01-1.05; $p = 1.55 \times 10^{-3}$), and PCSK9 (OR 1.19, 95% CI 1.03-1.38; $p = 1.65 \times 10^{-2}$). These three exposures were also tested in MVP African Americans using ARIC cis-pQTLs generated in African Americans, but no significant results were obtained. **Conclusions:** In the largest MR study to date of pQTLs in AS, we identified three causal proteins for AS - ACE, PCSK9, and IPTA, all of which replicated in an independent sample. These results suggested three proteins that could mediate the pathogenesis of AS and represent potentially actionable targets. Notably, ACE and PCSK9 are already recognized as viable drug targets. Additional research is warranted to determine whether these pharmacotherapies might be repurposed for AS.

Insulin resistance, a primary risk factor for the development of type 2 diabetes and coronary artery disease, has significant health implications. In two large European cohorts, we have previously shown that plasma proteins measured using the proximity extension assay (PEA) substantially increase the variance explained of a gold standard direct measure of insulin sensitivity (IS) beyond that explained by routinely acquired clinical risk factors. However, it remains unclear whether the same proteins can track IS in non-European populations, whether they can track short term changes in IS, and which associations we observed are causal.

To address these knowledge gaps, we measured 1471 plasma proteins with PEA in a diverse set of participants who had previously undergone one or more insulin suppression tests at Stanford University including 655 White, 122 South Asian, 95 East Asian, 86 Hispanic, and 54 Black volunteers. A total of 810 proteins associated with baseline IS in European subjects at FDR < 0.05, of which 395 passed Bonferroni correction. Associations observed correlated strongly with those observed in non-White populations (r=0.68 to 0.83, all $P<4.3\times10^{-113}$). Next, we integrated our Stanford data with the two European studies (RISC n=1024, and ULSAM n=889) through meta-analysis which yielded 255 candidate plasma proteins at FDR < 0.05, of which 75 remained significant even after adjusting for BMI. In a subset of participants who underwent short term interventions that substantially improved IS through the use of thiazolidinediones drugs (N=53) or weight loss (N=66), we measured the same 255 proteins a second time after the intervention and observed a very high concordance between the observed and the expected change of the protein levels based on the direction of association observed at baseline (79.6% concordance with chi^2 $p=6.7x10^{-16}$ before BMI adjustment, and 73.3% with chi^2 $p=1.3x10^{-8}$ after adjustment). Lastly, we conducted Mendelian randomization (MR) analyses leveraging recently identified genetic instruments by the UK Biobank Pharma Proteomics Project and identified fifteen candidate causal proteins at a nominal P<0.05. Seven (AIFM1, IL10RB, LBP, LEP, MEGF9, PTPRN2 and QDPR) showed persistent associations after MR sensitivity analyses. Our follow up study reinforces the utility of plasma proteins in the non-invasive assessment of IS beyond established clinical risk markers. The same proteins are likely to be informative across all populations and to be able to accurately track short term changes in IS. Lastly, we shed light on the molecular mechanisms underlying insulin resistance and identify several novel candidate therapeutic targets.

Ctr., Chicago, IL

Myeloid-origin human brain immune cells (HBICs), including microglia and perivascular macrophages (PVMs), have been identified as playing a central role in the onset and progression of Alzheimer's disease (AD). However, the field lacks a unified taxonomy describing HBIC subtypes due to their heterogeneity and the limited scale of previous studies involving human brain tissue. In this study, we provide a detailed consensus on HBICs using multi-modal single-cell assays from diverse populations across the lifespan with varying degrees of AD pathology. Establishing a unified taxonomy of human microglial states could help describe the progression of AD in terms of changes in microglial states. To achieve this, we generated two largest independent single-cell datasets to date. The first dataset provides a comprehensive, in-depth view of microglial transcriptomes using scRNA-seq profiles of live microglia purified from an autopsy of 137 unique donors. We identify 13 distinct phenotypes of human microglia and show how they react and adapt to environmental cues. We validate and further characterize the microglial taxonomy using the second dataset, snRNA-seq profiles collected from 1,470 unique donors, which provides a much greater breadth of coverage and span of a lifetime. We study the population-level variation in microglial heterogeneity using these complementary datasets. We observe state-specific expression of surface proteins from validated microglial subtypes using CITE-seq. We describe microglial states implicated at different stages of AD pathology. Based on our findings, we propose a two-stage disease mechanism for pathogenic progression (Amyloid and Tau) and cognitive impairments (dementia). We discover AD-risk candidate genes PTPRG, DPYD, and IL15, which are implicated in both the early and late stages of AD. Our resource and approach provide unprecedented systems-level insights into transcriptional dysregulation of HBICs and its implications in AD pathogenesis.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1711 Pleiotropic relationship between Alzheimer's disease and eleven immune diseases.

Authors:

N. Enduru, B. Fernandes, Y. Dai, Z. Zhao; The Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX

Background: Alzheimer's disease (AD) is a polygenic disease with an emerging global public health challenge. Recent evidence suggests that the pathogenesis of AD is not confined to neurons but instead underscores involvement of neuroinflammation in driving the disease. In this study, we aimed to investigate the shared genetic architecture between a plethora of immune diseases (ID) and AD using published genome-wide association studies (GWAS) and then identify genes related to both immune diseases and AD. **Methods**: We collected GWAS summary statistics data for AD and 11 featured IDs (allergic rhinitis, asthma, atopic dermatitis, celiac disease, Crohn's disease, hypothyroidism, primary sclerosing cholangitis, rheumatoid arthritis, systemic lupus erythematosus, ulcerative colitis, and vitiligo). We performed conjunctional/conditional false discovery rate (cFDR) analysis through pleioFDR to identify the shared pleiotropic relationship between AD and each ID. Additionally, local genetic correlation (LAVA) was conducted to assess genetic overlap at the pleiotropic loci between AD and each ID identified through conjFDR analysis. **Results**: We identified 70 unique shared loci from 71 SNPs between AD and ID with a conjFDR $_{AD\&ID} < 0.05$ across the 11 trait pairs. These loci were associated with 43 distinct protein-coding genes and 16 non-protein coding genes. Notably, two lead SNPs (rs12790721 and rs602662, nearest genes LINC01059 and FUT2, respectively, with CADD score > 12.37) exhibited high deleteriousness and seven lead SNPs (rs4233366, rs739954, rs2074404, rs10748526, rs3764310, rs4275659 and rs4958435, rs17229044, and rs1052553, nearest genes ADAMTS4, HBEGF, WNT3, TSPAN14, DHODH, ABCB9 and TNIP1, CLEC16A, and MAPT, respectively) showed potential regulatory functionality based on RegulomeDB scores. LAVA revealed 76 shared loci between AD and ID. Among them, 45 loci had significant heritability for both diseases in pair, 10 of which had significant correlation ($p < 0.05$). Twelve loci had 95% confidence intervals covering maximum variance value 1, suggesting complete shared genetic signal between the phenotypes. The FUMA for pathway analysis revealed several pathways associated with AD and IDs, including cytokine production, activation regulation of immune response, neuron projection, protein lipid complex, protein ligase and lipid bindings. **Conclusion**: There is a shared genetic overlap between AD and immune diseases, including shared molecular pathways.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1712 Pleiotropy evaluation across four abdominal hernia subtypes detects novel loci and shared genetic basis.

Authors:

H. Choquet[1], R. Mostaedi[2], J. Yin[1], T. Hoffmann[3], N. Ahituv[4], E. Jorgenson[5], M. Kvale[6]; [1]Kaiser Permanente - Div. of Res., Oakland, CA, [2]Kaiser Permanente - East Bay Richmond Med. Ctr., Richmond, CA, [3]Univ. of California, San Francisco (UCSF), San Francisco, CA, [4]UCSF, San Francisco, CA, [5]Regeneron Genetics Ctr., Tarrytown, NY, [6]Inst. for Human Genetics, San Francisco, CA

Purpose: Abdominal hernias can lead to serious medical morbidity, including bowel incarceration and strangulation, and emergency hernia repair surgery is associated with a substantial risk of morbidity and mortality. Array-based heritability estimates found a stronger contribution of genetic risk factors for umbilical hernia (16.0%) compared to inguinal (12%), ventral (7.0%), or femoral (6.0%), suggesting different etiology according to the hernia subtype. To date, more than 80 genetic loci have been associated with different forms of hernia, and several loci were associated with more than one hernia subtype. However, the overlap between the underlying genetic mechanisms remained largely unknown. **Methods:** We conducted a multiethnic genome-wide association (GWA) meta-analysis of each hernia subtype (inguinal, femoral, umbilical, ventral), combining results from the Kaiser Permanente Genetic Epidemiology Research on Adult Health and Aging (GERA) and the UK Biobank cohorts. Individual GWA analyses of each hernia subtype were performed using logistic regression adjusted for age, sex, and genetic ancestry principal components. Following our GWA analyses, we investigated genetic correlation between the four hernia subtypes using LD score regression. We also examined shared effects (pleiotropy) across hernia subtypes for each identified hernia-associated locus. **Results:** The total numbers of genome-wide significant loci ($P<5x10^{-8}$) associated with each hernia subtype (whether pleiotropic or not) from these GWA analyses were 63 (inguinal hernia), 26 (umbilical hernia), 14 (femoral hernia), and 11 (ventral hernia). Among those 98 unique loci, 25 were novel (i.e., have not been previously reported to be associated with any subtype of hernia). The four abdominal hernia subtypes were genetically correlated with one another ($0.34 \leq r_g < 0.76$; *P*-value<0.05). Patterns of pleiotropy across hernia subtypes were highly diverse, with only three loci (*LYPLAL1-SLC30A10*, *EFEMP1*, and *WT1-AS*) significantly associated with all four hernia subtypes; one locus (*CHRDL1*) significantly associated with three hernia subtypes; and five loci (*CWC27-ADAMTS6*, *AIG1*, *SRPX*, *RBPMS*, and *COL8A1*) significantly associated with two hernia subtypes. **Conclusions:** This large and multiethnic genetic study of abdominal hernias identified many novel genetic loci and subtype-specific genetic effects, which could help better understand the biological mechanisms through which hernias develop.

Ctr., Omaha, NE, [13]Univ. of Melbourne, Melbourne, Australia, [14]Natl. Jewish Hlth., Denver, CO, [15]Univ. of Michigan, Ann Arbor, MI, [16]Univ. of Alabama of Birmingham, Birmingham, AL, [17]Brigham & Women's Hosp., Boston, MA, [18]Brigham and Women s Hosp., Duxbury, MA, [19]Brigham and Women s Hosp., Needham Heights, MA

Rationale: Chronic obstructive pulmonary disease (COPD) is heterogeneous. Polygenic and other Omics-based risk scores can identify high risk COPD subgroups, but the clinical and biological characteristics of high-risk groups are unclear. **Objectives:** Define COPD subgroups using previously-published genetic risk (polygenic risk score, PRS) and blood gene expression (transcriptional risk score, TRS) and assess differences in disease severities, activities, and risk for progression. **Methods:** By maximizing differences in protein biomarkers, we created two PRS and three TRS groups in a training set [n=1,374 non-Hispanic white (NHW) COPDGene participants], which we characterized using STRING protein-protein interaction network analyses. We applied Enrichr drug repurposing analyses and multivariable regressions to test group associations with COPD-related outcomes, adjusting for potential confounders. **Measurements and Main Results:** We examined these six omics-defined groups in non-overlapping test sets (n=1,133 NHW COPDGene, n=299 African American (AA) COPDGene, n=468 ECLIPSE). Two groups differed substantially, defining ‘high disease activity’ and ‘severe disease risk’ subtypes. ‘High disease activity’ participants had low PRS/high TRS, accelerated prospective FEV_1 decline (COPDGene: -51 mL/year; ECLIPSE: -40 mL/year), and altered extracellular matrix, MMP12, TGF-β, and IL-16 biology. ‘Severe disease risk’ participants had high PRS/high TRS, lower spirometry, greater emphysema and airway thickness, and changes in STAT5, IL-20, and TNF signaling. Both subtypes had lower mean BMI than other subtypes, with altered growth hormone, leptin, and prolactin signaling. ‘High disease activity’ individuals were enriched in gene sets perturbed by treatment with fibrates, calcium channel blockers, and antithyroid medications; “severe disease risk” individuals were enriched in gene sets perturbed by treatment with 5-lipoxygenase, carbonic anhydrase, and angiotensin-converting enzyme inhibitors. **Conclusions:** PRS and TRS identified subtypes with distinct clinical and biological characteristics. Polygenic risk scores combined with other Omics can be used to dissect complex disease heterogeneity and identify subtype-specific therapeutic strategies.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1714 Polygenic risk advances overall risk stratification for Parkinson's disease in combination with substantia nigra hyperechogenicity.

Authors:

A. Metspalu[1], M. Kals[1], T. Toomsoo[2,3], M. Vaht[1], T. Nikopensius[1], M. Teder-Laving[1], A. Reigo[1]; [1]Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, [2]Confido Med. Ctr., Estonia, Tallinn, Estonia, [3]Sch. of Natural Sci. and Hlth., Tallinn Univ., Tallinn, Estonia

Parkinson's disease (PD) is the second largest neurodegenerative disease in the world. Both environmental and genetic factors play an important role in a complex multifactorial etiology of PD. The objective of this study was to determine whether the polygenic risk for PD was associated with an increased likelihood of PD in combination with hyperechogenicity of the substantia nigra (SN). We performed a pilot study from individuals of European ancestry with no evidence of PD and age of >55 years in Estonian Biobank.

Polygenic risk score (PRS) was calculated for everyone who met the inclusion criteria (n=41,042) and individuals with extreme PRS values for PD (the top and bottom 1%) were selected for the further analysis. From November 2021 to June 2022, all study participants were interviewed and underwent neurological assessments (including Sniffin' Sticks 12 items test for hyposmia, the Movement Disorder Society diagnostic for de novo PD, and transcranial sonography (TCS) for the area of echogenicity).

Four hundred and forty-seven individuals were invited to the study, 225 participated (response rate was 50.3%), of whom 107 (51 females) were at high genetic risk and 97 (45 females) low risk. Participants stratified by SN hyperechogenic area of SN⩾0.22 vs SN<0.22 were similar for comorbidities and family history of PD except for migraine with aura, which was more commonly present in the hyperechogenicity group (16% (9/56) vs 3% (3/148); p=0.001). The SN groups differed for polygenic risk, de novo PD and results of Sniffin' sticks test (all p<0.001). All 12 de novo PD patients had SN⩾0.22. A multivariable logistic model adjusted for age and sex showed a significant association between better Sniffin' sticks test result and a reduced risk of hyperechogenicity (adjusted odds (aOR) was 0.58, 95% CI 0.46-0.95; p<0.0001). The model explained 11% of the variance (area under the curve (AUC) was 0.71) in SN outcome. The addition of the PRS risk group significantly increased the variance explained to 21% (AUC=0.81). The aOR of PD for the high polygenic risk group was more than 6 times higher (aOR=6.35, 95% CI 2.85-14.13; p<0.0001). Interaction between Sniffin' sticks test and PRS risk groups was not significantly associated with SN outcome (p=0.78).

These finding show that the risk for PD is genetically influenced. An individual's PRS could be clinically actionable and adds predictive value for the development of PD, if used with other non-genetic predictors (lifestyle, comorbidities, echogenicity in SN). We showed for the first time that prodromal markers such as TCS and hyposmia can strengthen the effect of PRS in early detection of PD, which needs to be investigated prospectively.

Rationale: Patients with severe coronavirus disease 2019 (COVID-19) can develop residual lung abnormalities consistent with lung fibrosis. Existing studies assessing the genetic overlap of idiopathic pulmonary fibrosis (IPF) and COVID-19 have primarily concentrated on previously identified IPF genome-wide significant risk variants, rather than on combined whole-genome polygenic risk. **Objective:** We hypothesized that the use of IPF whole-genome polygenic risk scores (PRSs) will assist in further characterizing the shared genetic component with COVID-19. Here we derived PRS models from IPF genome-wide association study (GWAS) results and studied their association with COVID-19 severity. **Methods:** We used results from the largest meta-GWAS of clinically defined IPF risk (base dataset; n=24,589) and individual-level imputed data from the SCOURGE study of patients with COVID-19 (target dataset; n=15,024). We calculated IPF PRSs using PRSice-2 and assessed their association with COVID-19 hospitalization, severe illness, and critical illness. We also evaluated the association stratifying by age and sex. Results were validated using an independent PRS method. Enrichment analyses and pathway-specific PRSs were performed to study biological pathways associated with COVID-19 severity. **Results:** IPF PRSs were significantly associated with COVID-19 hospitalization and severe illness. The strongest association was found in patients aged 60 years or younger, especially among younger males (OR=1.16; 95%CI=1.08-1.25; $p=6.39x10^{-5}$). A pathway enrichment analysis of the variants included in the best model fit and subsequent pathway-specific PRS analyses supported the link of Cadherin and Integrin signaling pathways with COVID-19 severity when stratified by age and sex. **Conclusion:** Our results suggest that there is a genome-wide genetic overlap between IPF and severe COVID-19 that is dependent on age and sex and adds further support that the pathogenesis of both IPF and severe COVID-19 share underlying biological mechanisms. This could imply that individuals with high IPF genetic risk are at an overall increased risk of developing post-severe COVID-19 lung sequelae. **Funding:** Wellcome Trust 221680/Z/20/Z; GlaxoSmithKline Asthma + Lung UK Chair in Respiratory Research (C17-1); Instituto de Salud Carlos III (COV20_00622, PI20/00876); European Union (ERDF) 'A way of making Europe'; Fundación Amancio Ortega, Banco de Santander; Cabildo Insular de Tenerife (CGIEU0000219140 and 'Apuestas científicas del ITER para colaborar en la lucha contra la COVID-19'); Fundación Canaria Instituto de Investigación Sanitaria de Canarias (PIFIISC20/57).

Crescenz VA Med. Ctr., Philadelphia, PA, [8]Div. of Hematology/Oncology, Dept. of Med., Perelman Sch. of Med., Philadelphia, PA, [9]Dept. of Genetics, Perelman Sch. of Med., Univ. of Pennnsylvania, Philadelphia, PA

Background: Genome-Wide Association Studies (GWAS) have identified single nucleotide polymorphisms (SNPs) that are associated at low effect size with many cancers. Polygenic risk scores (PRS) have been shown to improve risk prediction in individuals of European genetic ancestry (EUR); however, predictive ability in patients of African genetic ancestry (AFR) is less clear. Furthermore, whether cancer PRS demonstrate pleiotropic effects on other cancers or diseases is unknown. **Methods:** We construct PRS from GWAS significant SNPs identified by the largest published GWAS for 13 cancers (bladder, breast, colorectal, esophageal, glioma, lung, melanoma, oral cavity, pancreatic, prostate, renal, testicular, and thyroid) in a large racially diverse biobank, The Million Veterans Program (MVP). We perform a phenome-wide association study (PheWAS) to determine associations between cancer-specific PRS and other phenotypes with emphasis on cross-cancer pleiotropy and cardiometabolic phenotypes. **Results:** All PRS were significantly associated with their respective cancers in EUR individuals (OR 1.04 to 1.70). In AFR individuals, PRS were significantly associated with their respective cancers for bladder, breast, colorectal, lung, pancreatic, prostate, testicular and thyroid (OR 1.05 to 1.48). Addition of the PRS component to basic models showed >1% increase in discriminatory accuracy (ΔAUC) for 7 of 13 cancers in EUR individuals, but only 1 of 13 cancers in AFR individuals. Cancer-cancer pleiotropy in EUR showed association of lung cancer PRS with Non-Hodgkin Lymphoma (OR=1.08, p<0.001), with other nominal associations. In AFR, bladder cancer PRS was associated with esophageal cancer (OR=1.32, p=0.03), breast with esophageal cancer (OR=1.30, p=0.04), ovarian with thyroid cancer (OR=1.34, p=0.03), testicular with non-Hodkin lymphoma (OR=1.16, p=0.01), and thyroid with kidney cancer (OR=1.10, p=0.04). Regarding cardiac phenotypes, colorectal PRS was associated with hypertrophic obstructive cardiomyopathy (OR=1.18, p=0.02), esophageal cancer with heart failure (OR=1.10, p<0.01), glioma with acute pericarditis (OR=1.20, p<0.01), and lung cancer with Granulomatosis with Polyangiitis (OR=1.51, p<0.001).**Conclusions:** Models including age, principal components, gender and cancer-specific PRS are strongly associated with their respective cancers in EUR individuals, and have less strong associations in AFR individuals, owing almost entirely to the non-PRS components of the model. While rare cross-cancer and cardiometabolic pleiotropic effects of cancer PRS exist, most cancer PRS show tissue and disease-specific genetic associations.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1717 Polygenic risk scores for major depressive disorder provide insights into medication use prediction in EHR-linked biobank.

Authors:

S. Lapinska[1], V. Venkateswaran[1], K. Boulier[1], Y. Ding[1], A. Pimplaskar[2], L. O. Loohuis[1], B. Pasaniuc[1]; [1]UCLA, Los Angeles, CA, [2]Univ. of California, Los Angeles, Los Angeles, CA

Major depressive disorder (MDD) is the most common psychiatric illness. Studies have shown that MDD has a complex etiology with possible population differences in predisposing genetic factors. Investigating the relationship between ancestry and MDD could provide insight into how individuals may respond to certain treatments. We use a publicly available polygenic risk score (PGS) trained on European individuals from the UK Biobank data for major depressive disorder to investigate the clinical utility of PGS in medication use prediction within the diverse UCLA ATLAS biobank (N &gt 40,000).First, we found that the standardized MDD-PGS is associated with the phecode for MDD across genetically inferred ancestry (GIA) groups including European American (EUR) (OR: 1.259, CI: [1.215, 1.306]), Hispanic Latin American (AMR) (OR: 1.117, CI: [1.036, 1.204]), African American (AFR) (OR: 1.126, CI: [0.971, 1.304]), and East Asian American (EAS) (OR: 1.425, CI: [1.264, 1.606]). Next, we identified binary medication-use phenotypes based on treatment options for individuals diagnosed with MDD using de-identified patient information within the EHR-linked ATLAS biobank. Medication-use was defined into three categories: long term use of the most recent medication class, treatment resistant, and efficacious to one medication class. For all analyses, we restricted to individuals diagnosed with MDD who have no other psychiatric comorbidities like bipolar, schizophrenia, substance use, and alcohol use disorders. Using a GIA- stratified logistic regression model adjusted for age, age2, sex, and first 5 principal components, we found MDD-PGS significantly associated with long term serotonin use in MDD diagnosed individuals with AFR ancestry (OR: 0.590, CI: [0.370, 0.941], p-value: 0.027). This suggests that higher genetic risk for MDD correlates with decrease in serotonin usage in individuals of AFR ancestries. In addition, MDD-PGS significantly associated with long term antipsychotic use in MDD diagnosed individuals with EAS ancestry (OR: 1.738, CI: [1.015, 2.978], p-value: 0.044) suggesting that these individuals have an increase in antipsychotic usage with higher genetic risk for MDD.Overall our study demonstrates the potential use of PGS to determine effective treatments for individuals diagnosed with major depressive disorder across ancestries. Further work to understand the relationship between polygenic risk scores, medication use, and ancestry is needed, but our current findings show a promising clinical utility of PGS.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1718 Polygenic risk scores predict blood pressure traits across the lifespan

Authors:

K. Øvretveit[1], E. M. L. Ingeström[1], M. Spitieris[1], V. Tragante[2], K. H. Wade[3], L. Thomas[1], B. Wolford[1], U. Wisløff[1], D. Gudbjartsson[2], H. Holm[2], K. Stefansson[2], B. Brumpton[1], K. Hveem[1]; [1]Norwegian Univ. of Sci. and Technology, Trondheim, Norway, [2]deCODE genetics, Reykjavik, Iceland, [3]Univ. of Bristol, Bristol, United Kingdom

Background: Hypertension is a major modifiable cause of morbidity and mortality that affects over 1 billion people worldwide. Hypertension-related disease risk occurs at high blood pressure (BP) levels and well down into the normal range. The genetic contribution to complex phenotypes such as BP traits is quantifiable with polygenic risk scores (PRSs), but the performance of such risk constructs can differ based on factors such as derivation method, trait polygenicity, and the size and characteristics of the base, training, and validation data.
Aims: Develop multiple PRSs for BP traits incorporating a range of <1,000 to >1,000,000 genetic variants, compare their strength of association with various BP traits across the lifespan, and test the predictive performance of the top performing PRSs on hypertension-related morbidity and mortality.
Methods: We included participants from the Trøndelag Health Study (HUNT; n = 86,569), deCODE genetics (n = 81,117), and the Avon Longitudinal Study of Parents and Children (ALSPAC) study (n = 6,807). Four methods were used to construct PRSs for systolic BP (SBP), diastolic BP (DBP), and pulse pressure (PP): a weighted PRS restricted to genome-wide significant variants, pruning and thresholding (P+T), and the two Bayesian approaches (LDpred and PRS-CS). 87 scores across the three BP traits were trained in an independent cohort (deCODE). The best performing scores were applied in cohorts of children (ALSPAC) and adults (HUNT).
Results: Bayesian methods incorporating >1,000,000 genetic variants improved phenotypic association by 44% to 80% compared to PRSs restricting to variants below the genome-wide significance threshold. These PRSs were associated with BP levels across the lifespan and hypertension-related disease risk. Differences between those with low (1st decile), average (2nd to 9th decile), and high (10th decile) PRS appear to emerge in the first 3-5 years of life and be maintained throughout the life course. In adulthood, those with a high SBP PRS had increased risk for cardiovascular and chronic kidney disease, whereas the risk was reduced among those with low a SBP PRS.
Conclusions: Given the importance of exposure time in disease pathogenesis and the differences in BP between genetic risk levels throughout life, PRSs may help identify high-risk individuals prior to hypertension onset, thereby improving prevention and management of this public health challenge.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1719 Polygenic risk scores: Prediction of type 2 diabetes mellitus in multiplex families from the multiethnic GENNID study.

Authors:

L. Simon, J. Y. Wan, B. Wu, K. L. Edwards; Univ. of California, Irvine, Irvine, CA

Background: Type 2 diabetes mellitus (T2DM) is a major global health problem. Prevalence differs by ethnicity in the US, with Blacks and Hispanics having higher rates compared to Asians and Whites. While T2DM is a complex, polygenic disease with a strong genetic component, T2DM-associated common variants identified through GWAS have only explained a small proportion of T2DM heritability. Composite genetic risk measures such as polygenic risk scores (PRS) may enhance T2DM risk prediction. Most existing T2DM PRS are derived from European-dominant source populations and may not perform as well in diverse populations. We selected ethnic-specific PRS (adjusted for age, sex and BMI) constructed from multiethnic populations by Polfus et al (2021) and evaluated how these ethnic-specific PRS performed in our multiethnic GENNID families enriched for T2DM.
Methods: The GENNID study target population consists of 1651 subjects in 340 T2DM multiplex families from African American (AA), European American (EA), Japanese American (JA) and Mexican American (MA) families. PLINK and R were utilized for data QC of the GENNID dataset and PRS analyses. PRS Beta weights were derived from Polfus et al for all 582 genome-wide significant variants and were then used to generate PRS scores for each ethnic group. Using GLMMs with a family random effect, we assessed T2DM PRS prediction by also computing the AUC of ROC curves for each GENNID ethnicity and evaluated the impact of adjusting these models for age, sex and BMI.
Results: Of the 582 SNPs included in the ethnic-specific PRS constructed by Polfus et al, 537, 562, 419, and 549 overlapped in GENNID AA, EA, JA, and MA ethnic groups, respectively. T2DM PRS risk prediction models adjusted for age, sex and BMI in GENNID yielded AUCs of 89.3% (95% CI: 84.4-94.3%) for AA, 61.3% (55-67.7%) for EA, 65.7% (54.5-76.8%) for JA, and 60.6% (54.4-66.8%) for MA. Using only computed PRS (without modeling covariate adjustments) resulted in poor AUCs with 95% CIs (within 50%) when applied to each GENNID ethnic group. Compared to those reported by Polfus et al, all AUCs were lower in GENNID except for the adjusted AA model.
Conclusions: We applied an existing multiethnic T2DM PRS to an independent multiethnic sample of families enriched for T2DM to quantify T2DM risk prediction. As our unadjusted PRS models yielded very poor AUCs compared to our adjusted PRS models, it appears necessary to adjust for appropriate covariates to optimize the generalizability of T2DM prediction using PRS. Future research aimed at understanding how to enhance the generalizability and effectiveness of PRS across multiethnic populations is still needed to optimize T2DM genetic risk prediction.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1720 Polygenic Scores for DZ Twinning in Mothers of Naturally and ART Conceived Twins and Singletons

Authors:

D. Boomsma[1], N. Hubers[1], C. Page[2], H. Mbarek[3], C. Lambalk[4], L. Ligthart[5], R. Pool[1], J- . Hottenga[1], S. Håberg[6], E. Ehli[7], G. Willemsen[5], J. Harris[8], N. Martin[9], J. van Dongen[10]; [1]VU Univ. Amsterdam, Amsterdam, Netherlands, [2]4The Ctr. for Fertility and Hlth., Norwegian Inst. of Publ. Hlth., Oslo, Norway, [3]Qatar Genome, Doha, Qatar, [4]AUMC, Amsterdam, Netherlands, [5]VU Univ., Amsterdam, Netherlands, [6]Ctr. for Fertility and Hlth., Norwegian Inst. of Publ. Hlth., Oslo, Norway, [7]Avera Inst. for Human Genetics, Sioux Falls, SD, [8]Norwegian Inst Pub Hlth, Silver Spring, MD, [9]Queensland Inst Med Res, Brisbane, Australia, [10]VU Amsterdam, Amsterdam, Netherlands

Natural dizygotic (DZ) twinning results from a double ovulation and has a genetic component. Endocrinology studies in mothers of DZ twins observed higher levels of follicle stimulating hormone (FSH) and *FSHB* was, together with *SMAD3*, one of the first loci identified as significant in genome-wide association studies (GWAS) of having DZ twins. Several additional loci such as *FSHR*, and *GNRH1* have recently been found that confirm the role of genes involved with female endocrinology in fertility. A polygenic score (PGS) for spontaneous DZ twinning explained ~1.5% of the phenotypic variance when comparing mothers of naturally conceived DZ twins to controls. Here we compare the PGS in mothers of naturally conceived DZ twins with other twin mothers in the Netherlands twin register (NTR) and in the Norwegian Mother, Father and Child Cohort Study (MoBa). In the NTR, we contrast the PGSs in mothers who conceived DZ or monozygotic (MZ) twins naturally and those who conceived DZ or MZ twins through artificial reproductive techniques (ART) and test differences with logistic regression. Mothers of naturally conceived DZ twins differed in age, body composition, parity and smoking behavior compared to the other groups. The PGSs, both corrected and uncorrected for these demographic and lifestyle traits, were higher in mothers of naturally conceived DZ twins (N=1423) compared to all other twin mothers (N=2263) or compared to fathers of twins (N=2158). For ART mothers whose fertility treatment involved hormones without IVF (N=187) the PGS was significantly lower than for the other three groups (DZ-IVF and MZ mothers). We are currently replicating and extending these analyses in mothers of twins and mothers of singletons from MoBa (N = ~ 95.000 mothers). Our study shows that mothers of spontaneously conceived DZ twins are genetically different and that a PGS for DZ twinning may also be associated with infertility treatment.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1721 Pooled and sex-specific European-ancestry GWAS meta-analyses of restless legs syndrome identify 164 risk loci, enabling advanced risk prediction, causal inference exploration, and treatment target identification

Authors:

B. Schormair[1,2], C. Zhao[2], S. Bell[3], M. Didriksen[4], M. S. Nawaz[5], P. Clinical Immunology, Copenhagen Univ. Hosp., RigsHosp.et, Copenhagen, Denmark, [5]deCODE Genetics/Amgen, Reykjavik, Iceland, [6]23andMe, Sunnyvale, CA, [7]Dept. of Neurology and Program in Sleep, Emory Univ., Atlanta, GA, [8]Montreal Neurological Inst.-Hosp., Montreal, QC, Canada, [9]Inst. of Epidemiology and Social Med., Univ. of Münster, Münster, Germany, [10]deCODE genetics, Reykjavik, Iceland, [11]Statens Serum Inst., Copenhagen, Denmark, [12]Univ. of Cambridge, Natl. Inst. for Hlth.and Care Res. Blood and Transplant Res. Unit in Donor Hlth.and Behaviour, Cambridge, United Kingdom

Restless legs syndrome (RLS) is a prevalent chronic sensorimotor disorder, affecting up to 10% of the elderly population in Europe and North America. It impacts severely on mental and physical health by disrupting sleep and daytime functioning and being frequently comorbid with metabolic, cardiovascular, and psychiatric diseases. Delayed diagnosis, sub-optimal therapy and the chronic nature of the disease further worsen the situation of affected individuals. Progress towards better health care for RLS patients is impeded by the limited knowledge of the underlying pathology and interrelationships with other disorders.

To advance disease prediction and find novel entry points for treatment, we performed a meta-analysis of genome-wide association studies (GWAS) in 1,589,569 individuals of European ancestry using N-GWAMA (116,403 cases and 1,473,166 controls). Our analyses also included the first sex-stratified GWAS and first genetic investigation of the X chromosome in RLS. Functional interpretation of the GWAS results was done by gene annotation and prioritization (using DEPICT, FUMA, MAGMA, MetaXcan), pathway and cell type enrichment analyses (DEPICT, MAGMA, CELLEX, CELLECT), as well as extensive genetic correlation (LDSC) and Mendelian randomization analyses (LHC-MR, IVW-MR). Finally, we evaluated the performance of different models integrating genetic and non-genetic effects in RLS risk prediction, using traditional polygenic risk scores as well as machine learning approaches (PRSice; GLM, DNN and RF models in H2O AutoML and PyTorch).

The pooled meta-analysis of both sexes increased the number of known risk loci to now 164 loci comprising 196 independent lead SNPs, with the first sex-specific GWAS on RLS revealing largely overlapping genetic predispositions of the sexes (r_g=0.96). Annotation of genes in risk loci by mapping against the druggable genome identified 13 potential candidates targeted by existing compounds for expanding treatment options, e.g. *GRIA1* and *GRIA4* encoding glutamate receptor subunits. Mendelian randomization suggested RLS as a causal risk factor of diabetes and hypertension. Among the tested risk prediction models, machine-learning approaches combining genetic and environmental information performed best (AUC=0.82-0.91). Our study identified targets for drug development, prioritized potential causal relationships between RLS and relevant comorbidities and risk factors for follow-up, and provided evidence that gene-environment interaction is likely highly relevant for RLS risk prediction.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1722 Population genetics analysis of *CLDN16* and *CLDN19* of familial hypomagnesemia with hypercalciuria and nephrocalcinosis.

Authors:

I. Patel[1], K. Lovrenert[1], M. Baum[2], F. Hildebrandt[3], D. Bodner[4], F. Schumacher[5], C-H. Wu[6]; [1]Case Western Reserve Univ., Cleveland, OH, [2]Boston Children's Hosp., Boston, MA, [3]Boston Children's Hosp, Boston, MA, [4]Univ. Hosp., Cleveland, OH, [5]Case Western Reserve Univ, Cleveland, OH, [6]Univ. Hosp./Case Western Reserve Univ, Cleveland Heights, OH

Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC) is an autosomal recessive progressive renal disorder characterized by excessive urinary calcium and magnesium excretion. FHHNC results in progressive loss of kidney function, typically presenting during early childhood. Current therapeutic options consist of oral magnesium supplementation and thiazide diuretics. Neither treatment has significant effects and about 50% of FHHNC cases result in the need for renal replacement therapy as early as 20 years of age. Efforts to uncover the genetic etiologies of FHHNC have resulted in the identification of two causal genes: *CLDN16* (Claudin 16, also known as Paracellin-1), located on chromosome 3q28, and *CLDN19* (Claudin 19), located on chromosome 1p34.2. Proteins encoded by *CLDN16* and *CLDN19* are integral membrane proteins, a component of tight junction strands, and primarily expressed on the Loop of Henle. As reports investigating the genetic epidemiology are relatively scarce, this investigation works to estimate the genetic prevalence of FHHNC through the *CLDN16* and *CLDN19* genes and compare it to the clinical prevalence.

The 1000 Genomes Project (1KG) was utilized to identify genetic variants in the general population of 2,504 individuals. The Human Gene Mutation Database (HGMD) was used to identify pathogenic variants of *CLDN16* and *CLDN19*. Overlapping variants procured from both databases were evaluated. The pathogenic allele frequency, carrier rate, and affected rate were calculated and estimated based on the Hardy-Weinberg equilibrium. 1KG contained 625 and 140 variants for *CLDN16* and *CLDN19*, respectively. HGMD contained 69 and 21 unique pathogenic variants of *CLDN16* and *CLDN19* respectively. The intersection between HGMD and 1KG resulted in no pathogenic variants of *CLDN16* and two pathogenic variants of *CLDN19* across three heterozygous carriers (pathogenic variant allele frequency of 0.06%). The expected carrier rates were 0 for *CLDN16*, and 1 in 835 for *CLDN19*, and for the cumulative rate combining both genes. The expected affected rates were 0 for *CLDN16*, 1 in 696,668 for *CLDN19*, and for the cumulative rate combining both genes.

FHHNC is a rare disorder and the population prevalence is unknown. Only ~100 patients with a *CLDN16* causative variant ~70 patients with a *CLDN19* causative variant have been described in the literature. This investigation found no *CLDN16* related carriers and three *CLDN19* related carriers. The genetics findings are not consistent with the current clinical observations, which requires further investigation.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1723 † Population-scale analysis of the trinucleotide repeat expansion in the Huntingtin gene (HTT) from 854,251 human exomes

Authors:

V. Pounraja[1], S. O'Keeffe[1], X. Bai[1], F. Grau[2], S. Wolf[1], R. Sundaramoorthy[2], M. D. Kessler[1], N. Parikshak[1], W. Salerno[1], G. Coppola[1], DiscovEHR Collaboration, Penn Medicine BioBank, Mayo Clinic Project Generation, S. Gelfman[1]; [1]Regeneron Genetics Ctr., Tarrytown, NY, [2]Regeneron Pharmaceuticals, Tarrytown, NY

Background: A pathological trinucleotide CAG repeat expansion (TRE) in the Huntingtin gene (HTT) causes Huntington's disease (HD) with variable risk (36-39 lower risk, ≥40 higher risk). However, population scale characterization of normal and expanded repeat length is lacking. Here, we leveraged whole-exome sequencing (WES) data to call HTT repeat expansions in the UK Biobank and five additional large EHR cohorts. Using these calls, we estimated prerisk/risk prevalence in various ancestries, and validated the results both experimentally and through association analyses.
Methods: We used gangSTR to call repeat expansions across 854,251 samples, including 762,895 samples of European ancestry (89%), 41,130 samples of African ancestry (5%), and 31,784 samples of South Asian ancestry (4%). To estimate the accuracy of this calling approach, we experimentally validated 27 HD cases and 27 randomly chosen controls using a PCR-based approach (Asuragen AmplideX PCR kit). We assessed various sequence derived metrics and applied strict quality control criteria to the full cohort, followed by comparison of the distributions of repeat lengths across cohorts and ancestries. Last, we binarized repeat length based on either prerisk/pathogenic (≥36 & ≥40) or percentile (Top 1%/0.1%/0.01%) cut-offs and associated them with case-control status using 49 HD cases and 558,736 controls.
Results: The sensitivity and specificity of the predictions estimated based on PCR validation was 74% and 100%, respectively. Four HD cases predicted with non-pathogenic expansions were validated to carry normal repeat length. The prevalence of pre-risk (0.23%; n=1,916) and pathogenic expansions (0.053%; n=437) were higher than the prevalence of HD in general population (0.003-0.006%), yet consistent with literature. This excess of carriers with expanded repeats could be attributed to false positives or patients at risk of developing HD. We also found the prevalence of prerisk expansions to be higher in Europeans compared to south Asians (0.24% vs. 0.16%; Fisher's exact p=7.4e-3). A meta-analysis showed that the top 0.1% repeat length of 38 associated most strongly with HD (OR=213.4; p=8.9e-37), compared with the risk threshold cutoff of ≥40 that had the largest effect size (OR=331.4, p=1.9e-32).
Conclusion: This is the largest population-scale characterization of HTT repeat expansions called using whole exome sequencing data. Our results demonstrate that normal and pathogenic repeat expansions can be identified with high specificity and adequate sensitivity and help refine population prevalence and penetrance estimates.

PB1724 Potentialmodificationsof *ABCG2 rs4148155* and *SLC22A12 rs75786299* on gout and nephrolithiasis: A hospital-based, case-control study.

Authors:

C-H. Lin, C-T. Lin, Y-M. Chen; Taichung Veterans Gen. Hosp., Taichung, Taiwan

Objective: A strong connection between gout and specific genetic variations, namely ABCG2 rs4148155 and SLC22A12 rs75786299, has been established. Gout, a condition characterized by excessive levels of uric acid, is a significant risk factor for the formation of urate stones. However, the precise interplay between ABCG2 rs4148155 and SLC22A12 rs75786299 in relation to gout and nephrolithiasis remains to be explored. Consequently, the objective of this study was to examine the correlation between these genetic variants and the occurrence of gout and nephrolithiasis.Methods: This case-control study utilized data from the Taiwan Precise Medicine Initiative (TPMI) and involved 35,280 adults. The genotypes *ABCG2 rs4148155* and *SLC22A12 rs75786299* were examined, and multivariable logistic regression was employed to analyze the adjusted odds ratios (ORs) of gout and nephrolithiasis Results: The study revealed that the rs4148155 G allele had a frequency of 33%, while the rs75786299 A allele had a frequency of 2.4%. Both the ABCG2 rs4148155 (GG and AG) and SLC22A12 rs75786299 (GA) polymorphisms showed significant associations with gout and nephrolithiasis. The risk of gout was 1.60 (1.51-1.69) for individuals carrying a single copy of the rs4148155 G allele and 3.22 (2.66-3.90) for individuals carrying both the rs4148155 G and rs75786299 A alleles. Similarly, the risk of nephrolithiasis was 1.09 (1.02-1.17, p=0.01) for single carriers of the rs4148155 G allele and 1.40 (1.09-1.81, p=0.009) for individuals carrying both the rs4148155 G and rs75786299 A alleles. Conclusion: This study supports an additive model for the development of gout and nephrolithiasis. Carriers of both the rs4148155 G and rs75786299 A alleles face an increased risk of developing these conditions. The findings underscore the importance of implementing precision healthcare strategies to address gout and nephrolithiasis in individuals carrying the rs4148155 G and rs75786299 A alleles.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1725 Precision risk profiling of Type 1 Diabetes individuals in the INNODIA, Danish and UK Biobank cohorts, using HLA imputation and haplotype analysis.

Authors:

S. Kaur[1], C. Brorsson[2], T. S. Ahluwalia[1], C. H. Johansen[2], S. Brunak[2], F. Pociot[1]; [1]Steno Diabetes Ctr. Copenhagen, Herlev, Denmark, [2]Univ. of Copenhagen, Copenhagen, Denmark

Background and aims: Genome wide association studies (GWAS) in Type 1 Diabetes (T1D) have identified ~152 susceptibility loci so far. One of the major risk locus in T1D is the major histocompatibility complex (MHC) region on chr6 encoding the human leucocyte antigen (HLA) proteins. Class II HLA DR and DQ loci contribute to an overall genetic risk of 30-50%. The MHC region is highly polymorphic with more than 6,000 classical HLA alleles and amino-acid polymorphisms. The accurate genotyping of this region is possible but highly expensive. In this study, we imputed the classical alleles and amino acid polymorphisms at class I and II HLA loci in the newly diagnosed type 1 diabetes (T1D) individuals from INNODIA and Danish Biobank cohorts to identify high-risk HLA haplotypes.

Materials and methods: The HLA imputation was performed on 695 INNODIA samples (301 T1D and 394 unaffected family members) originally genotyped on the Affymetrix UK Biobank Axiom Array using SNP2HLA and the T1D Genetics Consortium (T1DGC) reference panel. The T1DGC reference panel contains 5,868 SNPs (genotyped with Illumina Immunochip) and 4-digit classical HLA types for HLA-A, -B, -C, -DPA1, -DPB1, -DQA1, -DQB1 and -DRB1 for 5,225 unrelated individuals of European descent. The Danish Biobank samples consisting of 2,853 newly diagnosed T1D and 1,983 healthy control individuals genotyped on ImmunoChip were also imputed for HLA alleles and amino-acid polymorphisms. From the UK Biobank, genotyping data for 3,397 T1D individuals and 7476 healthy controls (Caucasians) were extracted for validation studies. The genotype concordance and imputation accuracy for the INNODIA samples were calculated for SNP2HLA imputed alleles and Axiom HLA Imputation.

Results and Conclusions: Using the T1DGC reference panel, we imputed 8,961 makers (1,390 haplotypes) for the 695 individuals (301 cases, 394 unaffected family members) genotyped in the INNODIA cohort. A total of 8,667 markers achieved high imputation accuracy (r^2 dosage>0.8) that included 348 two and four- digit HLA alleles and 384 amino acid positions (1,130 residues). Previous studies have shown that risk conferring residues at three positions (DQB1_aa57_alanine, DRB1_aa71_lysine and DRB1_aa13_histidine) tags the well-established DRB1*03 and DRB1*04 haplotypes known to confer the strongest risk. Our preliminary results showed strongest association for DQB1_aa57(AD|AV|AS), DRB1_aa13(HY|HF|HG) and DRB1_aa11 (VG|VL|VD) haplotypes based on a sliding window approach of 3-SNP haplotypes in both INNODIA and Danish Biobank cohorts. Further analyses are ongoing to validate the findings in the UK Biobank cohort.

Ctr. and NTT Basic Res. Lab., Nippon Telegraph and Telephone Corp., Tokyo, Japan, [5]Med. Business Planning Office, Nippon Telegraph and Telephone Corp., Tokyo, Japan, [6]Div. of Molecular Pathology, The Inst. of Med. Sci., The Univ. of Tokyo, Tokyo, Japan

Obesity is a global health threat and is associated with age-related changes. Body mass index (BMI) is the most widely used measure of obesity. However, the genetic effects on BMI changes with age during adulthood remain less understood. We evaluated BMI changes using polygenic score (PGS) in a working-age cohort comprised of employees of Nippon Telegraph and Telephone Corporation (NTT) group companies who underwent annual health examinations. This longitudinal cohort consisted of up to 36,389 participants with whole genome genotypes, including data from 1990 to 2022 (range in age: 17 - 67 years). The data of all participants was collected with written informed consent. After stringent quality control, genotype data were imputed using the 1000 Genomes Project reference panel (phase3v5, N = 2504). We constructed PGS using PRS-CSx for 1,015,557 SNPs from GWAS of BioBank Japan (n=158,284) and that of Tohoku Medical Megabank (n=47,070) summary statistics. The association of BMI-PGS and severe obesity (BMI>35) was evaluated by Kaplan-Meier curves and a multivariate Cox proportional hazards regression analyses. Among individuals in the top decile of BMI-PGS, 7.2% developed severe obesity, compared with only 2.4 % of those in the remaining samples (log-rank test $p=1.75x10^{-101}$). As a result of Cox proportional hazards regression adjusted for baseline BMI, the effect of PGS was hazard ratio of 1.22 per 1-SD ([95%CI 1.14-1.32], $p=7.75x10^{-7}$).We also estimated a baseline and linear change over time of individual BMI trajectory using the longitudinal linear mixed effects model, where the baseline and change were modeled as random intercept and slope, respectively. The estimated random slope was in the range of [-0.96-1.61]. Including fixed effects, 76% of individuals had a positive slope and a tendency to gain weight. Further, we evaluated the effect of BMI-PGS on the estimated random effects using linear regression adjusted for sex, age, and genotype principal components (PCs). This analysis identified the significant effect for the baseline (beta per 1-SD of PGS increase 0.30 [95%CI 0.29-0.31], $p=3.40x10^{-718}$) as expected, as well as the linear change (beta per 1-SD of PGS 0.079 [95%CI 0.068-0.089], $p=1.22x10^{-49}$), which further shed light on the genetic architecture of age-related BMI changes.In summary, we have demonstrated that BMI-PGS not only strongly affects baseline BMI but also affects BMI changes. These results suggest that BMI-PGS can predict future obesity independently of baseline BMI.

PB1727 Predicting mechanisms of action at genetic loci associated with discordant effects on type 2 diabetes and abdominal fat accumulation.

Authors:

Y. Aberra[1], L. Ma[2], J. L. Bjorkegren[2], M. Civelek[1]; [1]Univ. of Virginia, Charlottesville, VA, [2]Icahn Sch. of Med. at Mount Sinai, New York, NY

Metabolic syndrome (MetSyn) is a cluster of dysregulated metabolic conditions that occur together to increase the risk for cardiometabolic disorders such as type 2 diabetes (T2D). One key condition associated with MetSyn, abdominal obesity, is measured by computing the ratio of waist-to-hip circumference adjusted for the body-mass index (WHRadjBMI). WHRadjBMI and T2D are complex traits with genetic and environmental components, which has enabled genome-wide association studies (GWAS) to identify hundreds of loci associated with both. Statistical genetics analyses of these GWAS have predicted that WHRadjBMI is a strong causal risk factor of T2D and that these traits share genetic architecture at many loci. To date, no variants have been described that are simultaneously associated with protection from T2D but with increased abdominal obesity. Here, we used colocalization analysis to identify genetic variants with a shared association for T2D and abdominal obesity. This analysis revealed the presence of five loci associated with discordant effects on T2D and abdominal obesity. The alleles of the lead genetic variants in these loci that were protective against T2D were also associated with increased abdominal obesity. We further used publicly available expression, epigenomic, and genetic regulatory data to predict the effector genes (eGenes) and functional tissues at the 2p21, 5q21.1, and 19q13.11 loci. We also computed the correlation between the subcutaneous adipose tissue (SAT) expression of predicted effector genes (eGenes) with metabolic phenotypes and adipogenesis. We proposed a model to resolve the discordant effects at the 5q21.1 locus. We find that eGenes gypsy retrotransposon integrase 1 (*GIN1*), diphosphoinositol pentakisphosphate kinase 2 (*PPIP5K2*), and peptidylglycine alpha-amidating monooxygenase (*PAM*) represent the likely causal eGenes at the 5q21.1 locus. Taken together, these results are the first to describe a potential mechanism through which a genetic variant can confer increased abdominal obesity but protection from T2D risk. Understanding precisely how and which genetic variants confer increased risk for MetSyn will develop the basic science needed to design novel therapeutics for metabolic syndrome.

PB1728 Predicting Neurodegenerative Disease Risk using Feature Propagation on SNP Network with Brain Imaging Endophenotypes

Authors:

D-g. Lee, S-H. JUNG, L. Shen, D. Kim; Univ. of Pennsylvania, Philadelphia, PA

Background: The structural characteristics of the brain, specifically the decrease of individual gray (or white) matter volumes, provide valuable insights into brain function and cognitive decline, including the development of neurodegenerative diseases (NDDs). In addition, genetic factors can play a significant role in changes in brain volumes, influencing biological activities and interacting in complex ways. In this study, we aim to investigate the relationship between genetic factors, structural brain volume, and the risk of NDDs, such as dementia. Method: The proposed method utilizes a SNP network to capture interactions between genetic variants based on linkage disequilibrium scores. The network represents the complex relationships among genetic factors. Feature propagation, a technique that refines genetic variant information based on graph-based semi-supervised learning (GSSL), is then employed to predict NDD risk scores. Meanwhile, brain imaging endophenotypes, following the concept of transcriptome-wide association studies (TWAS), are used to enhance prediction power and identify significant regions affecting specific diseases. Moreover, a generative artificial intelligence model is applied to produce pseudo-imaging endophenotypes for samples with only genetic information. Result: The proposed method was applied to data including (i) both genetic and brain imaging information from two datasets: UK Biobank (UKBB), Alzheimer's Disease Neuroimaging Initiative (ADNI), and (ii) only genetic information from Alzheimer's Disease Sequencing Project (ADSP) dataset. The results were cross-validated from the two datasets (UKBB and ADNI), and a generative model was applied to ADSP data. The final prediction results were compared with other models, including the polygenic risk score-continuous shrinkage (PRS-CS) model. Compared to the other methods, the proposed method demonstrated superior prediction performance and revealed genetic variants and brain regions that impact NDDs. Conclusion: By integrating genetic information and brain imaging data, this study achieved improved disease risk prediction and a deeper understanding of the phased mechanism of NDDs associated with genetic variants and brain lesions. Furthermore, the insights gained into the relationship between genetics, brain structure, and diseases are expected to contribute to advancing our knowledge of disease progression and inform future research and clinical strategies for the prevention and management of these conditions.

PB1729 Prediction of Alzheimer's Disease Biomarkers Using Genomics and Cerebrospinal Fluid Metabolomics

Authors:

M. Francia[1], N. Ramesh[1], T. Boltz[1], L. M. Reus[1], M. Bot[1], W. F. van der Flier[2], P. Visser[2], S. van der Lee[2], B. M. Tijms[2], C. E. Teunissen[3], L. Olde Loohuis[1], R. Ophoff[1]; [1]Univ. of California Los Angeles, Los Angeles, CA, [2]Vrije Univ.it Amsterdam, Amsterdam, Netherlands, [3]Amsterdam UMC, Amsterdam, Netherlands

Metabolite measurements from the cerebrospinal fluid (CSF) have been employed as diagnostic tools for neurodegenerative disorders, such as Alzheimer's disease (AD). AD's pathogenesis is identified by lowered measured levels of CSF amyloid Beta 1-42 (AB), and increased levels of phosphorylated tau (pTau) and total tau (tTau). Due to their direct contact with the brain, metabolites from the CSF are relatively close to these phenotypes and could be used to study biological pathways and signatures associated with neurological disorders. Furthermore, CSF metabolites could help elucidate the effect of the genetic architecture of these disorders, as genome wide association studies (GWAS) have shown that metabolic features can have a heritable component. While the *APOE* e4 allele has been implicated as the main AD risk locus, other sites of the genome have been found to be associated with AD, indicating a complex, polygenic architecture. Therefore, CSF metabolites are suitable to identify biological pathways impacted by both AD genetic factors and its hallmark biomarkers. For this purpose, we collected more than 5,000 CSF metabolite measurements from AD and mild cognitive impairment patients, and healthy individuals from the Amsterdam Dementia cohort (ADC), as well as imputed genotype data. Using the most recent AD GWAS to calculated a polygenic risk score (PRS) for AD that adds the effect of the *APOE* alleles as a weighted sum, we found a modest prediction of pTau and tTau by the PRS in linear models after correcting for age and sex, however this effect was mainly driven by *APOE* e4 allele counts, and is smaller in comparison to the large effect size that is seen for AB. No CSF metabolites were found to be significantly predicted by the PRS or *APOE* e4 allele counts. We then used an elastic net model to predict AD biomarkers levels using the measured CSF metabolites. This approach identified 18 and 20 metabolites that predicted CSF pTau and CSF tTau levels respectively, among them Cholesterol, Isothreonic acid, and Nicotinoylglycine. Within these CSF metabolites, we did not find any that predicted CSF AB levels. These results indicate that these biomarkers show independent, but biologically correlated aspects of AD pathogenesis. AB reflects the influence of the *APOE* e4 allele while pTau and tTau are associated with ongoing cellular processes. This is consistent with prior reports that sporadic AD pathogenesis could be driven by a dual-cascade. Further analysis on a separate cohort of healthy individuals, in which the same CSF metabolites were measured, is currently ongoing to replicate these results.

Univ. of Singapore, Singapore, Singapore, [13]Dept. of Infectious Diseases, The Univ. of Melbourne, The Peter Doherty Inst. for Infection and Immunity, Melbourne, Australia

Studies have shown that atherosclerosis begins during childhood and interventions for coronary artery disease (CAD) should commence early to reduce the incidence of CAD in adulthood. To identify individuals at high CAD risk for interventions, risk assessments would have to be conducted. During childhood, the threshold levels of CAD risk factors that are well established in adults, such as those for plasma lipid levels, are not applicable for children. One way to predict CAD risk in children would be to use polygenic risk scores (PRS) that are constructed from single-nucleotide polymorphisms associated with CAD. In this study, we used various PRS of CAD risk in Chinese adult populations that were reported in two previous studies to determine if they could predict measures of early cardiovascular health at ages 6, 8 and 10 in children of the Growing Up in Singapore Towards healthy Outcomes (GUSTO), a multi-ethnic birth cohort from Singapore. One of the PRS used was consolidated from CAD and eight CAD related traits PRS and thus referred to as metaPRS. However, since the GUSTO children are still young, their eventual CAD outcomes are unknown. To overcome this, we constructed a CAD Risk Index (CRI) to estimate their risk of CAD using gender, body mass index, plasma high-density lipoprotein levels, plasma low-density lipoproteins levels, triglyceride glucose index and carotid-femoral pulse wave velocity. The CRI is used as an outcome variable for evaluating the performance of the various PRS. We found the metaPRS to be significantly associated with CRI in Chinese at ages 6 (beta 0.304, SE 0.140, p 0.031), 8 (beta 0.327, SE 0.126, p 0.010) and 10 (beta 0.347, SE 0.149, p 0.021) and in pooled ethnic groups at ages 8 (beta 0.203, SE 0.093, p 0.029) and 10 (beta 0.251, SE 0.110, p 0.023) but not at age 6 (p 0.068). We also found childhood smoking exposure to be significantly associated with the CRI at age 6 (beta 0.031, SE 0.009, p 5.80×10^{-4}). We have validated the metaPRS and found it to be significantly associated with CAD in the Chinese adult population in Singapore. We concluded that PRS is a useful tool for predicting future CAD risk in children.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1731 Predictive modeling of alcohol consumption using blood-based biomarkers: A machine learning approach

Authors:

M. Hassan[1], A. Gentry[1], R. Peterson[2,1], B. Webb[3,1]; [1]Virginia Commonwealth Univ., Richmond, VA, [2]SUNY Downstate Hlth.Sci. Univ., Brooklyn, NY, [3]RTI Intl., Research Triangle Park, NC

Methods for predicting alcohol consumption are considered important tools for identifying individuals with a higher risk of Alcohol Use Disorder (AUD). Developing quick, accurate, and reliable tools for predicting alcohol use is important for research and translational applications. While self-report and structured diagnostic interviews serve these goals, biological-based indices may provide a complementary approach.Towards this goal, we applied machine learning (ML) methods to predict Alcohol Consumption (AC) and other outcomes from blood-based biomarkers. This research has been conducted using the UK Biobank Resource (ID30782). Five different phenotypic outcomes were predicted using 303 objective markers including 51 blood biochemistry assays, and 249 Nuclear Magnetic Resonance (NMR) metabolites, as well as covariates known to influence these outcomes including age, sex, and statin use. Outcomes included alcoholic Drinks per Week (DPW), height, Body Mass Index (BMI), Body Fat Percentage (BF%), and predicted Major Depression Symptoms (MDDsx). Four machine learning models were evaluated including LASSO, Ridge regression, Gradient Boosting Machines (GBM), and MBOOST. Performance was assessed across ML models using adjusted r-squared, Mean Absolute Error (MAE), and LDSC-based genetic correlation between observed and predicted measures in independent samples. Results show that LASSO achieved better performance compared to Ridge regression when solely trained on age and sex as features. The r-squared results for height, BF%, BMI, AC, and MDDsx are 0.53, 0.48, 0.01, 0.07, and 0.07 respectively. When adding blood-based measures, the results are improved for BF%, BMI, and DPW to 0.71, 0.46, and 0.33, respectively, but there is no significant change for height (0.55) or MDDsx (0.002). We also observed significant genetic correlation between observed and predicted AC. Compared to traditional methods for AC prediction, ML methods provide explainable models that are able to identify blood-based biomarkers and other features that are highly connected to AC. In addition, combination of ML and blood-based biomarkers presents an opportunity to predict patterns of alcohol consumption. A potential application of these predictions is in ever larger genetic studies where self-report or structured interviews related to AC may be absent but biomarkers may be available. Importantly, prediction of AC from blood-based measures represents a clinical opportunity to identify individuals for whom additional screening using structured interviews may be warranted.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1732 Pregestational Diabetes Induces GATA4 Expression and Activity in Neonatal Heart and Associated with Cardiac Fibrosis

Authors:

S. Mattapally; Mattapally Technologies, Birmingham, AL

Diabetes, cardiovascular disease, and congenital heart defects all run in families and are caused by a mix of hereditary and environmental factors. Most diseases are family, which shows a genetic predisposition, although environmental, stochastic, and epigenetic factors are also important. Enhancers are genomic sequences that are essential for controlling the levels of tissue-specific gene expression. As a result of chromosomal rearrangements, genetic diversity within enhancers, or epigenetic manipulation, an increasing number of disorders are connected to poor enhancer activity. Chakravarti group reported PAX3, is not expressed at this embryonic stage, there has been no discernible transcriptional shift in the human fetal gut development program controlled by RET Enhancers TFs, GATA2, RARB, and NKX2-5. The goal of the current investigation was to learn more about the cardiac consequences of pregestational diabetes. Here, we investigated if diabetes a pathological alteration in the newborn heart and creates an adverse environment for embryonic and fetoplacental development. Two groups of female Sprague Dawley rats (weighing 200-250g each) were created. (8 people per group). While Type 2 diabetes (Dia) was developed by nicotinamide and then a single intraperitoneal injection of 50 mg/kg streptozotocin (STZ), control (Con) rats were fed a normal diet. Following the diagnosis of diabetes, a trio breeding (two Con/Dia females and one Con male) was started to produce postnatal neonatal pups that were two days old from both a pregestationally diabetic and non-diabetic mother. In order to conduct molecular biology, biochemical, and histopathological research, newborn hearts were harvested and kept at -80^{o}C. In the newborn heart of the Dia group, we saw a significant (p 0.05) rise in lipid peroxidation and a significant (p 0.05) fall in endogenous antioxidants like SOD and GSH in a con group. Only neonates delivered to pregestationally diabetic mothers (Dia) were shown to have a substantial cardiac fibrosis in addition to oxidative stress as compared to controls. GATA4, NKX3-2, and SOX2 transcription factor activity in the neonatal heart of the Dia group increased more than twofold. We performed real-time PCR for mRNA quantification and western blot for protein expression to determine if enhanced transcription factor activity is linked to increased expression of mRNA, protein, or both. In neonatal diabetic hearts, we performed western blot for the genes GATA4, NKX2.5, SOX2, RB, and FOXO3A. Upcoming genomic technologies will be used in our research to uncover connections.

PB1733 Prenatal nutritional environment is associated with late-life cognition in the Health and Retirement Study, a natural experiment

Authors:

E. Vasiljevic[1], C. Engelman[2]; [1]Univ. of Wisconsin - Madison, Madison, WI, [2]Univ. of Wisconsin Madison, Madison, WI

INTRODUCTION: Early-life exposures are important to several late-life health outcomes. We sought to study the effect of an *in utero* nutritional environment and its interaction with Alzheimer's disease (AD) genetic risk on late-life cognitive function.
METHODS: We used a natural experiment created by the pellagra epidemic, a nutritional disease caused by a vitamin B_3 deficiency, in the early 20^{th} century, to evaluate the association between the *in utero* nutritional environment and late-life cognitive function in a subsample of Health and Retirement Study participants with data for all measures (N = 17,554). Pellagra mortality rates for a person's state of birth and gestation year were uses as a proxy for the prenatal nutritional conditions. Using mixed effects regression models, we tested the association between the *in utero* pellagra mortality rate and a 27-point global cognition score. We also stratified analyses by race and gender, and we evaluated whether the *in utero* exposure could modify the AD polygenic score's (PGS) effect on global cognition.
RESULTS: *In utero* pellagra mortality rates were significantly associated with late-life global cognition ($\beta = -0.025$, 95% confidence interval: −0.035 to −0.015). Within race and gender strata, the effects of *in utero* pellagra mortality rates on global cognition were no longer significant in all but two groups (Black females and females with other non-White racial backgrounds). The interaction between the *in utero* exposure and the AD PGS was significant. The genetic effect on cognition amplified with increasing (progressively worse) *in utero* exposure levels.
DISCUSSION: These associations imply that effects of the prenatal nutritional environment persist throughout the life course to affect late-life cognitive function. Moreover, the results imply that prenatal exposures can magnify genetic effects on late-life cognitive function. Dementia research would benefit from expanding research efforts to include more investigation of periods across the life course.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1734 Prevalence of overweight and obesity in individuals with Urea Cycle Disorders: results from a multicenter study of the Urea Cycle Disorders Consortium

Authors:

N. Ho[1,2], P. Lupo[1], K. Simpson[3], B. Rawls-Castillo[2], J. Barber[3], S. Ali[1,2], S. Elsbecker[4], N. Ah Mew[3], Members of the Urea Cycle Disorders Consortium, S. Nagamani[1,2], L. Burrage[1,2]; [1]Baylor Coll. of Med., Houston, TX, [2]Texas Children's Hosp., Houston, TX, [3]Children's Natl. Hosp., Washington, DC, [4]Univ. of Minnesota Masonic Children's Hosp., Minneapolis, MN

Urea cycle disorders (UCDs) are inborn errors of metabolism where dietary therapy comprises restricting protein in diet, supplying adequate calories, and avoiding fasting. Currently, it is not known whether such dietary therapy increases the risk for overweight and obesity in UCDs. Using data from "Longitudinal Study of Urea Cycle Disorders" (LS-UCD), an ongoing, multicenter, natural history study of UCDs conducted by the Urea Cycle Disorder Consortium, we calculated the overall prevalence of overweight and obesity in individuals with UCDs and compared the prevalence with that of the U.S. general population (NHANES dataset). For LS-UCD participants, data from individuals ages ≥2 years were included. Participants with incomplete data and those enrolled after liver transplantation were excluded. Height, weight, and clinical covariates, i.e., age, type of UCD, symptomatic status, history of hyperammonemia, and use of nitrogen-scavenging medications were analyzed from the participant's most recent study visit. Each participant's BMI (kg/m^2) was calculated and categorized using the CDC definitions for underweight, normal weight, overweight, or obese. Z-tests of two proportions were used to compare the proportion of overweight/obese in UCDs vs the U.S. general population; and logistic regression models were used to find associations between clinical factors associated with overweight/obesity in individuals with UCDs. The study analyzed data from 644 individuals (321 children; 323 adults). We found that overweight/obesity were as prevalent in the pediatric population of the LS-UCD (32%), as in the general U.S. pediatric population (35%, p=0.31). However, the prevalence of obesity was lower in adults in LS-UCD (31%), as compared to the U.S. general population (42%, p<0.001). In children, symptomatic status was associated with an odds ratio of 2.1 (CI 0.7-5.9) for obesity though this result was not statistically significant (p=0.06). In adults, age was associated positively with obesity/overweight. Odds ratios for obesity were 4.4 (CI 2.2-8.7) for 40-59 years, and 3.4 (CI 1.1-10.6) for >60 years, compared to the 20-39-year-old reference group. Given these findings, further assessment of longitudinal data is needed to follow the pediatric cohort over time and determine whether the prevalence of obesity remains similar to the general population as these children reach adulthood or whether there is a lower prevalence as they reach adulthood, similar to the adult cohort in our study. Routine nutrition assessments and long-term follow-ups may give insight into the lifelong effects of dietary therapy in UCDs.

PB1735 Prioritization of causal genes expressed in liver associated with nonalcoholic fatty liver disease using a Mendelian randomization approach

Authors:

E. Gobeil; CRIUCPQ-ULAVAL, Quebec, QC, Canada

Introduction: There is currently no specific preventive or curative pharmacological treatment for nonalcoholic fatty liver disease (NAFLD), a chronic disease that affects one in four adults worldwide. The genetic architecture of NAFLD needs to be precisely characterized to prioritize potential therapeutic targets and develop effective therapies. **Objective**: To identify liver-expressed genes significantly associated with NAFLD by combining genome-wide association study (GWAS) summary statistics, Mendelian randomization (MR), and genetic colocalization. **Methods**: We performed genetic colocalization and MR analyses on 75 independent NAFLD genetic loci identified by the Million Veteran Program (90,408 cases and 128,817 controls) using GWAS summary statistics from a meta-analysis of 16,532 NAFLD cases and 1,240,188 controls. Liver expression of these genes was assessed using bulk RNA sequencing in 246 participants undergoing bariatric surgery. **Results**: Genetic colocalization was confirmed at 7 loci (*AKNA, CWF19L1, C2orf16 (GCKR), EPHA2, HLA-G, SLC2A2/GLUT2 and TRIB1*). MR analyses revealed that hepatic expression of the *TRIB1, GCKR,* and *ZNF56 (TM6SF2)* genes was positively associated with NAFLD. **Conclusion**: Genetic colocalization analyses enabled us to identify which of the genes significantly associated with NAFLD are expressed in the liver, sharing a common variant. These genes could represent therapeutic targets of interest for the development of liver-targeted therapies to prevent or treat NAFLD.

PB1736 Profiling adaptive immune receptor repertoire (AIRR) in Graves' disease patients with antithyroid drug (ATD)-induced agranulocytosis.

Authors:

Y. Chen[1], S-K. Lai[2], I-H. Chiu[3], P-L. Chen[1,2,4,5,6]; [1]Graduate Inst. of Med. Genomics and Proteomics, Coll. of Med., Natl. Taiwan Univ., Taipei, Taiwan, [2]Genome and Systems Biology Degree Program, Academia Sinica and Natl. Taiwan Univ., Taipei, Taiwan, [3]epartment of Med. Res., Natl. Taiwan Univ. Hosp., Taipei, Taiwan, [4]Dept. of Med. Genetics, Natl. Taiwan Univ. Hosp., Taipei, Taiwan, [5]Div. of Endocrinology and Metabolism, Dept. of Internal Med., Natl. Taiwan Univ. Hosp., Taipei, Taiwan, [6]Graduate Inst. of Clinical Med., Coll. of Med., Natl. Taiwan Univ., Taipei, Taiwan

Graves' Disease (GD) is the primary cause of hyperthyroidism, with a prevalence ranging from 1.0% to 1.6% in the general population. Antithyroid drug-induced agranulocytosis (TiA) is a concerning adverse effect that occurs in 0.1% to 0.37% of GD patients during their treatment. Previous studies have suggested an association between TiA susceptibility and genetic variations, particularly in the human leukocyte antigen (HLA) genes. While genetic studies on GD and TiA have provided valuable insights, many aspects of the underlying pathophysiological and immunological mechanisms remain elusive. We hypothesize that the adaptive immune receptor repertoire (AIRR), including B lymphocyte receptors (BCRs, also known as immunoglobulins or antibodies) and/or T lymphocyte receptors (TCRs, also known as TRs), may contribute significantly to the missing genetic factors in TiA. To investigate the pathophysiological and immunological mechanisms of AIRR and TiA, we have recruited more than 64 TiA patients and collected serial samples from several individuals. We employed two single-cell RNA sequencing (scRNA-seq) platforms, BD Rhapsody and 10X Genomics, to assess the gene usage repertoire of V(D)J in both TCR and BCR. Subsequently, we identified the amino acid sequences of the complementarity-determining region 3 (CDR3) in major responsive clones from TiA patients at the acute and recovery stages (with an interval of at least six months between the two stages). Herein, we present our preliminary findings of six samples from two TiA patients. We observed distinct profiles of BCR clonotypes between the acute and recovery phases within the same patient, indicating a potential role of B cells in the pathogenesis of TiA. In contrast, no significant differences were observed in TCR clonotype profiles. Furthermore, there are no differences in major clonotype of TCR or BCR between TiA patients either in acute or recovery phases. The consistency of the V(D)J gene usage repertoire results across both platforms was confirmed by the samples of one patient. Based on these findings, we propose a digenic hypothesis regarding the risk of GD and/or TiA. The interaction between AIRR and antigens presented by HLA molecules is crucial for immune recognition and response. Certain HLA types, such as HLA-B38:02 and HLA-DRB1*08:03 genetic variations, have been strongly associated with TiA susceptibility. Therefore, we plan to further expand the cohort and analyze the correlation between AIRR and TiA by collecting data from patients with the same HLA type.

PB1737 Profiling the inflammatory bowel disease subtypes using genetics, serum biomarkers, and smoking information

Authors:

R. Liu[1,2], D. Li[3], T. Haritunians[3], Y. Ruan[1], M. Daly[2,1], H. Huang[2,1], D. McGovern[3]; [1]Broad Inst. of MIT and Harvard, Cambridge, MA, [2]Analytic and Translational Genetics Unit, Massachusetts Gen. Hosp., Boston, MA, [3]Widjaja Inflammatory Bowel Res. Inst., Cedars-Sinai Med. Ctr., Los Angeles, CA

Crohn's disease (CD) and Ulcerative colitis (UC) are two etiologically related yet distinctive subtypes of inflammatory bowel diseases (IBD). Due to the heterogeneous presentation of IBD, differentiating CD from UC can be challenging in up to 20% of patients using conventional clinical approaches in a subset of patients. Diagnostic uncertainty and subsequent misclassification in IBD are associated with higher rates of complicated disease and relapse. We employed a novel molecular-based IBD subtypes prediction model aggregating genetics, serum biomarkers, and smoking information for the first time to investigate the contribution of these factors to IBD subtypes.

We performed the genetic association analysis on the International IBD Genetics Consortium (IIBDGC) Immunochip samples (European ancestry) using phenotypes coded as CD (15,987) v.s. UC (12,613). We identified 36 loci associated with IBD subtypes, 25 of which overlap with known IBD genetic risk loci. NOD2 and MHC made the largest contribution to the variation of IBD subtypes, which explained 7.5% and 3% of variance, respectively. The polygenic risk score (PRS) model training using IIBDGC cohort and tested in an independent CEDARS cohort explained 19% of the variation in IBD subtypes.

We assessed the contribution of serum biomarkers (ASCA, ANCA, CBir1, OmpC, and I2) and smoking status in the variance of subtypes of IBD. The serology-only model and smoking-only model explained 40% and 1% of variance, respectively. Among serum biomarkers, CBir1 makes the largest contribution explaining 14% of variance. Conditional analysis revealed that the genetic, serology and smoking information each makes independent contributions to distinguish IBD subtypes despite the fact that their contributions are modestly overlapping. The combined model, with genetics, serology and smoking information, explained 46% of variance. We also found colorectal CD (L2) is significantly more challenging to be distinguished from UC than small bowel CD (L1) (17% and 46% of variance, respectively), indicating the different molecular basis underlying CD patients with different disease locations.

As the largest study incorporating genetics data with serum and environmental stimulations (smoking), our study revealed their complementing contributions to IBD disease subtypes and locations with statistical power, suggesting a model combining the molecular and environmental information may complement current diagnostic strategies and help classify patients based on biologic state.

PB1738 Protective Rare Variants for Cognitive Preservation in the Mid-Western Amish

Authors:

Y. Song[1], W. Wang[1], K. Miskimen[1], R. Laux[1], S. Fuzzell[1], S. Hochstetler[1], L. Main[1], M. Osterman[1], P. Wang[1], Y. Liu[1], M. Prough[2], D. Dorfsman[2], A. Fernandez[2], S. Slifer[2], L. Adams[2], L. Caywood[2], J. Clouse[2], S. Herington[2], A. Lynn[1], J. Vance[2], M. Cuccaro[2], P. Ogrocki[1], A. Lerner[1], M. Pericak-Vance[2], W. Scott[2], J. Haines[1]; [1]Case Western Reserve Univ., Cleveland, OH, [2]Univ. of Miami, Miami, FL

A shift in focus from risk to resilience for Alzheimer's disease (AD) encourages efforts to uncover novel AD biological mechanisms. Rare variants identified through whole genome sequencing (WGS) may represent an important and understudied component of complex trait genetics. While population-based studies are powered to discover associations with common genetic variants, founder populations are better powered for discovery of previously unknown rare alleles that have risen to higher frequency due to genetic drift. We examined WGS data from a Midwestern Amish population in a genome-wide search for rare coding variants shared only among cognitively unimpaired (CU) individuals, determined by consensus review of medical history and neuropsychological testing. Rare variants (allele frequency <0.05 across all samples) with a minor allele count (MAC)>10 in the CU group, and 0 in the cognitive impairment (CI) group were annotated to determine likely loss of function. Variants shared by CU individuals at least 80 years old at the most recent exam were further investigated for family relationship and allele frequency comparison with the general population. After extensive QC, 1,048 individuals were used to identify rare variants (n=11,854,817). Of these individuals, 634 were CU (mean age=81.53±6.10, 60% female) and 184 were CI (mean age=84.77±6.60, 62% female). 51,616 variants with MAC>10 were found only in CU, including 316 unique coding variants (288 *missense*, 4 *inframe_insertion*, 6 *inframe_deletion*, 11 *frameshift*, 4 *stop_gained*, 3 *splice_donor*) and 180 synonymous variants. Among them, 7 missense and 9 synonymous variants had MAC>20 and the rest had MAC of 11-20. Out of 7 missense and the rest 28 coding variants, 3 variants were shared by age ≥ 80 CU; one *frameshift* variant in MEGF6 and another in GPN2 on chromosome 1 and one *inframe_deletion* variant in NOP2 on chromosome 12. The allele frequencies of the 3 variants were (3.0×10^{-5}, 1.5×10^{-5}, 0.0124) in TOPMed compared to (0.0057, 0.0086, 0.0057) in our data, respectively. Each variant was shared within at least one CU sibship of size 2 to 8 and all variant sharing CU individuals were related within one big family including up to the 4th generation ancestors. Additionally, several untranslated region or nonsense-mediated decay transcript variants existed within 26 known AD gene regions, among which 8 of them are reported to harbor protective variants for AD. We identified numerous rare coding variants potentially impacting cognitive preservation, providing a rich resource for further investigation of genes that may influence cognitive function in older individuals.

PB1739 Proteome-derived unsupervised learning identifies biologically distinctive subtypes of Parkinson's disease.

Authors:

A. Doostparast Torshizi, S. Li; Janssen, Spring House, PA

Background: Parkinson's disease (PD) shows a high degree of heterogeneity. To develop safe and effective therapies, characterizing the right set of patients is of paramount importance. In this study, we have used high-throughput proteomics data from idiopathic PD patients as well as detailed cross-sectional and longitudinal clinical and pathological measurements to subtype patients using network modeling and unsupervised machine learning (ML).
Methods: We used the data generated by the Parkinson's Progression Markers Initiative (PPMI) with a total of 504 idiopathic patients. The CSF protein data contains 5,193 analytes corresponding to 4,198 unique proteins. Network modeling was applied to identify the set of features for unsupervised ML-based subtyping. Consensus-clustering based on two approaches, agglomerative hierarchical clustering and k-means, was applied. The identified subtypes were then followed up based on the following datasets: whole-genome sequencing data (WGS), Unified Parkinson's Disease Rating Scale (UPDRS), Montreal Cognitive Assessment Scale (MOCA) scores, and pathological measurements including alpha-synuclein (a-syn), total tau (tTau), and phospho-tau (pTau).
Results: Network modeling led to 1,387 features. Two subtypes S1 (n=215) and S2 (n=190) were identified. Baseline and 10-year longitudinal analysis measurements of a-syn, tTau, and pTau revealed significant increase in S1. Longitudinal analysis of UPDRS-I scores to assess intellectual impairment identified late-stage divergence between the two subtypes. Longitudinal evaluation of motor symptoms identified significant mid-stage increase in S1 which was complemented with cognition scores. Differential expression (DE) analysis between each subtype versus healthy controls revealed only 5 DE proteins in S1 while 603 proteins were DE in S2. Enrichment analysis of known PD-associated genetic variants in the identified subtypes revealed distinct genetic profiles between 2 subtypes.
Conclusion: Precision medicine-based therapeutic target discovery requires data-driven subtyping of patients. Using ML along with a wide array of molecular, phenotypic, and pathological measurements we identified two subtypes of idiopathic PD patients which paves the way to inform a more impactful target discovery.

PB1740 Proteomic Changes in the Development of Type 2 Diabetes

Authors:

H. Highland[1], P. Sharma[2], M. Graff[3], E. Frankel[4], W. Zhu[4], H-H. Chen[5], L. E. Petty[4], R. Roshani[4], M. Lee[6], E. R. Gamazon[7], J. B. McCormick[8], S. Fisher-Hoch[6], J. E. Below[9], K. E. North[10]; [1]Univ North Carolina at Chapel Hill, Chapel Hill, NC, [2]Univ. of North Carolina, Chapel Hill, NC, [3]Univ North Carolina, Chapel Hill, NC, [4]Vanderbilt Univ., Nashville, TN, [5]Academia Sinica, Taipei, Taiwan, [6]Univ. of Texas Sch. of Publ. Hlth., Brownsville, TX, [7]VUMC Clare Hall, Univ. of Cambridge, Nashville, TN, [8]UTH SPH Brownsville, Brownsville, TX, [9]Vanderbilt Univ Med Ctr., Nashville, TN, [10]Univ North Carolina, Wake Forest, NC

Background: The population at the Texas-Mexico border faces a rapidly increasing prevalence of type 2 diabetes (T2D) at rates higher than the general US population. This population has limited access to health care and medical treatments. While T2D is known to be a complex multifactorial disease, only part of the biological changes underlying disease progression are understood. The Cameron County Hispanic Cohort (CCHC) has followed Mexican American residents of South Texas over the last 20 years with stored biological samples.
Methods: Proteomics were measured from the plasma of 261 people at 2 timepoints on the O-link platform. Using 2010 ADA criteria, individuals were classified as having diabetes or not. Approximately 100 people developed T2D between visits. Using a linear mixed-effect model including T2D, age, sex, BMI, and PEER factors, we tested for changes in plasma protein levels with the development of T2D.
Results: Among 2921 proteins considered, 48 proteins displayed a significant change with incidence of T2D, using a stringent Bonferroni correction of ($p < 1.7x10\text{-}5$). Significant proteins included those involved in known T2D pathologies and glucose homeostasis, e.g. people with T2D have significantly lower levels of LPL, PTPRS, ISM1, PPY, and CCDC80. Adipogenesis and lipid metabolism proteins were also represented including APOA4 and LPL. Proteins involved in vascular changes, angiogenesis, and circulatory disorders were also altered, including increased AOC3, DPP6, and ADA2 and decreased TGFBR3, ISM1, TYMP, and CD248. Many associated proteins were related to extracellular structure and bone maintenance including MXRA8, PRCP, COL15A1, and DMP1.
Conclusions: Changes in the human proteome that occur in conjunction with the development of type 2 diabetes may show both mechanisms through which glycemic dysregulation occur and changes caused by this regulation. Vascular, microvascular, and endothelial changes are markers of many diabetes complications. Improved understanding of the proteomic changes highlights potential points of therapeutic intervention to decrease T2D complications.

PB1741 Pseudotime analysis of post-mortem brain RNA profiles identify FMOD as a key gene in Alzheimer's disease

Authors:

I. Piras, M. Naymik, M. Huentelman; Translational Genomics Res. Inst., Phoenix, AZ

Pseudotime (PT) methods are machine learning-based algorithms that enable extracting latent temporal information from cross-sectional studies. We applied PT analysis to Alzheimer's disease (AD) and control samples at various clinical and neuropathological stages. The analysis was conducted using post-mortem RNA-sequencing bulk data from four brain regions: Brodmann areas (BA) 10, 22, 36, and 44 (Mount Sinai dataset; #syn7391833). Using the phenoPath method, we generated PT trajectories, modeling the brain region as a covariate.PT trajectories significantly correlated with clinical and neuropathological variables (adj-p range: 2.5^{-13} to 0.040), except with Clinical Dementia Rating and Braak stage in BM10 and BM44, respectively (adj-p $\geq$ 0.461). Through this analysis, we identified 2,364 PT-associated genes (PTGs) across the four brain regions ($| r | \geq 0.6$ and BH < 0.05). Notably, differential expression analysis (#syn2580853) did not detect 60.9% of these PTGs. We generated multi-brain co-expression networks using the Multiscale Embedded Gene Expression Network analysis (MEGENA) method, revealing 752 modules significantly correlated with PT (adj-p < 0.05). Subsequent key-driver analysis of these associated modules, conducted leveraging a brain-specific Bayesian regulatory network, unveiled identified 1,323 significant key drivers linked to 298 unique genes (adj-p < 0.05). Interestingly, *FMOD* (Fibromoduline), emerged as the top key-driver in all the four brain regions (adj-p range: 3.4^{-86} to 3.5^{-45}). In all four brain regions, *FMOD* was consistently included in modules positively correlated with PT, enriched for extracellular matrix and collagen Gene Ontology functional classes, and pericyte genes. *FMOD* also showed a significantly positive correlation with PT in BA10, BA22 and BA36.This study primarily highlights the significance of *FMOD*, the gene coding for Fibromodulin. This small interstitial proteoglycan plays an important role in the organization of collagen. Across of four regions analyzed, *FMOD* emerged consistently as the top key driver, potentially involved in collagen and extracellular matrix alterations observed in AD (PMC8430252; PMC4931855; PMC6031366). Furthermore, our application of PT algorithm confirmed the capability of PT algorithm to order the samples according to disease severity purely based on molecular profiling, without providing previous knowledge. This approach also facilitated the identification of genes that were not detectable through differential expression analysis, thereby uncovering previously hidden associations between molecular and phenotypic characteristics.

PB1742 PyGAD machine learning algorithm improve COVID-19 prediction accuracy

Authors:

C. Fallerini[1,2], G. Martelloni[1,2], **K. Zguro**[1,2], G. Brunelli[1,2], S. Minetto[1,2], M. Lista[1,2], D. Maffeo[1,2], E. Pasquinelli[1,2], G. Rollo[1,2], S. Basso[1,2], E. Antolini[1,2], M. Rozza[1,2], A. Rina[1,2], S. Croci[1,2], A. Degl'Innocenti[1,2], M. Baldassarri[1,2], M. Bruttini[1,2], I. Meloni[1,2], GEN-COVID Multicenter Study, S. Furini[3], A. Renieri[1,2,4], S. Olmi[5]; [1]Med Biotech Hub and Competence Ctr., Dept. of Med. Biotechnologies, Univ. of Siena, Siena, Italy, [2]Med. Genetics, Univ. of Siena, Siena, Italy, [3]Dept. of electrical, electronic, and information engineering "Guglielmo Marconi", Univ. of Bologna, Bologna, Italy, [4]Genetica Medica, Azienda Ospedaliero-Univ.ria Senese, Siena, Italy, [5]CNR-Consiglio Nazionale delle Ricerche - Istituto dei Sistemi Complessi, Sesto Fiorentino, Italy

COVID-19 pandemia represented a worldwide challenge in the past 3 years. Even if the emergency is ending, prediction on susceptibility to severe disease is still a major medical need for better treatment and health policy actions. We have developed a novel predictive model called post-Mendelian because it is putting together the impact of rare variants, known to have impact in Mendelian disorders, with common polymorphisms in coding regions, likely impacting on the function, building on IPGS (Integrated PolyGenic Score). The biological value of the model was then validated by carrying functional analysis of a series of specific genes (features). Using LASSO logistic regression we were able to obtain a performance at 70-75%. We now present an improvement of the model using PyGAD machine learning algorithm based on the previously extracted features. We use the genetic algorithm PyGAD to fit the coefficients of the frequency of the variants, in the formula of the IPGS, to find the best correlation with the severity of the disease for every patient. Compared to the previous model, we maintain the linearity and the division into 4 pieces, each of them describing variants with different frequencies. The new model is reaching performances at 80-88%. The main change is related to avoiding fixed rules on the relationship between ultra rare, rare, low frequency and common variants and to fit the model: on a first analysis we observe that the best solution of the fit lives on a minimum of the parameters space which is degenerate, this means that, a priori, it is impossible to establish if a class of variants is more important that another one. The increased flexibility of the model may better represent the complex biological scenario and heterogeneity among patients, suggesting that we look for patterns that involve more variants with different frequencies. Further analysis will be necessary in order to validate the model in different populations with the final goal of translation in clinical practice for helping patients and public health decision makers.

PB1743 Quantifying individual-level mosaic chromosomal alteration fitness: genetic determinants and clinical consequences

Authors:

Y. Pershad[1], T. Mack[1], H. Poisner[1], Y. Jakubek[2], NHLBI TOPMed Consortium, R. Mathias[3], A. Reiner[4], P. Scheet[5], P. Auer[6], S. Jaiswal[7], J. Weinstock[8], A. Bick[1]; [1]Vanderbilt Univ., Nashville, TN, [2]Univ. of Kentucky, Lexington, KY, [3]Johns Hopkins Univ, Baltimore, MD, [4]Univ of Washington, Seattle, WA, [5]MD Anderson Cancer Ctr., Houston, TX, [6]Med. Coll. of Wisconsin, Milwaukee, WI, [7]Stanford Univ., Stanford, CA, [8]Johns Hopkins Univ., Baltimore, MD

Clonal hematopoiesis (CH) is characterized by a clonally expanded population of hematopoietic stem cells. CH can be caused by single nucleotide mutations in myeloid cancer driver genes, termed CHIP or larger structural rearrangements called mosaic chromosomal alterations (mCAs). Factors modulating variations in mCA clonal fitness are poorly understood.

To address this, we extended a recently developed method called passenger-approximated clonal expansion rate (PACER) to quantify mCA fitness from a single blood sample. In this study, we apply PACER to 6,381 individuals from the NHLBI TOPMed cohort with mCAs involving gain, loss, and copy-neutral loss of heterozygosity.

To validate PACER, we compared our fitness estimates to an alternative method that infers mCA fitness using variant allele frequency probability distributions from the UK Biobank. PACER estimates, aggregated by mCA location and type, exhibit a high correlation ($R2 = 0.49$) with this orthogonal approach.

Unlike prior methods, PACER enables quantifying mCA clone expansion rate at the individual level, facilitating the identification of germline risk loci associated with clonal expansion and quantifying phenotypic consequences of mCA expansion rate.

We leveraged PACER to identify germline mutations that alter mCA fitness. We conducted a genome-wide association study of mCA PACER and identified a single locus (TCL1A) that reached genome-wide significance. Our PACER analyses also nominate NRIP1, a loci previously associated with mCA prevalence at genome-wide significance, as acting through modulating clonal fitness.

We sought to understand whether individuals with mCAs expanding at a faster rate had adverse clinical outcomes. Within the subset of mCAs that are known to cause lymphoid malignancies, we identified that increased mCA expansion rates were associated with higher lymphocyte counts ($p = 0.019$). Future work will evaluate whether individuals with increased mCA expansion rate also are at highest risk of progression to overt hematologic malignancy.

PB1744 Quantifying the extent of pleiotropy using rare variant association data in 394,841 human exomes

Authors:

W. Lu[1], B. Neale[2], L. O'Connor[1], K. Karczewski[3]; [1]Broad Inst., Cambridge, MA, [2]Massachusetts Gen. Hosp., Boston, MA, [3]Broad Inst., Medford, MA

Pleiotropy, the property of a single genetic component acting on unrelated phenotypes, is pervasive in the human genome. Although previous studies have discovered widespread pleiotropy for common variants, a systematic analysis of the pleiotropic effect of rare coding variants is yet to be conducted. Utilizing Genebass, a large-scale rare variant association study on UKB WES data, we evaluate the impact of rare coding variants across diverse phenotypic domains, which quantifies the extent of exome-wide pleiotropy and provides additional context to GWAS loci. The data encompass over 8M single-variant tests and 75K gene-based burden tests across 4,529 phenotypes from 394,841 WES samples. Across 239 curated uncorrelated endpoint phenotypes, 313 (0.5%) genes are associated with multiple phenotypes, which occurs at a higher rate than expected by chance (permutation p < 1e-100; mean of permuted genes = 0.07%). Among 37 gene categories previously known to have functional relevance and/or a role in disease, we find a depletion of pleiotropic genes among groups with vital biological functions and an enrichment of pleiotropic genes within disease-related groups. We then identify hundreds of genes showing pleiotropy across 6 independent phenotypic domains. Particularly, pLoF variants in two developmental disorder related genes GIGYF1 and KDM5B are associated with the most phenotypic domains (4). For instance, pLoF variants in KDM5B are associated with phenotypes including atrial fibrillation and flutter, several blood biomarkers and physical measures, and fluid intelligence score, suggesting potential insights into the mechanisms of developmental disorders.

Pleiotropy can manifest as an allelic series, where variants with different functional impacts may exhibit heterogeneous phenotypic effects. We observe this phenomenon in the gene-based results of 31 genes. For instance, pLoF variants in ATM are only associated with 7 cancer diagnoses, such as breast and pancreas cancer, while its missense variants are only associated with 3 blood biomarkers. We develop a statistical test to explore allelic heterogeneity within genes. For a pleiotropic gene, we test whether its association with two traits stems from the same set of variants with highly correlated effects, or different variants. For example, we identify evidence for a heterogeneous effect of a subset of missense variants in the ALB gene (encoding albumin) on albumin and calcium levels, suggesting that their effects on calcium are not mediated by albumin level itself. In this way we demonstrate shared biological pathways among disease groups, providing insight into the genetic basis of human disease.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1745 Quercetin ameliorates the autoimmune, lipodystrophic and neurodegenerative phenotype observed in CLEC16A KO mice.

Authors:

R. Pandey[1], B. Strenkowski[2], C. N. Thaise[1], M. Bakay[2], H. Hakonarson[1]; [1]Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Children's Hosp. Of Philadelphia, Philadelphia, PA

CLEC16A is implicated in multiple autoimmune diseases. We generated an inducible whole-body knockout (KO) *CLEC16A* mice to address the role of CLEC16A loss of function. Published data from our KO mice suggests a derailed functional link between CLEC16A and impaired mitophagy and autophagy, two critical cellular processes involved in maintaining cellular homeostasis and preventing the accumulation of damaged organelles and proteins. While Quercetin, a natural flavonoid with antioxidant and anti-inflammatory properties, has been shown to modulate various cellular pathways, the effects of quercetin on mitophagy and autophagy in the context of CLEC16A deficiency remains unknown. In this study, we utilized *CLEC16A* KO mice as a model to investigate the impact of quercetin on mitophagy and autophagy to determine potential rescue of the observed defect and prevent the onset of the autoimmune, inflammatory, and neurodegenerative phenotypes. **Methods:** *CLEC16A* knockdown in adult mice leads to dysregulated mitophagy promoting robust autoimmune inflammatory response with severe neurological symptoms. We first confirmed the deficiency of CLEC16A in our mouse model using molecular and immunoblot analysis. Subsequently, we administered quercetin to *CLEC16A* KO mice and evaluated its effects on mitophagy and autophagy markers and phenotype rescue. **Results:** Our results demonstrate that CLEC16A deficiency resulted in impaired mitophagy and autophagy in various tissues. Importantly, treatment with quercetin significantly enhanced mitophagy and autophagy in these tissues. Quercetin administration resulted in upregulation of key mitophagy markers, including PINK1 and Parkin, as well as autophagy markers, including LC3-II with downregulation of P62. Overall Quercetin improved the survival of KO mice by modulating ER stress possibly by facilitating an increase in the number of autophagosomes and autolysosomes in quercetin treated *CLEC16A* KO mice compared to untreated controls. **Conclusion:** Overall, our findings suggest that quercetin supplementation promotes mitophagy and autophagy in *CLEC16A* KO mice, providing new insights into potential therapeutic strategies for autoimmune diseases associated with CLEC16A dysfunction. Further investigations are warranted to elucidate the precise molecular mechanisms underlying the beneficial effects of quercetin on these cellular processes and to evaluate its therapeutic potential in patients with multiple autoimmune diseases attributed to variants in CLEC16A by reversing the dysregulated mitophagy/autophagy processes introduced by these variants.

PB1746 Rapid Diagnosis and Longitudinal Monitoring of Bacteremia in Pediatric Septic Arthritis and Acute Hematogenous Osteomyelitis Cases Using Longread Sequencing

Authors:

P. Raj[1], T. Relangi[1], N. Tareen[2], R. Sridharan[1], B. Zhang[1], C. Arana[1], N. V. Oers[1], L. Copley[3], L. Hooper[1]; [1]UT Southwestern Med Ctr, Dallas, TX, [2]Children's Med. Ctr., Dallas, TX, [3]Children's Hosp., Dallas, TX

Existing gold-standard method for clinical diagnosis of bacterial infection is culture. But large blood specimen requirement and longer turnaround time often makes this method unsuitable for young children. We optimized a rapid metagenomic sequencing workflow that requires 1ml specimen (blood and joint fluid) to rapidly characterize pathogens using longread sequencing technology. We analyzed 50 specimens from healthy Children and 25 specimens from children diagnosed with Septic Arthritis, AHO and 22q11.2 deletion syndrome. Full length 16S rRNA gene sequencing and whole genome analysis identified presence of several pathogenic and commensal species including *Staphylococcus aureus, Streptococcus pyogenes, Haemophilus parainfluenzae, Veillonella parvula, Streptococcus oralis* and *Lactobacillus animalis*. Healthy blood showed the presence of *Streptococcus* DNA signature that was associated with elevated level of several pro-inflammatory cytokines in serum, such as INFg, IL1a, IL1b, IL17a and MIF. *Streptococcus pyogenes* species in Septic arthritis cases was strongly associated with inflammatory immune responses i.e. IL6, IL8. Our pipeline took 8 h from DNA extraction to taxonomic classification using EPI2ME pipeline. Sequencing results were 100% concordant with culture results in case of synovial fluid specimens. Blood and saliva specimens showed DNA signatures of commensal organisms which were validated using deep Illumina sequencing. Reference based genome assembly analysis was carried out in subset and variants were detected. Data analysis pipeline characterized pathogens at species level taxonomy. Host cytokine analysis showed activation of proinflammatory cytokines consistent with active bacteremia. We developed a metagenomics workflow that can rapidly characterize bacterial pathogens in blood and synovial fluid to guide clinical diagnosis and antibiotic therapy in children.

PB1747 Rare coding variants in *PREB* associate with sex-specific effects on LDL cholesterol.

Authors:

R. Hoffing[1], A. Dubey[1], A. Deaton[1], A. Xiao[1], K. Buckowing[1], L. Ward[1], A. Holleman[1], L. Krohn[2], P. LoGerfo[1], M. Plekan[1], S. Akle Serrano[1], P. Nioi[1]; [1]Alnylam Pharmaceuticals, Cambridge, MA, [2]Alnylam Pharmaceuticals, Montreal, QC, Canada

Sex-specific analyses can uncover new genome-phenome associations for complex traits that would otherwise be hidden. An exome-wide association study of LDL cholesterol was conducted separately for 187,061 men and 219,861 women in the UK Biobank. Aggregated rare predicted loss of function (pLOF) and damaging missense variants (REVEL $\geq$ 0.77) in *PREB* were found to associate with decreased LDL cholesterol in men ($p = 7.3x10^{-7}$, effect = 0.47 SD decrease), but not women (p = 0.46, effect = 0.06 SD increase). Silencing of *PREB* in HepB3 cells resulted in differential expression of known LDL-regulators, including *GPAM* ($p = 2.9x10^{-30}$, log2FC = -1.31), *HMGCR* ($p = 2.7x10^{-23}$, log2FC = -1.16), and *ACAT2* ($p = 8.8x10^{-21}$, log2FC = -1.12). A gene set enrichment analysis revealed significant downregulation of the cholesterol biosynthesis pathway ($p = 1.4x10^{-8}$, enrichment score = -0.86) upon *PREB* silencing. Overall, *PREB* shows genetic and functional evidence for a role in regulating LDL and could be a potential therapeutic target for hypercholesterolemia.

PB1748 Rare de novo deleterious variants increase risk of neural tube defects.

Authors:

Y. Lei[1], P. Lupo[1], R. Finnell[2]; [1]Baylor Coll. of Med., Houston, TX, [2]Baylor Coll. Med., Houston, TX

It is well established that Neural Tube Defects (NTDs) have complex environmental and genetic etiologies. However, the contribution of *de novo* mutations to the etiology of NTDs has not been well studied. We performed whole exome sequencing in 125 NTD trios which were mainly collected from Dell Children's Medical Center at Austin and Texas Children's Hospital at Houston. We identified 170 *de novo* variants which included 40 synonymous variants, 76 non-deleterious variants, 32 deleterious missense variants and 22 loss of function (LoF) variants. Eleven genes implicated in NTD mouse models including *EP300*, *PAX3*, *SHROOM3*, *SMURF2* and *TBXT* were detected in *de novo* deleterious variants class. The DenovolyzerR package was used for the statistical analysis. Compared with expected numbers calculated based on 1,078 autism spectrum disorder trios and 6,503 individuals from exome sequencing project, we observed a significant enrichment of *de novo* deleterious missense variants (1.42 folds, p=0.036) and *de novo* LoF variants (1.78 folds, p=0.008). Recurrent *de novo* deleterious variants were identified in *TBXT* gene, and a few gene families including *SATB* family (*SATB1* and *SATB2*) and *MED13* family (*MED13* and *MED13L*). Overall number of *de novo* variants in NTDs was also significantly high than expected (1.2 folds, p=0.012). There was no significant difference in number of *de nov*o synonymous variants and predicted to be tolerant missense variants compared to expected. Our study indicated that *de novo* deleterious variants contribute to risk of NTDs, while synonymous and tolerant missense variants did not increase NTD risks.

PB1749 Rare genetic variation in gonadotropin signaling identified in women with PCOS.

Authors:

G. Stokes[1], R. Bauer[1], C. Parker[1], R. Legro[2], M. Urbanek[3]; [1]Northwestern Univ., Chicago, IL, [2]Pennsylvania State Univ., Hershey, PA, [3]Northwestern Univ, Oak Park, IL

Background: Polycystic ovary syndrome (PCOS) is a complex endocrinopathy affecting 6-20% of reproductive age women. PCOS is defined by oligo/anovulation, hyperandrogenism, and abnormal ovarian morphology. Women with PCOS have altered frequency and amplitude of gonadotropin releasing hormone (GnRH) secretion, which causes an imbalance of gonadotropin hormones: luteinizing hormone (LH) and follicle stimulating hormone (FSH). An imbalance of LH:FSH ratio results in increased androgen production and oligo/anovulation—two cardinal characteristics of PCOS. Twin and family studies show PCOS to be highly heritable, and genome-wide association studies (GWAS) implicate several loci near genes involved in gonadotropin secretion. However, PCOS is a complex and polygenic disease, and current risk loci account for <10% of PCOS heritability with no known causal variants. Therefore, our goal is to determine whether genetic variation in gonadotropin genes contributes to PCOS pathogenesis by sequencing the gonadotropin genes in a PCOS cohort.
Objective: Our objective is to determine whether genetic variation in gonadotropin genes contributes to PCOS pathogenesis and to elucidate the molecular mechanisms of gonadotropin signaling dysfunction in PCOS.
Design/Methods: We performed targeted sequencing of gonadotropin pathway genes—*FSHR, LHCGR, FSHB* and *LHB*—in two cohorts of women with PCOS. We applied the American College of Medical Genetics (ACMG) criteria to each variant to determine a pathogenicity score. Variants were assigned a score based on population data, computational data, and functional data.
Results: We identified 14 rare missense variants (MAF < 0.01) in *FSHR* and *LHCGR* in a cohort of 673 women with PCOS and 123 reproductively healthy women. Additionally, we identified 8 rare missense variants in *FSHB* and *LHB* in a cohort of 602 women with PCOS and 165 reproductively healthy women. Based on ACMG criteria, there is strong existing evidence to classify 5 variants as likely pathogenic, 1 as pathogenic, and 5 as benign. 11 variants were identified as variants of unknown significance (VUS).
Future directions: PCOS GWAS loci have been found near gonadotropin genes, but no studies have identified pathogenic variants in gonadotropin genes or performed functional evaluations of gonadotropin gene variants. This study identifies and will functionally evaluate gonadotropin gene variants in women with PCOS. Identifying and understanding genetic contributions to complex endocrinopathies like PCOS can increase the ability to find causal variants and improve treatment efficacy.

PB1750 † Rare missense variants in protein intrinsically disordered regions: impact on condensates and common diseases

Authors:

R. Tian, C. Zhang, I. Klein; Dewpoint Therapeutics, Boston, MA

Biomolecular condensates are membrane-less compartments that concentrate a subset of biomolecules through phase separation from the surrounding cellular milieu and control numerous biological processes. Growing evidence supports that aberrant condensates serve as central nodes of dysregulation to drive the pathogenesis of various diseases, such as cancer, cardiomyopathy, neurodegeneration, and viral infections.
Intrinsically disordered regions (IDRs) within proteins contribute to condensate formation. Disease mutations located in IDRs perturb normal phase separation, leading to dysregulation of biological processes and pathogenesis. Here, we explored the role of genetic variation in IDRs in common diseases using whole-exome sequencing data in the UK Biobank. We examined 16 ICD10-defined diseases with >=1% case prevalence in individuals of European genetic ancestries, including autoimmune, cardiometabolic, eye, respiratory and neurological diseases.
We used 'metapredict' to predict 18,985 protein IDRs based on their amino acid sequence on the canonical transcript and annotated missense variants by degree of deleterious effects (likely, possibly and unlikely). To identify risk genes, we aggregated ultra-rare missense variants with each group of deleterious effects into a burden score and tested the association between the risk of a common disease and the gene-wide burden across the genome. We found that 1/3 of missense variants are located in IDRs across 80.9% of the protein-coding genes, which may play a role in some common diseases. We identified several IDR-wide significant (P<2.5e-6) disease-gene associations. Our initial findings include *ZNF366* in inflammatory bowel disease, *TGIF2* in non-alcoholic steatohepatitis risk and *CEP290* in heart failure risk. Both ZNF366 and TGIF2 are transcription factors (TFs) while CEP290 contains 13 coiled-coil domains. Given current knowledge on the role of TFs and coiled-coil domains in condensates, our findings suggest that *ZNF366*, *TGIF2* and *CEP290* may be involved in condensates that serve as central nodes of dysregulation in common diseases, and that mutations within these genes affect disease risk through disrupting the normal function of these condensates.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1751 Rare pathogenic missense variants in *LMNA* identified in women with polycystic ovary syndrome (PCOS)

Authors:

R. Bauer[1], L. Gorsic[1,2], R. Legro[3], M. G. Hayes[1], M. Urbanek[1]; [1]Northwestern Univ., Chicago, IL, [2]Mayo Clinic, Rochester, MN, [3]Penn State Hershey Med. Ctr, Hershey, PA

Background: Polycystic ovary syndrome (PCOS) is the most common form of anovulatory infertility among reproductive age women. In addition to experiencing reproductive symptoms, women with PCOS are at elevated risk of developing obesity, insulin resistance (IR), and type 2 diabetes. Familial partial lipodystrophy type 2 (FPLD2) is a disorder of lipid storage and insulin resistance caused by dominant missense alleles in the gene encoding the intermediate filaments lamin A/C (*LMNA*). Women with this Mendelian disorder of IR also experience symptoms of PCOS such as amenorrhea and hyperandrogenism. We therefore hypothesize that genetic variation in *LMNA* also contributes to PCOS. In other words, we hypothesize that PCOS falls into the phenotypic spectrum of disorders caused by variation in *LMNA.* **Objective:** We aim to identify and evaluate variation in *LMNA* that underlies PCOS pathogenesis in two cohorts of PCOS patients. **Methods:** We sequenced the *LMNA* gene in two cohorts, totaling 845 PCOS patients and 157 reproductively healthy controls. We comprehensively screened *LMNA* for genetic variation that is likely to alter the lamin A/C proteins, including missense, nonsense, splicing or frameshift variants. To determine which of these variants are pathogenic, we evaluated them according to criteria outlined by the American College of Medical Genetics (ACMG). **Results:** In the first cohort, we identified 7 missense variants in 8 cases out of 602, and no variants in 125 reproductively healthy controls ($X2=3.1$, $p=0.081$, $OR>1.78$ with study controls; $X2=46.8$, $p<1x10^{-8}$, $OR=8.5$ with gnomAD non-Finnish European population controls). 6 of these variants are pathogenic and 1 is likely pathogenic. When assessed individually, 6 of the 7 variants are significantly enriched in our cohort when compared to gnomAD non-Finnish European population controls ($OR > 5.0$). In the replication cohort, we identified 4 variants in 6 cases out of 243, and 1 out of 32 reproductively healthy controls ($X2=0.05$, $p=0.83$, $OR = 0.79$ with study controls; $X2=34.2$, $p<0.00001$, $OR= 7.73$ with population controls). Of the 4 variants in cases, 3 are pathogenic and 1 is likely pathogenic. The variant identified in a control is a variant of unknown significance. All *LMNA* variants in both cohorts are likely damaging as predicted by 3 computational methods. Additionally, 6 of the 11 variants in PCOS cases have previously been identified in individuals with lipodystrophy. **Conclusion:** Together with previous identification of *LMNA* variants in women with PCOS by our lab (Urbanek et al. 2009 *JCEM*) and others (Crespo et al. 2022 *JES*), this work further establishes pathogenic variation in *LMNA* as a disease mechanism for PCOS.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1752 Rare Recurrent Copy Number Variations in Children with Neurodevelopmental Disorders

Authors:

M. Khan[1], J. Glessner[1,2], X. Chang[1], Y. Liu[1], F. Otieno[1], M. Lemma[1], F. Mentch[1], C. Kao[1], M. March[1,2], J. Connolly[1], H. Hakonarson[1,2]; [1]Ctr. for Applied Genomics, Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA

Neurodevelopmental disorders (NDDs) such as attention deficit hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) are illustrative examples of clinical cases with diagnosis impeded by current lack of definitive corroborating genetics and genomics. Both NDDs have been shown to share similar biological etiologies as well as genetic pleiotropy. ADHD and ASD have complex genetic associations implicated by rare recurrent copy number variations (CNVs). Platforms aimed at investigating genetic-based associations, such as high-density microarray technologies, have been successful in elucidating some of the underlying disease biology associated with NDDs and related psychiatric diseases. Previous studies investigating NDDs have uncovered CNVs associated with genes within shared candidate genomic networks, such as metabotropic glutamate receptor (mGluR) protein-protein interactions. To examine shared biological pathways across two of the most common NDDs, we investigated CNVs across 15,689 individuals with ADHD (n = 7,920), ASD (n = 4,318), or both (n = 3,416), as well as 19,993 controls. Cases and controls were matched by genotype array (i.e., Illumina array versions). Three case-control association studies each calculated and compared the observed vs. expected frequency of CNVs across individual genes, loci, pathways, and gene networks. Quality control measures of confidence in CNV-calling, prior to association analyses, included visual inspection of genotype and hybridization intensity. To extend our previous observations implicating a key role of the mGluR network in both ADHD and autism, we exhaustively queried patients with ASD and/or ADHD for CNVs associated with the 273 genomic regions of interest within the mGluR gene network (genes with one or two degrees protein-protein interaction with mGluR 1-8 genes). We uncovered CNTN4 deletions enriched in NDD cases (P = 3.22E-26, OR = 2.49). Additionally, we found PRLHR deletions in 40 ADHD cases and 12 controls (P = 5.26E-13, OR = 8.45). We also discovered clinically diagnostic relevant 22q11.2 duplications and 16p11.2 duplications in 23 ADHD + ASD cases and 9 controls (P = 4.08E-13, OR = 15.05) and 22q11.2 duplications in 34 ADHD + ASD cases and 51 controls (P = 9.21E-9, OR = 3.93); those control samples were not with previous 22qDS diagnosis in their EHR records. Taken together, we have uncovered multiple disease causing CNVs in both ASD and ADHD cases. Our latest work and direction includes genome-wide gene interaction network analysis in subjects with multiple associated psychiatric comorbidities.

PB1753 Rare variant analysis of 30,648 heart failure cases using exome sequences from multi-ancestry population-based biobanks and clinical trials

Authors:

A. Nag[1], G. Alamgir[1], Q. Wang[2], A. Walentinsson[3], A. Genomics Initiative[1], J. Berumen-Campos[4], P. Kuri-Morales[4], R. Tapia-Conyer[4], J. Alegre-Díaz[4], J. Emberson[5], J. Torres[5], R. Collins[5], D. Saleheen[6], Q-D. Wang[1], K. Hansson[1], S. Petrovski[1], D. Paul[1], K. Smith[1]; [1]AstraZeneca, Cambridge, United Kingdom, [2]AstraZeneca, Waltham, MD, [3]AstraZeneca, Gothenburg, Sweden, [4]Natl. Autonomous Univ. of Mexico, Mexico City, Mexico, [5]Univ. of Oxford, Oxford, United Kingdom, [6]Columbia Univ., USA & CNCD, Pakistan, New York, NY

Background: Heart failure (HF) affects ~1-2% of adult populations and has a large unmet therapeutic need. Identifying genes harbouring rare variants that associate with HF risk may provide novel therapeutic targets. Methods: We ascertained HF cases (~31% non-Europeans) from three global population-based biobanks (UK Biobank, Mexico City Prospective Study, and Pakistan Genome Resource) and six AstraZeneca HF clinical trials with exome sequences, using a combination of ICD-10 codes and self-reported diagnoses. Exome sequences from biobank participants without cardiovascular diseases and participants in non-cardiovascular clinical trials were used as controls. We tested the aggregate effect of rare non-synonymous variants within a gene by performing collapsing analyses - under 10 different genetic models - per ancestral group across four analysis strata (i.e., three for biobanks and one for clinical trials). We used Fisher's exact test to compare the frequency of qualifying variants between HF cases and controls. For each gene, we then meta-analysed association statistics across ancestral groups and strata [cases=30,648, controls=258,060]. We also performed separate collapsing analyses for HF subtypes, i.e., HF with reduced ejection fraction [cases=8,100, controls=245,306] and HF with preserved ejection fraction [cases=3,194, controls=182,297]. Results: Across collapsing models, two genes achieved study-wide significance ($p<2.6x10^{-7}$), with rare variants in both previously reported to associate with HF: *TTN* ("ptv" model: OR=2.1, $p=1.0x10^{-42}$) and *LMNA* ("flexnonsyn" model: OR=1.5, $p=2.2x10^{-7}$). We also observed suggestive associations for other known HF genes, such as *FLNC* ("ptv" model: OR=4.4, $p=4.9x10^{-7}$), *MYH7* ("flexnonsynmtr" model: OR=1.3, $p=1.3x10^{-5}$)and *FBN1* ("ptv" model: OR=38.4, $p=1.6x10^{-6}$). We identified additional suggestively associated genes, which are currently undergoing further validation as potential therapeutic opportunities. No study-wide significant genes were identified in the HF subtype analyses. Conclusions: We assessed the contribution of rare genetic variation in HF, leveraging one of the largest and most diverse collections of HF cases with sequence data. Although our study did not identify any novel study-wide significant genes in relation to HF - which could partly reflect the heterogenous nature of the disease - access to larger sample sizes in the future holds the promise of providing novel human genetics-validated therapeutic targets.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1754 Rare variant analysis of MRI-derived fat distribution phenotypes strengthens detected effects compared to larger meta-analysis.

Authors:

L. Ganel[1], B. Geraghty[1], K. Landheer[2], P. Dornbos[1], P. Akbari[1], J. Bovijn[1], N. Verweij[1], L. Lotta[1], M. Germino[2], J. Marchini[1], A. E. Locke[1]; [1]Regeneron Genetics Ctr., Tarrytown, NY, [2]Regeneron Pharmaceuticals, Tarrytown, NY

While body mass index is an important predictor of obesity-associated disease outcomes, the distribution of fat is independently predictive of cardiometabolic morbidity. To assess the genetic factors underlying these fat distribution traits, we used a 3-dimensional fat segmentation machine learning model to estimate the volumes of six fat depots from whole-body MRI data in UK Biobank data (N = 49,169). From these volumes we also generated three summary fat measures and three fat distribution ratios, totaling twelve fat measures for genetic analysis. After correcting for BMI, height, and several other demographic, ancestry, and technical covariates, we performed the largest gene-based rare variant analysis of these fat distribution traits to date. We identified 7 genes significantly associated with at least one fat measure by using a gene-based framework that combines burden, SBAT, SKATO and ACATV tests into a single p-value per gene (GENE_P). These gene-phenotype associations covered 6 traits and included several known fat distribution genes such as *PDE3B, ACVR1C, PLIN4, INSR*. Some canonical obesity genes, such as *MC4R* and *LEPR*, were not associated with any of our traits, likely due to the mechanisms by which these genes regulate energy balance. Of the 24 significant gene-trait pairs, 10 were driven by burden signals (either from marginal or joint modeling of burden masks), 9 by single variants, and 5 by variance component tests. Nine of these gene-trait pairs were from sex-specific tests, of which 8 were specific to males. Next, we compared our results for visceral/gluteofemoral fat ratio (VGFR) to a published meta-analysis of BMI-adjusted waist-hip ratio (WHRadjBMI) in over 600,000 individuals (Akbari *et al*., *Nat. Commun.* 2022). Of the 14 genes tested for fat measures that were identified by Akbari *et al*. for WHRadjBMI, two were statistically significant for VGFR after Bonferroni correction and nine at least reached nominal significance, despite the dramatic difference in sample size. Using robust regression to compare the VGFR and WHRadjBMI effect sizes, we observed that estimated effects were, on average, >50% larger for VGFR (β=1.51, SE 0.19, Wald test P-value 5.76×10^{-15}). Given that the WHR meta-analysis sample size was over 12 times greater, the fact that VGFR effect sizes for true positive genes tended to be significantly larger suggests that the imaging-based phenotype more accurately reflects the biological processes underlying obesity. Overall, these data support the utility of machine learning-based segmentation of imaging data for fine-scaled phenotyping in genetic studies.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1755 Rare variant association analyses reveal the significance of carbohydrate metabolism in severe adolescent idiopathic scoliosis

Authors:

W. Wen[1], S. Zhao[2,1], Z. Zhao[1], H. Zhao[1], X. Cheng[1], G. Li[1], J. Cai[1], Q. Li[1], K. Xu[1], N. Wu[1]; [1]Peking Union Med. Coll. Hosp., Beijing, China, [2]Baylor Coll. of Med., Houston, TX

Background: Adolescent Idiopathic Scoliosis (AIS) is the commonest scoliosis form, with an unknown etiology. Anomalous energy metabolism, often evidenced by a lower BMI, is frequently seen in AIS patients, suggesting its role in disease onset. However, the link between metabolism and AIS pathogenesis remains largely unclear.
Methods: We conducted whole-genome or whole-exome sequencing on 368 severe AIS (Cobb angle > 40°) patients from a Chinese Han cohort, and 4000 unrelated control samples. We performed a gene-based weighted rare variant burden test using the ACAT package, categorizing variants into distinct mask levels, with weight values assigned based on variant type and bioinformatic prediction results. Furthermore, we explored the cumulative impact of genetic variants via an aggregate mutational burden analysis of gene sets, using Molecular Signatures Database (MSigDB) pathways. To corroborate our findings, we also analyzed differential muscle expression using RNA-sequencing data from 14 AIS patients and 15 controls.
Results: Our gene-based burden analysis identified *SLC16A8*, a proton-coupled lactate transporter predominantly expressed in retinal pigment epithelial cells, as a novel candidate gene for severe AIS (P = 3.80E-06, FDR = 0.009). *SLC16A8* is implicated in the regulation of glucose metabolism via lactate accumulation. A large majority of AIS cases with deleterious SLC16A8 variants demonstrated a pronounced severe spinal curve (Cobb angle > 60°) and early-onset high myopia (> 600 degrees) preceding scoliosis. Pathway-based burden analysis revealed a significant enrichment in carbohydrate metabolism pathways, with the galactose metabolic process (GO:0006012, P = 2.93E-05) as the top signal, amino sugar and nucleotide sugar metabolism (KEGG: map00520, P = 4.04E-05), carbohydrate derived catabolic process (GO:1901136, P = 6.46E-05) and deoxyribose phosphate catabolic process (GO:0046386, P=7.06E-05) as other key signals. Patients with deleterious variants in carbohydrate metabolism-related genes demonstrated a significantly larger spinal curve (P = 0.015). Concordantly, genes related to the positive regulation of catabolic processes and response to nutrient levels displayed significantly divergent expression between AIS cases and controls, substantiating the preliminary genomic findings.
Conclusion: Our findings indicate that genetic variants influencing carbohydrate metabolism could involve in the development and progression of AIS, thereby contributing a novel insight to the understanding of this disease.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1756 Rare variant contribution to the heritability of coronary artery disease based on 22,443 whole genome sequences from the NHLBI TOPMed Program.

Authors:

G. Rocheleau[1,2,3], S. Clarke[4,5], G. Auguste[6], J. Rotter[7], C. Miller[6,8,9], T. Assimes[4,5,10], P. De Vries[11], R. Ctr., Torrance, CA, [8]Dept. of Biochemistry and Molecular Genetics, Univ. of Virginia, Charlottesville, VA, [9]Dept. of Publ. Hlth.Sci., Univ. of Virginia, Charlottesville, VA, [10]Stanford Cardiovascular Inst., Stanford, CA, [11]Human Genetics Ctr., Dept. of Epidemiology, Human Genetics, and Environmental Sci., Sch. of Publ. Hlth., The Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX

Introduction: Twin studies and large multi-population genome-wide association studies (GWAS) have reported heritability of coronary artery disease (CAD) in the range of ~35-60%. However, these heritability estimates are based on genotyped and imputed variants, possibly missing a substantial contribution from rare variants. Whole genome sequence (WGS) data enables discovery of rare variants and can contribute a portion of missing heritability of CAD that is not explained by common variants. **Material and Methods:** To measure the contribution of rare variants to the CAD heritability, we applied the GREML-LDMS-I approach to the whole genome sequences (WGS) of 4,949 cases and 17,494 controls of European ancestry from the National Heart, Lung and Blood Institute (NHLBI) Trans-Omics for Precision Medicine (TOPMed) program. Variant were binned according to their linkage disequilibrium (LD) scores (below or above the median over all variants) and their minor allele frequencies (MAF) ($MAF \leq 0.1\%$, $0.1\% < MAF \leq 1\%$, $1\% < MAF \leq 10\%$, $10\% < MAF \leq 50\%$). We further assessed variant contributions to CAD heritability overlapping with cis-regulatory elements (CREs) using a cell-specific chromatin atlas of 13 cell types of the human coronary artery generated by single-nucleus assay for transposable-accessible chromatin with sequencing (snATAC-seq) profiling. Finally, we compared the enrichment of protein-altering (e.g. frameshift, missense) versus non-protein-altering (e.g. synonymous, intronic) variants to CAD heritability. **Results:** After stringent quality control in both the sample and variant set, we estimated the CAD heritability (on the liability scale) at 28.8% (standard error = 13.9%), assuming a population prevalence of 8.2% in sample of genetically inferred European participants. We observed that ultra-rare variants ($MAF \leq 0.1\%$) in low LD contributed the most with 62% of the total observed heritability. In contrast, common variants ($MAF > 10\%$) in high LD contributed only 18%. Ultra-rare variants in low LD demonstrated a ~5 fold enrichment towards CAD heritability in CREs for natural killer and endothelial cells, fibroblasts, fibromyocytes and pericytes, although they represent only 1% of all variants. Protein-altering variants showed a disproportionate enrichment compared to non-protein-altering variants, particularly for common protein-altering variants which contributed 2.9% of the total observed heritability with less than 0.05% of all variants. **Conclusion:** Ultra-rare variants in low LD contribute a substantial fraction to the total heritability of CAD and are enriched in CREs in specific cell types of the human coronary artery.

PB1757 Rare variant enrichment analysis in pediatric European Moyamoya Angiopathy patients

Authors:

E. Cabello[1,2], K. Steindl[1], I. Ivanovski[1], P. Boonsawat[1], P. Zanoni[1], N. C. Braun[1], M. Papik[1], A. Bahr[1], N. Khan[3], A. Rauch[1,4]; [1]Inst. of Med. Genetics, Univ. of Zürich, Zürich, Switzerland, [2]PhD Program Biomedicine (BioMed), Life Sci. Zurich Graduate Sch. (LSZGS), Zürich, Switzerland, [3]Moyamoya Ctr., Univ. Children's Hosp., Univ. of Zürich, Zürich, Switzerland, [4]Moyamoya Ctr., Univ. Children's Hosp., Univ. of Zurich, Zürich, Switzerland

Introduction: Moyamoya angiopathy (MMA) is a rare condition characterized by stenosis of the intracreanial internal carotid artery and its branches resulting in transient ischemic attacks and strokes in children. Although MMA has been mostly described and studied in Asia, latest reports show a continuous increase in the incidence and prevalence of MMA cases worldwide. Previous studies, mainly focused on adult patients and/or Asians, have suggested several susceptibility genes, with *RNF213* being the only recurrent one. Specifically, the p.R4810K variant in this gene has been found in East Asian populations and, when homozygous, it goes along with an earlier onset and worse prognosis. In adult Caucasian MMA patients, diverse *RNF213* rare variants have been positively associated, but not p.R4810K. **Methods:** The whole exome was sequenced from blood samples in a pediatric cohort of 105 MMA patients and 234 healthy control individuals (88% Europeans). After quality control and excluding common variants (MAF >2%) and homologous regions, we performed a rare-variant enrichment test using the R package *SKAT*. To verify the independence of our results, we repeated the test using the same Moyamoya cohort against a different control cohort of 160 individuals. **Results:** As a positive control for the validity of our approach, the results revealed significant enrichment of rare variants in the known gene *RNF213* on the top of the list in both tests (adjusted p-value=4.04×10^{-7}). There is a significant enrichment of rare variants in 23 genes in the first test (234 controls) and 16 in the second one (160 controls), 4 of them from both studies being already associated with Moyamoya (*RNF213*, *NF1*, *PCNT*, and *OBSCN*), and 7 are common in both studies, including *RNF213*. The remaining 5 genes are strong novel candidate genes for MMA susceptibility. **Conclusion:** we present an international MMA case-control study focusing exclusively on pediatric patients, mostly of European origin. The results show 5 novel candidate genes that could improve the understanding of MMA.

PB1758 Rare variant pathways: Analyzing gene set burden of biological pathways associated with rare variants in Parkinson's disease.

Authors:

V. Pitz[1], A. Y. Fu[2], S. Bandres-Ciga[3], A. Singleton[3,2], M. Makarious[2], C. Blauwendraat[3,1]; [1]Integrative Neurogenomics Unit, Lab. of Neurogenetics (LNG), NIH, Bethesda, MD, [2]Molecular Genetics Unit, Lab. of Neurogenetics (LNG), NIH, Bethesda, MD, [3]Ctr. for Alzheimer's and Related Dementias (CARD), NIH, Bethesda, MD

Aim: This study aims to identify biological pathways associated with Parkinson's disease (PD) based on their variant class and cumulative gene-set rare variant burden.
Background: Age, environmental factors, and genetics play a crucial role in the development of PD. The emergence of large-scale initiatives allows for the exploration of rare genetic variants (MAF<1%) as causal or significant risk factors for PD. Burden tests enable the assessment of cumulative burden of rare and protein-altering variants within specific gene sets that constitute pathways between cases and controls. This allows for the identification of gene-associated burden patterns, shedding light on biological pathways involved in PD pathogenesis.
Materials & Methods: We used data from the Accelerating Medicines Partnership Parkinson's disease (AMP-PD), comprising 2,253 cases and 2,834 controls as well as data from the UK Biobank (UKB) comprising 1,105 cases, 6,701 proxies, and 38,051 controls. Based on SnpEff and LOFTEE predictions, variant classes were extracted based on 1) Missense, 2) Moderate or high impact, 3) High confidence loss of function, and 4) Combined Annotation Dependent Depletion (CADD) PHRED score>20. We utilized canonical pathway gene-sets from the Molecular Signatures Database (MSigDB) and custom scripts based on the burden test algorithms Sequence Kernel Association Test-Optimal (SKAT-O) and Combined Multivariate and Collapsing with Weighted-Adaptive Least Absolute Deviations (CMC WALD) for each variant class and variants with minor allele frequencies (MAFs) <1% and <0.1%. Case-control analyses were performed separately and were adjusted for sex, and principal components (PCs) 1-5 in AMP-PD, while UKB was adjusted for sex, Townsend score, and PCs 1-5.
Results: A total of 3,358 cases, 6,701 proxies, and 40,885 controls were analyzed. We conducted rare and ultra-rare variant pathway analyses on 3,090 canonical pathway gene sets: UKB contributed most gene sets with all 3,090 being present, 2,679 of which were found in AMP-PD. We report pathways significantly associated with PD, based on: passing multiple test correction at P<1.6e-05, generating robust statistical outputs, and remaining significant in a meta-analysis of both data sets.
Discussion: Despite many associations found between genes and PD, our understanding of the biological processes and networks remains incomplete. Conducting the largest rare variant burden pathway analysis in PD, this study provides a valuable tool for identifying important biological pathways. The results have the potential to aid in functional prioritization and the identification of potential therapeutic targets.

PB1759 Rare variants enhance the ability to identify associated phenotypes in disease networks

Authors:

J. Woerner, R. Venkatesh, V. Sriram, D. Kim; Univ. of Pennsylvania, Philadelphia, PA

Complex diseases exhibit genetic associations with multiple phenotypes, but the role of rare variants in these pleiotropic connections is not well understood. Disease-disease networks (DDNs) offer insight into the relationships between complex disorders through graphical representations where nodes represent disease phenotypes and edges represent phenotype-associated genes or variants that are shared across nodes. We hypothesize that integrating rare variant information in DDNs improves our understanding of cross-disease relationships compared to using common variants alone. We constructed single nucleotide polymorphism (SNP)-based common variant and gene-based rare variant DDNs for 93 diseases using phenome-wide association study (PheWAS) summary statistics from the UK Biobank. Common variants were defined as having a minor allele frequency (MAF) &gt 0.01, while rare variants had an MAF &lt 0.001. The common variant network was then supplemented with edges exclusively derived from the rare variant network, resulting in an augmented DDN. The intersection between common and rare variant edges made up 2.09% of the total edges of the augmented DDN, indicating that rare variants uncover cross-phenotype associations not captured by common variants. The augmentation of the common variant DDN led to a 22.7% increase in information, identifying 280 new associations. Egocentric networks focusing on circulatory, endocrine, and neoplasm phenotypes were derived from the augmented DDN. We identified rare-variant edges linking myeloproliferative disease with hypervolemia, as well as type 1 diabetes with mitral valve disease. These genetic connections, well-supported in the literature, were not identifiable using data from common variants alone. These findings underscore the importance of including rare variants in addition to common variants in network analyses of polygenic diseases. Future directions involve integrating additional phenotypes into the rare variant augmented DDN and employing a graph-based semi-supervised learning approach to evaluate its translational utility.

PB1760 Reanalyzing legacy GWAS dataset using TOPMed imputation yields novel loci for orofacial clefting.

Authors:

X. Zhang[1], T. H. Beaty[2], E. Feingold[3], S. M. Weinberg[4], M. L. Marazita[4], J. R. Shaffer[3,4], J. C. Carlson[3,1]; [1]Dept. of Biostatistics, Sch. of Publ. Hlth., Univ. of Pittsburgh, Pittsburgh, PA, [2]Dept. of Epidemiology, Johns Hopkins Univ., Baltimore, MD, [3]Dept. of Human Genetics, Sch. of Publ. Hlth., Univ. of Pittsburgh, Pittsburgh, PA, [4]Ctr. for Craniofacial and Dental Genetics, Dept. of Oral and Craniofacial Sci., Sch. of Dental Med., Univ. of Pittsburgh, Pittsburgh, PA

Background: Genotype imputation is critical to the discovery and fine mapping of loci discovered via genome-wide association studies (GWAS). With improved representation of diverse populations in available haplotype reference panels, there is an opportunity to revisit legacy genome-wide SNP array datasets to identify any possible associations which may have been masked due to poor imputation quality or low variant frequencies in the reference panel. Here we illustrate this principle by performing a GWAS of cleft lip with or without cleft palate (CL/P) in a sample of 4,488 participants of Asian and European ancestry from 1,494 case-parent trios imputed using the TOPMed reference panel.
Methods: We used a total of 4,294,290 total variants (those genotyped were from an Illumina Human610-Quad v.1_B BeadChip; non-genotyped SNPs were newly imputed with high quality ($r2 \geq 0.80$) using the TOPMed Imputation Server) to test for association with CL/P via the transmission/disequilibrium test as implemented in PLINK.
Results: We observed genome-wide significant signals ($p < 5e\text{-}8$) for two novel loci (near RBFOX1 on chromosome 16 and the IGLV region on chromosome 22) in addition to the known clefting loci IRF6, 8q24, NTN1, and MAFB. The lead variant in the RBFOX1 locus (rs17242358, chr16:6429186 A>G [hg38], $p = 2.13e\text{-}9$) is an intronic variant in RBFOX1 with overall minor allele frequency (MAF) of 0.06; this variant is common in East Asians (gnomAD MAF = 0.12) and rare elsewhere (MAF < 0.01). RBFOX1 is expressed in the human craniofacial complex (particularly in muscle precursor, mesenchyme, ectoderm, and neuronal cells) and in brain tissue while being differentially expressed during neural tube development in mice, possibly reflecting a plausible biological role in the development of the face in early embryogenesis. The association signal in the IGLV region was led by rs141924550 (chr22:22757242 G>A, $p = 1.27e\text{-}8$), which is a non-coding transcript exon variant in lncRNA ENST00000689050, upstream of IGLV2-14 and downstream of IGLV3-15.
Conclusion: We observed two novel loci associated with risk of CL/P by updating imputation. Additional studies are necessary to validate these associations and to determine the biological underpinnings of these associations, which may point to new biological mechanisms contributing to orofacial clefting. Moreover, this strategy may be a fruitful avenue for other researchers to take full advantage of hidden associations in legacy GWAS datasets, especially those derived from collaborations using more diverse ancestries than previously represented in older imputation panels.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1761 † Reduced transferability of tobacco and alcohol use polygenic scores across populations

Authors:

G. Saunders; Univ. of Minnesota, Minneapolis, MN

Polygenic risk scores (PRS) based on a recent genome-wide association study (GWAS) of nearly 2.7 million individuals have been found to explain up to 9.6% of the variance in alcohol and tobacco use. This level of predictive power, however, is only true for individuals of European ancestries, the same ancestries upon which the discovery GWAS was based. The relative accuracy of scores derived from this same GWAS were between 0.5% and 62% in individuals of non-European ancestry, with average relative accuracies of 12% for African ancestries, 26% for East Asian ancestries, and 31% for American ancestries. This is consistent with a growing body of literature showing that the predictive power of polygenic scores declines with increasing genetic distance from the discovery sample ancestry. There are several factors that may explain the reduced transferability of PRS across populations including differences in linkage disequilibrium patterns, minor allele frequencies, and causal effect sizes. With the potential of PRS to provide clinical, research, and personal utility, understanding of the causes of reduced accuracy, and relative contributions to the problem, has important implications for equitable potential of PRS. In the current study we use summary statistics from a large-scale GWAS of tobacco and alcohol use to describe the relative accuracy of European-based PRS across diverse ancestries using >300,000 individuals from the All of Us cohort. We use two recently derived methods in samples of admixed ancestries to compare genetic effects sizes across ancestry within an individual, as well as within ancestry across individuals, to evaluate evidence for difference in causal effects sizes. This analysis is combined with a decomposition of the contribution of differences in linkage disequilibrium patterns and allele frequencies to reduce PRS accuracy across populations. Together, preliminary results suggests that differences in allele frequencies and linkage disequilibrium patterns explain a majority of reduced PRS transferability, with some evidence for small contributions of causal effect size differences. Finally, we compare these results to other medical, anthropometric, and psychiatric phenotypes to show how the pattern of results differs across human traits and behaviors. The results of this work inform effects to understand the genetic architecture of complex traits across genetic ancestries and to create more accurate polygenic risk scores for individuals from ancestries that have largely been left out of genomic research.

PB1762 Replication analysis of blood trait associations in the All of Us dataset

Authors:

N. Ma[1], A. Massarat[2], Y. Li[3], J. Margoliash[4], K. Frazer[5], M. D'Antonio[6], M. Gymrek[7]; [1]Dept. of Med., Univ. of California San Diego, La Jolla, CA, 92093, CA, [2]Univ. of California San Diego, La Jolla, CA, [3]Univ. of California San Diego, San Diego, CA, [4]Univ. of California, San Diego, La Jolla, CA, [5]UC San Diego, San Diego, CA, [6]Dept. of Med., Div. of BioMed. Informatics, Univ. of California San Diego, La Jolla, CA, 92093, CA, [7]Univ California San Diego, La Jolla, CA

The All of Us (AoU) cohort has the potential to enable detailed study of the influence of genetics and other factors on complex traits across diverse and admixed populations. To evaluate the feasibility of performing genome-wide association studies (GWAS) in AoU, we performed a replication analysis of association signals we and others previously identified in the UK Biobank for blood traits and serum biomarkers, including platelet count and LDL cholesterol. We first developed a data preprocessing pipeline to obtain reliable phenotype values from lab measurements by filtering outlier values, converting values to standardized units, and summarizing measurements for each sample access multiple (in some cases hundreds of) time points. We further implemented a genotype quality control (QC) pipeline for filtering individuals with low quality data, problematic variants, and low quality genotype calls from genotypes obtained from whole genome sequencing (WGS) of AoU participants. After filtering and QC, 52,458 and 36,053 individuals remained for analysis for platelet count and LDL cholesterol, respectively. Using these filtered datasets, we successfully replicated some of the strongest known blood trait associations. For example, we found a significant association between variants near CBL, with platelet count (lead variant p=9.17e-10 in AoU compared to p=3.77e-83 in UKB) and replicated an association we previously identified between repeat length of a CGG repeat in the promoter of CBL with this trait (p=3.77e-83 in UKB). Log transformed p-values from variants in this region were strongly correlated between UKB and AoU (r=0.9253, p< 10e-2000). In another example, we replicated a significant association between variants at the APOB locus with LDL cholesterol (lead variant p=2.92e-23 in AoU compared to p=2e-235 in UKB) including an association of a CAG repeat in the 5'UTR of APOB (p=1.37e-279 in UKB). Overall, our results demonstrate that some genetic associations identified in a relatively homogeneous population (White British from UK Biobank) can be replicated in the diverse AoU population. However, the reduction in power suggests that methodologies beyond ordinary least squares may need to be developed to achieve the full potential of extracting genetic associations in diverse populations.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1763 Revisiting the association of autoantibodies with *HLA-DRB1* in rheumatoid arthritis: non-shared epitope alleles *09 and *15 associated with elevated levels of anti-CCP2 antibodies.

Authors:

L. Padyukov[1], L. Panaifo[1], L. Israelsson[1], M. Hanson[1], RACI consortium, J. Askling[1], L. Alfredsson[1], L. Klareskog[1], C-L. Too[2], D. Lagutkin[1]; [1]Karolinska Inst, Stockholm, Sweden, [2]Inst. for Med. Res., Kuala Lumpur, Malaysia

Introduction: The presence of autoantibodies, such as anti-citrullinated protein antibodies (ACPAs), is a significant diagnostic marker in rheumatoid arthritis (RA). Human leukocyte antigen (HLA)-DRB1 alleles, particularly shared epitope (SE) alleles, have been implicated in the pathogenesis of RA and ACPA production. However, the levels of these autoantibodies in association studies have been considered only in relation to diagnostic threshold with analyses of ACPA positive vs. ACPA negative categories. This study aimed to investigate the association between HLA-DRB1 alleles and the actual measured levels of anti-cyclic citrullinated peptide 2 (anti-CCP2) antibodies in RA patients.
Methods: We used EIRA cohort dataset to address the connection between HLA-DRB1 alleles and autoantibody levels. Analyzed data included anti-CCP2 antibody level, HLA-DRB1 haplotype, sex, and age for totally 4393 patients. Anti-CCP2 antibody levels were measured by commercial ELISA. The association between HLA-DRB1 allele presence and anti-CCP2 antibody levels was primarily assessed using the Mann-Whitney-Wilcoxon test and then with Tobit regression, adjusting for age and sex as covariates. For the replication we employed WTCCC+NARAC combined cohort and MyEIRA cohort with the same set of statistical methods. Additionally, we assessed association of HLA-DRB1 alleles with the levels of anti-cytomegalovirus (CMV), anti-Epstein-Barr virus (EBV), and anti-parvovirus antibody in a subset of the EIRA cohort as a control.
Results: We confirmed the strong association of the levels of anti-CCP2 with SE alleles with stronger effect for HLA-DRB1*04 and *10 compared to *01 allelic group. In addition, our results showed a statistically significant and reproducible association between the presence of HLA-DRB1 alleles *09 and *15 and elevated levels of anti-CCP2 antibodies in RA patients. We also observed a trend for association with the *16 allele, but the sample size of patients carrying this allele was insufficient to draw definitive conclusions. No significant associations were detected for anti-viral antibodies except for HLA-DRB1 alleles *04 and *15 in relation to anti-EBV IgG levels.
Conclusion: This study demonstrates that elevated levels of anti-CCP2 antibodies are significantly associated with non-SE HLA-DRB1 alleles *09 and *15 in RA patients, suggesting a potential role of non-SE HLA-DRB1 alleles in autoantibody production in RA patients. This elevation is likely to be RA-specific. Further research is pending to confirm the association with the *16 allele and to elucidate the underlying mechanisms driving these associations.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1764 Rhinovirus-activated epithelial cells likely drive genetic susceptibility to childhood-onset asthma

Authors:

D. Fernandez Salinas[1,2,3,4], S. Djeddi[1,2,3], G. X. Huang[5,6], V. Rezende da Costa Aguiar[1,2,3], C. Mohanty[7], C. Kendziorski[7], J. Boyce[5,6], J. Gern[8], N. Barret[5,6], M. Autonoma de Mexico, Cuernavaca, Mexico, [5]Jeff and Penny Vinik Ctr. for Allergic Disease Res., Brigham and Women's Hosp., Boston, MA, [6]Dept. of Med., Harvard Med. Sch., Boston, MA, [7]Dept. of Biostatistics and Med. Informatics, Univ. of Wisconsin-Madison, Madison, WI, [8]Dept.s of Pediatrics and Med., Univ. of Wisconsin Sch. of Med. and Publ. Hlth., Madison, WI

Asthma is a complex disease caused by genetic and environmental factors. Genome-wide association studies (GWAS) have identified hundreds of variants contributing to asthma susceptibility, most of them implicating non-coding risk alleles. Studies have identified T cells as the likely driver of asthma through functional genomics, however, the role of epithelial cells remains under-studied. Furthermore, epidemiological studies for asthma indicate that wheezing caused by infection with rhinovirus (RV), which is the most frequent cause of the common cold, increases the risk of developing asthma in children. Rhinovirus infects airway epithelial cells (AECs), which are known to have roles in type 2 inflammation.

Here we hypothesized that specific cell states of airway epithelial cells may play a role in mediating genetic susceptibility to asthma. We compiled bulk and single-cell transcriptomic and epigenomic datasets of AECs exposed to different stimuli such as cytokines and viruses. We used GWAS summary statistics from 4 different cohorts involved in multiple asthma endotypes and associated diseases: childhood-onset asthma (COA), adult-onset asthma, allergy/eczema, and all asthma to characterize AEC states mediating genetic risk. We additionally used 4 unrelated well-characterized traits as positive and negative controls. We used a single-cell disease-relevance score (scDRS, Zhang, et al. Nat Genet. 2022) that identifies cells over-expressing GWAS genes in a weighted manner. We also used Linkage Disequilibrium Score-regression in Specifically Expressed Genes (LDSC-seg, Finucane, et al. Nat. Genet. 2018) to identify cell-state specific annotations with enrichment of heritability.

First, we validated that T cell-specific open chromatin and gene expression is significantly enriched in genetic risk to asthma. Then, we found that genes upregulated in RV-infected epithelial cells were associated specifically with COA (with replication in 3 independent transcriptomic datasets). Single-cell data indicates that within epithelial cells, non-ciliated subsets predominantly up-regulate COA-associated genes, specifically at 24 and 42 hours post-infection. Interestingly, while influenza virus also induced significant upregulation of asthma-associated genes in epithelial cells, SARS-CoV2 did not. We found no evidence of stimulation with cytokines (IFNa, IFNg, IL13, or IL17) upregulating asthma-associated genes in epithelial cells.

Overall, our results indicate that part of the "missing regulatory effects" for childhood-onset asthma are likely hidden in RV-activated non-ciliated epithelial cells.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1765 Risk stratification for different subtypes of ischemic stroke based on polygenic risk score and carotid intima-media thickness

Authors:

T-H. HSIAO[1], H. Tung[2], C-S. Liao[1]; [1]Dept. of Med. Res., Taichung Veterans Gen. Hosp., Taichung City, Taiwan, [2]Neurological Inst., Taichung Veterans Gen. Hosp., Taichung City, Taiwan

Rationale Ischemic stroke is a common multifactorial disease. Different subtypes, based on the TOAST classification, presented the different underlying pathogenesis. Polygenic risk scores (PRS) calculate the weighted sum of the number of the genetic variants to predict the inherent risk of the specific disease. Carotid intima-media thickness (IMT) and plaques reflect the condition of atherosclerosis, which are associated with the risk of ischemic stroke. Thus, we combined PRS and IMT to identify the subjects with highest risk of developing stroke among whom not experienced it. **Methods** Stroke patients enrolled in the stroke registry file, Taiwan Precision Medicine Initiative (TPMI) project and received carotid sonographic exams were selected. The gender and age matched non-stroke controls were selected from TPMI dataset. We selected 14 disease-associated PRSs for analysis and also compared with the IMT values and the presence of carotid plaques in stroke and control groups. We identified the PRS associated with different subtypes of ischemic stroke. Then, the selected PRS were applied for the controls, to survey if they also process the predicting power to present thicker IMT and carotid plaques. **Results** We found stroke patients had significant thicker IMT and presence of carotid plaques compared with the non-stroke controls, expect older stroke patients in TOAST 2, TOAST 3 and TOAST 5 subtype. For stroke subtype, PRS of body fat percentage are associated with *large-artery atherosclerosis stroke (OR = 2.4, p = 0.037)*, small artery disease stroke (*OR = 3.0, p = 0.018*) *and* cardio-embolic stroke (*OR = 2.6, p = 0.019*). Stroke subjects with undetermined etiology were associated with PRS of coronary artery disease (*OR = 3.4, p = 0.017*), body fat percentage (*OR = 6.0, p = 0.002*) and hip circumference (*OR = 2.8, p = 0.025*). **Conclusion** Subjects with higher core of coronary artery disease or systolic blood pressure PRSs will have higher risk of developing stroke with undetermined etiology (TOAST 5), as well as thicker IMT and presence of carotid plaques during the age of 40-60. Therefore, we can use the carotid sonographic exam as the screening tool to monitor such high stroke risk subjects based on score of coronary artery disease and systolic blood pressure PRSs. Additionally, more strict blood pressure control and active coronary disease risk reduction are suggested for these high risk subjects.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1766 RNA Editing modulates inflammation in Parkinson's disease: analysis of adenosine-to-inosine RNA editing in human iPSC-derived astrocytes and neurons.

Authors:

A. Wagen[1,2], K. D'Sa[1,2], M-L. Choi[3,2,4], S. Strohbuecker[2], G. R. Young[5], R. H. Reynolds[1], S. Garcia-Ruiz[1], Z. Chen[1], E. Gustavsson[1], A. Ghareeb[2], J. Bayne[2], J. Brenton[1], M. Grant-Peters[1,2], S. G. Rodriques[1], S. Gagliano Taliun[6], M. H. Horrocks[7], S. Gandhi[1,2], M. Ryten[8]; [1]Univ. Coll. London, London, United Kingdom, [2]The Francis Crick Inst., London, United Kingdom, [3]Korea Advanced Inst. of Sci. and Technology, Daejeon, Korea, Republic of, [4]Univ. Coll. London, Ucl, United Kingdom, [5]MRC London Inst. of Med. Sci., London, United Kingdom, [6]Univ. of Montreal, Montreal, QC, Canada, [7]The Univ. of Edinburgh, Edinburgh, United Kingdom, [8]UCL Great Ormond Street Inst. of Child Hlth., London, United Kingdom

Inflammation is increasingly implicated in the early pathogenesis and of Parkinson's disease (PD), with widespread microglial and astrocytic activation, and interferon signalling in patient samples and disease models. Cytosolic double-stranded RNA (dsRNA), evolutionarily a sign of viral infection, can trigger these responses via multiple intracellular sensors to activate the innate immune cascade. This response is dampened by adenosine-deaminase-acting-on-RNA (ADAR), and specifically the ADAR1p150 isoform, which edits RNA by deaminating adenosine to inosine (A-to-I). This negative feedback is particularly important in humans, as the expansion of retrotransposons has resulted in an increase in endogenous dsRNA that might trigger inflammation. Here we explore the contribution of A-to-I RNA editing to PD in a human induced pluripotent stem-cell (hiPSC)-derived astrocyte cell-model treated with α-synuclein oligomers (α-synO), a toxic species in PD. Using α-synO, we treated hiPSC-derived astrocytes from 5 neurotypical donors, as well as astrocytes in co-culture with hiPSC-derived neurons. We explored single-cell and bulk RNA sequencing, as well as editing rates using a pipeline optimised with JACUSA2. We found that in astrocytes, treatment with α-synO triggered a type 1 interferon response, and expansion of an inflammatory astrocytic sub-population. *ADAR* (ADAR1) expression increased by 0.90 log2fold (p.value = $1.25e^{-5}$) with an increase in the proportion of the ADAR1p150 isoform from 39 to 68%. Consistent with these findings, treatment significantly increased the number of A-to-I editing sites (p.value < $2e^{-16}$), and the proportion of editing at each site: 27,262 sites had increased editing verse 1,489 sites with decreased editing. The increase in editing preferentially affected the 3' untranslated region (p.value < $2e^{-16}$), consistent with the cytosolic location of ADAR1p150. The co-culture model followed the same pattern, though the neuronal monoculture did not, indicating astrocytes as a driver of this process. These results support an important role for innate immune responses in the pathogenesis of PD and suggest that modulation of the interferon response through RNA editing could represent a novel therapeutic strategy.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1767 Robust prediction of cancer-associated Venous Thromboembolism (VTE) using routinely-collected clinical and panel-sequencing data

Authors:

I. Moon[1], H. Jeong[1], M. Ghassemi[1], A. Gusev[2]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]Dana-Farber Cancer Inst., Boston, MA

Venous Thromboembolism (VTE), a frequent yet fatal complication, has a significant impact on patients with active cancer, leading to elevated mortality risk, compromised quality of life, and disruption of treatment regimens. The Khorana score, a current clinical standard for predicting VTEs, has shown inconsistent performance due to the heterogeneity of risk, characterized by factors such as tumor types and cancer stages. Here, we aim to improve the prediction of cancer-associated VTE across a wide range of cancer patients by leveraging a robust optimization framework and comprehensive clinical data.

We leveraged two large cohorts of cancer patients treated at the Dana-Farber Cancer Institute (DFCI) for prediction and association: 7,286 outpatient cancer patients with Khorana scores, and 29,565 patients with panel sequencing data.

We trained DeepSurv (Katzman et al., 2016), a neural network based time-to-event prediction algorithm, to predict time-to-VTE on the first group using patient covariates and routine lab test results. We noted a significant improvement over Khorana scores across 14 tumor types (overall AUC: DeepSurv 0.703 vs. Khorana 0.612). However, tumor-type specific model performance varied, with highest accuracy for skin cancers including melanoma (AUC: DeepSurv 0.909 vs. Khorana 0.697) and lowest accuracy for prostate cancers (AUC: 0.621 vs. 0.446). This heterogeneity severely limits the deployability of the model. To address this, we plan to use a distributionally robust optimization framework, which aims to optimize worst-case loss across predefined group-specific distributions and ensures consistent performance across the groups.

In our second group of patients, who had tumor panel sequencing data, we identified multiple somatic variants with significant associations to VTE incidence: including TP53 and KRAS mutations (H.R.: 1.24, p: 6.86e-13, and H.R.: 1.41, p: 5.18e-11, respectively). Leveraging these insights, we plan to develop an integrative model incorporating both the lab test results and the panel-sequencing data. We will investigate whether it captures additional heterogeneity in patients at an elevated VTE risk.

Our initial results suggest that a model with a rich set of clinical data improves the existing clinical standards for predicting VTE, while specific somatic variants show promise in capturing additional heterogeneity. For further improvements, we aim to utilize a robust optimization method and incorporate somatic variants into the model. We anticipate that our work will enable more tailored preventative measures for those at high VTE risk, while benefiting a wider demographic of cancer patients.

PB1768 Schizophrenia and long-read RNA-seq: Analysis of differential isoform usage in the dorsolateral prefrontal cortex.

Authors:

A. Abrantes[1], N. Ancalade[1], S. Sekle[1], F. Memic[2], A. Dijkstra[3], E. Tseng[4], G. Sheynkman[5], A. Smit[6], P. Sullivan[1,2], P. Giusti-Rodriguez[7]; [1]Univ. of North Carolina-Chapel Hill, Chapel Hill, NC, [2]Karolinska Inst.t, Stockholm, Sweden, [3]Amsterdam UMC, Amsterdam, Netherlands, [4]Pacific BioSci.s, Menlo Park, CA, [5]Univ. of Virginia, Charlottesville, VA, [6]Vrije Univ.it Amsterdam, Amsterdam, Netherlands, [7]Univ. of Florida Coll. of Med., Gainesville, FL

Over the past 15+ years, genetic studies have been notably successful in revealing the architecture of multiple psychiatric disorders, including schizophrenia. It is now widely acknowledged that schizophrenia is highly polygenic, consisting of both common variants of unknown significance (identified through genome-wide association studies [GWAS]) and rare coding variants. Despite these advances, the roles and the underlying mechanisms of specific genes implicated by GWAS are not well understood.

Multiple lines of evidence implicate alternative splicing in the pathophysiology of schizophrenia. In this scenario, single-nucleotide polymorphisms (SNPs) residing in GWAS implicated loci for schizophrenia could affect changes in the distribution of isoform expression within a gene. These genes would not necessarily be differentially expressed in a typical DEG study. Hence, we generated a comprehensive isoform survey of postmortem human dorsolateral prefrontal cortex (DLPFC) from schizophrenia cases and controls and identified case-control isoform-level differences. We combine the strength of PacBio SMRT long-read RNA sequencing in conducting detailed isoform census with the capacity of short-read RNA sequencing for the quantification of isoform abundances. We then implement a case vs. control differential isoform usage analysis (DIU) using a combination of established and in-house pipelines.

From several hundred thousand discovered long-read isoforms we curated a transcriptome with tens of thousands of high confidence novel isoforms. Many of these novel isoforms are differentially expressed in schizophrenia DLPFC vs healthy controls. Differentially expressed genes are enriched in gene sets related to synaptic structure and function, RNA binding and splicing, as well as cell types previously implicated in schizophrenia. We use publicly available splicing data, genotyping, proteomics, and single nucleus sequencing results from colleagues to verify and support our results.

PB1769 † Screening for polygenic risk for eight common conditions in an unselected and diverse primary care patient population

Authors:

S. Suckiel[1], E. R. Soper[1], K. E. Bonini[1], P. N. Marathe[1], J. A. Odgis[1], T. I. Gray[1], N. S. Abul-Husn[2], E. E. Kenny[1]; [1]Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]23andMe, Sunnyvale, CA

Background: There is growing evidence of the predictive abilities of polygenic risk scores (PRS) for common diseases. Applying PRS clinically could improve health outcomes by identifying at-risk individuals and informing personalized medical care. Nevertheless, clinical PRS are just emerging, and there is little data on their application to identify genomic risk at population scale.
Methods: The NHGRI-funded eMERGE IV Network is implementing cross-ancestry PRS for eight common conditions to be reported to adult (18-75 years) participants as part of a comprehensive genome-informed risk assessment. The conditions include atrial fibrillation (AF), breast cancer (BC), chronic kidney disease (CKD), coronary heart disease (CHD), hypercholesterolemia (HC), obesity (OB), prostate cancer (PC), and type 2 diabetes (T2D). High-risk PRS thresholds were set at the top 2-10%, depending on the condition. We evaluated the prevalence of high-risk PRS in the first 1,131 participants recruited from primary care clinics at one eMERGE IV site (Mount Sinai). We also performed chi-square testing to compare rates of high-risk PRS by sex and examined disease occurrence in participants who had related high-risk PRS and were <50 years old.
Results: Participants were 71% (805) female and the mean age was 47 (SD=16). Most self-reported as Hispanic/Latino/Spanish (578, 51%), White/European American (234, 21%), or Black/African American/African (160, 14%). Of the 1,131 participants, 23% (260) had a high-risk PRS for one of the eight conditions, 3% (33) for two conditions, and 0.3% (3) for three conditions; 74% (835) did not have a high-risk PRS for any of the conditions. There were 6% (63) with high-risk PRS for CHD, 5% (52) OB, 4% (48) AF, 3% (38) CKD, 3% (32) T2D, and 2% (26) HC. There were no differences in high-risk PRS rates between males and females for these six conditions. In addition, 10% (31/326) of males had a high-risk PRS for PC, and 6% (45/805) of females had a high-risk PRS for BC. Among participants <50 years, no one with a related high-risk PRS reported having AF, BC, CKD, or PC, and only one had CHD or T2D. However, a considerable number of participants <50 with a related high-risk PRS had OB (10/22, 45%) or HC (6/15, 40%).
Conclusions: In a cohort of unselected adults recruited from primary care, nearly a quarter had a high-risk PRS result for at least one of eight conditions. Except for OB and HC, most participants <50 with high-risk PRS did not have the related condition. These findings suggest that clinical PRS can help identify at-risk individuals prior to disease onset when risk-management strategies could positively impact prevention.

PB1770 Search strategy for oligogenic models of cardiomyopathy

Authors:

S. Batalov[1], M. Bainbridge[2]; [1]Rady Children's Inst. for Genomic Med., San Diego, CA, [2]Rady Children s Hosp., San Diego, CA

Cardiomyopathies (CM) are the leading cause of cardiac death, after hypertension and coronary artery disease, with over 200,000 new cases per year. Cardiomyopathy, including hypertrophic, dilated and left ventricular non-compaction, is caused by >40 genes, some of which can cause multiple forms of CM. Genetic CM is inherited in an autosomal dominant fashion and, like many other autosomal dominant diseases is often highly variable in penetrance and severity. It has long been recognized that genetic interactions (epistasis) play a role in explaining this phenotype. Increasingly, in the past 5 years, there have been numerous clinical reports of digenic inheritance and genetic modifiers (secondary mutations) of CM in small pedigrees and cohorts. Previous studies provide compelling observations that in some cases multiple variants can act epistatically to cause CM or to cause more severe CM but demonstrating the causal impact of polygenic inheritance requires experimental evidence.
We present a prioritization algorithm to identify interacting variants that are good candidates for epistasis. RCIGM has a CAP/CIiA accredited clinical lab and generated DNA libraries and whole genome sequencing data for >2,500 samples, with CM cohort comprising ~15% of all clinical patients (selected using defined set of 636 CM-related HPO terms). These data have been aligned to reference genome and variants called using the DRAGEN pipeline, annotated using CASSANDRA software to determine the effect of each mutation (intronic, nonsynonymous etc.), the evolutionary conservation, and in silico predicted deleteriousness, using REVEL (and a combination MutPred, FATHMM, VEST, PolyPhen, SIFT, PROVEAN, MutationAssessor, MutationTaster, and additional methods). Variants are filtered based on MAF from gNomad and our own sample database, to be above 0.1% in at least one subpopulation but not to exceed 1% in any sub-population. Gene (protein-protein) interactions are inferred using STRINGdb (v.11.5) combined score. Together, these factors enrich for mutations that are uncommon but alter evolutionarily conserved amino acids in pathogenic mutation-rich regions. These methods are refined such that known epistatic interactors are prioritized (1,059 CM-related gene targets from literature: including Richter 2020, Szot 2018, initially gated to only near-coding positions, within 12 bp of all coding exons), with significance p-values < 10^-9 using permutation analysis.
Using the prioritization algorithm and the existing cardiomyopathy cohort at RCIGM as well as public databases we identified good candidates for functionalization in vivo/in vitro in mice (in progress).

PB1771 SERPINE3 is an RPE-specific protease inhibitor critical for retinal function

Authors:

H. Li[1], D. McGaughey[2], L. Dong[1], J. Liu[1], T. Johnson[1], R. Hufnagel[3]; [1]NIH NEI, Bethesda, MD, [2]Johns Hopkins Univ, Baltimore, MD, [3]Natl. Eye Inst., NIH, Bethesda, MD

Purpose: Serpin family E member 3 (SERPINE3) is a putative serine proteinase inhibitor with unknown function in mammalian retina. Here, we define the cellular expression of SERPINE3 in human and mouse, define target proteases, and explore its function in a novel mouse model. **Methods:** Human and macaque expression data from eye-Integration and plae were analyzed. Protease assay using fluorescently-labeled peptide substrate was performed for screening the SERPINE3 against all major classes of proteases. *Serpine3-VenusGFP* knockin mice were generated using CRISPR-mediated homologous recombination in mouse zygotes, replacing exon 2 with a Venus reporter. For analyzing the function of Serpine3 in RPE regeneration, sodium-iodate injury model, anti-ZO1 staining and anti-cell proliferation specific markers' staining were performed. **Results:** *SERPINE3* is specifically expressed in human and macaque retinal pigment epithelium (RPE). Through compartment analysis, SERPINE3 protein was observed in cytoplasm and extracellular vesicles of human iPSC-derived RPE. In mouse eye, Serpine3 protein and *Serpine3-Venus*GFP reporter expression were localized exclusively to RPE, and the GFP+ cells were able to reenter cell cycle after sodium-iodate injury. *Serpine3*$^{Gfp/Gfp}$ homozygous mice are viable. Protease inhibition screen of 75 candidates identified Caspase 1, Caspase 2, Caspase 3, and Caspase 5 as putative SERPINE3 targets. **Conclusion:** In mammalian retina, SERPINE3 is expressed specifically in the RPE and a high level in the peripheral mature RPE. The subtype of Serpine3-GFP+ RPE cells are able to reenter cell cycle under the sodium iodate treatment. Deletion of Serpine3 in mouse accelerates sodium iodate-induced RPE degeneration. SERPINE3 targets include multiple caspases implicated in retinal inflammation and cell death structural retinal abnormalities, supporting a protective role of SERPINE3 to prevent RPE degeneration.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1772 Severe COVID-19 infection Increases Long-term Cardiovascular Risk Through Gene-Pathogen Interaction with ABO Blood Type

Authors:

J. Hilser[1], N. Spencer[1], K. Afshari[1], F. Gilliand[1], H. Hu[1], A. Deb[2], A. Lusis[2], W. Tang[3], J. A. Hartiala[1], S. Hazen[3], H. Allayee[1]; [1]Univ. of Southern California, Los Angeles, CA, [2]Univ. of California Los Angeles, Los Angeles, CA, [3]Cleveland Clinic, Cleveland, OH

Background: COVID-19 is associated with increased post-acute risk of major adverse cardiac events (MACE), such as myocardial infraction (MI), stroke, or all-cause mortality. However, it is not known whether increased cardiovascular disease (CVD) risk in COVID-19 patients persists beyond one year after infection and whether genetic factors modulate such risk. **Methods:** COVID-19 cases were identified in the UK Biobank based on positive PCR tests for SARS-CoV-2 infection (n=8,167) or ICD-10 codes for COVID-19 (n=1,872) between February 1, 2020 and December 31, 2020. Controls (n=217,591) were defined as subjects without a PCR^+ test for SARS-CoV-2 infection or who were never assigned a COVID-19 ICD-10 code during the same interval. Cox proportional hazards models were used to evaluate association between COVID-19 and long-term risk of MACE with follow-up to October 31, 2022 (1003 days). A candidate gene approach was used to test if COVID-19 modulated risk of thrombotic events (MI or stroke) through interactions with ABO blood type and previously identified variants for COVID-19 severity (rs11385942), susceptibility to SARS-CoV-2 infection (rs73062389), or coronary artery disease (CAD) (rs4977574). **Results:** Among all cases and controls, COVID-19 was associated with significantly increased risk of MACE, which was more pronounced among severe COVID-19 cases (HR=4.14, 95% CI 3.77-4.55; $P=2.0x10^{-194}$). Compared to patients with CVD but without COVID-19, risk of MACE among severe COVID-19 cases without CVD was even higher (HR=1.23, 95% CI 1.09-1.38; $P=1.0x10^{-3}$). Severe COVID-19 also increased risk MI or stroke to a greater in subjects with non-O blood types (HR=2.29, 95% CI 1.85-2.84; $P=2.5x10^{-14}$) than subjects with blood type O (HR 1.27, 95% CI 0.92-1.76; P=0.15), resulting in a significant interaction between the *ABO* locus and COVID-19 ($P\text{-int}=3.2x10^{-3}$). By comparison, COVID-19 did not modulate risk of incident MI or stroke as a function of variants for severe COVID-19 (P-int=0.75), SARS-CoV-2 infection susceptibility (P-int=0.59), or CAD (P-int=0.46). **Conclusions:** Risk of MACE in COVID-19 patients remained significantly elevated nearly 3 years after SARS-CoV-2 infection, with severe COVID-19 representing a CAD risk equivalent. Increased risk of thrombotic events was particularly evident among severe COVID-19 with non-O blood types and would represent one of the first known gene-pathogen exposure interactions for CVD outcomes. Additional studies will be needed to determine the underlying biological mechanism(s) for the genetic interaction between *ABO* blood type and severe COVID-19 and whether risk of MACE persists beyond 3 years in COVID-19 patients.

PB1773 Sex chromosome overdosage impairs neuronal synapses in human iPSC-derived neurons and brain organoids.

Authors:

A. Adamo, V. Astro, L. V. Cortez Medina, K. Cardona Londono, R. Alghamdi; King Abdullah Univ. of Sci. and Technology, Thuwal, Saudi Arabia

Sex chromosome overdosage in Klinefelter Syndrome (KS; 47,XXY), Jacob Syndrome (JS; 47,XYY), and high-grade sex-chromosome aneuploidies (48,XXXY and 49,XXXXY) leads to a shared broad spectrum of clinical features, including motor, speech, and language delays. The severity of intellectual disabilities directly correlates with the number of extra sex chromosomes. However, the in vitro modelling of these conditions is, to date, largely unexplored. We investigated the impact of sex-chromosome aneuploidies during early neurodevelopment using an induced pluripotent stem cells-based disease-modelling approach. We postulated that the neurodevelopmental deficits in KS, JS and high-grade SCAs subjects lie in the overdosage of escape genes located within the pseudoautosomal region (PAR) of the X and Y chromosomes. We used a paradigmatic cohort of KS, JS, high-grade SCAs, and 46,XY iPSCs to obtain 2D neuronal cultures and 3D cortical brain organoids. Combining a transcriptomic and functional approach, we demonstrated that sex chromosome overdosage negatively impacts the electrophysiological properties of iPSC-derived neurons in a dosage-sensitive manner. Our unique iPSC cohort represents an ideal platform to investigate the molecular and cellular impact of X and Y overdosage during early development and could serve as a clonal cellular model to study X inactivation erosion.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1774 Sex differences in genetic architecture of clinical laboratory tests: A lab wide analysis in the electronic health record

Authors:

F. Blostein[1], A. Lake[2,1], M. Niarchou[1], J. Kim[1], P. Straub[1], B. Bose[3], J. L. Winters[1], D. Velez Edwards[1], B. Stranger[3], L. Davis[1]; [1]Vanderbilt Univ. Med. Ctr., Nashville, TN, [2]Vanderbilt Univ. Sch. of Med., Nashville, TN, [3]Northwestern Univ., Chicago, IL

Sex differences exist in the prevalence, incidence, and presentation of heritable, complex diseases. Similarly, sex differences exist in the distributions of some clinical laboratory tests, and in their utility as disease biomarkers. To date, the genetic etiology of these differences is understudied and poorly understood. We investigate sex differences in genetic architecture for over 1,000 clinical laboratory tests among approximately 94,000 genotyped patients in the Vanderbilt University Medical Center electronic health record (BioVU). We perform sex-stratified genome-wide association analyses for clinical laboratory median values and variance, followed by sex*SNP interaction analyses for those SNPs that have significant main effects in at least one sex. Because sex and gender correlate, and sociocultural forces create differences in health care behaviors and treatment, we additionally evaluate differences in ordering of clinical laboratory tests for male and female patients and assess epidemiological methods to address potential ascertainment bias (e.g., inverse probability weighting). Accounting for and understanding sex differences in the genetic architecture of laboratory test values can improve their sensitivity and specificity as clinical biomarkers. Further, understanding sex differences in the genetic etiology of clinical laboratory tests may elucidate sex differences in disease mechanisms.

Hlth., Baltimore, MD, [27]Rush Alzheimer's Disease Ctr., Rush Univ. Med. Ctr., Chicago, IL, [28]Dept. of Neurology, Massachusetts Gen. Hosp./Harvard Med. Sch., Boston, MA

Sex and gender differences are present across multiple domains of cognition in aging and Alzheimer's disease (AD). For example, clinically healthy women show cognitive advantages in episodic memory and verbal fluency tasks, whereas men show advantages in visuospatial tasks. However, women tend to lose cognitive advantages to men during disease, experiencing more rapid cognitive decline. Additionally, genetic studies of AD cognitive endophenotypes have identified loci that associate with cognition, but these studies have not considered sex/gender. In this study, we investigated if genetic contributors to cognition in older adults differed by sex, leveraging harmonized memory, executive functioning (EF), language, and global cognition scores across 9 cohort studies of aging and AD. For each domain, we conducted sex-stratified and sex-interaction genome-wide meta-analyses, gene-set analyses, and genetic correlation tests among a cross-ancestral sample of over 35,000 older adults (mean age at baseline=73 years, 57% female, 14% AD cases, average number of observations per participant>4, 88% non-Hispanic White and 12% non-Hispanic Black). Linear regression associations covaried for age and ancestry principal components. Beyond the well-known *APOE* locus, we identified 3 sex-specific genome-wide loci. First, *HS3ST4*, associated with global cognitive decline among males (rs10852291: β_M=-5.29x10^{-3}, P_M=4.73x10^{-8}, β_{int}=6.26x10^{-3}, P_{int}=2.77x10^{-6}) but not among females (β_F=7.70x10^{-4}, P_F=0.35). This locus also showed a male-specific association with fluid intelligence in the UK Biobank (β_M=-2.30x10^{-2}, P_M=7.49x10^{-3}; β_F=1.44x10^{-3}, P_F=0.86). Second, *TMEM245/CTNNAL1* interacted with sex on baseline EF (rs112083348: β_{int}=-0.10, P_{int}=2.67x10^{-8}; β_M=0.05, P_M=5.18x10^{-4}; β_F=-0.05, P_F=4.92x10^{-5}). This locus was also associated in a UK Biobank sex-aware GWAS of an EF-related task (β_M=1.63x10^{-2}, P_M=6.07x10^{-3}; β_F=5.88x10^{-3}, P_F=0.28). Furthermore, rs112083348 is an eQTL for *CTNNAL1* in two brain regions affected in AD: the hippocampus and the dorsolateral prefrontal cortex. Finally, *VRK2* associated with language decline among females (rs11898834: β_F=2.75x10^{-3}, P_F=9.99x10^{-10},

$\beta_{int}=2.94x10^{-3}$, $P_{int}=6.93x10^{-5}$) but not among males ($\beta_M=-7.50x10^{-5}$, $P_M=0.89$). Notably, rs11898834 is an eQTL for *VRK2* in whole blood, and is a top locus in a sex-aware GWAS on developmental stuttering. Overall, our results are evidence of a sex-specific component to the genetic architecture of cognitive performance. We look forward to our next steps of incorporating bulk and single-cell transcriptomic analyses into our sex-aware exploration of cognition.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1776 Sex differences in the pleiotropy of hearing problems with imaging-derived phenotypes: a brain-wide imaging study.

Authors:

J. He, B. Cabrera-Mendoza, G. A. Pathak, D. Koller, R. Polimanti; Yale Univ., New Haven, CT

Background: Hearing problems (HP) are one of the major health burdens in the elderly. While changes in the peripheral auditory system play an important role, genetic variation associated with brain structure and function could also be involved in HP predisposition. **Methods**: We analyzed a large-scale HP genome-wide association study (GWAS; Ntotal=501,825, 56% females) and GWAS data related to 3,935 brain imaging-derived phenotypes (IDPs) assessed in up to 33,224 individuals (52% females). To investigate systematically HP pleiotropy with brain structure and function, i.e., loci affecting both traits, we conducted genetic correlation, latent causal variable (LCV), Mendelian randomization (MR), and multivariate logistic regression analyses. Additionally, we performed local genetic correlation and multi-trait colocalization analyses to identify genomic regions and loci implicated in the pleiotropic mechanisms shared between HP and brain IDPs. **Results**: We observed a widespread genetic correlation of HP with multiple IDPs in the sex-combined analysis (Ntraits=171) and in females (Ntraits=120) and males (Ntraits=89), separately. Applying Bonferroni correction accounting for the number of IDPs tested, the LCV analyses showed that some of these genetic correlations could indicate cause-effect relationships. For seven of them, the possible causal effects were supported by an independent MR approach: vessel volume in the sex-combined analysis, hippocampus volume, cerebellum grey matter volume, primary visual cortex volume, and rfMRI-ICA100 node 46 in females, and global mean thickness and mean orientation dispersion index in superior corona radiata in males. The local genetic correlation analyses identified 13 pleiotropic regions of HP with respect to these seven IDPs. We also observed a colocalization signal for the rs13026575 variant between HP, primary visual cortex volume, and *SPTBN1* transcriptomic regulation in females. **Conclusion**: This study provides evidence that brain structure and function may have a role in HP predisposition via possible cause-effect relationships and shared regulatory mechanisms.

PB1777 Sex-specific Associations of Gene Expression in Brains with Alzheimer's Disease Pathology and Cognitive Performance within X Chromosome.

Authors:

M. Clifton[1], M. Seto[1,2], R. Buckley[2,3,4], K. Gifford[1], A. Jefferson[1], P. De Jager[5,6], D. Bennett[7], Y. Wang[7], L. Barnes[7], J. A. Schneider[7], T. J. Hohman[1,8], L. Dumitrescu[1,8]; [1]Vanderbilt Memory and Alzheimer's Ctr., Vanderbilt Univ. Med. Ctr., Nashville, TN, [2]Ctr. for Alzheimer's Res. and Treatment, Dept. of Neurology, Brigham and Women's Hosp./Harvard Med. Sch., Boston, MA, [3]Dept. of Neurology, Massachusetts Gen. Hosp./Harvard Med. Sch., Boston, MA, [4]Melbourne Sch. of Psychological Sci., Univ. of Melbourne, Melbourne, Australia, [5]Ctr. for Translational & Computational Neuroimmunology, Dept. of Neurology, Columbia Univ. Med. Ctr., New York, NY, [6]Cell Circuits Program, Broad Inst., Cambridge, MA, [7]Rush Alzheimer's Disease Ctr., Rush Univ. Med. Ctr., Chicago, IL, [8]Vanderbilt Genetics Inst., Vanderbilt Univ. Med. Ctr., Nashville, TN

Alzheimer's disease (AD) disproportionately affects women, who make up two-thirds of all clinical cases of AD. Despite known sex differences in AD neuropathology, the response to pathology, and the genetic predictors of clinical AD, sex differences in the brain transcriptomic signatures of AD endophenotypes have not been fully characterized, especially the contribution of the X chromosome. We leveraged bulk RNA-sequencing data from three brain regions [dorsolateral prefrontal cortex (DLPFC), posterior cingulate cortex (PCC), and caudate nucleus (CN)] from the Religious Orders Study and Rush Memory and Aging Project (ROS/MAP). Propensity scoring was used to match male to female participants due to disproportionate sample sizes. As a result, there were 791 participants (50% male; mean age at death=88 years). Gene-expression from approximately 500 genes on the X chromosome were included sex-stratified regression models assessing tissue-specific associations with amyloid and tau burden at autopsy, along with longitudinal global cognition. Age at death and post-mortem interval were included as covariates. Sex-specific genes were defined as those associated with a trait in only one sex (FDR-corrected $P<0.05$). Of the 724 significant associations, 33% were sex-specific. We observed more female-specific (26%) compared to male-specific (7%) effects. Interestingly, across all tissues, fewer sex-specific associations were observed with amyloid (3%) compared to tau tangles (14%) or longitudinal cognition (16%), which supports the hypothesis that sex differences are more likely to appear downstream after the onset of amyloid accumulation. Several genes showed particularly strong effects among females in two of the three brain tissues, including DYNLT3 ($P_M>0.11$, $P_F<8.67x10\text{-}4$) and ATRX ($P_M<0.1$, $P_F>0.003$) with tau tangles. Additionally, female-specific associations were observed with POU3F4 expression with both cognition ($P_M>0.06$, $P_F<0.002$) and tau tangles ($P_M>0.15$, $P_F<0.003$) in both DLPFC and CN. Conversely, male-specific associations were observed between TRMT2B ($P_M<6.51x10\text{-}4$, $P_F>0.07$) and tau tangles within the DLPFC and CN. Our results highlight X chromosome transcriptomic associations with AD endophenotypes, including ATRX, which has been related to hippocampal-dependent memory impairments in male mice. Similar sex-specific patterns with AD were observed in independent AMP-AD cohorts for DYNLT3, POU3F4, and TRMT2B. These findings highlight the exciting potential of the often overlooked X chromosome to select new targets for mechanistic evaluation.

PB1778 † Sex-stratified analysis of adipose cell-types and cell states identify genes underlying transitions from obesity to its key comorbidity, type 2 diabetes

Authors:

Z. Wang[1,2], S. Lee[1], M. Alvarez[1], S. Rajkumar[1], A. Kar[1], K. Gelev[1], S. Heinonen[3], B. W. d. Kolk[3], U. Säiläkivi[4], T. Saarinen[4], K. H. Pietiläinen[3,5], P. Pajukanta[1,2,6]; [1]Dept. of Human Genetics, David Geffen Sch. of Med. at UCLA, Los Angeles, CA, [2]Bioinformatics InterDept.al Program, UCLA, Los Angeles, CA, [3]Obesity Res. Unit, Res. Program for Clinical and Molecular Metabolism, Faculty of Med., Univ. of Helsinki, Helsinki, Finland, [4]Dept. of Abdominal Surgery, Abdominal center, Helsinki Univ. Hosp. and Univ. of Helsinki, Helsinki, Finland, [5]Hlth.y Weight Hub, Abdominal center, Helsinki Univ. Hosp. and Univ. of Helsinki, Helsinki, Finland, [6]Inst. for Precision Hlth., David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Sex affects gene expression in subcutaneous adipose tissue (SAT). However, it is not known which genes underly cell-type and subcell-type (i.e. cell state) level sex-specific differences in SAT gene expression, and whether they contribute to transitions from obesity to its key comorbidity, type 2 diabetes (T2D). To address this knowledge gap, we conducted a large single nucleus RNA-sequencing study on SAT from 69 Finns with obesity (n=20 males, n=49 females), including 6 males and 7 females with obesity and normal glucose levels (ObNoC); 6 males and 12 females with obesity and prediabetes (ObPrD); and 6 males and 22 females with obesity and T2D (ObT2D). In our adipocyte differential expression (DE) analysis between all 20 males and 49 females, we observed 508 genes (adjp<0.05) upregulated in males. We hypothesized that the sex-specific genes reflect differences in cell states by sex, and that these differ by obesity comorbidities and transitions to comorbidities (TTC). We first identified differentially abundant cellular neighborhoods (DA) between the males and females using Milo (controlling cell counts and ages; FDR<0.1). In the DA analysis (n=69), we found prominent sex-specific DAs in all adipose cell-types, particularly in adipocytes. The adipocyte DAs more abundant in females had 1,263 DE genes (DEGs) with transcription factor (TF) motif enrichment in a key adipogenesis TF, *CEBPD*, using Homer. Next, we performed stratified analysis by comorbidity. In ObNoC, the DEGs from DAs more abundant in males (n=181 DEGs) or more abundant in females (n=539 DEGs) did not show gene ontology (GO) or TF motif enrichments. In ObPrD, the T cell DAs more abundant in males contained 3 DEGs, *TXK*, *LEF1*, and *BACH2*; and endothelial cell DAs more abundant in males had 953 DEGs with a TF motif enrichment in *NFIC*. In ObT2D, the adipocyte DAs more abundant in males contained 2,213 DEGs with GO enrichments in protein modification and autophagy, and TF motif enrichments in *PKNOX1* and *TFAP2C*. In the TTC analysis, we observed DAs in the following transitions in females: ObNoC to ObT2D; and ObPrD to ObT2D. From ObNoC to ObT2D, the adipocyte DAs more abundant in ObNoC had 923 DEGs with TF motif enrichments in *HINFP*, *RELB*, and a T2D GWAS gene, *TFAP2B*, while the 586 DEGs from the adipocyte DAs more abundant in ObT2D showed TF motif enrichment in *TCF3*, and were enriched for female glycated hemoglobin GWAS SNPs using Magenta (FDR<0.05). From ObPrD to ObT2D, the adipocyte DAs more abundant in ObPrD had 735 DEGs. In conclusion, our analyses identify sex-specific genes at the SAT cell-type and cell-state resolution, as well as female DAs with DEGs for transitions from obesity to its key comorbidity, T2D.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1779 † Sex-stratified rare-variant association analysis using 419,000 UK Biobank exomes reveals sex-biased genetic associations with disease and quantitative traits.

Authors:

E. Oerton[1], Q. Wang[2], A. Nag[1], K. Smith[1], K. Carss[1], S. Petrovski[1]; [1]Ctr. for Genomics Res., Discovery Sci., R&D, AstraZeneca, Cambridge, United Kingdom, [2]Ctr. for Genomics Res., Discovery Sci., R&D, AstraZeneca, Waltham, MA

Due to physiological or environmental differences between females and males ('female' and 'male' here defined by sex karyotype), genetic associations may appear to be stronger in one sex than the other, or may even be absent in one sex entirely. These sex differences can reveal important information about the gene-phenotype relationship that may be obscured by standard sex-combined analyses. In this work, we apply our rare-variant collapsing PheWAS pipeline to 419,000 European-ancestry UK Biobank exomes, analysing females and males separately in order to identify sex-biased autosomal gene-phenotype associations. As well as 4,852 binary (case-control) and 1,264 quantitative traits, we apply this pipeline to Nightingale metabolite and Olink protein measurements, in the first biobank-scale study of sex-biased metabolomic and proteomic quantitative trait loci (QTLs). Females and males for each trait (including both cases and controls for binary traits) were downsampled to ensure equivalent power in both sexes. Defining 'sex-biased' as being genome-wide significant ($p<10^{-8}$) in one sex, with a non-significant ($p>=0.05$) p-value in the other and/or a significant difference in effect size as assessed by the Breslow-Day (binary traits) or Cochran's Q (quantitative traits) tests, we find 106 binary sex-biased traits. These include an association between protein-truncating variants in *DSP* and dilated cardiomyopathy which is highly significant in females with an odds ratio of 32.4 ($p = 3.92x10^{-12}$), but non-significant in males (OR 3.4, $p = 0.261$). We also find 1,035 quantitative sex-biased traits across 461 genes, including 385 mQTLs and 438 pQTLs. 55 of the sex-biased associations are genome-wide significant only in the sex-stratified analysis ($p<10^{-8}$ in stratified vs $p>=10^{-6}$ in combined), despite having only half the sample size of the sex-combined analysis. This illustrates the value of conducting sex-stratified analysis, unveiling biological insights that may remain concealed when considering males and females as a combined group. These sex-biased genetic associations shed light on potential sex-specific pleiotropy and enhance our understanding of sex-biased disparities in disease biology; further, they aid in identifying individuals most likely to benefit from therapeutic interventions targeting related gene targets.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1780 Shared genetic architecture and pleiotropy across uterine fibroids and hypertension.

Authors:

A. Pigg Akerele[1,2,3], J. N. Hellwege[2], J. A. Piekos[3], N. K. Khankari[2], T. L. Edwards[2], D. R. Velez Edwards[2]; [1]Meharry Med. Coll., Nashville, TN, [2]Vanderbilt Univ. Med. Ctr., Nashville, TN, [3]Vanderbilt Univ., Nashville, TN

Uterine fibroids (leiomyomata, UF) are among the most common gynecologic diseases in females of reproductive age, having an estimated cumulative prevalence of 70%. Women with fibroids experience debilitating symptoms (like severe pain and infertility) and a host of comorbidities (like polycystic ovarian syndrome, endometriosis, anemia, and hypertension (HTN)). Complications stemming from UF are a major indication for pelvic surgery and causes an economic burden of tens of billions of dollars per year. There is a need to better understand the genetic liability of risk for this phenotypically heterogeneous and complex disorder.

Multiple genetic loci have been identified to be associated with disease susceptibility for UF and shared risk factors, like HTN. In efforts to understand causal relationships between UF and HTN, we conducted a Mendelian Randomization analysis and evaluated the genetic correlations across blood pressure (BP) trait loci and UF. We used data from a cross-ancestry genome-wide association study (GWAS) meta-analysis of UF including published and unpublished data (44,205 cases and 356,552 controls), as well as data from a cross-ancestry GWAS meta-analysis of BP phenotypes (including diastolic BP [DBP], systolic BP [SBP], and pulse pressure [PP], N=447,758). We also evaluated genetic heritability and correlation of BP phenotypes and UF with linkage disequilibrium score regression (LDSC). Bi-Directional Two-Sample Mendelian Randomization (MR) was conducted to assess potential causal relationships between BP traits and UF. Genetic instruments for the MR analysis were selected from summary-level data of BP traits and UF by linkage disequilibrium clumping of genome-wide significant SNPs ($p<5e-8$) with an r2 threshold of 0.1.

LDSC results indicated a positive genetic correlation between DBP and UF (0.140, $p = 0.0004$), and SBP and UF (0.076, $p = 0.016$), and PP and UF (0.008, $p > 0.05$). MR using BP traits as exposures and UF as the outcome showed that DBP and pulse pressure both increase risk for UF ($b = 0.024$, $p = 0.002$ and $b = -0.010$, $p = 0.0008$, respectively). Having UF as the exposure and BP traits as the outcomes indicated a relationship between UF and DBP and UF and PP ($b = 0.46$, $p = 0.005$ and $b = -0.51$, $p = 0.015$, respectively). SBP as the outcome and as the exposure did not provide significant results. Our results provide evidence that HTN has shared genetic effects with UF that may contribute to the severity of the disease. Future directions of this study are to expand LDSC and MR analysis to other reproductive conditions. Through this work we will elucidate the shared genetic architecture and pleiotropy among women's gynecologic disorders and hypertension.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1781 Shared genetic architecture between congenital kidney defects and autism spectrum disorders.

Authors:

S. Krishna Murthy[1], H. Rasouly[1], S. Bheda[1], M. Marasa[1], N. Vena[1], E. Fiaccadori[2], A. Materna-Kiryluk[3], G. Masnata[4], V. Tasic[5], M. Saraga[6], K. Kiryluk[1], G. Ghiggeri[7], S. Sanna-Cherchi[1], A. Gharavi[1]; [1]Columbia Univ., New York City, NY, [2]Univ. di Parma, Parma, Italy, [3]Uniwersytet Medyczny w Poznaniu, Poznan, Poland, [4]Univ. of Cagliari, Cagliari, Italy, [5]Univ. Children's Hosp., Skopje, Macedonia, The Former Yugoslav Republic of, [6]Univ. Hosp. of Split, Split, Croatia, [7]Giannina Gaslini Inst., Genova, Italy

Background: Shared pathogenesis of congenital anomalies of the kidney and urinary tract (CAKUT) and autism spectrum disorder (ASD) has been suggested. Copy-number variants associated with ASD were reported to be enriched in CAKUT patients. Unlike ASD, CAKUT is often identified prenatally. Identification of syndromes including both ASD and CAKUT has the potential to improve prenatal diagnosis of syndromes associated with ASD.**Methods**: A total of 281 trios with CAKUT and no family history of disease were analyzed for de-novo variants enrichment using denovolyzer. In addition, 1,723 unrelated probands and 22,252 unrelated controls were matched based on genetic ancestry to perform gene-set burden analysis. Multiple gene-sets were pre-defined including i) a gene-set of 632 constrained genes (pLI score > 0.9, LOEUF>0.35) ii) highly expressed (top decile) in nephron-progenitor cells (NPCs) in 18wks human embryonic kidneys and iii) a gene-set of 547 constrained genes associated with ASD extracted from AutDB, a publicly available web-portal for on-going collection of genes linked to the disorder. Only rare loss-of-function variants (LoFs, gnomAD allele frequency $<10^{-5}$) were included in the analysis. Since the 2 cohorts were independent, we calculated the Fisher combination p-value for each gene-set enrichment analysis.**Results**: In the 281 trios, we observed 9 de-novo LoFs in the NPCs gene-set compared to the 1.2 expected (7.56-fold enrichment, p-value= $4.56x10^{-6}$). In the case-control analysis, we identified 78 probands with LoFs variants in the NPCs gene-set compared to 503 controls (1.81-fold enrichment, p-value= $3.53x10^{-5}$). The NPCs gene-set Fisher combination p-value reached $3.79x10^{-9}$. Using the ASD gene-set, we observed 10 de-novo LOFs compared to the 1.7 expected (5.74-fold enrichment, p-value= $1.76x10^{-5}$). The genes driving this enrichment included genes known to be associated with kidney anomalies and ASD (*PSMD12; KAT6B*), as well as genes known to be associated with ASD, but not with CAKUT (*KMT2A, TLK2, MAGEL2, ADNP, SIK1*). In the case-control analysis, we identified 88 probands with LoFs variants in the same gene-set compared to 660 controls (1.52-fold enrichment, p-value=$1.5x10^{-3}$). The Fisher combination p-value reached $5.38x10^{-7}$.**Conclusions**: A significant enrichment for rare LoFs in genes associated with ASD was observed in individuals with CAKUT. Future studies analyzing enrichment for LoFs in genes associated with CAKUT could further inform the scope of this overlap.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1782 Shared genetic effect of kidney function on bipolar disorder and major depressive disorder: a large-scale genome-wide cross-trait analysis

Authors:

S. Yu[1], B. Liao[1], X. Jin[1], Y. Lin[2]; [1]Dept. of Urology, Inst. of Urology (Lab. of Reconstructive Urology), Chengdu, China, [2]Hlth.Management Ctr., Gen. Practice Med. Ctr., and Med. Device Regulatory Res. and Evaluation Ctr., West China Hosp., Sichuan Univ., Chengdu, Sichuan, PR. China, Chengdu, China

Background:
Epidemiological studies have revealed a significant association between impaired kidney function and certain mental disorders, particularly bipolar disorder (BIP) and major depressive disorder (MDD). However, the evidence regarding shared genetics and causality is limited due to residual confounding and reverse causation.
Methods:
In this study, we conducted a large-scale genome-wide cross-trait association study to investigate the genetic overlap between 5 kidney function biomarkers (eGFRcrea, eGFRcys, blood urea nitrogen (BUN), serum urate, and UACR) and 2 mental disorders (MDD, BIP). Summary-level data of European ancestry were extracted from UK Biobank, Chronic Kidney Disease Genetics Consortium, and Psychiatric Genomics Consortium.
Results:
Using LD score regression, we found moderate but significant genetic correlations between kidney function biomarker traits on BIP and MDD. Cross-trait meta-analysis identified 1 to 19 independent significant loci that were found shared among 10 pairs of 5 kidney function biomarkers traits and 2 mental disorders. Among them, 3 novel genes: *SUFU*, *IBSP*, and *PTPRJ*, were also identified in transcriptome-wide association study analysis (TWAS), most of which were observed in the nervous and digestive systems (FDR < 0.05). Pathway analysis showed the immune system could play a role between kidney function biomarkers and mental disorders. Bidirectional mendelian randomization analysis suggested a potential causal relationship of kidney function biomarkers on BIP and MDD.
Conclusions:
In conclusion, the study demonstrated that both BIP and MDD shared genetic architecture with kidney function biomarkers, providing new insights into their genetic architectures and suggesting that larger GWASs are warranted.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1783 Shared genetic signal discovery in multi-trait analysis of lung and liver fibrosis**.**

Authors:

G. Parcesepe[1,2], E. Joof[1,2], R. J. Allen[1,2], J. K. Quint[3], I. D. Stewart[3], G. Aithal[4,5], R. G. Jenkins[3], L. V. Wain[1,2], DEMISTIFI consortium; [1]Univ. of Leicester, Leicester, United Kingdom, [2]NIHR Leicester BioMed. Res. Ctr., Leicester, United Kingdom, [3]Imperial Coll. London, London, United Kingdom, [4]Univ. of Nottingham, Nottingham, United Kingdom, [5]NIHR Nottingham BioMed. Res. Ctr., Nottingham, United Kingdom

Fibrosis is the pathological scarring of organ tissues, and is estimated to account for 45% of deaths in the developed world. There are no drugs that can halt, let alone reverse fibrosis. Our goal was to identify genes that could represent new targets for the development of anti-fibrotic therapy and that would benefit patients with one or more fibrotic disease. Taking lung and liver fibrosis as exemplars, we applied genetic association methods that combine diseases with shared underlying fibrotic pathology to improve power to identify shared risk variants and genes. Organ-specific fibrosis Genome-wide Association Studies (GWAS) were conducted in UK Biobank utilising a recently published consensus list of fibrotic diseases of the lung and liver. LD Score Regression was used to calculate genome-wide correlation and multi-trait analysis of GWAS was performed (MTAG) with $P<5x10^{-8}$ threshold for significance. MTAG exploits correlation between traits, to improve effect estimates, and gives trait-specific association statistics. The genome-wide genetic correlation between lung and liver fibrosis was 0.470 (P=0.047). When combining the GWAS using MTAG, there was increased significance of previously reported signals across the genome for both traits, including the signal at *IVD* previously associated with idiopathic pulmonary fibrosis (IPF) ($P=3.31x10^{-5}$ to $P=8.63x10^{-6}$), and the *SERPINA1* locus (alpha-1 anti-trypsin deficiency and non-alcoholic fatty liver disease (NAFLD))) ($P=1.29x10^{-6}$ to P=6.29x10-^{7}). Conversely, there was a decrease in the significance of signals at other known loci, including the *MUC5B* locus (IPF)) ($P=6.33x10^{-48}$ to $P=5.25x10^{-35}$) and the *PNPLA3* locus (NAFLD, alcoholic liver disease, and chronic hepatitis C)) ($P=5.18x10^{-42}$ to $P=1.70x10^{-35}$). An increase in association significance for signals in either trait suggests that these may represent shared genetic risk factors for lung and liver fibrosis. Signals that were attenuated when traits were combined may represent organ-specific signals. This could provide valuable insight into the shared and distinct fibrotic mechanisms in the liver and lung that can inform development of new anti-fibrotic therapies.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1784 Shared polygenic risk and causal inference between kidney function and inflammatory biomarkers: a large-scale genome-wide cross-trait analysis

Authors:

Y. Lin[1], H. Jin[2], G. Liao[3], L. Du[4], J. Li[5], L. Liang[1]; [1]Harvard Sch. of Publ. Hlth., Boston, MA, [2]West China Hosp., Sichuan Univerisity, Chengdu, China, [3]State Key Lab. of Oral Diseases, Natl. Clinical Res. Ctr. for Oral Diseases, West China Hosp. of Stomatology, Sichuan Univ., Chengdu, China, [4]West China Hosp., Sichuan Univerisity, CHengdu, China, [5]Brigham & Women s Hosp., Harvard Med. Sch., Boston, MA

With an increasing risk of mortality and morbidity, chronic kidney disease was expected to become the fifth leading cause of death globally. Various studies indicated that kidney dysfunction was prone to have a high risk of inflammation in the human body, which presented as disorders of diverse biomarkers containing, CRP, IL-6, leukocytes and its subtypes. However, most findings were limited due to small sample sizes, lack of biomarker categories and environmental confounding. We aimed to evaluate the shared genetic architecture between kidney function and systemic chronic inflammation. We recruited 11 kidney function biomarkers from UK Biobank and CKDgen(N=~400,000 to ~1,200,000) and 137 chronic inflammatory biomarkers from UK Biobank, deCODE, INTERVAL, KORA and other publicly released population databases(N = 30,000 to 400,000). Based on the large-scale genome-wide analyses(GWAS), we performed linkage-disequilibrium score regression to detect a genetic correlation between these 2 kinds of traits. Using Causal Analysis Using Summary Effect Estimates(CAUSE), we examined the bi-directional causal inferences between these traits. Traditional two-sample Mendelian randomization approaches, including IVW, MR-Egger and MBE, were additionally applied as sensitivity analyses. A total of 72 significantly genetically associated pairs between kidney function and inflammation biomarkers were identified. Cystatin C showed significant associations with 27 inflammatory factors, while eGFRcys showed significant associations with 45 inflammatory factors (FDR<0.01). Among them, the most significant associations were observed with Leptin (Cystatin C: Rg = 0.35, FDR = 6.53E-13; eGFRcys: Rg = -0.38, FDR = 7.06E19). Serum creatinine showed significant associations with 8 inflammatory biomarkers, while eGFRscr showed significant associations with 12 inflammatory biomarkers. The most significant association with serum creatinine was TNFaR2 (Rg = 0.38, FDR = 1.91E-13), while the most significant association with eGFRscr was TNFaR1 (Rg = -0.498,FDR = 7.58E-21). Inflammatory biomarkers,namely VCAM1, IL2Rb, Leptin, and TNFaR1 had a causal effect on Cystatin C, while TNFaR1, IL18Bpa, MPIF1, and IL2Rb had a causal effect on serum creatinine (FDR <0.05). In summary, we identified shared genetic architecture associated with kidney function and chronic inflammation in large population-based studies. We further characterized the shared polygenic risk of these biomarkers to provide insights into the molecular mechanism of the pathogenesis of impaired kidney function or to immune and inflammatory systems.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1785 Shared sex-specific functional genetic risk factors in self-reported clinical depression and Alzheimer's disease.

Authors:

T-C. Wang[1], A. C. Naj[2], W. Bush[3], L. Dumitrescu[4], P. Below[1]; [1]Vanderbilt Univ., Nashville, TN, [2]Univ. of Pennsylvania, Philadelphia, PA, [3]Case Western Reserve Univ, Cleveland, OH, [4]Vanderbilt Univ. Med. Ctr., Nashville, TN

In Alzheimer's disease (AD), roughly two-thirds of affected individuals are females, compared to males. Similar sexually dimorphic disease prevalence has been observed in individuals with self-reported clinical depression. Studies have suggested that individuals with depression have a higher risk of developing AD. In this study, we investigated the overlapping sex-specific functional genetic architecture of depression and AD to reveal shared biological mechanisms. We performed tissue-specific transcriptome-wide association analyses (SPrediXcan) on GWAS summary data for AD and sex-stratified depression. These analyses were to determine if there was an overlap in genes associated with AD and depression while investigating whether genetically regulated expression (GReX) of these genes exhibits a consistent direction of effect on both phenotypes. The AD GWAS included 111,326 clinically diagnosed/proxy AD cases and 677,664 controls analyzed by Bellenguez et al. The sex-stratified depression GWAS summary data were based on UK Biobank participants, including 8,166 male cases and 43,675 male controls in addition to 16,921 female cases and 49,020 female controls. The SPrediXcan analysis included eQTLs from 19 GTEx tissues, consisting of the colon sigmoid, liver, whole blood, adrenal gland, colon transverse, pituitary, and 13 brain-associated tissues. The AD SPrediXcan analysis yielded 3,128 significant tissue-specific associations (false discovery rate [FDR] < 0.05). The analysis of the male depression SPrediXcan model resulted in 24 such associations surpassing the significant threshold (FDR < 0.05), whereas no significant gene associations were observed in females. GReX of three genes, *TMEM106B*, *PPP1R18*, and *ZSCAN9*, was associated with both AD risk and male depression. Interestingly, the association of predicted expression of *TMEM106B* in whole blood was observed in both datasets but with opposite directions of effect (*TMEM106B* in AD: effect size=-0.057, P_{FDR}=0.013; in male depression: effect size=0.019, P_{FDR}=0.043). *TMEM106*B encodes a protein that regulates lysosomal function, and it has been implicated in AD and depression studies. Emerging evidence suggests that *TMEM106B* plays a crucial role in regulating microglial proliferation and survival in response to demyelination. Overall, our results suggest that there are genes that contribute to both depression and AD in a sex-specific manner. We plan to follow up with our current results to identify the causality of these associations between tissue-specific gene expressions and phenotypes, and in sex-stratified AD summary statistics.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1786 Significance of diversity and inclusion in the genomic study of speech and language disorder

Authors:

A. Hashim[1], M. H. Raza[2]; [1]Univ. of Kansas, Lawrence, KS, [2]The Univ. of Kansas, Lawrence, KS

Speech and language-related disorders like stuttering, speech sound disorder (SSD), and specific language impairment (SLI) affect a human's ability to communicate. The prevalence of these disorders is 5% to 10% among 2-5 year old children in the United States. Twins' studies demonstrate the highest heritability estimates of these communication disorders to 0.90. However, the genetic basis of these disorders is not well understood. Family studies identified several gene loci, and through next-generation sequencing, several candidate genes have been proposed. Population-based genetic studies also suggested the genetic and epigenetic basis of these disorders. The majority of the data collected is from individuals of European descent and the precision medicine, that is produced by the data, cannot be applied to individuals of different backgrounds due to limited diversity and inclusion in the genetic studies. The diversity in human genetic research is expanding to various research fields, but some areas like speech-language impairment still lack the inclusion of individuals from different origins and ethnicities. The diversity and inclusion in these areas are essential to the utility of clinical interventions in precision medicine. My research goals are to enhance the understanding of epigenetic and its effects on genomic research of speech-language disorders in diverse populations. Precision medicine can be improved with the addition of data from different population groups. I also plan to investigate how the quality of life of individuals with speech and language-related disorders can be improved by studying people of different descents.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1787 Single-cell analysis reveals a population of Th17 tissue-resident memory T cells in the small bowel of Crohn's disease.

Authors:

Y. Lee[1], J. Baek[1], S. Park[1], Y. Kim[1], S. Hwang[2], J. Lee[2], S. Park[3], S-K. Yang[3], B. Han[4], K. Song[1], Y. Yoon[2], B. Ye[3], H-S. Lee[1]; [1]Dept. of Biochemistry and Molecular Biology, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [2]Div. of Colon and Rectal Surgery, Dept. of Surgery, Inflammatory Bowel Disease Ctr., Asan Med. Ctr., Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [3]Dept. of Gastroenterology, Inflammatory Bowel Disease Ctr., Asan Med. Ctr., Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [4]Dept. of BioMed. Sci., BK21 Plus BioMed. Sci. Project, Seoul Natl. Univ. Coll. of Med., Seoul, Korea, Republic of

Crohn's disease (CD) is a chronic inflammatory disorder that affects all layers of the bowel wall, characterized by patchy inflammation with skip lesions. Tissue-resident memory T cells (Trms) have been implicated in CD, yet their specific phenotype and molecular features in the context of CD pathogenesis remain poorly understood. To address this, we conducted single-cell RNA sequencing on T cells isolated from small bowel tissues of patients with CD, aiming to elucidate the characteristics of CD-predominant Trms. Samples were collected from 7 patients with CD and 4 patients with ulcerative colitis (UC), with small bowel tissues from patients with UC serving as controls. We isolated the lamina propria (LP) and submucosa/muscularis propria-enriched fraction (SM/MP) from each patient's small bowel tissues to assess the distribution of T-cell subsets and transcriptional signatures across different locations. Subsequently, we sorted T cells from each sample and performed single-cell RNA sequencing. Differential expression analysis was conducted using the Seurat V4 package, and transcription factor module activities were calculated using the SCENIC package with the RcisTarget database. We identified a total of 58,123 T cells, comprising 24,987 LP T cells and 33,136 SM/MP T cells, across 22 samples. These T cells clustered into 16 distinct clusters, with 3 clusters identified as Trm clusters. The Trm cluster exhibited high expression levels of genes associated with tissue residency, including *ITGAE*, *ITGA1*, and *CD69*. The CD4+ Trm subset, characterized by a Th17 transcriptional profile with notable expression of *IL17A*, *IL22*, *CCR6*, and *CCL20*, was designated as Th17 Trm. Among all clusters, only Th17 Trm cluster showed a significantly higher proportion in patients with CD compared to patients with UC in both the LP and SM/MP regions. Th17 Trm cells demonstrated pronounced upregulation of master transcription factors *RORC* and *PRDM1*, as well as *IL23R*, encoding a receptor for IL-23. When comparing the transcriptional landscape of CD and UC Th17 Trm cells, we observed a significant increase in genes related to IFN-γ production/response in patients with CD compared to patients with UC. In conclusion, our findings provide compelling evidence for a consistent increase in the proportion of Th17 Trm cells across different layers of the small bowel in patients with CD. These CD-predominant Th17 Trm cells display transcriptional characteristics reminiscent of Th1 cells, suggesting their potential contribution to the pathogenesis of CD.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1788 Single-cell level analysis of obese individuals' two main fat depots discovers differences in cell-type marker genes and their genetic risks for obesity.

Authors:

It is not known whether obesity influences cell-type level gene expression and its genetic regulation differently in the two key human fat depots, subcutaneous (SAT) and visceral adipose tissue (VAT), and how that relates to the main obesity comorbidity, type 2 diabetes (T2D). We hypothesized that there are differences in cell-type level VAT and SAT expression profiles and that regional variants of the VAT and SAT-specific cell-type marker genes may contribute differently to the genetic risk for obesity. To this end, we performed a dual-tissue single nucleus RNA-sequencing analysis from 7 obese individuals from the Finnish KOBS cohort. After uniform quality control using DIEM and DecontX and conducting clustering, integration, and cell-type assignments using Seurat, CCA, and SingleR, we identified shared and tissue-specific marker genes for each SAT and VAT cell type. Through a GWAS enrichment analysis with MAGENTA, we found that marker genes specific to SAT adipocytes and macrophages were enriched at a 95% enrichment level for BMI (p=0.002) and T2D (p=0.033), whereas the adipocyte marker genes shared between SAT and VAT were enriched for an abdominal obesity proxy, waist-hip-ratio adjusted for BMI (WHRadjBMI) (p=0.0095). No significant GWAS enrichments were identified using the VAT-specific cell-type marker genes. To further investigate the genetic obesity risk related to the adipocyte expression in SAT vs. VAT, we built regional polygenic risk scores (PRS) for WHRadjBMI in the UK Biobank cohort using PLINK for SNPs in the cis-regions of the shared and SAT/VAT-specific adipocyte marker genes. We observed that the regional PRS built from the local SNPs around the SAT-specific adipocyte genes explained 0.785% of the variance in WHRadjBMI (permuted p=0.017). Overall, this suggests that SNPs in the cis-regions of adipocyte markers specific to SAT adipocytes play a larger role in obesity than regional VAT-specific marker gene SNPs. Our follow-up pathway enrichment analysis with WebGestalt for the SAT adipocyte-specific marker genes identified 22 enriched pathways (FDR<5%) centered on fatty acid and triglyceride metabolism. The adipose master transcription factor SREBF1 is found in 19 of the 22 pathways, supporting the key role of SAT in lipogenesis and fatty acid metabolism. In conclusion, our dual tissue single-cell level omics results, along with GWAS enrichment and PRS analyses, suggest that there are differences in SAT and VAT adipocyte marker genes and the risks their regional variants cause for obesity. Specifically, we observed that adipocytes and macrophages in SAT were more implicated in traits associated with obesity than their counterparts in VAT.

PB1789 Single-cell multi-omic dissection of opioid use disorder reveals gene regulatory circuitry changes across multiple brain regions

Authors:

B. James[1,2], R. M. Linville[1,2], K. Galani[1,2], L-L. Ho[1,2], Z. Liu[1,2], N. Sun[1,2], S. Pineda[1,2], D. Mash[3], B. Ruzicka[4,5], B. Madras[5,4], D. H. Gabuzda[6,7], M. Heiman[1,2], M. Kellis[1,2]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]Broad Inst. of MIT and Harvard, Cambridge, MA, [3]Dept. of Neurology, Miller Sch. of Med., Univ. of Miami, Miami, FL, [4]McLean Hosp., Belmont, MA, [5]Dept. of Psychiatry, Harvard Med. Sch., Boston, MA, [6]Dept. of Cancer Immunology and Virology, Dana-Farber Cancer Inst., Boston, MA, [7]Dept. of Neurology, Harvard Med. Sch., Boston, MA

Opioid use disorder (OUD) is a chronic relapsing disorder engaging addictive and emotional centers of the brain. The opioid crisis in the US is an epidemic, with over 100,000 deaths in 2022 alone, and over a million deaths in the last two decades. OUD is largely mediated by changes in the brain's reward system, including the mesocortiolimbic pathway that transmits dopamine from the ventral tegmental area (VTA) to both the the prefrontal cortex (PFC) and nucleus accumbens (NAc). While mechanisms of addiction have been extensively studied along this pathway in rodents, the role of specific cell types and brain regions in human OUD are not fully understood in humans. To address this, we profiled postmortem human PFC and NAc using single-cell multiomics from 26 OUD and 26 control individuals. With over a million snRNA cells and a million snATAC cells, most of which have paired barcodes, we identify cell type-specific epigenomic and transcriptomic profiles of the human NAc and PFC. We initially focused on expression patterns of opioid receptors. Genetic studies have identified the OPRM1 locus, the gene encoding the mu opioid receptor, as the most significant genetic risk locus for OUD. Notably, we identify a subtype of medium spiny neurons (MSNs) of the NAc that express highest levels of *OPRM1*, while in the PFC OPRM1 expression is highest in VIP+/CLSTN2+ inhibitory neurons. This MSN subtype was previously annotated in mouse brain by Otof expression, and by a cross-species comparison, we find conserved markers including Adarb2, Sema3a, and Foxp2. In human, this cell subtype is marked by thyrotropin releasing hormone degrading enzyme (TRHDE) expression, and we validate this finding by *in situ* hybridization. Next, we identify gene regulatory networks that are dysregulated across OUD, and use multi-omics to prioritize genomic loci. We also identify the peaks of these eccentric MSNs as highly enriched for OUD genetic variants. We identify large scale changes across neurons, glia, and vasculature, as well as epigenomic changes upstream of these. Overall, we develop a comprehensive map of OUD in the human brain and use this to map regulatory changes happening at several levels.

PB1790 † Single-cell RNA-seq analysis of microglia reveals functional heterogeneity in the substantia nigra of Parkinson's disease donors.

Authors:

R. Kubler[1,2], D. Mattei[1], K. BP[1], O. Narcis[1], M. Rosen[1], B. Jang[1], L. De Witte[2], T. Raj[1]; [1]Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]Donders Inst. for Brain, Cognition and Behaviour, Njmegen, Netherlands

Background: Parkinson's disease (PD) is characterized by the presence of α-synuclein-containing Lewy bodies and the selective loss of dopaminergic neurons in the substantia nigra. Recent studies have identified numerous genetic risk variants associated with PD. Our previous work identified PD risk loci that alter gene expression in microglia and monocytes. However, previous studies predominantly captured oligodendrocytes when transcriptionally profiling the substantia nigra of PD patients. The functional role of PD risk variants in microglia of the substantia nigra, therefore, remains unclear. We sought to address this gap by using single-cell RNA-seq to characterize transcriptional microglia subtypes and their enrichment for PD variants in microglia isolated from fresh and frozen substantia nigra tissues of PD patients and controls. **Methods:** We sequenced 110,000 oligodendrocyte-depleted brain nuclei (37,000 *in-silico*-filtered microglia) from 16 donors and an additional 60,000 fresh microglia cells from 19 donors. **Results:** Our analysis revealed 19 distinct microglia identities with diverse transcriptional phenotypes, including phagocytosis, chemotaxis, neuroinflammatory, and disease-associated microglia (DAM) signatures. We found that expression of inflammatory and DAM genes was increased in PD microglia. *GPNMB*, a PD microglia expression QTL gene, was a marker for microglia cluster M2, an identity strongly enriched for DAM I genes. Cluster M5 was significantly enriched for Nalls et al. (2019) PD brain eQTL genes and DAM II markers. It further overexpressed *TMEM163* and *CTSB*, two microglia-specific eQTL and splicing QTL genes colocalized with PD risk loci. Chemotactic microglia cluster M9, enriched for DAM I and PD-DAM genes, was significantly overexpressing *TMEM163* and *P2RY12*, also a colocalized PD microglia eQTL gene. We further identified a highly heterogeneous cluster (M0) enriched for epigenetic and cell differentiation markers but not mapping to any previously published microglia phenotypes. Pseudotime analysis revealed a central cluster, dividing into distinct (anti-)inflammatory DAM clusters, highly enriched for M0 microglia. **Conclusions:** Our findings provide novel insights into the heterogeneity and dynamics of microglia functionality in the substantia nigra. In particular, DAM clusters expressed PD QTL genes as markers. We further indicated the presence of a novel, heterogeneous microglia cluster (M0) that might serve as a transitioning stage for microglial phenotypic differentiation. How these microglia states in the substantia nigra of PD patients contribute to disease progression remains to be elucidated.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1791 *SOX7*: Novel autistic gene identified by analysis of multi-omics data and human brain organoids.

Authors:

J. Zhao[1], S. Gonzales[2], N. Choi[3], P. Acharya[3], M-Y. Lee[3]; [1]Miami Dade Coll. Kendall Campus and Sch. for Advanced Studies, Miami, FL, [2]Florida Intl. Univ., Miami, FL, [3]Univ. of North Texas, Denton, TX

Background: Genome-wide association studies (GWAS) based on DNA information have identified thousands of mutations associated with autism spectrum disorder (ASD). However, more than 99% of identified mutations are non-coding. Thus, it is unclear which of these mutations might be functional and thus potentially causal variants. Transcriptomic profiling using total RNA-sequencing has been one of the most utilized approaches to link protein levels to genetic information at the molecular level. The transcriptome captures molecular genomic complexity that the DNA sequence solely does not. Some mutations alter a gene's DNA sequence but do not necessarily change expression and/or protein function. To date, few common variants reliably associated with the diagnosis status of ASD despite consistently high estimates of heritability. **Objectives:** It is necessary to integrate DNA and RNA testing together to identify true causal genes. **Methods:** We performed gene-based association studies with adaptive test using GWAS summary statistics with two large GWAS datasets (ASD 2019 data: 18,382 ASD cases and 27,969 controls [discovery data]; ASD 2017 data: 6,197 ASD cases and 7,377 controls [replication data]) which were obtained from the Psychiatric Genomics Consortium (PGC). In addition, we investigated differential expression for genes identified in gene-based GWAS with a RNA-seq dataset (GSE30573: 3 cases and 3 controls) using DESeq2 package. We further investigate function of identified genes with autistic brain organoids. **Results:** We identified 5 genes significantly associated with ASD in ASD 2019 data (*KIZ-AS1*, $p=8.67\times10^{-10}$; *KIZ*, $p=1.16\times10^{-9}$; *XRN2*, $p=7.73\times10^{-9}$; *SOX7*, $p=2.22\times10^{-7}$; *PINX1-DT*, $p=2.14\times10^{-6}$). Among these 5 genes, gene *SOX7* (p=0.00087), *LOC101929229* (p=0.009), and *KIZ-AS1* (p=0.059) were replicated in ASD 2017 data. *KIZ* (p=0.06) was close to the boundary of replication in ASD 2017 data. Genes *SOX7* (p=0.0017, adjusted p=0.0085), *LOC101929229* ($p=5.83\times10^{-7}$, adjusted $p=1.18\times10^{-5}$), and *KIZ* (p=0.00099, adjusted p=0.0055) indicated significant expression differences between cases and controls in the RNA-seq data. Human brain organoids support the gene *SOX7* associated with ASD. *SOX7* encodes a member of the *SOX* (SRY-related HMG-box) family of transcription factors pivotally contributing to determining of the cell fate and identity in many lineages. The encoded protein may act as a transcriptional regulator after forming a protein complex with other proteins leading to autism. **Conclusion:** Gene *SOX7* in the transcription factor family could be associated with ASD. This finding may provide new diagnostic and therapeutic strategies for ASD.

(DZHK), Partner Site Heidelberg, Heidelberg, Germany, [5]Spatial Proteomics Group, Max-Delbrück-Centrum for Molecular Med. in the Helmholtz Association (MDC), Berlin, Germany

Myocardial infarction (MI), commonly known as a heart attack, continues to be the leading cause of death worldwide. Recent studies have highlighted the significance of tissue inflammation during the early acute phase of MI, which plays a vital role in the healing process following a heart attack. During the inflammatory phase of MI immune cells infiltrate the infarct region to remove dying and necrotic cells. Here we investigated the dynamics of immune cell infiltration during the first four days in a minimally invasive mouse model of acute myocardial infarction using combinatorial single-molecule FISH (smFISH) and sequential immunofluorescence (seqIF). We evaluated several approaches for cardiac cell segmentation and established computational pipelines to process and quantify both transcriptomic and antibody based imaging modalities for cardiac tissue. Our time series of immune infiltration during MI using spatially resolved methods revealed significant invasion of monocytes and neutrophils during the first 2 days via the endocardium, i.e. the inner lining of the heart. We characterized the proteome of the endocardial layer at 1 day post infarction using laser-microdissection coupled to high sensitivity proteomics and identified von-Willebrand-Factor (vWF) as an important player in immune cell recruitment. Our results reveal the endocardium as a significant and important novel target for immune cell infiltration during the inflammatory phase of MI.

PB1793 Statistical physics of fitness landscape discovers risk genes and pathways specific to male and female with Alzheimer's Disease.

Authors:

K. Lee, M. Samieinasab, F. Nazem, I. Al-Ramahi, Y. Lagisetty, J. Botas Miret, C. Wang, K. Wilhelm, P. Katsonis, J. Asmussen, J. Botas, O. Lichtarge; Baylor Coll. of Med., Houston, TX

Identifying genes linked to complex diseases is a challenge. Association studies demand large cohorts, and multimodal omics integration is context sensitive. This study tests a third approach in Alzheimer's Disease, exploiting freely available but massive evolutionary and phylogenetic coupling data on sequence variation and speciation. In the context of fitness landscapes, these couplings lead to computable values for the influence of genes in a population. We may then compare a gene's influence in sequenced cases vs controls cohorts and test the hypothesis that significant deviations identify genes linked to disease risk.

In 4768 AD cases and 4689 controls, from NIAGADS, 122 genes had significantly greater influence in cases or in controls. These genes overlapped ($p = 3.10^{-5}$) or interacted ($z = 4.85$) with AD GWAS genes. They interacted mutually ($p = 0.0033$) and with AD-related processes ($n = 58$, $p = 7.10^{-13}$). In a live *Drosophila* tauopathy model, they modulated neurodegeneration: the knockdown or overexpression of 64 genes ameliorated or worsened age-dependent neuronal dysfunction ($p < 0.05$). These data support the association of these genes to AD.

Next, robustness to down-sampling suggested we could analyze smaller, sex-separated cohorts. We found 82 genes in males (2010 cases, 1938 controls) and 69 genes in females (2758 cases, 2751 controls) overlapping by 15 ($p < 10^{-53}$). Many male (36) and female (34) genes were new and significantly connected to known AD processes ($p < 10^{-7}$). The 136 genes, combined, overlapped ($p < 0.0001$) and interacted ($z > 3.5$) with AD genes.

Critically, all these genes predict AD risk after training when tested on never seen before held-out subjects. Male-specific genes trained in males had AUCs of 0.74 (0.67 without *APOE*) in males, and 0.65 (0.59) in females. Female-specific genes trained in females had AUCs of 0.74 (0.65) in males and 0.68 (0.61) in females. Sex-neutral genes obtained from and trained on both males and females reached peak AD risk AUCs of 0.80 (0.75) in males, 0.71 (0.67) in females.

These data support the identification of new AD-associated genes informing relevant molecular pathways and improving risk evaluation from germline variants. This performance required fewer than 5000 cases and 5000 controls, and it was consistently better in males where risk prediction from germline variants compared favorably to the state-of-the-art. These results are consistent with key genetic and environmental differences leading to AD in males and females, and support usage of evolutionary and phylogenetic information to probe complex human diseases.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1794 Structural variation in Keratoconus

Authors:

M. Rydzanicz[1], A. Wysocka[2], K. Jaskiewicz[2], M. Maleszka-Kurpiel[3,4], M. Kabza[5], M. Gajecka[5,2]; [1]Dept. of Med. Genetics, Med. Univ. of Warsaw, Warsaw, Poland, [2]Inst. of Human Genetics, Polish Academy of Sci., Poznan, Poland, [3]Chair of Ophthalmology and Optometry, Poznan Univ. of Med. Sci., Poznan, Poland, [4]Optegra Eye Hlth.Care Clinic, Poznan, Poland, [5]Chair and Dept. of Genetics and Pharmaceutical Microbiol., Poznan Univ. of Med. Sci., Poznan, Poland

Background: Keratoconus (KTCN) is a degenerative disorder of the eye characterized by progressive stromal thinning, that results in the conical shape of the cornea. We limited our research to corneal epithelium (CE) samples, as characteristic clinical changes in KTCN occur in this layer. We defined 3 topographic regions (TRs, *central*, *middle*, *peripheral*) based on the epithelial thickness and corneal topography maps. The preliminary studies were undertaken on a group of KTCN patients and non-KTCN individuals. WGS was performed to assess KTCN-specific structural variants (SVs). The aim of this project was to characterize KTCN-specific SVs affecting gene function, to unravel their role in KTCN pathogenesis.
Material and methods: CE samples were collected during a standard procedure of crosslinking in KTCN patients [12 experimental CE samples (4 unrelated patients x 3 topographic regions)] and in controls undergoing a photorefractive keratectomy to correct vision errors [6 control samples (from 2 individuals with mild myopia phenotype x 3 TRs)]. The extraction of DNA, RNA, and protein was performed. Quality and quantity of samples were verified before WGS, performed with the TruSeq Nano DNA HT LibraryPrep Kit (Illumina), HiSeqX platform (Illumina), and 30X coverage. The reads after bioinformatic processing were mapped to reference genome GRCh38. Structural variants calling has been performed using Manta and cnMOPS, and tools' outputs were combined into a single consensus. SVs which had at least 90% mutual overlapping with any region detected by at least one bioinformatic tool were used in further analysis.
Results: Implemented pipeline enabled the recognition of long deletions localized in non-coding regions of the genome and in gene introns. We removed the SVs present in non-KTCN samples and obtained 779 variants for KTCN patients. After a literature search, GeneCard, and gnomAD analysis, as well as BAM files verification, we received the definitive number of 24 SVs. Assessing the previously published KTCN-specific *loci*, we did not observe differences in the number and the length of deletions comparing KTCN patients and control individuals. The number of recognized deletions per person (in both examined groups) ranges from 4159 to 4381.
Conclusions: The identified genomic features further confirm the heterogeneous genetic background of KTCN. The preliminary results should be verified using long-read sequencing.
Support: The National Science Centre grant no. 2018/31/B/NZ5/03280.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1795 Subtyping complex traits using tissue-specific polygenic risk scores.

Authors:

A. Kim, S. Grimes, S. Chhetri, R. Keener, M. Arvanitis, A. Battle; Johns Hopkins Univ., Baltimore, MD

Disease subtyping can accurately categorize clinical patients into disease subgroups and address the heterogeneity of disease phenotypes. Complex traits can be highly polygenic and often have a pathophysiology that involves multiple tissues; variants affecting each of these tissue types can contribute to the risk. Although integrative methods for subtyping based on genetics and electronic health records exist, current approaches do not incorporate the tissue-specific genetic architecture of complex traits. Here, we leveraged functional genomic annotations and tissue or cell type-specific annotations to build 25 tissue-specific polygenic risk score (TS-PRS) models of body mass index (BMI) for 336,335 individuals of white British ancestry in UK Biobank. Using the reference catalog of human epigenomes from the Roadmap Epigenomics Consortium to identify enhancer regions that are unique to a tissue or cell type, we identified tissue-specific variants from BMI genome-wide association study from the GIANT consortium and estimated PRS using LDpred-funct. Among the 25 TS-PRS models, the pluripotent stem cell and brain PRS models explained the most phenotypic variance (R^2=0.046 and R^2=0.043, respectively), supporting the known substantial brain component of BMI. To further evaluate our framework, we generated TS-PRS models for a related phenotype, waist-to-hip ratio adjusted for BMI, which is thought to manifest through mesenchymally derived tissues. Indeed, the mesenchymal stem cells PRS model explained the most phenotypic variance (R^2=0.031), demonstrating that our method identifies appropriate tissues for complex traits. To identify the molecular mechanisms that are correlated with a subset of tissues a complex trait is primarily manifesting through, we calculated the Pearson correlation coefficients between BMI TS-PRS and liver enzyme levels, in addition to anthropometric and lipid measurements. Our pluripotent stem cells and brain BMI TS-PRS models were statistically significantly associated with liver enzyme levels. The association between brain BMI TS-PRS and liver enzyme suggests that tissue subtyping may be able to provide mechanistic insight for individuals by which obesity plays a role in the risk of diseases associated with elevated liver enzyme levels. Our TS-PRS method yields mechanistic insights into complex traits and may help identify subgroups of individuals whose genetic susceptibility to the trait is mediated in a tissue-specific manner. We expect this method to scale across diverse complex traits and improve our understanding of their underlying tissue-specific biology to better diagnose and treat affected individuals.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1796 Survival GWAS with inverse probability weighing to estimate population-unbiased polygenic risk scores of psychiatric disorders using the iPSYCH case-cohort of Danish nation-wide register data.

Authors:

L. Huang[1], D. Helenius[1], V. Appadurai[1], W. Thompson[2], T. Werge[1]; [1]Inst. of Biological Psychiatry, Roskilde, Denmark, [2]Univ. of California, San Diego, La Jolla, CA

[Aim] We aim to estimate population-unbiased survival polygenic risk scores (PRS) to predict the absolute risk of psychiatric disorders such as schizophrenia, bipolar disorder, autism and ADHD, which addresses both selection bias and age-of-onset, that can be reliably implemented into clinical practice. **[Background]** Case-control GWAS is known to suffer from selection bias which may inflate the risk estimates. In addition, case-control GWAS does not account for age-of-onset, which is a hallmark for psychiatric disorders. The PRS constructed from case-control GWAS may give rise to biased risk estimates that could lead to invalid or premature clinical interventions if implemented. **[Study design and data]** In our study, we used the iPSYCH case-cohort that is built from Danish nation-wide psychiatric register data with full genotyping profile from Danish Neonatal Screening Biobank. iPSYCH2012 case-cohort includes individuals born in Denmark between 1981 and 2005, diagnosed with one or more of the investigated disorders or selected as a random control. iPSYCH2015 augmented this cohort by increasing the birth year up until 2008 with 4 additional years of follow-up. **[Method]** We conduct survival GWAS on 4 psychiatric disorders using Cox proportional hazard model to address age-of-onset, and Barlow's inverse probably weighing to adjust for strong case-ascertainment by upweighing controls, to provide estimates comparable to a true cohort study. The adjusted robust variance is calculated by a jack-knife estimator to account for increased variance introduced by weighing, which provides more precise estimates. **[Results]** Analysis is ongoing. We have computed the weighted hazard ratio estimates from survival GWAS on the iPSYCH2012 cohort, which will then be used to compute PRS in the iPSYCH2015 cohort to estimate the disease risk. **[Discussion]** We propose Barlow's weighted survival PRS as a robust alternative to case-control PRS in predicting absolute risk of disease.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1797 Systolic blood pressure, preeclampsia, and leiomyoma genes - a multivariable Mendelian randomization and mediation analysis

Authors:

N. Vaitinadin[1], M. Shi[2], J. Mosley[3], A. Giri[3]; [1]Vanderbilt Univ Med. Ctr., Nashville, TN, [2]VUMC, Nashville, TN, [3]Vanderbilt Univ. Med. Ctr., Nashville, TN

Introduction Preeclampsia (PE) (sudden-onset hypertension (>20 weeks gestation) with proteinuria, maternal organ/uteroplacental dysfunction or angiogenic imbalance) affects ~4 million women annually, causing death of >70,000 women and 500,000 babies, and long-term sequelae like heart failure. Epidemiologic literature suggests rise in diastolic blood pressure (DBP) is more predictive for PE than systolic BP (SBP). It is not clear which of the known genetic associations of PE is an independent risk factor. **Methods** Publicly available European ancestry genome-wide association study (GWAS) summary statistics (SS) were used to develop single nucleotide polymorphism (SNP)-based genetic instruments (P-value$\leq 5x10^{-08}$, $r^2<0.001$) for known associations of PE - SBP (mm Hg) and DBP (mm Hg) (458,577 subjects), body mass index (BMI, kg/m^2) (339,224), and high density lipoprotein (HDL, mg/dl) (188,577), along with SS for PE or eclampsia (7212 cases, 194266 controls), the outcome. We performed 1) univariate two-sample Mendelian randomization (MR), using inverse variance weighted method (IVWM) for results; MR-Egger, and weighted-median methods for sensitivity analyses, 2) multivariable (MV)MR to determine independent risk factors after multivariable adjustment, 3) analysis to quantify proportional change in effect size after adjustment, and 4) FUMA based analysis of independent risk factor SNPs to annotate uterus associated genes using GTEx v8. MR results are reported as odds of PE per ten-unit change in SBP/DBP/HDL, and per standard deviation (SD) change in BMI. **Results** In 1) IVWM analysis, SBP (OR= 2.23 [95% CI= 1.82, 2.72]), DBP (3.32 [2.46,4.48], HDL (0.22 [0.09,0.55]), and BMI (1.58 [1.34,1.86]) associated with the odds of a diagnosis of PE; 2) MVMR analysis, only SBP (1.82 [1.11, 3.00] remained significant, after multivariate adjustment for BMI, DBP, and HDL; 3) proportion-explained analysis, ~18% reduction in the OR of SBP, after adjustment for BMI, DBP, and HDL; and 4) in FUMA based analyses, out of 7 gene associations, the top 2 uterus associated genes for SBP SNPs were *ZNF859*, and *CDC25A*. **Conclusions** Genetic predisposition to elevated SBP, rather than DBP, associated with increased odds of PE, independent of BMI, DBP, and HDL; adjustment attenuated risk, suggesting shared genetic mechanisms between SBP, DBP, BMI, and HDL. SBP is an independent risk factor for PE. SBP SNPs map to uterine *ZNF859* and *CDC25A*, known leiomyoma associated genes, suggesting a pleiotropic role in PE development.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1798 Temporal landscape of the Alzheimer's Disease plasma proteome: an 1800-sample cohort study

Authors:

A. Siddiqui[1], H. Guturu[1], A. Alavi[1], B. Lacar[1], G. Venkataraman[1], D. Hornburg[1], M. de Geus[2], P. Kivisakk[2], S. Batzoglou[1], S. E. Arnold[2]; [1]Seer, Redwood City, CA, [2]Massachusetts Gen. Hosp., Boston, MA

Introduction

The pathophysiological mechanisms that drive the development and progression of Alzheimer's Disease (AD) are still not fully understood, and ongoing research continues to identify biomarkers that can be used to diagnose the disease earlier, predict progression, and help in the development of more effective treatments. Here, we leveraged recent advances in plasma proteomics to conduct an unprecedented deep and unbiased study of the temporal landscape of the AD plasma proteome.

Methods

Our cohort is comprised of subjects with three different conditions: normal cognition, AD, and other neurodegenerative diseases, which included 1,802 samples from > 1,000 unique individuals from whom between 1 and 6 blood draws were analyzed over the course of 12 years. The plasma samples were randomized based on conditions, where all longitudinal samples from the same individual were analyzed on the same plate. The samples were processed with the Proteograph™ XT workflow and then analyzed using a high-throughput Liquid Chromatography (LC) coupled to a Data Independent Acquisition (DIA) on a single Thermo Fisher Scientific Orbitrap™ Exploris™ 480 Mass Spectrometer (MS) in 11 weeks. Further, whole exome sequencing data from 149 subjects of this study were generated for proteogenomic analyses including protein variant identification, and array genotyping is planned for all individuals.

Results

LC-MS data were acquired on 1,802 samples. We assessed several DIA spectral library search strategies, including library-free analysis with match between runs and a project-specific gas-phase fractionation (GPF) library. We identified 5,253 protein groups using the library-free search and 4,007 using the GPF library (FDR < 0.01). Preliminary analysis showed a strong biological signal, demonstrating the statistical power of the data. Using 10-fold cross validation and a customized AutoML framework, we could separate controls from dementia-affected individuals (AUC = 0.81). Further, we identified both known AD-associated biomarkers (e.g., SPP1, CRP, F12, and C9) as well as novel biomarkers, supporting the potential for new insights into AD.

Conclusions

A comprehensive characterization of the temporal landscape of AD of this scale and depth using unbiased proteomics has not been previously published, and this work represents a new opportunity to extend our knowledge of AD and other neurodegenerative disease. Our preliminary analysis is promising, and we plan to extend this work to better understand the trajectory of AD-associated protein changes over time and the biological pathways that underlie the observed differences.

PB1799 Tensor decomposition of multi-dimensional splicing events across multiple tissues to identify splicing-mediated risk genes associated with complex traits

Authors:

Y. Yan[1], R. Chen[2,3], Y. Tan[2,3], A. Tiwari[2,3], X. Zhong[2,4], B. Li[2,3]; [1]Dept. of Biostatistics, Vanderbilt Univ., Nashville, TN, [2]Vanderbilt Genetics Inst., Nashville, TN, [3]Dept. of Molecular Physiology and Biophysics, Vanderbilt Univ., Nashville, TN, [4]Dept. of Med., Div. of Genetic Med., Vanderbilt Univ. Med. Ctr., Nashville, TN

Identifying risk genes associated with complex traits remains challenging. The integration of gene expression data with Genome-Wide Association Study (GWAS) through Transcriptome-Wide Association Study (TWAS) methods has discovered candidate risk genes for a variety of complex traits. Splicing, which explains a comparable heritability of complex traits as gene expression, has not been fully explored yet due to the challenge of multidimensionality of splicing events. It is even more challenging to model splicing events across tissues. To fully take the advantages of multiple splicing events in a gene and the shared splicing across tissues, we employed tensor decomposition in conjunction with sCCA (sparse Canonical Correlation Analysis) to extract meaningful information from high-dimensional multiple splicing events across multiple tissues. We then build gene-based splicing predictive models using GTEx data and apply the models to GWAS summary statistics of Alzheimer's disease (111,326 cases and 677,663 controls) to identify splicing-mediated risk genes associated with AD. In total, we identified 174 significant risk genes at Bonferroni correction. Gene Ontology analysis showed that the risk genes identified are enriched in AD-related functions, e.g., amyloid-beta-related pathways, endocytosis, and immunity functions. Compared to the models using single-tissue of the brain frontal cortex, our results demonstrated significant enrichment of AD-related pathways and identified additional AD risk genes that were not detected in the brain tissue analysis alone, while preserving most of the top genes identified in brain tissue. As AD genetics is mostly implicated in microglia that occupy only a small proportion of the cells in the brain, using transcriptomics data in brain tissues for AD may not capture the full spectrum of AD genetics. Our across-tissue modeling is able to extract the splicing information relevant to AD for risk gene discovery. Furthermore, our across-tissue splicing models can be applied to other complex traits to help identify splicing-mediated disease risk genes.

PB1800 Testing an autism spectrum disorder polygenic score in individuals with African-European admixed ancestries

Authors:

A. Flynn-Carroll[1], K. Hou[1], J. B. Williams[2], J. K. Lowe[1], L. M. Hernandez[3], M. E. Kumagai[1], B. Pasaniuc[1], D. Geschwind[4]; [1]UCLA, Los Angeles, CA, [2]Univ. at Buffalo, Buffalo, NY, [3]Univ. of California, Los Angeles, Los Angeles, CA, [4]Univ California Los Angeles, Santa Monica, CA

Autism spectrum disorder (ASD) is a common neurodevelopmental syndrome defined by moderate to severe disfunction in social skills, communication, and repetitive behavior. Heritability estimates for ASD range from 64-91%, indicating a strong genetic component. Polygenic scores (PGS) have previously been used to quantify an individual's risk of ASD, but most of these scores have been developed in populations of predominantly European ancestries, and their accuracy has not been well documented in non-European populations. Individuals with African ancestry are particularly underrepresented in genetic studies of neuropsychiatric disorders. Moreover, admixed individuals are routinely excluded from large scale genomic studies as there is a lack of developed methods to help account for population sub-structure. Here, we test the performance of a PGS developed in a European population, on an admixed group of individuals with both African and European ancestry. We further test a method using ancestry partial scores to better adapt this score for use in an admixed population.

We tested the ASD PGS from Grove et al. 2019 in individuals of African-European admixed ancestries from the Simons Foundation Powering Autism Research (SPARK) dataset. SPARK was formed by a collection of 31 university-affiliated research clinics from across the United States who collected the genetic and phenotypic data of individuals diagnosed with ASD and their families. The SPARK sample population of 68,316 has 4,608 individuals with African ancestry (7%) and 50,970 with European ancestry (75%). The African ancestry subset had a significantly decreased odds ratio for the PGS as compared to that of the European subset, indicating that the PGS explained less of the variation in disease status of individuals with African ancestry, though the polygenic score was not well powered in either population (EUR OR 1.02, 95% CI:1.02-1.03 & AFR OR 0.99, 95% CI: 0.98-1.01). In addition, we tested the accuracy of ancestry partial scores using the same European-derived PGS weights to calculate a European-specific and African-specific score. We created an unrelated subset of 3,758 individuals with African-European ancestries (average African proportion = 50%), 2,143 of whom have an ASD diagnosis. There was no significant increase in explanatory power in the African admixed individuals with the partial scores (Total OR 1.02, 95% CI:0.98-1.05 & AFR partial OR 1.00, 95% CI: 0.95-1.05). Future work should focus on increasing sample size and developing an ASD PGS in African American and other admixed populations to better understand the role of common variants in ASD diagnosis outside of a European population.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1801 The ancestral origin of rare variants contributing to Inflammatory Bowel Disease in Hispanics

Authors:

T. Haritunians[1], J. L. Mccauley[2], E. A. Torres[3], L. Gomez[2], D. Li[1], M. Daly[4,5], C. Stevens[4], J. Leavitt[6], O. M. Damas[2], M. A. Quintero[2], J. Cho[7], M. T. Abreu[2], D. P. B. McGovern[1], A. H. Beecham[2]; [1]Cedars-Sinai Med. Ctr., Los Angeles, CA, [2]Univ. of Miami, Miami, FL, [3]Univ. Puerto Rico, San Juan, Puerto Rico, [4]The Broad Inst., Cambridge, MA, [5]Univ. of Helsinki, Helsinki, Finland, [6]GastroHlth., Miami, FL, [7]Icahn Sch. of Med. at Mount Sinai, New York, NY

Genetic studies of inflammatory bowel disease (IBD) have largely focused on the identification of common variants contributing to disease pathogenesis over the last several decades. Rapidly expanding sequencing technologies and extensive collaborative networks have made it possible to investigate the role of rare variation on IBD and its individual components, Crohn's disease (CD) and ulcerative colitis (UC). A recent large-scale sequencing study of more than 30,000 CD patients and 80,000 population controls identified 45 rare coding variants associated with CD. We sought to establish the relationship of each of these variants to CD, UC, or IBD in a Hispanic cohort of 1660 IBD cases (927 CD; 689 UC; 44 undetermined IBD) and 5614 controls and to determine the role of ancestral allele origin on risk. In total, 37 of the variants were present and passed quality control of whole genome sequence data. Local ancestry was evaluated with RFMixV2. Single variant associations controlling for population substructure were assessed with Regenie, and local-ancestry aware regression was performed with Tractor to assess ancestral-specific allele frequencies and effects. For CD, we observed replication ($p<0.05$) for 8 of 37 variants. The strongest associations were observed for known *IL23R* protective R381Q and *NOD2* risk R702W. Additional known coding variants replicating for CD included *LRRK2* N2081D, *TYK2* A928V, and the *CARD9* splice variant. We identified an association ($p<0.05$) with only two variants, *IL23R* R381Q and *CCR7* M7V, with UC in our cohort. Almost all the associated rare variants were observed on a European background within the admixed sample. One variant, *SNX20* R109H, demonstrated a striking Amerindian-specific effect for UC (p=3.7E-06; compared to mixed model regression for all ancestral origins p=0.38) with higher allele frequency observed amongst Amerindian alleles (MAF = 0.06) compared to European alleles (MAF = 0.01) within our admixed cohort. Further work is needed to assess the linkage disequilibrium (LD) between this variant and established *NOD2* risk variants across populations. We have demonstrated that although European-identified rare CD risk variants are largely of European origin within the Hispanic admixed sample, there is some evidence for heterogeneity of effect across ancestral backgrounds due to differing allele frequency and LD structure. Incorporating ancestrally diverse populations is critical to furthering our understanding of IBD risk and accelerating individualized treatment for all patients.

PB1802 The Causal Relationship between Type 2 Diabetes mellitus and Chronic Periodontitis - A Mendelian Randomization study.

Authors:

M. Olujitan[1], A. Alade[2], E. Aladenika[3], A. Oladayo[1], W. Awotoye[3], T. Busch[2], S. Miller[2]; [1]Univ. of Iowa, Coralville, IA, [2]Univ. of Iowa, Iowa City, IA, [3]Univ. of Iowa, Iowa, IA

Introduction: Periodontitis is a complex, multifactorial inflammatory disease of the tooth-supporting structures. It has far-reaching consequences on quality of life and is a matter of public health concern. Several Epidemiological studies have implicated type 2 Diabetes Mellitus (T2DM) as a prominent risk factor for the disease, with some even suggesting a bidirectional relationship between T2DM and Periodontitis. However, due to the complex nature of these conditions, the underlying mechanisms that may explain this interrelationship are still poorly understood. Our study aimed to investigate genetic liability to periodontitis through T2DM. **Methods:** We employed the Mendelian Randomization technique which uses genetic variants as Instrumental Variables to assess causal relationships between two traits. We accessed summary statistics on Single Nucleotide Polymorphisms (SNPs) that showed genome-wide significance for T2DM (62 SNPs) and extracted the summary statistics for the T2DM-associated SNPs on periodontitis. This data is available through the *MRC Integrative Epidemiology Unit (IEU) OpenGWAS* database. Our analyses utilized the Inverse-Variance Weighted (IVW) method, and the MR-Egger method was used to assess horizontal pleiotropy. In addition, we performed a case-control association analysis in PLINK using genotype data from T2DM-significant SNPs obtained from 252 cases and 904 controls at the College of Dentistry, University of Iowa. **Results:** Our results showed a causal relationship between DM and Chronic Periodontitis (IVW method; OR 1.09, 95%CI - [1.01, 1.19], p = 0.03), suggesting that the genetic predisposition to Diabetes mellitus increases the risk of Chronic Periodontitis by 9% in this population of individuals. The MR-Egger method showed no evidence of directional pleiotropy. Additionally, our case-control analysis showed no significant SNP associations. **Conclusion:** These findings further give credence to the observed association between DM and Periodontitis which has been reported in previous epidemiological studies and contribute to a better understanding of the complex relationship between DM and periodontitis.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1803 The Cellular Composition of the Subgenual Anterior Cingulate Cortex in Bipolar Disorder, Schzophrenia and Major Depressive Disorder

Authors:

I. Adoremos, N. Akula, A. Schulmann, F. McMahon, A. Pavan, S. Marenco; NIH, Bethesda, MD

Gene expression differences in the subgenual anterior cingulate cortex (sgACC) from people with psychiatric disorders have been studied, but little is known about changes in cell type composition that drive these differences. Using various RNA sequencing data sources, this study aims to identify cell-specific biomarkers for various psychiatric disorders by estimating changes in neuronal cell types in the sgACC, an important component of limbic circuitry. We employed deconvolution, a computational method to estimate cell type-specific proportions from bulk tissue with a single-cell reference dataset. Postmortem sgACC samples from 185 donors (55 controls, 44 SCZ, 35 BD, 51 MDD) underwent RNA sequencing. Bisque deconvolution software was implemented, due to its ability to manage noisy biological data. Cell type fractions for endothelial cells, microglia, astrocytes, oligodendrocytes, oligodendrocyte precursor cells (OPC), inhibitory neurons and excitatory neurons were acquired for each sample in the deconvolution analysis. ANOVA was subsequently implemented to identify, for each cell type, whether diagnosis impacts proportion estimates, subsequent pairwise t-tests to identify key differences in cell type proportions across each diagnostic group, and Tukey's tests to adjust p values for multiple comparisons. OPCs showed the most significant impact in individuals with SCZ, with ANOVA results ($p < 0.001$, $F = 6.43$), a significant t-test for SCZ ($t = 3.00$, $p = 0.003$), and Tukey's test (p-adjusted= 0.03). Inhibitory neurons also showed significant ANOVA results ($p = 0.009$, $F = 3.99$), suggesting reduced neurons in SCZ individuals. Astrocytes showed a marginally significant ANOVA result ($p = 0.05$, $F = 2.65$), with SCZ individuals having higher proportions. Tukey's tests showed no deviation for inhibitory neurons (p-adjusted= 0.14) and astrocytes (p-adjusted = 0.24) in SCZ individuals from controls. Results suggest that the changes in cell type proportions are most pronounced in SCZ individuals, specifically among OPC, inhibitory neurons, astrocytes. In conclusion, these findings suggest associations between psychiatric diagnoses and cell-type proportions in postmortem sgACC. Limitations of this study include potential variability introduced by the postmortem nature of samples, limitations of the deconvolution method in capturing cellular heterogeneity, and the adequacy of the sample size for detecting smaller effects. Future work could benefit from larger and more diverse samples, improved deconvolution techniques, and novel biomarker identification to offer potential therapeutic targets.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1804 The ClinGen Kidney Disease Clinical Domain Working Group: Defining the genetic architecture of kidney disease.

Authors:

A. Byrne[1], H. Dziadzio[1], E. Edoh[1], A. Girod[1], V. Gitau[1], P. Robertson[1], T. P. Sneddon[2], R. Webb[1], M. G. Sampson[3,1,4], Z. Stark[5,6], R. Lennon[7,8], A. J. Mallett[9,10,11], ClinGen Kidney Disease Clinical Domain Working Group; [1]Broad Inst. of MIT and Harvard, Cambridge, MA, [2]Univ. of North Carolina Hlth., Chapel Hill, NC, [3]Boston Children's Hosp., Boston, MA, [4]Harvard Med. Sch., Boston, MA, [5]Murdoch Children's Res. Inst., Melbourne, Australia, [6]Australian Genomics, Melbourne, Australia, [7]The Univ. of Manchester, Manchester, United Kingdom, [8]Royal Manchester Children's Hosp., Manchester, United Kingdom, [9]Townsville Hosp. and Hlth.Service, Townsville, Australia, [10]James Cook Univ., Townsville, Australia, [11]The Univ. of Queensland, Brisbane, Australia

Kidney disease affects one in ten people with 10% of individuals having a monogenic cause. Genomic medicine holds enormous promise for transforming the diagnosis, care, and treatment of patients and their families, but in order to reach its full potential, systematic evaluation of the clinical validity of gene-disease relationships (GDRs) and accurate assessments of variant pathogenicity are required. To address this need, the ClinGen Kidney Disease Clinical Domain Working Group (CDWG) was established in 2019, convening Gene Curation Expert Panels (GCEPs) and Variant Curation Expert Panels (VCEPs) across five broad disease areas to cover the full spectrum of nephropathies: Kidney Cystic and Ciliopathy Disorders, Tubulopathies, Glomerulopathies, Congenital Anomalies of Kidney and Urinary Tract (CAKUT), and Complement-Mediated Kidney Diseases.

GCEPs addressing all five disease areas are working to evaluate GDRs following the framework defined by ClinGen, with a total of 420 genes identified as 'in-scope'. To date, 120 GDRs have been assessed resulting in 82 Definitive, 5 Strong, and 11 Moderate classifications, with the remaining GDRs being classified as Limited (16), Disputed (5), and No known disease association (1), highlighting the importance of such rigorous assessment before including genes in clinical testing panels. VCEPs addressing the two most common genetic kidney diseases, Polycystic Kidney Disease (*PKD1* and *PKD2*) and Alport Syndrome (*COL4A3*, *COL4A4* and *COL4A5*), are also underway, working to define gene- and disease- specific modifications to the ACMG/AMP variant classification framework. Once complete, these refined criteria are expected to help increase consistency in the application of the framework for these genes, and to improve the accuracy of variant classification. Additionally, leadership within the Kidney Disease CDWG are contributing to efforts, both internal and external to ClinGen, to establish consensus recommendations for kidney disease nomenclature and ontology. At present, the inaccuracies and inconsistencies in disease naming can hinder clinical recognition, impacting patients by restricting eligibility and access to appropriate testing, monitoring, and treatment.

Together, the work of the Kidney Disease CDWG to define the clinical relevance of genes and variants across the spectrum of nephropathies will help ensure diagnostic accuracy as genomic testing moves to be commonplace in the nephrology clinic.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1805 The combined effect of clonal hematopoiesis of indeterminate potential and mosaic chromosomal alterations on cardiovascular health outcomes in individuals diagnosed with cancer in the UK Biobank.

Authors:

M. Sun[1], J. Sandoval[1], L-P. Lemieux Perreault[2], A. Barhdadi[1], M-C. Cyr[1], L. Busque[3], J-C. Tardif[1], M-P. Dube[1]; [1]Montreal Heart Inst., Montreal, QC, Canada, [2]Beaulieu-Saucier Pharmacogenomics Ctr., Montréal, QC, Canada, [3]Maisonneuve-Rosemont Hosp, Montreal, QC, Canada

Background: Individuals diagnosed with cancer face an elevated risk for cardiovascular disease. Recent studies have linked clonal hematopoiesis (CH) to cardiovascular outcomes in the broader population. This investigation aims to ascertain the influence of clonal hematopoiesis of indeterminate potential (CHIP) on the short-term and long-term cardiovascular health and survival outcomes within a cohort solely comprised of cancer patients. Additionally, we examined the clinical relevance of co-existing mosaic chromosomal alterations (mCAs) with CHIP gene mutations in relation to cardiovascular and survival outcomes. **Methods**: Our study comprised 19,566 cancer-diagnosed individuals from the UK Biobank. Whole-exome sequencing data, derived from blood DNA, served to identify CHIP mutations, while genotyping array data was employed to delineate mCAs. Primary endpoints included time to cardiovascular-related emergency admission, death from cardiovascular disease causes, death from coronary artery disease causes, and death from any cause, based on a median of 7.2 years of follow up. Cox regression models were used with adjustments for age, sex, smoking status, chemotherapy, radiotherapy, prevalent cardiovascular disease, the duration between recruitment date and cancer diagnosis date, and genetically inferred genetic ancestry. **Results**: Of the 19,566 individuals diagnosed with cancer, 1,166 (6.0%) were found to carry at least one CHIP mutation. Of all patients, 302 (1.2%) individuals carried both CHIP and mCA, whereas 864 (4.4%) carried CHIP alone, and 3,648 (18.6%) carried mCA alone. Multivariable analyses showed that CHIP mutation carriers had a higher risk of death from cardiovascular diseases compared to non-carriers (hazard ratio [HR]: 1.66, 95% confidence interval [CI]: 1.14-2.42, *P*=0.008). CHIP alone led to an increased risk of death from cardiovascular causes compared to individuals with neither type of CH (HR: 1.74, 95% CI: 1.12-2.87, *P*=0.014). **Conclusions**: Our findings suggest that CHIP mutations independently contribute to an increased risk of death from cardiovascular causes among cancer patients, regardless of mCA co-occurrence.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1806 The contribution of common and rare exonic variants to cognitive performance across early childhood and adolescence

Authors:

D. Malawsky, M. Koko, W. Huang, M. Hurles, H. Martin; Wellcome Sanger Inst., Hinxton, United Kingdom

Twin studies and SNP-based estimates suggest the heritability of cognitive performance (CP) increases across development, with estimates of narrow sense heritability increasing by >50% between early childhood and adulthood. However, the contribution of rare variants to CP has been relatively understudied. Here, we investigate the contribution of common and rare exonic variants to CP in >6,000 unrelated individuals from the Avon Longitudinal Study of Parents and Children. Between 702 and 5,125 of the individuals with exome sequence and SNP array data had IQ measured at any given time point (at age 4, 8, or 17). We imputed missing IQ values at different ages using a range of variables including development scores at 18 months, parental socioeconomic status, birth weight, and cognitive-behavioral traits measured across childhood. Cross-validation of the imputation showed high imputation accuracy ($r>0.6$). We find that the Shet burden, a measure of the exome-wide burden of likely deleterious loss-of-function variants (LoFs) that takes into account genic constraint, is negatively associated with IQ across all ages ($p<10^{-4}$). In a linear mixed modeling framework and based on imputed IQ data, we find the variance explained by Shet burden decreases with age (age*Shet interaction $p<10^{-4}$). Compared to those with median Shet burden, individuals in the top 5% have an average decrease of 6 IQ points at age 4, which is attenuated to a 3 point difference at age 17. This trend was also evident using the non-imputed IQ data, albeit less significant due to reduced sample size ($p=0.001$). To evaluate the convergence of rare and common variant effects, we evaluated the relative contribution to Shet burden from top-ranked genes in an educational attainment (EA) GWAS. We found an enriched contribution from 916 genes fine-mapped in EA GWAS to the association between Shet burden and IQ at all ages, accounting for 60% of the total variance explained and ~4 times more variance than a randomly-chosen set of 916 genes with the same Shet distribution. In contrast to the rare variant effect, we find that EA and CP polygenic indices (PGIs) explained increasing variance with age (age*PGI interaction $p<10^{-10}$). In conclusion, our study provides insight into the contribution of common and rare exonic variants to CP across development in a comprehensive manner, highlighting the diminishing impact of deleterious LoF variants and increasing impact of common variants to the heritability of IQ across ages. We are now seeking to replicate these findings in two other UK birth cohorts of comparable sample sizes with new exome-sequence data, Millenium Cohort Study and Born in Bradford.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1807 The effect of *GBA* variants on Turkish patients with Parkinson's disease.

Authors:

T. Abali[1], M. K. Yekedüz*[2], R. Yilmaz[3,4], G. Kayis[1], E. Y. Unutmaz[5], A. V. Karacan[1], S. N. Kibrit[1], S. Ceylaner[6], M. C. Akbostancı[3,4], F. T. Eminoğlu[2,7]; [1]Ankara Univ. Sch. of Med., Ankara, Turkey, [2]Ankara Univ. Sch. of Med., Dept. of Pediatric Metabolism, Ankara, Turkey, [3]Ankara Univ. Sch. of Med., Dept. of Neurology, Ankara, Turkey, [4]Ankara Univ. Brain Res. Ctr., Ankara, Turkey, [5]Ankara Univ., Faculty of Language, History and Geography, Dept. of Psychology, Ankara, Turkey, [6]Intergen Genetics Ctr., Ankara, Turkey, [7]Ankara Univ. Rare Diseases Application and Res. Ctr., Ankara, Turkey

Objective We investigated genetic and clinical aspects of Turkish PwP with and without *GBA* variants.
Background Genetic risks play an important role in Parkinson's disease (PD) which is the second most common neurogenerative disease in elderly population. One risk for PD is variants in the *GBA* gene, which encodes the lysosomal enzyme glucocerebrosidase. The effect of heterozygous *GBA* variants on patients with PD (PwP) is well described; however, comprehensive data on this topic from Asia Minor has yet to be reported.
Method Deep-phenotyping of the PwP was achieved by evaluating disease-related information, and comprehensive motor, and non-motor symptom assessments including cognitive, psychiatric and autonomous nervous system symptoms. *GBA* variants were investigated by whole exome sequencing. The classification of the detected variants was done according to ACMG criteria-impact for Gaucher disease. Plasma beta-glucocerebrosidase enzyme and its substrate Lyso-Gb1 levels in PwP with a detected variant were also achieved. Clinical assessments were compared between the groups of PwP with a pathogenic *GBA* variant (PwP-pat-*GBA*) and without any variant (PwP-no-*GBA*). PwP with benign or unknown variants were excluded. Enzyme and substrate levels were also compared between PwP-pat-*GBA* and benign variants (PwP-ben-*GBA*).
Result Of the 379 PwP, 30 were in the PwP-pat-*GBA* group, 25 were PwP-ben-*GBA*, and 324 were PwP-no-*GBA*. Comparison of PwP-pat-*GBA* and PwP-no-*GBA* groups showed that the age of onset, was significantly lower in the PwP-pat-*GBA* (mean, (SD), 52.7 (10.5) vs. 57.3 (11.9); p=0.042). Also, the levodopa equivalent daily dose (mg/day) was significantly higher in the PwP-pat-*GBA* (973.8 (506.8) than PwP-no-*GBA* (728.3 (434.5), p=0.004) indicating a need for higher dose of medication for the former group. In addition, the presence of hallucinations and psychosis was higher in PwP-pat-*GBA* (n=10 (34.5%)) than in PwP-no-*GBA* (n = 46 (14.4%); p=0.005). Orthostatic hypotension was also significantly more prevalent in PwP-pat-*GBA* (n=16 (53.3%)) than PwP-no-*GBA* (n=102 (31.9%); p=0.017). Other assessments showed no significant differences. Comparison of the groups for enzyme and substrate levels showed no significant difference despite the lower enzyme and higher Lyso-Gb1 levels in the PwP-pat-*GBA* group.
Conclusion We report the largest data on *GBA* variants in PwP from Asia Minor. These results are compatible with previous studies and underline that PwP with pathogenic *GBA* variants have an earlier age of onset and perform worse in some clinical assessments. More studies are needed to elucidate the exact mechanisms linking lysosomal *GBA* and PD.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1808 The Genetic Architecture of Bronchopulmonary Dysplasia in Extremely Preterm Infants.

Authors:

M. Guardado[1], C. Chapin[1], D. Torgerson[2], R. Hernandez[2], P. Ballard[1], M. Steurer[1]; [1]Univeristy of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA

Extremely premature infants are at high risk of developing Bronchopulmonary Dysplasia (BPD), a developmental lung disease characterized by the continuing requirement for supplemental oxygen and respiratory support at 36 weeks postmenstrual age. 10,000-15,000 infants develop BPD in the United States each year. Rates of BPD vary between racial/ethnic groups, with infants of mothers who self-report as Black or African-American having lower rates of BPD than infants of mothers who self-report as non-Hispanic white. Genetic studies have identified several variants associated with BPD, however, there is continuing debate based on the degree to which BPD is a heritable disease. Existing twin-based studies have produced conflicting results regarding the heritability of BPD. Using genotype arrays and genome-wide imputation, we analyzed ~34 million single nucleotide polymorphisms (SNPs) across 751 unrelated individuals with/without BPD from two clinical cohorts, spanning three racial/ethnic US population groups. We estimated the narrow sense heritability of BPD by binning alleles based on their frequency and performed frequency-binned heritability analysis to describe the common-to-rare variant architecture of BPD. We estimate that the heritability of BPD is ~20%, with rare variants (MAF<0.01) contributing to the signal that is found. The study's findings suggest that BPD has a heritable component. By demonstrating the heritability of BPD, the study supports the notion that genetic variations play a role in the risk and development of the disease. The signal of increased heritability of BPD due to rare variants may explain some of the challenges faced by genetic association studies, which are known to have a lower power to detect causal effects for rare variants than common variants. The study suggests the need for whole-genome sequencing in BPD studies to capture rare genetic variant's effect on BPD effectively.

PB1809 † The genetic architecture of pain intensity in the Million Veteran Program

Authors:

S. Toikumo[1,2], R. Vickers-Smith[3,2], Z. Jinwala[1], H. Xu[1], D. Saini[1], E. Hartwell[1,2], M. V. Pavicic[4], K. A. Sullivan[4], K. Xu[5,6], D. A. Jacobson[4], J. Gelernter[5], C. T. Rentsch[7,6], Million Veteran Program, E. Stahl[8], M. Cheatle[1], H. Zhou[5], S. G. Waxman[5,6], A. C. Justice[5,6], R. L. Kember[1,2], H. R. Kranzler[1,2]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Crescenz VAMC, Philadelphia, PA, [3]Univ. of Kentucky, Lexington, KY, [4]Oak Ridge Natl. Lab., Oak Ridge, TN, [5]Yale Univ Sch. of Med., New Haven, CT, [6]VA Connecticut Hlth.care System, New Haven, CT, [7]London Sch. of Hygiene & Tropical Med., London, United Kingdom, [8]Regeneron Genetics Ctr., Tarrytown, NY

Chronic pain is a common problem, with more than one-fifth of adult Americans reporting pain daily or on most days. It adversely affects quality of life and imposes substantial personal and economic costs. Efforts to treat chronic pain using opioids played a central role in precipitating the U.S. opioid crisis. Despite an estimated heritability of 25-50%, the genetic architecture of chronic pain is not well characterized, in part because study samples have largely been limited to individuals of European ancestry. To help address this knowledge gap, we conducted a cross-ancestry meta-analysis of pain intensity in 598,339 participants in the Million Veteran Program, which identified 125 independent genetic loci, 82 of which are novel. Ancestry-specific GWASs identified 86 independent loci in European Americans, 1 independent locus (nearest gene *PPARD*; chr 6) in African Americans, and 2 independent loci (nearest genes *RNU6-461P*; chr 3 and *RNU6-741P*; chr 15) in Hispanic Americans. Pain intensity was genetically correlated with other pain phenotypes, level of substance use, substance use disorders, other psychiatric traits, education level, and cognitive traits. In Mendelian randomization analyses, pain intensity had a significant positive bidirectional causal effect with genetically predicted opioid use, depressed affect subcluster, major depressive disorder, neuroticism, use of drugs to treat peptic ulcer, and smoking cessation (coded as current smoking). Integration of the GWAS findings with functional genomics data showed enrichment for putatively causal genes (n = 142) and proteins (n = 14) expressed in brain tissues, specifically in GABAergic neurons. Drug repurposing analysis identified anticonvulsants, beta-blockers, and calcium-channel blockers, among other drug groups, as having potential analgesic effects. Our results provide insights into key molecular contributors to the experience of pain and highlight potential drug targets.

PB1810 The genetic regulatory architecture of Alzheimer's disease in iPSC-derived microglia from diverse ancestries.

Authors:

S. Moura[1], L. Bertholim Nasciben[1], A. Ramirez[1], J. Shepherd[1], L. Coombs[1], D. Van Booven[1], S. Simon[1], P. Whitehead[1], L. Adams[1], T. Starks[2], P. Mena[1], M. Illanes-Manrique[3], S. Tejada[1], G. Byrd[4], M. Cornejo-Olivas[5], B. Feliciano-Astacio[6], L. Wang[1], A. Griswold[1], J. Young[1], M. Pericak-Vance[1], D. Dykxhoorn[1], J. Vance[1]; [1]Univ. of Miami, Miami, FL, [2]Wake Forest Sch. of Med., Winston-Salem, NC, [3]Inst. Natl. de Ciencias Neurológicas, Lima, Peru, [4]NC A&T State Univ, Greensboro, NC, [5]Inst. Natl. de Ciencias Neurologicas, Lima, Peru, [6]Central Univ. of the Caribbean, Bayamon, Puerto Rico

Most Alzheimer's disease (AD)-GWAS studies have focused on Non-Hispanic Whites. However, recent studies have begun to study AD genetic risk in diverse populations, including admixed populations (e.g., Hispanics and African Americans). We have previously shown the brain genomic regulatory architecture (GRA) varies among different ancestries, particularly in astrocytes and microglia, potentially leading to different genetic susceptibility in AD. To further dissect the ancestry-specific GRA in AD, we assessed the GRA and transcriptome of iPSC-derived central nervous system cells, including microglial cells, from diverse ancestries. These analyses will complement those from the brain providing a more complete understanding of the ancestry-specific regulatory architecture underlying AD. Specifically, we characterized the GRA in iPSC-derived microglia (iMG) from individuals with high global Amerindian (AI), African (AF), or European (EU) ancestries. We derived iPSCs lines with >90% genomic content from different ancestries - EU, AF, and AI from AD patients and unaffected controls. iPSC lines were validated for pluripotency and chromosomal stability and were differentiated into MG. iMG cells were validated via immunocytochemistry for cell type-specific markers. To study the regulatory architecture of these admixed populations and the associated impact on gene expression, we performed bulk ATAC-seq and RNA-seq, followed by differential accessibility and expression analyses. We identified a total of 2,466 differentially expressed genes (DEGs) and 1,743 differentially accessible genes across ancestries. Interestingly, several DEGs were involved in cholesterol biosynthesis and metabolism, lipid metabolism, lysosomal activity, endocytosis, and Aβ-clearance - all highly relevant processes in AD pathology. Moreover, we observed that 10 of the 78 AD-GWAS risk loci were differentially expressed. Specifically, *ABCA1, ABI3, CTSB,* and *TREM2* between AI and AF, *AGRN* and *APP* between AF and EU, and *APOE, CR1, JAZF1,* and *NTN5* between AI and EU. Surprisingly, we observed that only *CTSB* is also differentially accessible between AI and AF. Lastly, on the chromatin accessibility level, we observed the most differences between AI and AF, followed by AF and EU, and AI and EU. We provide novel insights into ancestry-specific risk factors and candidate genes in AD pathophysiology. Specifically, we report novel data on chromatin accessibility and transcriptomics data in AF and AI microglia, a key player in AD pathology. Our data suggest the possibility of differential effect of AD-associated variants in the different ancestries.

PB1811 The impact of a G6PD variant on the risk of developing diabetic complications

Authors:

N. Arora[1], P. Straub[2], M. Shuey[2], N. Cox[2], J. HIRBO[2]; [1]Tulane Univ. Sch. of Med., New Orleans, LA, [2]Vanderbilt Univ. Med. Ctr., Nashville, TN

Glycated hemoglobin (HbA1c), a key indicator for diabetes diagnosis and prognosis, has been shown to have significantly higher average levels among individuals of African ancestry compared to individuals of European ancestry. However, HbA1c may be falsely lowered in individuals with the rs1050828 variant causing glucose-6-phosphate dehydrogenase (G6PD) deficiency, a hemolytic red blood cell disorder that disproportionately affects individuals of African descent, leading to an extended undiagnosed period of diabetes while still being hyperglycemic. The effects of a prolonged undiagnosed period on the risk of developing diabetic related complications in patients with diabetes and the rs1050828 variant have not been previously quantified. To determine the risk of complications in patients with diabetes and the rs1050828 variant compared to patient with diabetes without this variant, a longitudinal cohort of individuals with a coded Type 1 (T1D) or Type 2 (T2D) diabetes diagnosis with or without G6PD deficiency was compiled from BioVU from 2007 to June 2020, along with certain comorbid conditions they developed. We utilized poisson regression modeling to determine the difference in risk of diabetic complications between individuals of African ancestry with (n=1038) and without (n=4867) the G6PD deficiency variant. We estimated a 21.6% increased risk of developing diabetic complications in patients with T1D or T2D of African ancestry with the G6PD variant (rs1050828) compared to those without the variant (p=2.75E-06). In addition, there was a 60.5% increased risk of developing ketoacidosis (p=0.00218) and 76.2% increased risk of developing ophthalmic manifestations (p=0.000827) for those with the variant relative to those without in subjects with T1D. Because the rs1050828 variant causing G6PD deficiency falsely lowers HbA1c and increases the risk of developing diabetic related complications, especially ophthalmic manifestations in T1D, we showcase the need to routinely test individuals of African ancestry for G6PD variants and utilize multiple measures of glycemic control in addition to HbA1c for diabetes diagnosis and prognosis.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1812 The influence of genetic interaction between CHRNB4 andThe influence of genetic interaction between CHRNB4 and depressive symptoms on smoking dependence

Authors:

W. Cui; Zhejiang Univ., Hangzhou, China

Smoking dependence is a chronic mental disorder contributed by both genetic and environmental factors. Depression increases the risk of becoming a smoker, primarily because of difficulty in quitting. Smoking behavior can be influenced by the interaction between genetic variants and depressive symptoms. However, among individuals with mild to severe depression, the genetic differences in the susceptibility to smoking dependence and the underlying mechanisms remain to be elucidated. By using gene-environment interaction analysis, we found that the genetic interaction between CHRNB4 and CES-D, a measure of depressive symptoms, contributes to smoking dependence. Besides, the smoking motivation analysis revealed a significant association between CHRNB4 variants and the pleasant feelings after smoking. Moreover, through gene-gene interaction analysis, significant interactions between CHRNB4 and glutamate receptor genes (GRIA1, GRIN2B and GRM1) were determined in smokers, but not in non-smokers. Further, in animal studies, by using fear conditioning test, significant difference has been determined in Chrnb4 KO and WT mice under a chronic restraint stress (CRS) model, indicating a sustaining negative affect in mood disorders may be involved in the regulatory effect of Chrnb4 on nicotine dependence.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1813 The large effect of *APOC3* A43T SNP on serum triglycerides is partially independent from that of serum APOCIII levels In Amerindians

Authors:

W-C. Hsueh[1], L. J. Baier[2], R. L. Hanson[1]; [1]NIDDK, Phoenix, AZ, [2]NIH, Phoenix, AZ

Introduction: We previously identified a major locus for serum triglyceride (TG) levels in Amerindians, which largely reflects the effect of a functional SNP (A43T, or rs147210663) in *APOC3*. The T43 allele frequency ~3% in our Amerindian cohort but is extremely rare in non-Amerindian populations. It truncates APOCIII, causing loss of function and a lowering of circulating APOCIII levels. Its effect reduces TG level by ~1 SD unit (per allele), which is among the largest effects for any complex trait reported to date.
Hypothesis: To further explore the functional mechanism underlying this association, we analyzed the relationships among A43T, TG and APOCIII levels; we hypothesized that this SNP's effect on TG may be mediated through low levels of APOCIII, as measured in the peripheral blood.
Methods: We measured serum APOCIII level in 4,569 Amerindian subjects who were a subset of a cohort study in which the A43T genotype, TG and APOCIII levels were measured. There were 210 carriers of a T43 allele. All analyses were modeled using linear regressions based on cross-sectional data, with age, sex, diabetes status, specimen age, batch effects, and population admixture included as covariates. The natural logarithms of APOCIII and TG levels were taken to reduce skewness.
Results: The phenotypic correlation between APOCIII and TG was 0.50. We found a strong association between the A43T SNP and TG levels (β=-0.90±0.065 SD unit per copy of the T43 allele, p=3.5e-47, explaining 4.4% variance) that was only partially attenuated with further adjustment for APOCIII levels (β=-0.49±0.058 SD unit, p=1.4e-21, explaining 2.0% variance); this suggests partial mediation at 46%. On the other hand, there was also a strong association between the A43T SNP and APOCIII levels (β=-0.78±0.068 SD unit, p=3.1e-35, explaining 3.3% variance) which remained significant after adjustment for the TG effect (β=-0.31±0.061 SD unit, p=8.7e-10, explaining 0.82% variance).
Conclusion: Our results suggest that the *APOC3* A43T SNP effect on TG may be partially independent from APOCIII; however, further studies are needed to explore whether APOCIII distribution in lipids or plasma influence the observed relationship. Given partial mediation, these findings may lend further strength to the possibility of making APOCIII a therapeutic target for CVD interventions.

PB1814 The Major Depression Working Group of the Latin American Genomics Consortium (LAGC-MDD): Introduction, Insights, and Pipelines.

Authors:

R. Peterson[1], N. Corral-Frias[2], D. Nunez[3], V. Ota[4], J. Cárcamo[1], C. Machado[1], L. Hernandez Amaya[5], M. Velásquez Toledo[6], S. Nagamatsu[3], E. Dunn[7], B. Torres-Hernández[8], C. Lattig[9], P. Giusti-Rodriguez[10], J. Montalvo Ortiz[3]; [1]SUNY Downstate Hlth.Sci. Univ., Brooklyn, NY, [2]Univ. de Sonora, Sonora, Mexico, [3]Yale Sch. of Med., New Haven, CT, [4]UNIFESP, Sao Paulo, Brazil, [5]Univ. de Los Andes, Bogota, Colombia, [6]Univ. de los Andes, Bogotá, Colombia, [7]Massachusetts Gen. Hosp., Boston, MA, [8]Univ. of Puerto Rico-Med. Sci. Campus, San Juan, PR, [9]Univ. de los Andes, Bogota, Colombia, [10]Univ. of Florida Coll. of Med., Gainesville, FL

Major depressive disorder (MDD) is considered a complex disorder arising from both genetic and environmental factors and interactions between them. Twin studies, from primarily European ancestries, estimate the heritability of MDD as approximately 37%. Although there have been advancements in the etiological understanding of MDD, several limitations remain, including the lack of ancestral diversity in cohorts and large heterogeneity among the depression phenotypes assessed. Given that MDD is one of the most common mental health disorders in Latin America and rates are on the rise, it is imperative that there are large-scale focused consortia efforts to advance the understanding of this debilitating disorder in these under-studied populations. The Latin American Genomics Consortium (LAGC) was founded in 2019 in order to accelerate capacity building, improve representation of Latin American individuals in genetic studies, forge methodological advancements, and provide a forum for networking across countries. Building on these ideals, in 2022 the LAGC-MDD Working Group was formed and seeks to connect depression researchers internationally in order to perform the first large-scale genome-wide association study (GWAS) meta-analysis of depression phenotypes in individuals of admixed American descent from Latin America, the United States, and abroad. The purpose of this presentation is to provide an introduction to the LAGC-MDD Working Group (OSF: https://tinyurl.com/mr3xpwby) while providing insights from our genomic analytic pipelines and phenotypic harmonization efforts. Currently, we have aggregated data from across 33 datasets. These cohorts were collected from 5 countries including Brazil, Colombia, Mexico, Peru, and the US. The approximate meta-analysis sample size is 135,000 cases and 240,000 controls. Importantly, we explicitly assess and model heterogeneity across depression phenotypes from psychometric and genomic approaches (e.g., gSEM, Tractor) to parse heterogeneity and maximize power of our datasets for GWAS. These approaches are expected to improve polygenic risk prediction especially when coupled with environmental risk factors. Although 33 datasets have been aggregated, the majority of samples are from the US. Data collection and capacity building efforts in Latin American countries are critically needed and the LAGC is actively working towards this. To improve depression rates in Latin America and beyond, we will need to advance our knowledge of the risk architecture of MDD. The best way forward is to ensure precise measurement and ancestral inclusivity among samples - major goals of the LAGC-MDD working group.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1815 The Polygenic Genetics Landscape of Nephrolithiasis: Identifying Index SNPs and Their Associations by Linkage Disequilibrium

Authors:

E. Su[1], A. Salem[1], D. Hoying[1], J. Chang[1], M. Baum[2], D. Bodner[3], F. Hildebrandt[4], F. Schumacher[5], C-H. Wu[1]; [1]Case Western Reserve Univ. / Univ. Hosp., Cleveland, OH, [2]Boston Children's Hosp./Harvard Med. Sch., Boston, MA, [3]Univ. Hosp., Cleveland, OH, [4]Boston Children's Hosp, Boston, MA, [5]Case Western Reserve Univ, Cleveland, OH

Nephrolithiasis, alternatively referred to as urolithiasis, kidney stones, or urinary stones, are hardened formations composed of minerals and salts that form within the urinary system. The causes of nephrolithiasis are multifaceted, and the likelihood of developing this condition is influenced by a combination of genetic, metabolic, and environmental factors. Research indicates a substantial involvement of genetic factors and familial background in the occurrence of kidney stones.We reviewed all genome-wide association studies (GWAS) pertaining to nephrolithiasis, and compiled a list of SNPs that reached genome-wide significance ($p < 5 * 10\text{-}8$). However, none of the SNPs reaching genome-wide significance were directly replicated. We then grouped these SNPs into linkage disequilibrium (LD) blocks by identifying their nearest gene, and used a LD correlation coefficient threshold of $r2 > 0.4$ as the criteria of significant linkage. LDpair tool and GRCh38 genome build were employed for the LD computation. The SNP with the stronger association with nephrolithiasis was identified as the index SNP in each LD block. 47 SNPs were found to have reached genome-wide significance. 32 SNPs out of the 47 were identified to share a nearest gene with one or more other SNPs. With previously-described methods, 11 nearest genes and 15 index SNPs were identified being rs10917002 and rs1256328 from ALPL, rs780093 from GCKR, rs56235845 from RGS14, rs1155347 near KCNK5, rs12669187 from MINDY4, rs1000597 near MINDY4, rs7328064 from DGKH, rs578595 from WDR72, rs35747824 from PDILT, rs2079742 near BCAS3, rs13041834 and rs17216707 near CYP24A1, and rs199565725 and rs12626330 from CLDN14. Of note, ALPL, DGKH, WDR72, and CYP24A1 overlap with known monogenic genes. Although there was no SNP that was directly replicated among the 47 genome-wide significant SNPs associated with nephrolithiasis, our study highlights 15 index SNPs that are in LD blocks that have been implicated more than once among these GWAS. These index SNPs may provide perspectives for polygenic loci of nephrolithiasis, and may guide future research for the causes and treatment of nephrolithiasis

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1816 The prefrontal cortex transcriptomic landscape of the comorbidity between post-traumatic stress disorder and opioid misuse

Authors:

J. Martinez-Magana[1], S. T. Nagamatsu[2], D. L. Núñez-Ríos[1], J. Krystal[2], M. Girgenti[2], Traumatic Stress Brain Research Group, J. Montalvo-Ortiz[1]; [1]Yale Univ., Orange, CT, [2]Yale Univ., New Haven, CT

Opioid misuse is highly comorbid with posttraumatic stress disorder (PTSD). Individuals with comorbid opioid misuse and PTSD exhibit higher severity of symptoms, worse disease course, and poorer treatment adherence and response. Understanding the neurobiology of opioid misuse, PTSD, and its comorbidity could help us identify novel targets for interventions and treatments. Our study aimed to apply multiple bioinformatics approaches to comprehensively characterize the transcriptional landscape of opioid misuse, PTSD, and its comorbidity in four human prefrontal cortex (PFC) regions. We found that individuals affected with the comorbidity exhibit a higher number of differentially expressed genes in the PFC than those without the comorbidity. Further, we observed a set of genes that showed a discordant expression profile between those with comorbidity and those without, specifically in the orbitofrontal cortex and subgenual prefrontal cortex. These discordant genes were enriched in early developmental stages and across multiple brain regions. By conducting a single-cell clustering analysis, we found that these genes were enriched in early and adult neuronal developmental cell clusters, specifically immature neurons, Cajal-Retzius, and interneurons, and glutamatergic neurons, respectively. Lastly, using a systems biology approach, we identified a highly co-expressed set of synaptic genes with discordant effects and potential druggable action, mainly pointing to the cholinergic system. Our findings helped disentangle the PFC transcriptomics signatures of opioid misuse, PTSD, and its comorbidity and revealed potential signatures and profiles specific to each trait.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1817 The QGPRS Study: An ensembl learning classifier integrating multi-trait polygenic scores improves risk stratification for T2D in Qatar Biobank cohort

Authors:

I. Ahmed[1], S. Taheri[2], M. Ziab[1], A. Bhat[1], J. Lakshmi[1], H. Mbarek[3], R. Badji[3], O. Chagoury[2], K. Fakhro[1], A. Akil[1]; [1]Sidra Med., Doha, Qatar, [2]Hamad Med. Corp., Doha, Qatar, [3]Qatar Genome, Doha, Qatar

Background: Type 2 diabetes (T2D) is a common disease with multiple genome-wide association studies having reported >500 genetic variants associated with the disease. Translating these associations into specific predictive models has remained a challenge to predict and prevent disease risk. Polygenic scores (PRS) have been shown to provide enhanced power for detecting disease susceptibility and stratifying the high-risk individuals. PRS is an individual-level score that encapsulates the impact of multiple genetic variants on an individual's phenotype. Therefore, the score can be utilized as an outcome predictor in clinical prediction and disease screening programs as it provides an assessment of the entire genetic risk of an individual for a particular trait. When compared to single-trait PRS models, incorporating information from multiple genetically correlated traits can improve prediction accuracy and power for PRS analyses.**Objective:** In this study we aimed to identify genomic variants associated with T2D risk in Qatar Biobank (QBB) cohort and construct machine learning (ML) models with multiple PRS predictors for an enhanced evaluation of the risk.**Methods:** We carried out genome-wide association studies (GWASes) with 12 different T2D related traits to identify genomic variants linked to clinical characteristics of diabetes. A cohort of 14278 QBB participants served as the basis for each GWAS. Multiple weighted PRS models were constructed using the associated set of variants for each trait and combined risk from all 12 predictors was evaluated using ML models.**Results:** Our predictive models displayed a strong ability to stratify cases from controls, and our best model achieved an accuracy of 0.85, area under a receiver operating characteristic curve (AUC) of 0.92, an area under the precision-recall curve (AUC-PR) of 0.8522, and an F1 score of 0.757.**Conclusion:** PRS models have the potential to identify individuals that are at-risk for developing T2D and associated complications in our population. Stratifying people with T2D into groups based on their predisposition for problems could help identify those who would benefit most from an early intervention.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1818 † The Question That Must Be Asked: Is Behavioral Genetics a Null Field?

Authors:

S. Pittelli; El Dorado County, California, Hilton Head, SC

The field of Behavioral Genetics continues to grow as our understanding of DNA has improved, along with our ability to study it. Large amounts of money and resources have been invested in understanding the genetic basis for mental disorders, human intelligence and character traits. To date, however, after over a half century, there has been very little success in discovering causal genetic pathways. Despite this, there seems to be a singular focus on larger and larger genetic studies, with the hope of finding the elusive "missing heritability."To date, there is little discussion of the null. Few question the entire premise of the field of behavioral genetics, that genetic variation among individuals and groups are the primary or at least a significant causal influence. The purpose of this paper is to aggressively question the assumptions of behavioral genetics and to make the case that it is largely a null field, or at least that the influence of genetic variation on behavior is minimally significant. The following questions will be considered: - Have twin studies created a Frankenstein which is now too big to fail?- Are Genome Wide Association Studies (GWAS) likely to end in the same way as candidate gene studies, with optimistic results fading over time and leaving us with more false positive findings, albeit in a more watered down fashion?- Are ever-increasing databases getting us closer to substantial findings or simply creating more heads of a hydra?- Are polygenic scores anything more than a rough measure of population stratification?- Would the findings in GWAS best an actual null?- Does the lack of a standardized statistical approach create a risk of "p-hacking"?- Do the UK Biobank and the other large databases in use allow for a representative sample of a population, or do these databases suffer from their own biases that lead to false positive results, repeated continuously?- Is the current "meta-analysis" approach to GWAS an unconscious attempt to avoid the problem of unreplicated results?- Is the field of behavioral genetics causing more harm than good? A healthy field of study would allow for these types of questions. Currently, there appears to be a consensus mentality, created not by debate or evidence, but by a determination to preserve the field. It's time to question the assumptions of the field of Behavioral Genetics, whether that allows for its advancement or leads to its demise.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1819 The role of tenascin-X in idiopathic gastroparesis: Whole genome sequencing analysis.

Authors:

P. Moszczynski, S. Smieszek, J. Carlin, C. Xiao, G. Birznieks, M. Polymeropoulos; Vanda Pharmaceuticals, Inc., Washington, DC

Tenascin-X (TNX) is a glycoprotein involved in the regulation of tissue structure via anti-adhesive interactions with collagen in the extracellular matrix. Deficiency often manifests as Ehlers-Danlos syndrome (EDS), involving joint hypermobility, skin hyperelasticity, pain and gastrointestinal (GI) dysfunction. TNX gene localizes to the major histocompatibility complex class III region on chromosome 6. TNX deficient mice have accelerated gastric emptying and markedly increased vagal afferent responses to gastric distension. These observations in knockout mice correlated closely with GI symptoms in genetically confirmed TNX-deficient patients with EDS, including disrupted motility and bowel habit and visceral pain.

We previously reported a significantly higher frequency of TNX variants in idiopathic gastroparesis patients as compared with ancestry, sex and age matched controls. TNX enrichment remained significant after Bonferroni correction (*P*-value< 0.001). A 160-fold (p= 8.18743E-26) increase of EDS cases was also reported in this set of gastroparesis patients. All EDS cases were of Caucasian ancestry and females with idiopathic gastroparesis.

In the current study, we replicated this enrichment of TNX variants in the largest whole genome sequencing set of gastroparesis cases (n>1700). We explored the type and frequency of identified TNX variants and focused on all coding/splicing variants in TNX with a minor allele frequency (MAF)<0.05. We see 83 non-synonymous variants with at least 2-fold enrichment. Several of these variants were previously reported in association with EDS in CLINVAR and the functional roles of the remaining ones are to be confirmed. TNX variant, TNX:NM_019105:exon26:c.A9044G:p.K3015R, is identified in our cohort with a high CADD score of 23.3 and is seen in two patients with EDS and idiopathic gastroparesis. We have also identified a subset of patients with copy number variations, specifically with TNX microdeletions. This analysis is ongoing.

These results suggest a statistically significant enrichment of moderate to rare TNX non-synonymous variants in the idiopathic gastroparesis set of patients. Furthermore, they suggest an enrichment of such gene variants in the entire cohort of patients with idiopathic gastroparesis, not only in individuals with confirmed EDS status. TNX appears to be associated with stabilizing the newly produced collagen fibrils, suggesting that all recessive forms of EDS affect post-translational modification of collagens. This finding would not be delineated with a classic GWAS approach yet may explain a proportion of underlying pathophysiology manifesting as gastroparesis.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1820 The role of the genetic influence of dietary preferences on type 2 diabetes and cardiometabolic traits.

Authors:

M. Lee, B. F. Voight; Univ. of Pennsylvania, Philadelphia, PA

Type 2 diabetes mellitus (T2D) is a common glycemic disorder which places patients at elevated risk for cardiovascular co-morbidities and premature mortality. Despite success in genetic studies for T2D, full elucidation of the underlying disease mechanisms is still challenging because susceptibility is also mediated by environmental risk factors (e.g., diet, physical activity), where correlation and causality have not been fully characterized. Our current understanding of the environmental factors underlying T2D risk is driven mainly by observational studies, motivating new approaches to explore this component in more detail. Diet is closely associated with cardiometabolic health, and it is a major environmental risk factor for T2D. Diet however does carry a genetic basis, as shown previously via twin studies and more recently, association studies for macronutrient intake, dietary habits, and food preferences. To characterize the role of diet on susceptibility to T2D, we performed integrated analyses using genome-wide association summary statistics between 42 dietary preference traits, T2D, and 21 cardiometabolic risk factors for T2D. Linkage Disequilibrium Score Regression revealed a shared genetic architecture between diet and T2D, with identification of 289 genetically correlated pairs ($P < 5.41 \times 10^{-5}$). Dietary preferences were largely correlated with adiposity and lipid traits. Pairwise colocalization detected 1,259 loci where diet and T2D share putative causal variants. Univariable mendelian randomization (MR) observed the causal relationships of dietary preferences with T2D, but multivariable MR suggested that many of these associations are potentially explained by cardiometabolic and/or educational factors. Overall, our findings elucidate the genetic relationship between diet, anthropometry, and liability to T2D.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1821 The roles of genetic susceptibility and sedentary behavior in the development of all-cause dementia in the UK Biobank

Authors:

Y. Klimentidis; Univ. of Arizona, Tucson, AZ

Background: Recent work suggests that sedentary behavior is a risk factor for late-onset Alzheimer's disease (LOAD) and related dementias. However, it is not clear how this relationship differs according to an individual's level of genetic susceptibility. **Aim:** We used polygenic risk scores (PRS) of LOAD and of all-cause dementia in addition to a measure of time spent watching television to assess associations with incident all-cause dementia in the UK Biobank. **Methods:** We used GWAS of LOAD (n_{case}=21,982, $n_{control}$=41,944) from a large-scale meta-analysis, and GWAS of all cause dementia from FinnGen (n_{case}=12,042, $n_{control}$=254,976) along with LDpred software to generate a PRS for each disease outcome among UK Biobank participants >60 years old. We used self-reported time spent watching television as a measure of sedentary behavior. We examined the genetic correlation between the LOAD and the all-cause dementia GWAS. Associations of each PRS and time spent watching television with incident all-cause dementia (n=3,507) in the UK Biobank were assessed using Cox proportional hazards models. Interactions of time spent watching television with each PRS were also assessed. **Results:** The genetic correlation between LOAD and all-cause dementia was relatively strong (r^2=0.65). In Cox proportional hazards models, both the PRS for LOAD and the PRS for all-cause dementia were strongly associated with all-cause dementia. We found an association of time spent watching television with incident all-cause dementia, however this association did not differ on the basis of genetic risk level. **Conclusion:** We find that both the PRS of LOAD and the PRS of all-cause dementia PRS are strongly associated with all-cause dementia in the UK Biobank, and that time spent watching television is associated with greater risk of all-cause dementia regardless of an individual's level of genetic risk.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1822 The rs4728142 of *IRF5* as potential novel predictor of radiographic joint damage in rheumatoid arthritis.

Authors:

S. Ali[1], M. Hanif[1], F. Younas[1], A. Usmani[1], L. Hayat[1], W. Mateen[1], A. Hamza[1], J. M. Malik[2]; [1]COMSATS Univ. Islamabad, Islamabad, Pakistan, [2]Rehmat Noor Clinic, Rawalpindi, Pakistan

Rheumatoid arthritis (RA) is a chronic autoimmune condition causing progressive joint degradation and functional disability. The disease has a complex etiology with involvement of different genetic and environmental risk factors. We conducted a case-control association study of RA including 850 participants (450 RA cases and 400 controls). Cases were clinically diagnosed RA patients; while controls were healthy individuals who were matched with cases in age, sex and ethnicity. All participants gave informed written consent. Genotyping was carried out through PCR-based methods for 15 genetic variants from five genes. Multivariate logistic regression analysis was used to determine the association of genetic variants with RA. A protective effect of rs6920220 on overall RA susceptibility was observed [A vs. G allele odds ratio (OR) = 0.23, 95% confidence interval (CI) = 0.18-0.29]. The rs4728142 exhibited association with increased overall RA susceptibility (G vs. A allele OR = 2.3, 95%CI = 1.89-2.8). Stratified analysis by clinical characteristics showed a significant association of rs4728142 with greater risk of radiographic joint damage among RA patients (G vs. A allele OR = 4.77, 95%CI = 3.15-7.22). In conclusion, we report rs4728142 of *IRF5* gene as a novel putative predictor of radiographic damage of joints in RA.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1824 The shared and divergent target genes, pathways and relevant cell types for 15 autoimmune diseases from genome-wide association studies—using IL12/IL23 pathway genes as an example

Authors:

W. Yang[1], X. Dang[1], Y-F. Wang[2]; [1]Univ. of Hong Kong, Hong Kong, China, [2]Chinese Univ. of Hong Kong (Shenzhen), Shenzhen, China

Genome-wide association studies (GWAS) have revealed more than 600 associated loci for various autoimmune diseases. However, for most of these loci, the association mechanism(s) are unclear, including the target gene(s). Lack of functional understanding is the major challenge for translating genetic findings into clinical applications. In this study, we compared the association signals for 15 most common autoimmune diseases, using linkage disequilibrium and conditional analyses to identify the shared and specific association signals. We annotated these signals using genomic data such as eQTL, histone marks, and promoter interactions. Relevant cell types and signaling networks are constructed and compared among these diseases. We identified 620 genomic loci, 353 of which are shared by at least two autoimmune diseases, suggesting shared target genes in most of these cases. However, we also identified widespread independent association signals in most of these loci. There are a total 1586 association signals for the 15 autoimmune diseases, and only a small minority of these signals (325, 20.5%) are shared by at least two diseases, emphasizing different molecular mechanisms for the associations among the autoimmune diseases (differences in target genes, regulatory mechanisms, cell types and other cellular contexts). To use the locus of *IL23R* and *IL12RB2* and other genes in the IL12 and IL23 pathway as an example, it is clear that *IL23R* is associated with psoriasis (PS), inflammatory bowel disease (IBD), ankylosing spondylitis (AS), while *IL12RB2* is associated with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and primary biliary cirrhosis (PBC). Analysis of eQTL data on the associated genetic variants reveals that Tfh, Th17 and memory CD4 T cells are the most relevant cell types where *IL23R* expression is regulated, and NK cells and Th1 cells are the most relevant cell types for regulating *IL12RB2* expression. Similarly, *IL12A* (encoding for P35) is associated with PBC, SLE and multiple sclerosis (MS) and the eQTLs are mostly B cell-specific, while *IL12B* (encoding for P40) is associated with PS, IBD and AS. *IL12RB1* is found to be associated with Systemic Sclerosis (SSc), whose expression eQTLs are ubiquitous in various immune cells. The different significance of IL12 signaling and IL23 signaling for different autoimmune diseases may help with designing new clinical trials and precision treatment of these diseases.

PB1825 The shared genetic architecture of inflammatory bowel disease with clinical, psychiatric, diet, and behavioral traits

Authors:

V. Shaw, J. Byun, R. Pettit, Y. Han, C. Amos; Baylor Coll. of Med., Houston, TX

Background: Inflammatory bowel disease (IBD) development is a complex, multifactorial process that involves extrinsic and intrinsic factors, such as host genetics, the immune system, the gut microbiome, and environmental risks. To help understand the genetic contribution of clinical, behavioral, psychiatric, and diet-related traits, we aim to provide a deeper and comprehensive characterization of the shared genetic architecture between IBD and hundreds of potentially related traits by using GWAS summary statistic data and a regression statistical framework known as cross-trait linkage disequilibrium score regression (LDSR).
Methods: Utilizing publicly available summary statistics from previously published IBD GWAS7 and hundreds of traits from the United Kingdom BioBank (UKBB), we perform LDSR analysis to estimate cross-trait genetic correlations between Crohn's disease (CD), ulcerative colitis (UC), and IBD summary statistics and the UKBB traits of interest.
Results: Nominally significant ($p < 0.05$) genetic correlations were observed for 181 traits in overall IBD, 239 traits in CD, and 94 traits in UC. We replicate the known association between smoking behavior and CD/UC, namely that current tobacco smoking has a positive genetic correlation with CD ($rg = 0.12$, $p < 0.01$) while "ever smoking" has a negative genetic correlation with UC ($rg = -0.07$, $p = 0.042$). Education-related traits, such as professional qualifications (e.g., nursing, teaching) or obtaining a college/university degree, were negatively genetically correlated with IBD, respectively ($rg = -0.14$, $p < 0.01$; $rg = -0.11$, $p < 0.01$). Globally, all three strata (IBD, CD, and UC) demonstrated increased genetic correlations for psychiatric-related traits related to anxiety and depression.
Conclusions: The present analysis reveals the shared genetic architecture between dozens of traits and IBD, CD, and UC. Future work should focus on establishing directionality of the traits and utilize the traits to help decompose the genetic heterogeneity of IBD.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1826 Tissue-specific alterations in alternative splicing associated with aging.

Authors:

K. Zimmerman[1], S. Puppala[1], J. Chan[1], P. Nathanielsz[2], L. Cox[1], M. Olivier[1]; [1]Wake Forest Sch. of Med., Winston-Salem, NC, [2]Univ. of Wyoming, Laramie, WY

Alternative splicing is a complex cellular process that enables production of a diverse set of RNA products from a single gene. Using comprehensive RNA-Seq data on four different tissues from a cohort of healthy baboons that span the adult age range, differential expression analysis and weighted gene co-expression network analysis (WGCNA) was computed to identify genes significantly associated with age. In the liver, we identified a large age-associated WGCNA module ($r=0.46$, $p=0.002$) that was significantly enriched for mRNA-splicing ($p=1.7x10^{-14}$). With the differentially expressed genes, we also identified networks enriched for the spliceosome in the brain and heart. In the liver, brain, and heart we also identified significant associations between the numbers of genes expressing the maximum number of isoforms and age. In the liver, isoform numbers decreased with age ($\beta=-4.9$, $p=6.7x10^{-4}$), while numbers were not significantly different in muscle ($\beta=-2.3$, $p=0.75$) and significantly increased with age in the brain ($\beta=17.1$, $p<2.0x10^{-16}$) and heart ($\beta=5.8$, $p=1.9x10^{-3}$). These results reveal splicing-related changes associated with age, even in a model of healthy aging. This work demonstrates that splicing alterations are tissue-specific and appear to be particularly amplified in the brain with aging. Further work is needed to establish the associations identified here and whether they are tissue-specific. It will also be important to explore how these changes interact with the environment, how they occur at the cellular level, and whether RNA-splicing is actually an adaptive mechanism that cells deploy in response to a challenge.

PB1827 *TMEM106B* and *APOE* increase risk for TDP-43 and HS pathologies underlying Alzheimer's Disease Related Dementias

Authors:

D. Godrich[1], J. Pasteris[1], T. Phongpreecha[2], E. Martin[1], A. Naj[3], R. Mayeux[4], P. Crane[5], D. Bennett[6], L. Molina-Porcel[7], G. Schellenberg[3], M. Pericak-Vance[1], M. Cuccaro[8], W. Scott[1], T. Rundek[1], W. Kukull[5], T. Montine[2], G. Beecham[1], the Alzheimer's Disease Genetics Consortium (ADGC); [1]Univ. of Miami Miller Sch. of Med., Miami, FL, [2]Stanford Univ., Palo Alto, CA, [3]Univ. of Pennsylvania, Philadelphia, PA, [4]Columbia Univ, New York, NY, [5]Univ. of Washington, Seattle, WA, [6]Rush Univ. Med. Ctr., Chicago, IL, [7]Inst. de Investigaciones Biomédicas August Pi i Sunyer, Barcelona, Spain, [8]John P. Hussman Inst. for Human Genomics, Miami, FL

Alzheimer disease (AD) is pathologically characterized by plaques and tangles. However, pathologies from other AD-related dementias, such as hippocampal sclerosis (HS) and Transactive response DNA-binding protein of 43 kDa (TDP-43) proteinopathy, commonly co-occur. Studying the genetics of pathologies underlying ADRD can provide a better understanding of disease. The role of *APOE* in HS and TDP-43 proteinopathy remains unclear, and previous studies suggested association of *TMEM106B* (rs1990622) with TDP-43 proteinopathy and HS. Here, we investigate the interplay between TDP-43 proteinopathy, HS, cognitive decline, *APOE,* and *TMEM106B*. Data come from 898 autopsied individuals from the National Alzheimer's Coordinating Centers (NACC), 511 of which also have genotype data. Logistic regression was used to model and compare the independent and interactive effects of HS and TDP-43 proteinopathy on cognitive decline (change in MMSE), adjusting for sex and age at death. We also examined the relationship between genetic factors (*APOE* and *TMEM106B*) and TDP-43 proteinopathy and HS, comparing models with individual and joint effects. Mediation analyses were performed to explore direct and indirect effects. The majority (N = 468, 52%) of participants had neither TDP-43 proteinopathy nor HS, while a subset had TDP-43 proteinopathy only (N=230, 26%), HS only (N=40, 4%), or both TDP-43 proteinopathy and HS (N=160, 18%). Regression models showed significant independent effects of both TDP-43 proteinopathy and HS on cognitive decline, but the interaction was not significant. Both loci showed incomplete dominance (*TMEM106B*: heterozygote OR = 2.1, p = 5E-3; alternate homozygote OR = 2.8, p = 2E-4; *APOE* ***ε4*** heterozygotes OR = 2.4, p = 7E-6; ***ε4*** homozygotes OR = 2.6, p = 4E-3). HS showed similar effects for *TMEM106B* (het OR = 3.2, p = 4E-3, hom OR = 3.6, p = 2E-3). *APOE4* was not associated with HS. Mediation analyses revealed direct and mediation effects of TDP-43 proteinopathy on cognitive decline, while HS did not. *APOE* had a direct effect on TDP-43 proteinopathy, and its effect on HS was significant only when mediated by TDP-43 proteinopathy. The same was seen with *TMEM106B*. The associations with *APOE* suggest a common risk factor for the AD and ADRD pathologic changes. However, mediation models suggested that TDP-43 proteinopathy may be the main driver of effect on cognitive decline both independently and together with HS. These findings also suggest that *TMEM106B*, while significantly associated with both TDP-43 proteinopathy and HS, may only affect HS via TDP-43 proteinopathy mediation. Our study also suggests that TMEM106B may follow an incomplete dominance mode of inheritance.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1830 Tradeoff between prediction accuracy and transferability in the design of polygenic risk scores of bipolar disorder.

Authors:

A. Dominguez[1], Y. Zhang[1], C. Pato[2], S. McCarroll[3], M. McInnis[4], M. Boehnke[1], L. Scott[1], S. Zollner[1,4]; [1]Dept. of Biostatistics, Univ. of Michigan, Ann Arbor, MI, [2]Dept. of Psychiatry, Rutgers BioMed. and Hlth.Sci., Newark, NJ, [3]Harvard Med. Sch., Boston, MA, [4]Dept. of Psychiatry, Univ. of Michigan, Ann Arbor, MI

Polygenic risk scores (PRS) use evidence from genome-wide association studies (GWAS) to predict genetic risk for complex traits. However, most GWAS participants are European (EUR), making prediction for non-EUR samples less accurate. Factors like allele frequency differences and linkage disequilibrium can lead to differences in mean PRS across samples. Our goal is to investigate how varying the number of markers in PRS of bipolar disorder (BPD) impact prediction and mean PRS across populations.

Using clumping & thresholding method and majority EUR summary statistics from the Psychiatric Genomics Consortium (PGC), we calculate and assess predictive accuracy of PRS at 13 p-value thresholds for 3,334 African (AFR) Americans from the InPSYght study and 5,670 individuals with majority EUR ancestry from Prechter Bipolar Study and Michigan Genome Initiative (MGI). Additionally, we calculate PRS for 2,504 individuals from 1000 Genomes Project (1KGP) to assess differences in mean PRS across populations. We use principal component analysis to obtain measures of ancestry and control for population stratification.

To assess predictive performance of PRS for case-control samples (2,010 cases/5,994 controls), we use logistic regression to model case status adjusting for sex and five principal components (PCs). Predictive accuracy increases with more markers in PRS but plateaus at $p < 10^{-3}$ (R^2=6.4%). Moreover, the difference in mean PRS between AFR and EUR samples increases with more markers. To assess ancestry impact on PRS, we use regression with PRS as outcome and PCs as the predictor adjusting for sex and affection status. For thresholds $p < 10^{-3}$ and lower, R^2 stays below 8%. At larger thresholds, PCs explain more variance in PRS with a maximum at $p < 0.9$ (R^2 =57.6%). Although more markers in PRS improve prediction, PCs become more associated with PRS.

To compare results, we compute PRS for four additional traits: asthma, height, schizophrenia, and type 2 diabetes. Across traits, as we include more markers, differences in mean PRS across populations and correlations between PRS and PC1 increase. Using simulations, we assess whether correlation between PRS and PC1 is expected under population differentiation. The correlations for our simulated PRS and PC1 were centered at zero regardless of how many markers used, suggesting correlations between our observed PRS and PC1 are not expected under population differentiation.

In this study, including more markers into PRS improves prediction, but also accrues subtle confounding from the original GWAS. There is a tension between having complex, informative PRS with more markers and their susceptibility to population structure.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1831 Trans-ancestry GWAS meta-analysis of peripheral artery disease uncover 89 loci and post-GWAS analyses map the signals to candidate effector genes and disease mechanisms.

Authors:

H. Kim, E. B. Fauman, J. Chiou, FinnGen, UKB-PPP, M. R. Miller; Pfizer, Cambridge, MA

Peripheral artery disease (PAD) is a common cardiovascular morbidity that affects more than 230 million adults worldwide and has limited treatment option leading to high unmet medical need. Compared to other major cardiovascular diseases, existing GWAS of PAD have been relatively small in sample size and identified a limited number of associated loci. In this study, we conducted the largest meta-analysis of PAD GWAS to date, increasing the number of cases by more than 2-fold and maximizing statistical power for discovery.Our study incorporated published GWAS from Million Veteran Program (MVP), Genetics of Lower Extremity Arterial Disease (GoLEAD), and Biobank Japan (BBJ) and a new GWAS from FinnGen, including a total of 64,726 cases and 1,216,879 controls. We first performed fixed-effect meta-analysis among the European ancestry, followed by fixed- and random-effect meta-analyses across different ancestries. This trans-ancestry meta-analysis uncovered 89 loci, of which 69 have not been reported before. Finemapping of the loci revealed a total of 106 independent signals.To assess whether the PAD genetic signals are mediated by the known risk factors of PAD, we ran colocalization analyses against GWAS of lipids, blood pressure, body mass index, waist-to-hip ratio adjusted for BMI, type 2 diabetes, smoking, and C-reactive protein. Of the 106 signals, 50 were colocalized with at least one risk factor with consistent effect direction, suggesting the underlying biological mechanisms for those signals. Many signals did not colocalize with any of the known risk factors, suggesting that there may be additional unknown mechanisms that mediate PAD pathogenesis.To find the genes that likely mediate the signals, we used the following heuristics: 1) whether there is only a single protein-coding gene near the signal, 2) colocalization with protein QTLs generated by UKB-PPP (pharma proteomics project), 3) presence of protein sequence altering variants in close LD with the lead variant, and 4) manual review by experts. Using this approach, 64 signals could be mapped to the likely effector gene(s).Future work will focus on integrating PAD GWAS result with omics datasets generated from tissues relevant to PAD to 1) prioritize genes based on their transcriptomic profile, 2) refine signal-to-gene mapping using multi-omics signature, 3) inform cell and tissue type of action, and 4) identify cell and tissue types that are enriched for PAD genetic signals. In summary, this work extends our knowledge on the genetic underpinnings of PAD and suggests biological mechanisms that may underlie the PAD genetic signals.

PB1832 Trans-ancestry PRSs of lipid traits: quantification and contextualization in large cohorts and biobanks.

Authors:

Y. Cai[1], Z. Wang[2], M. Kim[1], R. Smit[2], S. Graham[3], Y. Hu[1], S-A. Love[4], J. Lundin[1], S. Buyske[5], K. Young[4], C. Willer[6], K. North[4], C. Kooperberg[1], R. J. F. Loos[7], U. Peters[1], M. Graff[4], The Global Lipids Genetics Consortium, Population Architecture through Genomics and Environment; [1]Fred Hutchinson Cancer Ctr., Seattle, WA, [2]Icahn Sch. of Med. at Mount Sinai, New York, NY, [3]Univ. of Michigan, Ann Arbor, MI, [4]The Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Rutgers Univ, Piscataway, NJ, [6]Regeneron, Tarrytown, NY, [7]Univ. of Copenhagen, Copenhagen, Denmark

Lipid profiles are heritable risk factors of cardiovascular disease (CVD), a leading cause of global mortality. Polygenic risk scores (PRSs) for lipids can help predict early CVD risk, however, their portability in non-European ancestry individuals may be limited. In addition, effectiveness of lipid PRSs can be influenced by various factors including participant demographics, medication usage and disease status. Therefore, comprehensive evaluation of lipid PRSs in diverse populations, accounting for demographic and clinical characteristics, is crucial for accurate and equitable clinical application.

We applied trans-ancestry PRSs for lipid traits developed by the Global Lipids Genetics Consortium (GLGC) to the Population Architecture through Genomics and Environment (PAGE) study with 71K diverse participants. We evaluated the PRSs for lipid levels using incremental R^2 stratified by self-reported race and ethnicity groups. As expected, the PRSs' performed best in the European population. PRS performed poorly in populations with low presence in GLGC GWAS.

We also conducted stratified analyses of PRS performance on various factors (e.g., age, sex, blood pressure, lipids-lowering medication usage, smoking status, diabetes status), while adjusting for self-reported race and ethnic groups. A z-test method was applied to determine if R^2 was significantly different between strata. Taking LDL as an example, the stratified analyses showed significantly better PRS performance in women. Furthermore, R^2 was significantly higher in participants not using lipids-lowering medication (statins, fibrates, etc.) or not having type-II diabetes. No significant difference in PRS performance was observed based on age and smoking status. We further tested these factors separately within each race and ethnic group to explore potential differences, and overall, these PRS performance characteristics were consistent across populations.

Preliminary replication of our PAGE analyses in six additional diverse studies, which included 69k individuals of non-EUR ancestry, show consistency with our PAGE results, although the current sample size in some race and ethnic groups may impose certain limitations. Overall, we found that PRS performance varied across populations. Stratified analyses revealed differences based on demographic factors, medication usage and disease status, such as higher PRS performance in women and those without lipid-lowering medication or type-II diabetes. Collaborative efforts with other studies will enhance the robustness and reproducibility of our results.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1833 Transcriptional and epigenetic profiles of CD8+ T lymphocytes in multiple sclerosis.

Authors:

E. Paraboschi[1], F. Airi[2], G. Liberatore[3], V. Rimoldi[4], E. Nobile-Orazio[3], R. Asselta[4]; [1]Humanitas Univ., Humanitas Res. Hosp., Pieve Emanuele, Italy, [2]Humanitas Univ., Pieve Emanuele, Italy, [3]IRCCS Humanitas Res. Hosp., Rozzano, Italy, [4]Humanitas Univ., IRCCS Humanitas Res. Hosp., Pieve Emanuele, Italy

Alternative splicing (AS) is a post-transcriptional mechanism that increases the information content of the transcriptome. AS is strictly connected to the backsplicing (BS) process, a mechanism that leads to the generation of circular RNA products (circRNAs). AS and BS rely on the same spliceosomal machinery and trans-acting factors and may be tuned by genetic and epigenetic determinants, as DNA methylation. A dysregulation of AS/BS has been implicated in human disorders, including multiple sclerosis (MS), a chronic autoimmune neurodegenerative disease in which autoreactive T lymphocytes attack antigens of the central nervous system.
The aim of the project is to unravel the mechanisms involved in the dysregulation of AS/BS processes in MS CD8+ T lymphocytes by integrating different omics data.
We collected data on gene expression, AS profile, circRNA landscape, and methylation status of CD8+ T lymphocytes of 20 MS patients and 20 controls, using massive sequencing and array approaches. A first analysis evidenced the presence of several differentially expressed genes (210, FDR<0.1), circRNAs (200, P<0.05) and AS events (600 genes carrying at least one significantly dysregulated AS event, FDR<0.05), as well as of differentially methylated positions (DMPs, 1200 genes, FDR<0.05) in MS cases. Among the top genes, we observed an upregulation of *MALAT1* in MS patients (1.3-fold) that was exacerbated in males. This result was particularly interesting, since *MALAT1* is involved in transcriptional/post-transcriptional regulation of gene expression, including AS and BS. Moreover, we also observed a strong upregulation of *MALAT1*-derived circRNAs (4-fold increase) in males. Regarding the DMPs, we again noted that *MALAT1* was among the top differentially methylated genes, with patients showing a significant demethylation compared to controls (logFC=-0.34). This result suggests a mechanism guiding *MALAT1* upregulation which, in turn, could be the cause of the global dysregulation of the AS and BS landscapes.
Next, all the omics were integrated in the unified framework of MOFA2 that infers a low-dimensional data representation in terms of factors which can be analyzed. We identified a factor that was associated with the disease status ($P<10^{-5}$). The top features of each omic layer were then used to run an enrichment analysis that highlighted, among the top results, “T cell receptor signaling pathway”, “cellular response to stress”, and “TNF signaling pathway”. We plan to implement in the framework also the genetic information on MS-associated SNPs.
Acknowledgments. This work is supported by Fondazione Regionale per la Ricerca Biomedica (FRRB), Early Career Award.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1834 Transcriptome Study of Metabolically Healthy Obesity in Two Cohorts of African American

Authors:

A. Gaye; NIH/NIHGRI, Bethesda, MD

Background: Some obese individuals, named metabolically healthy obese (MHO), do not develop known metabolic consequences of obesity such as insulin resistance, type 2 diabetes and dyslipidemia. Previously, we defined a cluster of co-expressed mRNAs downregulated in MHO subjects that may underlie the activation of endoplasmic reticulum (ER) and related-stress pathways that lead to a chronic inflammatory state. This follow-up project aims to investigate microRNAs (miRs) that modulate mRNAs related to MHO and establish their relationship with key pathways linked to ER-stress revealed in our initial work. **Methods:** The data consist of whole blood microRNA sequencing data of respectively 75 and 210 samples from the MHGRID and GENE-FORECAST cohorts. In both datasets, Random Forests (RF) was used to identify miRs that predict MHO and other cardiometabolic traits and WGCNA was applied to define clusters of co-expressed miRs associated with MHO and related traits. An in-vitro model was designed with high fat (palmitic acid) treated HepG2 cells to determine if the miRs lead to an alteration of biological functions related to ER stress, inflammation and autophagy. **Results:** RF identified 96 miRs predictive of MHO and 11 cardiometabolic traits in MHGRID and GENE-FORECAST. 5 clusters of co-expressed miRs were correlated with MHO status, fasting glucose, BMI, hypertension status and TG/HDL. 129 pathways relevant for obesity, ER-stress and insulin resistance were significantly enriched in the RF and WGCNA results. 48 hours after transfecting the HepG2 cells with a set of miRs that have experimentally validated mRNA targets, significant changes in expression were observed in a number of genes involved in ER-stress and autophagy related pathways. We also observed significant changes in the level of Bip, XBP1, ATF6 and CHOP proteins, compared with controls. **Conclusions:** We undertook an unbiased transcriptome-wide analysis of metabolically healthy obesity in 2 independent datasets of African American subjects and the results confirmed our earlier findings implicating ER-stress. The results of the in-vitro model suggest that the miRs associated with MHO we identified induce changes in biological functions related to ER-Stress in HepG2 Cells.

PB1835 Transcriptome-wide association study for frequent cocaine use identifies gene dysregulation in CD4+ T cells linked to immune response and cancer pathways.

Authors:

B. Quach[1], S. N. Giamberardino[1], C. Willis[1], K. Weitzel[1], D. Brannock[1], D. B. Hancock[1], D. Konkle-Parker[2], H. H. Bolivar[3], C. D. Lahiri[4], E. F. Topper[5], M. H. Cohen[6], S. G. Kassaye[7], J. DeHovitz[8], M. H. Kuniholm[9], N. M. Archin[10], P. C. Tien[11,12], K. Xu[13,14], B. E. Aouizerat[15], E. O. Johnson[1]; [1]RTI Intl., Durham, NC, [2]Univ. of Mississippi Med. Ctr., Jackson, MS, [3]Univ. of Miami-ACRU, Miami, FL, [4]Emory Univ., Atlanta, GA, [5]Johns Hopkins Univ., Baltimore, MD, [6]Cook County Hlth.System, Chicago, IL, [7]Georgetown Univ., Washington, DC, [8]Downstate Hlth.Sci. Univ., Brooklyn, NY, [9]Univ. at Albany, State Univ. of New York, Rensselaer, NY, [10]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [11]Univ. of California, San Francisco, San Francisco, CA, [12]Dept. of VA Med. Ctr., San Francisco, CA, [13]Yale Univ., New Haven, CT, [14]Veteran's Affairs Connecticut Hlth.care System, West Haven, CT, [15]New York Univ., New York, NY

Background: In 2021, 4.8 million (1.7%) people in the U.S. reported using cocaine. Cocaine use affects immune cells and increases susceptibility to infectious diseases, such as HIV, and contributes to the development of health conditions such as cardiovascular disease and chronic kidney disease. Existing transcriptomics research that investigates the effects of cocaine has focused primarily on addiction and brain tissue. There is a lack of transcriptome-wide studies evaluating the modulation of immune cell gene expression by cocaine in blood and how it relates to disease pathogenesis.
Methods: We measured gene expression using paired-end RNA-seq in CD4+ T cells isolated from peripheral blood samples, among individuals with and without cocaine use, to characterize transcriptomic changes by cocaine use status. Samples were from participants enrolled in the Women's Interagency HIV Study with self-reported frequent cocaine use (at least once/week or greater, N=64) or no cocaine use (N=195) within 6 months prior to blood draw. All samples were from women living with HIV who had an undetectable plasma HIV RNA level for at least 2 consecutive study visits. Individuals in the frequent cocaine use and no cocaine use groups had similar age distributions (median ages of 47.3 and 47.6, respectively). Transcriptome-wide differential expression testing was conducted using negative binomial regression with gene expression as the outcome variable and cocaine use status and self-reported race as independent variables. Gene set overrepresentation analysis was conducted for the significantly differentially expressed genes (DEGs) using a hypergeometric test.
Results and discussion: We identified 824 DEGs (FDR<0.05). Of these, a significantly higher proportion showed increased expression in the frequent cocaine use group (624 DEGs; Binomial test p<2.2e-16). DEGs were enriched in Gene Ontology and Molecular Signatures Database biological pathway terms related to immune cell migration, T cell adhesion, T cell activation, and vascular injury and repair. DEGs were also overrepresented in cancer-related signaling pathways, including EGFR signaling, PI3K signaling, and oncogenic MAPK signaling (FDR<0.05). Further, 382 DEGs have an eQTL based on queries against CD4+ T cell eQTL maps in the Database of Immune Cell eQTLs, Expression, and Epigenomics, suggesting that genetic variation may modulate gene expression for almost half of the frequent cocaine use dysregulated genes. Together, these results highlight potential genes and pathways that may lead to altered immune function and health outcomes in women as a result of cocaine exposure.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1836 Transcriptomic analysis of multiple tissues in obesity in Africans

Authors:

G. Chen[1], A. Doumatey[2], J. Zhou[2], L. Lei[2], A. Adeyemo[1], C. Rotimi[3]; [1]NIH, Bethesda, MD, [2]NIH, Bethersda, MD, [3]NIH, Woodstock, MD

Obesity is a complex disease associated with an increased risk of cardiometabolic disorders. Its prevalence has increased globally making it a major public health problem. While many genetic variants associated with obesity risk have been identified, studies of associated tissue and related molecular changes are scarce outside Europe, North America, and Asia. The present study was designed to identify differentially expressed genes (DEG) in obesity in a study of Nigerians enrolled in the Africa America Diabetes Mellitus (AADM) Study. Primary tissues were obtained from participants with obesity (BMI>=30 kg/m^2) and without obesity (BMI<30 kg/m^2) for RNA-seq analysis and included whole blood samples (n=72), subcutaneous adipose tissue (n=50), and skeletal muscle (n=57) - obtained via percutaneous needle biopsy of the vastus lateralis muscle. Samples were sequenced on the Illumina Novaseq 6000 platform and after quality control, 57,821 transcripts mapping to the human reference genome build-37 (hg19) were analyzed. DEG, defined as absolute fold-change >=2 and FDR < 0.05, were identified using a negative binomial generalized linear model (*DESeq2*) and adjusting for age, sex and type 2 diabetes. Enrichment analysis was conducted using Clarivate *Metacore*™. We identified 195, 104, and 8 DEGs in blood, adipose tissue, and skeletal muscle, respectively. While there was little overlap between DEGs identified in the three tissues, the pathways enriched in those of blood and adipose tissue showed more overlap. The *phosphatidylinositol-4,5-diphosphate pathway*, and *signal transduction_Angiotensin II/AGTR1 signaling pathway* were both enriched in blood and adipose tissue. DEGs in adipose tissue were uniquely enriched for several immune response (e.g. IFN-gamma in macrophage activation, *IL-12 signaling pathway*), signal transduction (e.g. *Soluble CXCL-16 signaling*, *FGFR2 signaling*) and cell cycle processes (e.g. *The metaphase checkpoint*, *Initiation of mitosis*). DEGs in blood were enriched for a more heterogenous range of pathways that included *Beta-adrenergic receptors signaling via Cyclic AMP* and *NOTCH signaling*. These findings indicate that obesity is associated with different transcriptomic changes that is tissue dependent, with adipose tissue showing signatures of cellular expansion and differentiation (indicative of adipocyte hypertrophy and differentiation) as well as an immune cell response (consistent with the well-known role of adipose tissue macrophages in obesity-related inflammation). Our findings add to the slowly growing literature on omics profiling to inform cardiometabolic disease pathophysiology in diverse populations.

Creeping fat (CF) is a poorly understood feature of Crohn's disease (CD), characterized by the wrapping of mesenteric adipose tissue (MAT) around the inflamed intestine. The aim of this study was to investigate the transcriptional profile and compositional features of CF. We collected 59 MAT samples: 23 paired samples from patients with CD (CF [CD-CF] and MAT around the uninflamed intestine [CD-MAT]) and 13 MAT samples from non-CD patients (Con-MAT). Differentially expressed gene (DEG), functional pathway, cell deconvolution, and gene co-expression network analyses were performed. We identified a total of 529 DEGs ($|\log_2 \text{FoldChange}|>1.5$; false discovery rate <0.05), of which 428 exhibited transitional transcriptomic changes. Of these, 323 genes showed an incremental pattern from Con-MAT to CD-MAT, and to CD-CF, while 105 genes displayed a decremental pattern. Genes with an incremental pattern were related to immune cell responses, including B-cell and T-cell activation, while genes with a decremental pattern were involved in cell trafficking and migration. Cell deconvolution analysis revealed significant changes in cellular composition between the CD-CF and Con-MAT groups, with increased proportions of B-cells/plasma cells (p-value=1.16×10^{-4}), T-cells (p-value=3.66×10^{-3}), and mononuclear phagocytes (p-value=3.53×10^{-2}) in the CD-CF group. In contrast, only the B-cell/plasma cell component showed a significant increase (p-value=1.62×10^{-2}) in the CD-MAT group compared to Con-MAT. To conclude, dynamic transcriptional changes and altered cellular components may be crucial for the shift from Con-MAT to CD-MAT and to CD-CF, providing insight into the mechanisms behind CF and highlighting its possible role in CD pathogenesis.

PB1838 Transcriptomic Dysfunction Disparities: Greater Burden in Female Brainshighlights Immune and Synaptic Pathways for psychiatric disorders

Authors:

Y. Xia[1], C. Xia[2], Y. Jiang[3], Y. Chen[4], R. Dai[5], C. Liu[5], C. Chen[2]; [1]Yale Univ., New Heavon, CT, [2]Central South Univ., Changsha, China, [3]Vanderbilt Univ., Nashville, TN, [4]Central South Univ., Cambridge, MA, [5]SUNY Upstate Med. Univ., Syracuse, NY

- One Sentence Summary: Sex differences in psychiatric disorders:greater burden of transcriptomic dysfunction in females highlights immune and synaptic pathways.
- Many psychiatric disorders exhibit strong sex differences, but the underlying mechanisms remain poorly understood. We analyzed transcriptome data from 2160 postmortem brain samples from the PsychENCODE project in a sex-stratified design, comparing schizophrenia (SCZ), bipolar disorder (BD), and autism spectrum disorder (ASD) with controls. We found that females had a higher burden of transcriptomic dysfunction than males, evidenced by a larger number of differentially expressed genes(based on the same sample size)and a greater magnitude of expression level changes. Additionally, female patients had greater overall connectivity dysfunction, a higher proportion of modules with significant connectivity changes, and a higher proportion of modules with higher connectivity burden, indicating more severe organization disruption of co-expression in females. We identified several modules enriched with DEGs, burden genes, and genome-wide association study genes involved in immune and synaptic functions across different brain cell types. Hub genes, including SCN2A, FGF14, and C3, were highlighted in those modules. Our results support the hypothesis that the burden of transcriptomic dysfunction differs between sexes in psychiatric disorders and highlight the importance of immune and synaptic-related pathways in sex differences.

PB1839 Transcriptomic profiles of corneal epithelium reflect irregularities in epithelial thickness maps of post-refractive ectasia patients

Authors:

K. Jaskiewicz[1], M. Maleszka-Kurpiel[2,3], M. Kabza[4], R. Ploski[5], M. Rydzanicz[5], M. Gajecka[4,1]; [1]Inst. of Human Genetics, Polish Academy of Sci., Poznan, Poland, [2]Chair of Ophthalmology and Optometry, Poznan Univ. of Med. Sci., Poznan, Poland, [3]Optegra Eye Hlth.Care Clinic, Poznan, Poland, [4]Chair and Dept. of Genetics and Pharmaceutical Microbiol., Poznan Univ. of Med. Sci., Poznan, Poland, [5]Dept. of Med. Genetics, Med. Univ. of Warsaw, Warsaw, Poland

Background: Post-refractive ectasia is characterized by progressive corneal steepening and thinning, leading to severe progressive irregular astigmatism and deterioration of visual acuity. Such ectasia complicates 0.66% of the laser-assisted in situ keratomileusis (LASIK) procedures, as well as the small incision lenticule extraction and photorefractive keratectomy. Post-refractive ectasia, like keratoconus, is classified under “ectatic diseases”. The exact pathophysiology of post-LASIK ectasia remains unknown, however observed histological abnormalities are similar to keratoconus. Here, for the first time in the KTCN research, we present a transcriptomic profile of corneal epithelium (CE) in patients with post-refractive ectasia.
Materials and Methods: In the preliminary study 4 post-refractive ectasia patients (3 males and 1 female) undergoing cross-linking procedure and 5 mild myopia patients (3 males and 2 females) undergoing refractive error correction (controls) were ascertained. The *central*, *middle*, and *peripheral* CE topographic regions were separated from each obtained CE, based on CE thickness mapping. The RNA samples from 27 experimental samples were extracted using RNA/DNA/Protein PurificationPlus MicroKit (Norgen Biotek). The NGS libraries were prepared using TruSeq Stranded TotalRNA LibraryPrep Gold (Illumina) and sequenced on Novaseq platform (80mln read pairs per sample). RNA-seq data was analyzed implementing the previously established pipelines (PMID 30994860).
Results: We observed a characteristic doughnut pattern (thin cone center surrounded by thickened annulus) on each ectatic epithelial thickness map. We recognized characteristic transcriptomic profiles reflecting irregularities in epithelial thickness across the three analyzed regions. We identified differentially expressed genes involved in the hallmarks of DNA repair, E2F targets, mTORC1 signaling, Myc targets, unfolded protein responses, and reactive oxygen species, with a characteristic decrease in *middle* CE region and upregulation in *central* and *peripheral* CE regions. Moreover, the hallmark of interferon-gamma, but not inflammatory responses, was evenly upregulated in all regions.
Conclusions: The phenotypic abnormalities in distinct CE regions are related to the identified transcriptomic alterations. Further detailed studies would help identify patients at high risk of developing ectasia, and thus disqualify them from refractive corneal surgery and prevent postoperative complications.
Support: The National Science Centre grant no.2018/31/B/NZ5/03280.

PB1840 Trans-Ethnic Analysis of PCOS Subtype Genomewide Association Signals Reveals 3 Shared Subtype-Specific Loci.

Authors:

K. Brewer[1], R. Sisk[2], H. Lee[3], L. Moolhuijsen[4], K. van der Ham[4], Y. Louwers[4], J. Visser[4], M. Dapas[2], S. Franks[5], J. Laven[4], C. Li[6], A. Dunaif[1]; [1]Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]Northwestern Univ., Chicago, IL, [3]Ewha Womans Univ. Sch. of Med., Seoul, Korea, Republic of, [4]Erasmus Med. Ctr., Rotterdam, Netherlands, [5]Imperial Coll. London, London, United Kingdom, [6]Univ. of Southern California, Los Angeles, CA

The phenotypic variation in PCOS suggests underlying genetic heterogeneity, but a recent genomewide association study (GWAS) meta-analysis of European ancestry (EA) PCOS cases found similar genetic architecture of PCOS defined by NIH and Rotterdam diagnostic criteria, suggesting these criteria do not identify biologically distinct disease phenotypes. Using hierarchical clustering (HC) in EA NIH PCOS cases, we identified stable PCOS subtypes, designated reproductive, metabolic, and background (Dapas. PLoS Med, 2020). These subtypes appeared to capture biologically meaningful differences as they were associated with novel and distinct genomewide significant loci. We performed an updated GWAS meta-analysis with additional EA NIH PCOS cases, and a trans-ethnic meta-analysis including a Korean ancestry (KA) NIH PCOS cohort (Lee. Hum Reprod, 2015). PCOS subtypes were identified by HC. Genotyping was as follows: EA discovery cohort (620 cases, 2951 controls), Illumina OmniExpress; EA replication cohort (371 cases, 926 controls), Metabochip; and KA cohort (417 cases, 926 controls), HumanOmni1-Quad v1. All data were imputed using the TOPMed (R2) panel. Eight loci were genomewide significant in the EA meta-analysis: 4 novel loci (reproductive subtype); 2 loci (metabolic subtype), including *C9orf3*; 2 loci (background subtype), including *FSHB/ARL14P*. Five of 6 other lead SNPs in the original analysis remained nominally significant. Three loci were genomewide significant in the trans-ethnic meta-analysis: a novel locus on chr 3, *EPHA6*, a receptor tyrosine kinase that binds GPI-anchored ephrin-A family ligands (rs140766105, p=1.08x10-8, reproductive subtype); a previously identified locus on chr 9, *C9orf3* (*AOPEP*), an aminopeptidase that catalyzes the hydrolysis of amino acid residues (rs10761370, p=4.12x10-9, metabolic subtype); a previously identified locus on chr 11, *FSHB/ARL14P*, which encodes the β-subunit of FSH and is associated with fertility (rs10835649, 1.23x10-11, background subtype). We have replicated the 8 subtype loci in the EA meta-analysis suggesting these subtypes have distinct genetic architecture. For the first time, a trans-ethnic meta-analysis demonstrates that 3 subtype-specific loci play a role in PCOS pathogenesis across diverse populations.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1842 Uncontrolled hypertension is associated with AGT proteomics and risk for clinical sequelae.

Authors:

L. Krohn, R. Hoffing, A. Holleman, P. LoGerfo, M. Plekan, S. Akle, L. Ward, D. Zappe, H-C. Tu, P. Nioi, A. Deaton; Alnylam Pharmaceuticals, Cambridge, MA

Background: Hypertension is a major preventable risk factors for cardiovascular disease. Despite the availability of effective anti-hypertensive agents, hypertension remains a widespread and largely uncontrolled condition. In this study, we aimed to quantify the unmet need in hypertension management in the UK and investigate the impact of uncontrolled hypertension on risk for clinical sequelae. We also assessed angiotensinogen (AGT) as a potential therapeutic target for blood pressure control using a genetic instrument for AGT lowering. **Methods:** Clinical data were collected from UK Biobank intake, hospital, and general practitioner (GP) records. We gathered per-visit systolic blood pressure (SBP) readings and anti-hypertensive prescriptions for those with GP data (N=159,055). Visit-to-visit SBP variability was analyzed using variation independent of the mean (VIM; Yano Y, *AJH*, 2017). As a proxy for AGT-lowering, we selected the strongest pQTL from GWAS of array genotypes on normalized proteomic data from 46,554 participants (rs699-A, beta= -0.33, p < 4e-323). For those with genetic data (N=431,567), we extracted rs699 array genotypes for risk analyses. We assessed the influence of both uncontrolled hypertension and AGT on hypertension-related risks with logistic and Cox regression, each adjusted for age, sex, medication-adjusted LDL, BMI, alcohol intake, smoking status, and type 2 diabetes. **Results:** Of those with GP data, 70% qualified for hypertension, 74% of whom were prescribed one or more anti-hypertensive medication(s) within the covered time frame. Only 23% of the medicated population achieved consistent SBP control (all reads < 140 mm/Hg), while 28% had severely uncontrolled SBP after treatment (2 consecutive reads >=155 mm/Hg) and the highest risk for major adverse cardiac events (MACE, HR=1.2, p=4.6e-11). High visit-to-visit SBP variability is associated with increased risk for- and faster time to- MACE (VIM quartile HR=1.92, p=7.5e-53). The *AGT* rs699-A variant is associated with reduced risk and time to hypertension diagnosis (HR=0.90, p=9.6e-33) and stroke after hypertension diagnosis (HR=0.88, p=0.02), as well as less risk for uncontrolled hypertension after medication (OR=0.98, p=0.005). **Conclusions:** Consistently controlled blood pressure and lower visit-to-visit blood pressure variability are associated with reduced risk for clinical sequelae from hypertension. Genetically lower angiotensinogen is associated with reduced risk for hypertension and sequelae, suggesting that lowering angiotensinogen via *AGT* silencing may improve blood pressure control and reduce MACE.

PB1843 Uncovering Novel Genetic Loci and Biological Pathways Associated with Age-Related Cataracts through GWAS Meta-Analysis.

Authors:

S. Diaz Torres[1], S. Lee[2], L. Garcia Marin[3], A. Campos[4], G. Lingham[2], J. Ong[5], D. Mackey[6], K. Burdon[7], X. Dong[8], S. MacGregor[1], P. Gharahkhani[1], M. Renteria[1]; [1]QIMR Berghofer Med. Res. Inst., Brisbane, Australia, [2]The Univ. of Western Australia, Perth, Australia, [3]Queensland Inst. of Med. Res., Brisbane, Australia, [4]Inst. for Molecular BioSci., Brisbane, Australia, [5]QIMR Berghofer Med. Res. Inst., Herston, Australia, [6]Lions Eye Inst., Nedlands, Australia, [7]Univ. of Tasmania, Hobart, Australia, [8]Brigham & Women's Hosp, Cambridge, MA

Age-related cataract is a highly prevalent eye disorder that results in the clouding of the crystalline lens and is one of the leading causes of visual impairment and blindness. The disease is influenced by multiple factors including genetics, prolonged exposure to ultraviolet radiation (UVR), and a history of diabetes. However, the extent to which each of these factors contributes to the development of cataracts remains unclear.This study presents the largest genome-wide association study of cataracts to date, using data from 127,985 cases and 837,371 controls. We performed gene enrichment analysis to identify genes and biological pathways associated with cataracts. We integrated our results with gene expression reference datasets to identify genetic variants modifying risk for cataracts through changes in the expression of specific genes. We further explored drug-gene interactions to better understand the potential impact of pharmacological interventions on cataract development. Finally, we explored whether a causal relationship underlies the known comorbidity between type 1 diabetes and cataracts using a mendelian randomization framework, and the association between UV exposure and cataract risk in adults using a polygenic risk scoring approach.Our study identified 85 independent genome-wide significant loci, 37 of which are novel. Gene-based association tests identified 126 genes associated with cataracts, hinting at a potential relationship between negative regulation of lipid biosynthesis and the development of cataracts. Four of the genes identified GNL3, JAG1, METTL21A, and CREB1 are involved in drug-gene interactions. Moreover, Mendelian Randomisation analysis identified a putative causal relationship between genetic predisposition to type 1 diabetes and an increased risk of cataracts. Lastly, we found evidence indicating that early-life exposure to UVR may have an impact on the later development of cataracts.Our findings advance our understanding of the genetic basis of cataract and provide new insights into its etiology. We identified multiple genes and biological pathways associated with the condition, including associations with four genes from which drug repurposing could be proposed. Our results suggest a causal association between type 1 diabetes and cataracts. Also, we highlighted a surrogate measure of UV light exposure as a marker of cataract risk in adults and drug-genes interactions that has the potential of informing novel therapies.

PB1844 Uncovering phenotypic abnormalities associated with metabolic genes using *All of Us.*

Authors:

K. Bates, L. Howell, B. Bates, D. Stone, J. Bryan, J. Grose, M. Bailey, M. Davis; Brigham Young Univ., Provo, UT

The occurrence of metabolic disease has grown to epidemic proportions. These diseases can result from impaired regulation of metabolic pathways. Stroke, heart disease, and diabetes are a few examples of the health complications that can occur when cells excessively expend essential nutrients, such as glucose, toward one pathway at the expense of other crucial pathways. Understanding the complex genetic regulation of these pathways can increase our ability to treat and prevent metabolic disease and improve the quality of life of millions of individuals. PAS kinase (PASK) is a nutrient sensing protein kinase that senses the availability of glucose and allocates it towards different pathways. Additionally, PASK has two substrates, upstream stimulatory factor-1 (USF1) and ataxin-2 (ATXN2), that have been shown to regulate lipid metabolism and glucose homeostasis in mammalian systems. We seek to reveal associations between PASK, USF1, and ATXN2 variants and a variety of human phenotypes and diseases using the All of Us Research Program dataset. With more than 180,000 individuals that have both genetic and electronic health record (EHR) data, the All of Us Research Program dataset is an incredible asset for uncovering novel relationships between these genes and disease. After completing basic quality control procedures, our final cohort includes 171,882 individuals, with more than 75% of the cohort representing minority or traditionally underrepresented populations in biomedical research. Almost 70,000 of these individuals are of African/African American, Indigenous American/Latino, South Asian, East Asian, or Middle Eastern ancestries. Using the PheWAS package, we identified phenotypes (represented as phecodes) based on the insurance billing codes found in their EHRs. We ran logistic regression to identify associations between PASK, USF1, and ATXN2 variants with phecodes and metabolic lab values. Our preliminary findings suggest single-nucleotide polymorphisms (SNPs) in USF1 associated with infectious disease ($p < 0.0001$), as well as SNPs in ATXN2 associated with increased hemoglobin A1C levels ($p < 0.0001$) and SNPs in PASK associated with increased triglyceride levels ($p < 0.001$). We anticipate discovering more associations between these genes and metabolic phenotypes, in addition to other phenotypes that may be unexpected, including cancer, mental illness, or neurodegenerative disease. These associations may provide valuable insight into several disorders and suggest novel molecular pathways for future study.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1845 Uncovering Potential Susceptibility Genes for Knee Osteoarthritis through Whole Exome Sequencing.

Authors:

A. BISWAS, B. Garg, R. MALHOTRA; All India Inst. of Med. Sci., New Delhi, India

Title: Whole-Exome Sequencing Reveals Potential Susceptibility Genes for Knee Osteoarthritis. **Introduction:** Knee osteoarthritis (kOA) is a major cause of disability in the elderly with the global prevalence of 16% and 22-39% in India. Major risk factors for the kOA is aging, diet, lifestyle and most importantly genetic modality. Till date, genetic predisposition is not fully understood and also there is lack of genetic studies from India. **Aims & Objectives:** The primary objective of this study was to identify casual genes that predispose individuals to kOA in Indian population.**Materials and methods:** In this study, we have sequenced 50 Knee OA patients with confirmed diagnosis through radio-graphical intervention and 20 age and sex matched healthy controls through whole exome sequencing. Clinical history, demographical information & blood sample were collected for serological and molecular work. DNA was isolated and subjected to whole exome sequencing (100X) after preparing libraries using nextera exome enrichment kit. All the variants were filtered out for the candidate's genes reported in previous literature and also, in an independent filtering, all non-synonymous and pathogenic variants were listed as per Clinvar which were associated with osteoarthritis or any related disorders. The expression profiles of mRNAs in blood were assessed using whole transcriptome sequencing focussing on all the prioritised genes from exome study.**Results:** Germline variants were identified in previously known kOA susceptibility genes such as *BTNL2* and *HLA DPB1*, and several other genes with potentially deleterious variants for kOA. In an independent filtering for casual variants which were associated with kOA or related bone disorders based on clinvar database, we found previously reported variants in genes *NACA2, TLR10, GLE1 and MATN3* having high MAF as compared to 1000genomes and SAS data frequency. Interestingly, whole exome analysis demonstrated that most samples shows multiple modifier variants whereas rare variants were specific to the individuals which were evident when 191 associated genes evaluation. All the prioritised genes reported were differentially expressed as compared to controls.**Conclusion:** Our findings indicate that kOA patients harbour potentially deleterious causative germline variants in genes that function in several candidate causative pathways including immune responses, inflammatory and cartilage degradation. Genetic testing for a wider variety of kOA-predisposition genes could provide better screening approach for high-risk groups of osteoarthritis.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1846 Uncovering the nuclear genetic basis of mtDNA heteroplasmy.

Authors:

R. Alhariri[1], W. Shi[1], D. Puiu[2], N. Pankratz[3], N. Lake[4], M. Lek[5], Y. Huang[6], E. Tsai[6], K. G. Meilleur[6], J. Shi[6], H. Runz[6], D. Arking[1]; [1]McKusick-Nathans Inst., Dept. of Genetic Med., Johns Hopkins Univ. Sch. of Med., Baltimore, MD, [2]Dept. of BioMed. Engineering, Johns Hopkins Univ., Baltimore, MD, [3]Univ. of Minnesota, Minneapolis, MN, [4]Yale Univ., New Haven, CT, [5]Yale Univ. Sch. of Med., New Haven, CT, [6]Biogen, Cambridge, MA

Background: Mitochondrial heteroplasmy, the coexistence of mutated and wildtype mitochondrial DNA within a cell, is associated with overall mortality and aging-related phenotypes. Mitochondrial mutations can be inherited maternally or acquired somatically, with previous work estimating that about 70% of heteroplasmies are somatic and increase in an age-dependent manner.
Methods: To study the relationship between nuclear encoded variation and mitochondrial heteroplasmy, we conducted genome-wide association studies on heteroplasmy count as well as a functional approximation of the deleteriousness of the heteroplasmic mutations, using the mitochondrial local constraint score sum (MSS). MSS utilizes a conservation-based metric that accounts for class of mutation as well as constraint at a nucleotide and gene-level. We included 162,853 participants of European Ancestry from the UK Biobank. Whole-genome sequencing data from whole blood DNA samples were used to call heteroplasmy through the MitoHPC pipeline. 11,392,286 SNPs with a minor allele frequency (MAF) >0.005 were included in the GWAS after imputation.
Results: Genes were identified through positionally mapping variant hits in genes or up to 10 KB to the nearest gene. rs2906685 in *DNAH11* was identified as a lead SNP (Beta=-0.017; p= 1.83x10^-10) in the GWAS associated with heteroplasmy count, while 14:96204037_CA_C in *TCL1A* (Beta=0.0061; p=1.20x10^-09) and rs2736100 in *TERT* (Beta=0.0046;p=3.71x10^-10) were identified in our GWAS on MSS. Encoding the axonemal arm of a ciliary dynein, *DNAH11* may be biologically relevant to the development of heteroplasmy given dynein's relation to mitochondrial motility which regulates fusion and fission dynamics. Comparatively, *TERT* has been reported to serve a protective role against mitochondrial DNA from damage and reduce the production of reactive oxygen species. Less is known about *TCL1A* which has been described as a potential tumor suppressor gene.
Conclusion: *DNAH11* and *TERT* were identified as two genes that may be associated with mitochondrial processes of motility and DNA damage repair. Future directions involve validating findings in a cross-ancestry cohort through the inclusion of participants from TOPMed and AllofUs.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1847 Understanding dynamic molecular regulations in brains with regard to Tuberous Sclerosis diseases.

Authors:

S. Yoo[1], Y. liu[1], E. Lee[1], Q. Chen[1], S. McGee[2], L. Wang[1], J. Zhu[1]; [1]GeneDx, Stamford, CT, [2]GeneDx, Gaithersburg, MD

Tuberous Sclerosis Complex (TSC) is an autosomal dominant disorder affecting 1 in 6000 newborns in the US driven by variants in *TSC1* or *TSC2*. These variants can affect diverse organ systems including the brain, eye, heart, kidney, skin, and lung. The primary affected tissue/organ is the brain which results in several neurologic disorders such as epilepsy, developmental delay, and autism.

Proteins encoded by *TSC1* and *TSC2* form a complex that inhibits the mTOR pathway, in turn regulating many pathways essential for cell growth in all cells. To understand the relationship between TSC and mTOR pathway in the brain and other organ systems, we first investigated cell type-specific expression of *TSC1*, *TSC2*, and *mTOR* and inferred mTOR complex 1 pathway activity (mTORC1 activity). Across 79 human cell types, cells in the brain and eye had the lowest mTORC1 activity while these cells had the highest gene expression levels of *TSC1*, *TSC2*, and *mTOR. TSC1* and *mTOR* expression levels and mTORC1 activity were significantly anti-correlated across cell types. The results suggest that brain- and eye-specific cells are more likely to be affected by TSC-mTOR pathway dysregulation. In brain and non-brain human bulk tissue profiles in the GTEx database, the three genes were tightly correlated in brain tissues but less correlated in other tissues (t-test $p=1.9x10^{-19}$). To understand the co-regulation in the brain, we identified *ARNT2*, *ETV5*, and *BHLHE41* as key transcription factors contributing to the brain-specific co-regulation. *ARNT2* plays a role in the development of brain, visual, and renal function, consistent with the top tissues affected in tuberous sclerosis diseases.

The tightly co-transcriptional regulation of *mTOR, TSC1,* and *TSC2* results in stable mTORC1 activity in the brain. Variants in *TSC1* or *TSC2* will disturb the stable state among mTORC1 activity and result in lower or higher mTORC1 activity. To test the hypothesis, we checked microcephaly (likely due to lower mTORC1 activity) and macrocephaly (likely due to higher mTORC1 activity) phenotypes in individuals with *TSC2* variants. In the GeneDx database, among patients with TSC2 variants, 291 patients were with microcephaly, and 185 were with macrocephaly. The corresponding variants in *TSC2* were not enriched in any TSC2 structure domain, suggesting that the lower or higher mTORC1 activity was determined by other genetic or environmental factors. For example, rs1042602 in tyrosinase was significantly associated with macrocephaly among patients with TSC2 variants, suggesting whole genome sequencing or whole exome sequencing is necessary to understand the disease heterogeneity.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1848 Understanding the genetic complexity of puberty timing across the allele frequency spectrum.

Authors:

K. Kentistou, ReproGen Consortium; Univ. of Cambridge, Cambridge, United Kingdom

Pubertal timing varies considerably and has been associated with a range of health outcomes in later life. To elucidate the underlying biological mechanisms, we performed multi-ancestry genetic analyses in ~800,000 women, identifying 1,080 independent signals associated with age at menarche. Collectively these loci explained 11% of the trait variance in an independent sample, with women at the top and bottom 1% of polygenic risk exhibiting a ~11 and ~14-fold higher risk of delayed and precocious pubertal development, respectively. These common variant analyses were supported by exome sequence analysis of ~220,000 women, identifying several genes, including rare loss of function variants in *ZNF483* which abolished the impact of polygenic risk. Next, we implicated 660 genes in pubertal development using a combination of *in silico* variant-to-gene mapping approaches and integration with dynamic gene expression data from mouse embryonic GnRH neurons. This included an uncharacterised G-protein coupled receptor *GPR83*, which we demonstrate amplifies signalling of *MC3R*, a key sensor of nutritional status. Finally, we identified several genes, including ovary-expressed genes involved in DNA damage response that co-localise with signals associated with menopause timing, leading us to hypothesise that the ovarian reserve might signal centrally to trigger puberty. Collectively these findings extend our understanding of the biological complexity of puberty timing and highlight body size dependent and independent mechanisms that potentially link reproductive timing to later life disease.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1849 Unleashing the Power of Telomere Length Genetics: Unravelling Disease Associations and Rare Variant Impacts from 483,778 UK Biobank Genomes

Authors:

O. Burren[1], R. Dhindsa[2], S. Deevi[1], **S. MacArthur**[1], J. Mitchell[1], S. Wen[1], A. Nag[1], N. Razdan[3], H. Olsson[4], K. Smith[1], S. Wasilewski[1], A. Platt[5], M. Fabre[1], K. Carss[1], Q. Wang[1], S. Petrovski[1]; [1]Ctr. for Genomics Res., Discovery Sci., BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom, [2]Ctr. for Genomics Res., Discovery Sci., BioPharmaceuticals R&D, AstraZeneca, Waltham, MA, [3]BioSci.s COPD & IPF, Res. and Early Dev., Respiratory & Immunology, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [4]Translational Sci. and Experimental Med., Res. and Early Dev., Respiratory & Immunology, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [5]Translational Sci. and Experimental Med., Res. and Early Dev., Respiratory & Immunology, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom

Genetic perturbations that influence human telomere length (TL) have also been linked to a spectrum of human diseases, including the discovery of TL associated genes that have been found to possess antagonistic pleiotropy (e.g., reduced risk of cancer and increased risk of interstitial lung diseases). Thus, elucidating the genetic drivers of TL biology will further our understanding of many complex diseases. We compared TL estimates obtained from qPCR[1] and TelSeq[2] (WGS) for 483,778 participants from the UK Biobank (UKB), revealing only a partial correlation (r^2=0.15). To optimize the biological signal and enhance the statistical power of our genetic association analyses, we constructed a composite score (PC1)[2] derived from a principal component analysis (PCA) incorporating both WGS and qPCR measurements. PC1 successfully identified known TL associations, such as with age (β = -0.02, SE ± 0.00, P<$2x10^{-16}$). Applied to common variant analysis, PC1 significantly improved genetic locus discovery yield and narrow-sense heritability (7.9%, SE ±0.9%) compared to independent qPCR (6.8%, SE ±0.8%) or WGS (4.9%, SE ±0.7%) TL measurements alone.
Given the access to 483,778 WGS we conducted analyses to target rare (MAF<0.1%) coding variants individually and in an aggregated gene collapsing framework, performing the largest study of rare variant contribution to TL, to date. We identified 50 rare variants and 22 distinct genes associated with PC1 (p<$1x10^{-8}$). Many of these genes overlapped common variant loci, allowing us to establish allelic series (e.g., *ACD*) and to prioritise causal genes and variants linked with large effects on telomere dysfunction. Three genes were known drivers of clonal haematopoiesis (CH), prompting subsequent targeted somatic variant analyses. We uncovered novel signals, including a positive association between somatic variants in *SRSF2* and longer TL (Effect=0.65, SE ± 0.17, P=1.3 x 10^{-4}), as well as an inverse relationship between TL and *DNMT3A* clone size (Effect=-0.69, SE ± 0.09, P=$3.7x10^{-12}$). Our study highlights the biological insights that arise from integrating orthogonal data modalities within a substantial sample of participants. We reveal a complex interplay between telomere length and clonal haematopoiesis, shedding light on the broader genetic antagonistic pleiotropy existing between cancer and other age-related diseases. Furthermore, our findings emphasise the substantial effects of rare germline and somatic variants on TL, offering valuable implications for both disease pathogenesis and the development of therapeutic strategies. 1. Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1850 Unraveling Oligodendrocyte Heterogeneity in Neurodegenerative Disorders.

Authors:

N. Rahimzadeh, S. Morabito, V. Swarup; Univ. of California, Irvine, CA

Myelin loss and white matter changes are prominent features observed in neurodegenerative disorders, particularly in multiple sclerosis (MS) and Alzheimer's disease (AD). While MS exhibits extensive demyelination, AD also displays pathological signs of white matter lesions and degeneration. Oligodendrocytes (ODC), specialized cells in the nervous system, play a vital role in generating myelin, forming the myelin sheath that envelops axons. The myelin sheath not only supports axon metabolism, but it also enables the rapid and saltatory propagation of action potentials. Understanding the underlying causes of demyelination in MS can provide valuable insights into AD and guide therapeutic interventions aimed at preserving white matter integrity. Single-cell/nucleus transcriptomics holds great promise in advancing our understanding of cellular heterogeneity and its contribution to disease pathology. In this study, our objective is to leverage publicly available single-nuclei RNA-seq datasets for MS, including Absinta et al. (n = 72,959), Schirmer et al. (n = 48,919), Jakel et al. (n = 17,799), as well as AD datasets, including Morabito and Miyoshi et al. (n = 191,890), Mathys et al. (n = 80,660), and Olah et al. (n = 16,242). Using a single-cell variational inference (scVI) model, specifically a variational auto-encoder, we will integrate and harmonize these datasets. By integrating the reported nuclei from each study, we will gain sufficient statistical power to investigate the heterogeneity of ODC populations across MS and AD. Our downstream analysis will include the identification of gene-regulatory networks using weighted correlation network analysis and trajectory analyses to infer cell states across the disease spectrum. This analysis will enable us to uncover both shared and distinct ODC populations associated with the studied traits.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1851 Unraveling sex differences in the complex genetic architecture of blood pressure and insights into cardiovascular disease pleiotropy.

Authors:

M-L. Yang, C. Xu, X. Zhou, S. Ganesh; Univ. of Michigan, Ann Arbor, MI

Background: Blood pressure (BP) plays a vital role in the development of cardiovascular diseases (CVDs). However, significant sex differences exist in terms of prevalence and clinical considerations. The molecular and genetic basis of sex-specific BP patterns remains poorly understood, impeding our understanding of the relationship between BP genetics, specific forms of hypertension, and cardiovascular diseases. Further investigation in this area is necessary to advance our knowledge of sex-specific cardiovascular health.
Methods: We conducted sex-stratified and combined-sex genome-wide association studies (GWAS) on BP traits using UK Biobank (UKB) data. Our analysis aimed to reveal sex differences in genetic associations and identify loci with sex-specific effects. Additionally, we examined the association between sex-specific BP polygenic risk scores (PRS) and hypertension phenotypes, as well as several cardiovascular diseases. Leveraging cross-trait colocalization in a sex-stratified manner, we further identified genetic regions associated with BP that exhibited sex-specific risks for associated CVDs.
Results: Our analysis identified 1,375 loci associated with BP traits, including 29 novel and 1,346 previously known loci. Of these, 412 were specific to females, and 142 were specific to males. Sex-stratified GWAS revealed 90 unique loci (7%) compared to combined-sex GWAS. Gene-by-sex interactions and sexually dimorphic effects (SDE) analysis highlighted four genomic regions, including the chromosome 13q34-*COL4A1*/*COL4A2* locus implicated in both analyses. We identified 18 BP-associated loci with significant SDE, such as chromosomes 17q23.3-*PECAM1*/*TEX2*, 19q13.2-*ACTN4*/*CAPN12*, and 13q34-*COL4A1*/*COL4A2*. In the sex-stratified PRS analysis, we found a strong female-specific association between PRS of pulse pressure and fibromuscular dysplasia (FMD), a hypertension subtype primarily affecting women. This association may stem from robust female-specific signals within the regions encompassing *COL4A1*, *COL4A2*, *CDKN2B-AS*, and *MAP9*. Our study revealed sex-specific genetic effects on BP regulation in established genetic loci linked to CVDs, shedding light on the underlying mechanisms and observed sex disparities.
Conclusion: Our findings emphasize the central role of blood pressure in cardiovascular disease risks and partially explain variations in CVD patterns across different biological sexes.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1852 Unraveling shared genetics across asthma subtypes and 70 biological and physiological asthma-related traits.

Authors:

R. Vernet[1], C. Linhard[1], Y. Suzuki[2], H. Mohamdi[1], J. Sambourg[1], F. Demenais[1], H. Aschard[2], H. Julienne[2,3], E. Bouzigon[1]; [1]INSERM, Université Paris Cité, UMR 1124, Group of Genomic Epidemiology of Multifactorial Diseases, Paris, France, [2]Inst. Pasteur, Université Paris Cité, Dept. of Computational Biology, Paris, France, [3]Inst. Pasteur, Université Paris Cité, Bioinformatics and Biostatistics Hub, Paris, France

Asthma is a heterogeneous disease with a large spectrum of clinical expression over the life span, reflecting the multiple underlying biological mechanisms or endotypes. This clinical and biological heterogeneity might be at least partly due to genetic heterogeneity across patients. To better understand the etiology of asthma heterogeneity, we investigated the patterns of genetic correlations, between various asthma subtypes and multiple biological and physiological traits involved in asthma pathophysiology.

We built a harmonized comprehensive database of 75 GWAS summary statistics of asthma, asthma subtypes (moderate-severe asthma, childhood onset, adult-onset and time-to-asthma onset) and asthma-associated traits (blood cell counts, various cytokines, total serum Immunoglobulin E levels, lung function phenotypes and body-mass index). We applied the JASS (Joint Analysis of Summary Statistics) pipeline on all 75 traits to: i) curate and harmonize GWAS Summary Statistics, ii) impute missing statistics, and iii) compute SNP heritabilities (h^2) and genetic correlations (r_g) based on LD Score regression.

The highest SNP heritabilities were found for moderate-to-severe asthma (h^2=0.18, SE=0.02), childhood-onset asthma (h^2=0.15, SE=0.03), and time-to-onset of asthma (h^2=0.11, SE=0.03) while adult-onset asthma showed lower heritability (h^2=0.02, SE=0.002). Out of the 1,225 pairs of asthma subtypes and biological traits, 45 had significant genetic correlations with $p<4.1x10^{-5}$ (after Bonferroni correction for the number of trait pairs) and seven additional pairs had nominally significant genetic correlations ($p<0.05$).

All asthma subtypes were significantly correlated with lung function traits (FEV_1, FVC and FEV_1/FVC, r_g ranging from -0.31 to -0.45; $p<1.5x10^{-5}$), and eosinophil counts (r_g 0.27 to 0.39, $P<4x10^{-5}$). Interestingly, we also observed genetic correlations that were specific to asthma subtypes. Moderate-to-severe asthma was correlated with obesity and BMI (r_g ~0.20, $P\leq2x10^{-3}$), basophil counts (r_g 0.10, P=0.02) and eosinophil cationic protein levels (r_g=0.68, P=0.04). Adult-onset asthma was significantly correlated to obesity and BMI (r_g=0.15-0.18, $p < 0.01$) and basophil counts (r_g=0.12, p=0.004).

In this study, we observed genetic factors shared by all asthma sub-types and some physiological traits. We also detected specific patterns of genetic correlations of asthma sub-types with biological and physiological traits, which shows a genetic contribution to asthma heterogeneity. (Funding: ANR-20-CE36-0009)

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1853 Unraveling the genetic architechture of autoimmune gastritis and pernicious anmeia.

Authors:

B. M. Morris, A. W. Reynolds; Baylor Univ., Waco, TX

Autoimmune gastritis (AIG) is a condition characterized by inflammation of the stomach lining due to autoimmune destruction of parietal cells that affects between 0.5-2.5% of the US population. Parietal cells are specialized epithelial cells, found in the fundus of the stomach, aid in digestion and nutrient absorption by secreting hydrochloric acid and intrinsic factor. AIG leads to multiple disease end-stage phenotypes, including iron deficiency anemia, pernicious anemia, and increases the risk of developing gastric cancers; but it is unclear why some patients develop different end-stages of the disease and what risk factors influence this. Pernicious anemia (PA), one end-stage of AIG, causes malabsorption of vitamin B12 (cobalamin), an essential micronutrient that helps maintain healthy blood cells, nerves, DNA synthesis and structural stability, methyltransferase activity, and many other important metabolic processes. Quick diagnosis of PA is vital, as left untreated, the condition can cause permanent neurological damage and even death. However, a positive diagnosis of PA can be difficult because of slow progression and nondescript symptoms that can mask the underlying disease, leaving many patients undiagnosed or misdiagnosed for 5 - 10 years. To better understand the genetic risk factors of AIG and PA we used whole-genome sequence data from the All of Us research program to conduct a genome-wide association study (GWAS) on 3761 AIG cases, 979 PA WGS cases, and 245,388 healthy controls. Using a statistical fine-mapping approach, we identified credible sets of putatively causal variants associated with AIG and PA. We compared our findings with previously published GWAS of other autoimmune diseases to shed light on common autoimmune disease risk factors. These findings contribute to ongoing efforts to characterize polygenic and pathway risk scores for AIG, PA, and other autoimmune diseases, laying the foundation for future improvements in clinical guidelines and diagnostic and therapeutic strategies.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1854 Unraveling the genetic enigma of Endometriosis: Novel insights and gene discovery on a deeply characterized cohort.

Authors:

A. Santin[1], B. Spedicati[1,2], A. Morgan[2], S. Lenarduzzi[2], P. Tesolin[1], G. G. Nardone[1], D. Mazzà[2], G. Di Lorenzo[2], F. Romano[2], F. Buonomo[2], A. Mangogna[2], M. P. Concas[2], G. Zito[2], G. Ricci[1,2], G. Girotto[1]; [1]Dept. of Med., Surgery and Hlth.Sci., Univ. of Trieste, Trieste, Italy, [2]Inst. for Maternal and Child Hlth., I.R.C.C.S. “Burlo Garofolo”, Trieste, Italy

Background: Endometriosis (EM) is a multifactorial gynecological disorder. Despite its prevalence, EM is one of the most underdiagnosed and undertreated disorders, with a nine-year diagnostic delay from symptoms onset. Therefore, detangling the genetic mechanisms underlying EM etiopathogenesis could be relevant to identify novel molecular targets as diagnostic and therapeutic biomarkers. Several Genome-Wide Association Studies have been reported in literature, allowing the detection of candidate genes; however, the causal genetic mechanisms underlying EM are still undetermined.
Methods: Eighty patients with confirmed EM diagnosis were enrolled at I.R.C.C.S. "Burlo Garofolo" hospital (Trieste, Italy). All patients underwent a deep clinical assessment, comprising the evaluation of the most common EM-associated symptoms, food preferences, and lifestyle habits. Whole-Exome Sequencing (WES) analysis was firstly focused on a selected list of 46 EM-associated genes and subsequently on novel candidates discovery. Results were then compared with a cohort of 105 healthy women.
Results: WES allowed the detection of over 60 rare predicted damaging heterozygous variants within 24 genes. Results were classified into three main groups: a) recurrent genes shared among many patients, b) private variants within specific genes, c) variants within novel candidates. In group a) we identified rare predicted damaging missense variants within *LAMA5* gene, already associated with EM stage III-IV. Interestingly, 3/5 EM patients carrying variants within this gene were diagnosed with EM stage III-IV.In group b), a rare predicted damaging missense variant in *WT1* gene was detected in a 35-year-old woman. *WT1* is involved in female fertility regulation and linked with EM-associated dysmenorrhea. Notably, this patient was diagnosed with infertility and reports severe dysmenorrhea. Concerning group c), eight EM patients carry rare damaging variants within *ABCA13* gene encoding a gangliosides transporter, a novel candidate involved in pain processing. Finally, to deepen the polygenic architecture of EM, an evaluation of the analyzed genes was conducted, revealing a statistically significant ($p<0.05$) higher burden of genes in EM patients than in controls.
Conclusions: For the first time, a joint approach of a detailed clinical characterization and WES was performed, allowing the detection of rare variants within EM-associated genes and novel candidates, thus identifying intriguing genotype-phenotype correlations. Ongoing analyses will be aimed at deepening the complex relation between EM-associated pain, food preferences, and EM disease severity.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1855 Unraveling the genetics of cellular senescence for target discovery for IPF.

Authors:

R. Mishra[1], L. Benedetti[2], S. Hopkins[3], P. Gormley[4], A. Hutchinson[5], A. Cortes[6], J. Davitte[7], W. Fahy[6], C. Buser-Doepner[1], R. Scott[8], A. Chu[9]; [1]GlaxoSmithKline, Collegeville, PA, [2]GlaxoSmithKline, Stevenage, United Kingdom, [3]GlaxoSmithKline, Steve age, United Kingdom, [4]GSK, Cambridge, MA, [5]GlaxoSmithKline, Cambridge, United Kingdom, [6]GSK, Stevenage, United Kingdom, [7]GSK, Collegeville, PA, [8]GSK, Cambridge, United Kingdom, [9]GlaxoSmithKline, Cambridge, MA

Idiopathic pulmonary fibrosis (IPF) is a complex, rapidly progressive lung disease with significant morbidity, mortality, and unmet medical need. Current antifibrotic treatments slow disease progression but do not halt it and have significant tolerability issues. There is an urgent need to identify new drug targets, with senescence and telomere biology emerging as important mechanisms in the pathobiology of IPF. Given the previously established causal link between telomere biology and IPF, we use leukocyte telomere length (TL), a biomarker for cellular senescence, among individuals of the U.K. Biobank (UKB) to unravel potential novel therapeutic targets for IPF. We used the log-transformed, Z-standardized TL released by UK Biobank. TL was measured in peripheral leukocytes of 411,886 participants of European ancestry represented as the ratio of telomere repeat number relative to a single copy gene. We ran a genome-wide association study using REGENIE, adjusting for age at baseline assessment, genetic sex, genotyping array, and the first 10 genetic principal components. We performed mendelian randomization by constructing genetic risk scores (GRS) for TL and testing the association with the largest public GWAS of IPF (Partanen et al 2021). Longer TL was significantly associated with lower odds of IPF (p-value = $5.68x10^{-54}$). We colocalized all 133 genome-wide significant TL loci with the IPF GWAS and filtered for cellular senescence-related genes. Out of the 133 loci, only one locus demonstrated evidence of a shared signal with IPF and mapped to a cellular senescence related gene, thymidylate synthetase (*TYMS)*. This observation also suggested this locus is associated with longer TL and lower odds IPF. Colocalization using GTEx tissues suggested increased telomere length was also associated with increased expression of *TYMS*. Since the *TYMS* loci does not reach genome-wide significance in IPF (p= 1.75e-06), this target hypothesis for IPF would be missed. Additionally, *TYMS* was shown to be a potential poor prognostic biomarker for IPF patients in a recently published, independent study using a gene expression profile of cellular senescence-related genes. Our findings link the genetics of TL and IPF together and illustrate how telomere length genetics can enable target discovery in IPF.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1856 Unraveling the shared genetic architecture of insulin resistance, type 2 diabetes, and cardiometabolic diseases independent of traditional risk factors.

Authors:

A. Ranta[1], B. Balliu[2,3], D. Sharma[1], M. Räsänen[1], T. Quertermous[1], J. W. Knowles[1], I. Carcamo-Orive[1]; [1]Dept. of Med., Div. of Cardiovascular Med., Cardiovascular Insitute and Stanford Diabetes Res. Ctr., Stanford Univ. Sch. of Med., Stanford, CA, [2]Dept. of Pathology and Lab. Med. & Dept. of Computational Med., UCLA David Geffen Sch. of Med., Los Angeles, CA, [3]Dept. of Biostatistics, UCLA Fielding Sch. of Publ. Hlth., Los Angeles, CA

Cardiometabolic diseases associated with insulin resistance (IR), such as coronary artery disease (CAD), type 2 diabetes (T2D), and non-alcoholic fatty liver (NAFLD), are the leading cause of death worldwide. IR is essential for developing T2D and NAFLD and is a major risk factor for CAD even in the absence of T2D, partly due to shared risk factors (i.e., hypertension and hyperlipidemia). However, recent data suggest that some IR genes have effects on CAD not accounted for by traditional risk factors.

We previously conducted a custom colocalization analysis to identify novel genes with primary effects on insulin sensitivity, leveraging publicly available GWAS from IR-related traits and tissues. Of the loci analyzed, ~25% showed colocalization with a single gene, but many loci lacked a plausible causal gene. Several reasons could explain this, including: i) underpowered QTL datasets, ii) relevant lncRNA, or other QTL types, have not been well characterized, iii) larger GWAS are needed, iv) better partitioning (LD blocks) of disease-associated loci are needed to distinguish independent GWAS signals.

To fill these gaps and study the shared genetic architecture of IR and cardiometabolic diseases we build on our prior work by including the latest large scale multi-ethnic GWAS for cardiometabolic traits and diseases (i.e. T2D, CAD and NAFLD-20 GWAS in total), incorporating millions of additional subjects. We are expanding our QTL tissue coverage (subcutaneous and visceral adipose, skeletal muscle, liver, pancreas) to include the vasculature and generating more extensive QTL maps (eQTL and sQTL) by merging GTEx and STARNET, which has > 600 samples for tissues of interest and includes annotations for lncRNA QTLs. To leverage size and power differences between tissue QTL datasets, we integrate tissue-specific QTLs maps generated from the recently developed FastGxC method. We also apply the recently generated LD blocks from 1000 Genomes phase 3 data to achieve a better partition of disease-associated loci.

We have so far found that a number of loci (~50 genes) are colocalized with IR and cardiometabolic diseases. Approximately 40% of the identified genes are not shared with traditional risk factors. Among the identified shared colocalized genes are *CCDC92*, which has been previously identified as a cardiometabolic gene, and other novel causal gene candidates. In summary, we have created a comprehensive list of prioritized IR/cardiometabolic disease candidate causal genes and assigned actionable tissues for targeted validation.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1857 Untangling the role of heritable individual-level exposures in type 2 diabetes risk: how genetics impacts our unhealthy behaviors.

Authors:

N. Carvalho[1,2], C. J. Patel[2]; [1]Georgia Inst. of Technology, Atlanta, GA, [2]Harvard Med. Sch., Boston, MA

Genotypes, behavior, and environmental exposures form a complex web of associations with each other. Epidemiological research that assumes independence between these factors can therefore confound true associations with disease risk. Expanding on prior work, we built a polyexposure score (PXS) for type 2 diabetes (T2D) risk composed of 25 independently associated individual-level behaviors in the UK Biobank. In the following, we estimated the PXS for T2D to have a modest but significant heritability ($h^2 = 0.119$); TV consumption and alcohol intake were among the most heritable and risk-associated individual-level behaviors. Genes associated with PXS for T2D were expressed in the brain, suggesting that the genetic architecture of the PXS captures cognitive features. We found that the PXS also enhances dissection of diabetes etiology: for example, we found distinct genetic correlations between the PXS and other metabolic traits such as BMI and glucose control. For example, BMI is found to have a higher genetic correlation with the PXS for T2D onset ($r_g = 0.57$) than T2D onset itself ($r_g = 0.42$), suggesting the existence of risk behaviors associated with insulin resistance rather than production. Furthermore, PXS and polygenic risk scores for T2D are largely independent from each other (are weakly correlated) on an individual-level but have a weak association when looking across UK regions. We discuss potential causal pathways for diabetes risk and highlight the importance of studying malleable disease-associated behaviors and their genetic architectures in order to identify at-risk groups and effective preventative treatments.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1858 Untangling the shared genetic architecture between Alzheimer's and cardiometabolic disease.

Authors:

C. Cunha, M. Ureña, T. Kilpeläinen, R. J. F. Loos; Novo Nordisk Fndn. Ctr. for Basic Metabolic Res., København, Denmark

Obesity and type 2 diabetes (T2D) associate with an increased risk of late-onset Alzheimer's Disease (LOAD). However, the genetic relationship between these conditions remains unclear. The increase in sample size of LOAD GWAS' has been largely driven by proxy cases based on parental diagnoses (self-reported impression of off-springs that either parent had dementia) and non-age matched controls (referred to as controls hereafter) in the UK Biobank (UKBB), which may lead to misclassification. We aimed to assess the genetic relationship between obesity, T2D, and LOAD with and without proxies and controls by genetic correlation and cross-phenotype association analyses. We leveraged the largest European-ancestry GWAS summary statistics for BMI, type 2 diabetes (T2D) and LOAD (w/ UKBB proxies and controls), LOAD (w/o UKBB proxies, and LOAD (w/o UKBB proxies and controls). We used LDSC to estimate genetic correlation (GC) between BMI, T2D and LOAD and performed cross-phenotype variant discovery by identifying variants associated with obesity-LOAD, T2D-LOAD, or all three outcomes. The GC between BMI and LOAD weakened when removing proxies for LOAD (-0.07 vs -0.13), while the T2D-LOAD GC estimates also faded when proxies (0 vs -0.09) and controls (-0.03 vs -0.09) were removed. Further, we identified 150 genome-wide significant (GWS) loci for LOAD. Removing proxies and proxies/controls yielded a loss of 17 and 20 loci, respectively, highlighting that proxies create a more heterogenous LOAD phenotype relating more broadly to dementia. The lost loci are likely correlated with dementia, but unspecific to LOAD. Importantly, the *APP* gene - central to the prevailing amyloid cascade hypothesis in LOAD - was not found when removing proxies and controls. We report 73 and 337 independent signals shared between BMI-LOAD and T2D-LOAD, respectively. Removing proxies and controls led to a loss of ≈80% in overlapping GWS hits between our trait-pairs, likely highlighting novel and "truer" variants mediating cardiometabolic disease and LOAD. We establish *INO80E* (DNA and chromatin biology), *DOC2A* (Ca^{2+}-dependent neurotransmission), *ACE* (blood pressure regulation), *NECTIN2* (T-cell signaling) and *SLC39A13* (zinc transport) as strong mediators of all BMI-T2D-LOAD/dementia. Little is known about the biological function of these genes. In conclusion, we show that the use of proxies and controls leads to heterogeneity in cross-cardiometabolic genetic risk assessment and identify several genetic loci that may mediate the relationship between cardiometabolic disease and LOAD. Our findings provide new insights into the cardiometabolic genetic risk towards Alzheimer's Disease.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1859 Unveiling cell-type-specific molecular signatures in autoimmune diseases

Authors:

T-M. Ko; Natl. Yang Ming Chiao Tung Univ., Taiwan, Hsin-chu, Taiwan

Objective: Systemic lupus erythematosus (SLE) presents a challenge in identifying viable treatment targets due to cellular heterogeneity within immune profiling. Overcoming these challenges by addressing cellular heterogeneity can greatly aid in the identification of exploitable targets for SLE treatment. Methods: In this study, we employed single-cell sequencing and integrative analysis of single-cell transcriptomics to explore cell-type-specific molecular targets associated with SLE within the heterogeneous circulating immune cells across different demographic groups. Results: Through comprehensive computational analysis of single-cell data, we successfully identified potential cell-type-specific molecular targets that are expressed in a particular T-cell subpopulation in SLE. By integrating trajectory inference and intercellular communication profiling, we observed that the specific T cells were activated through OX40 signaling interaction with NK cells in SLE patients. Furthermore, we confirmed the significance of these cell-type-specific molecular targets in SLE by demonstrating that the JAK-STAT signaling pathway predominates as the differential pathway involved in T-cell activation. These findings were consistent across single-cell transcriptomics datasets from two independent adult SLE cohorts, encompassing both Asian and non-Asian populations. Conclusions: Our study highlights the utility of integrative analyses of single-cell multi-omics in guiding and monitoring therapy for lupus patients, especially those undergoing treatment with biologics, particularly JAK inhibitors. By addressing cellular heterogeneity and identifying cell-type-specific molecular signatures, this approach holds promise for the advancement of targeted therapies in SLE and potentially other autoimmune diseases.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1860 Unveiling the resilience effect in high-risk Alzheimer's Disease individuals at single-cell resolution

Authors:

Y. Dai[1], X. Li, Female[2], B. S. Fernandes, Female[3], Z. Zhao[4]; [1]UTHlth., Houston, TX, [2]Univ. of Texas HSC at Houston, Houston, TX, [3]UTHlth.at Houston, Houston, TX, [4]Univ Texas HSC Houston, Houston, TX

Background: Alzheimer's disease (AD) is a progressive and debilitating neurological disease that currently affects millions of people in the US and worldwide with enormous societal and economic costs. Despite extensive research efforts, the pathophysiology of AD remains poorly understood, and there is no known cure for the disease. A considerable proportion of elderly people carry a high genetic AD risk, as evidenced by Polygenic Risk Scores (PRS), but evade AD, thus showing a resilience factor to AD. Our previous work also demonstrated that genetic components play their roles in the resilience effect. With the advent of single-cell technology, we have been able to observe the resilient effect of AD in those with cognitively normal (CN) individuals who possess a high PRS load for AD. **Methods:** We adapted single-nucleus RNA-seq data from the Synapse portal (syn2580853), which contains 454 individuals from Religious Orders Study/Memory and Aging Project (ROS/MAP). We obtained the matched whole-genome-sequence (WGS) data from the Synapse portal (syn11724057). LDPred2 was used to estimate the individual's risk by adapting the effect size from Wightman et al., 2022 GWAS summary statistics. We stratified high-risk individuals from the snRNA-seq data and conducted differentially expressed genes (DEGs) analyses for each cell type among high-risk AD and high-risk CN individuals. Lastly, the functional enrichment analysis was applied to identify enriched gene ontology (GO) terms and canonical pathways. **Results:** After we obtained the 407 individuals with matched snRNA-seq and WGS data, we applied LDPred2 to estimate their AD risks and further stratify the high-risk individuals for 20 quantile of top risks, which includes 53 high-risk AD, 15 high-risk CN, as well as 16 mild cognitive impairment (MCI) individuals. We merged the snRNA-seq data and identified distinct distribution differences among cell AD, MCI, and CN in a few cell clusters, such as oligodendrocytes and excitatory neurons. After, we conducted a pair-wise DEG analysis between CN, MCI, and AD. The most significant DEGs with FDR correction are from excitatory neurons (2304 DEGs), oligodendrocytes (1804 DEGs), and microglia (934 DEGs), in AD and CN groups. Interestingly, we found that MCI individuals tend to have expression profiling more similar to AD rather than to CN individuals. The gene set enrichment analyses highlighted a few well-known pathways tau protein binding, and response to oxidative stress, as well as a few new epigenetic modifications and metabolite pathways that related to histidine metabolism and thiolester hydrolase activity.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1861 Using multiple approaches to identify the novel role of trafficking mechanisms underlying epilepsy

Authors:

T. Nagai[1], E. Knapik[2], E. Gamazon[2,3]; [1]Vanderbilt Univ., Nashville, TN, [2]Vanderbilt Univ. Med. Ctr., Nashville, TN, [3]Clare Hall, Univ. of Cambridge, Cambridge, United Kingdom

Epilepsy is a neurological disease that affects millions of people worldwide. The current approach to treating epilepsy focuses on using antiepileptic drugs (AEDs) to control seizure activity. However, despite the availability of various AEDs that have been approved over the past decade, a significant proportion of epilepsy cases remain drug resistant. The development of AEDs has primarily focused on proteins that are direct components excitatory and inhibitory synapses, limiting the targets through which these drugs can reduce seizures. Expanding the repertoire of mechanisms targeted by AEDs would greatly benefit patients with drug-resistant epilepsy. In our study, we employed two different approaches: population genetics and patient data analysis, as well as zebrafish seizure models, to identify and functionally validate novel genes associated with epilepsy. By utilizing a transcriptome-wide association study (TWAS) method called PrediXcan, we identified AP3D1, a component of the AP3 trafficking complex, as being associated with epilepsy. Additionally, analysis of novel rare variants revealed the potential involvement of SEC24C, a protein associated with the COPII protein trafficking complex, in seizure activity. To further investigate these genes we utilized CRISPR-Cas9 to generate zebrafish models with disrupted AP3D1 and SEC24C activity. Our behavioral assay using pentylenetetrazole (PTZ), a seizure-inducing agent, showed that loss of AP3D1 and SEC24C function increased seizure susceptibility in the zebrafish models. Furthermore, analysis using transgenic GCAMP6s zebrafish demonstrated significant alterations in brain activity caused by the disruption of these trafficking proteins, both in a rested state and under PTZ-induced conditions. By combining population genetics, patient data analysis, and zebrafish models, our study provides novel insights into the complex genetic and functional aspects of epilepsy. These findings highlight the crucial role of trafficking mechanisms in seizure susceptibility and epilepsy. Targeting these trafficking proteins could potentially lead to the development of new therapeutic strategies for drug-resistant epilepsy.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1862 † Using plasma proteomics and Mendelian randomization to identify causal proteins for neurological disease

Authors:

L. Belbasis, C. Van Duijn, D. Bennett, R. Walters; Univ. of Oxford, Oxford, United Kingdom

Neurological diseases impose a large economic burden and are a major public health issue. Observational and genome-wide association studies (GWAS) have identified risk factors and genetic variants positively associated with risk of neurological diseases. However, the role of circulating proteins in the development of neurological diseases is under-studied. We have applied a two-sample Mendelian randomization (MR) approach to explore the causal relevance of the plasma proteome to a range of neurological diseases. Non-overlapping *cis* protein quantitative trait loci (pQTLs) were identified from three large proteogenomics studies in populations of European ancestry, for use as instruments for protein abundance in two-sample MR. These were tested for association with neurological diseases in the latest publicly-available GWAS for Alzheimer's disease (AD), Parkinson's disease (PD), Amyotrophic Lateral Sclerosis (ALS) and Multiple Sclerosis (MS). Out of 2,178 unique *cis* pQTLs and 7,788 tested protein-disease associations, 91 associations for 86 proteins were significant at 5% false discovery rate (FDR). Thirty-seven proteins were associated with AD risk, 7 with PD risk, 8 with ALS risk and 39 with MS risk. Five out of the 86 proteins were associated with AD and an additional neurological disease. Enrichment analysis for each outcome for predicted protein-protein interactions (PPIs) in the STRING database identified a greater degree of interactions than expected for proteins associated for both AD and MS. Thirty-four (92%) of the proteins associated with AD and 32 (82%) of the proteins associated with MS were part of a single PPI network. We further tested association of the 86 proteins with brain imaging phenotypes and risk factors of neurological diseases using the two-sample MR approach. Out of 704 protein-brain imaging tests and 371 protein-risk factor tests, 5 and 36 were significant at 5% FDR, respectively. This comprehensive assessment of associations between circulating proteins and neurological diseases identifies proteins that may be potential drug targets for disease management, biomarkers for disease prediction, or mediators of risk factor-disease associations. Ongoing work includes testing for colocalisation of protein and disease GWAS signals, and seeking replication in populations of non-European ancestry.

PB1863 Using rare genetic mutations to revisit structural brain asymmetry

Authors:

J. Kopal[1], S. Jacquemont[2], C. Moreau[3], D. Bzdok[4], K. Kumar[5], G. Huguet[6]; [1]CHU Saint Justine, Montreal, QC, Canada, [2]CHU Sainte justine Res. Ctr., Montreal, QC, Canada, [3]Canada, [4]McGill Univ., Montreal, QC, Canada, [56]CHU Ste justine, Montréal, QC, Canada

Asymmetry between the left and right brain is a key feature of brain organization. Hemispheric functional specialization underlies some of the most advanced human-defining cognitive operations, such as articulated language, perspective taking, or rapid detection of facial cues. Yet, genetic investigations into brain asymmetry have mostly relied on common variant studies, which typically exert small effects on brain phenotypes. Here, we leverage rare genomic deletions and duplications to study how genetic alterations reverberate in human brain and behavior. We quantitatively dissected the impact of eight high-effect-size copy number variations (CNVs) on brain asymmetry in a multi-site cohort of 552 CNV carriers and 290 non-carriers. Isolated multivariate brain asymmetry patterns spotlighted regions typically thought to subserve lateralized functions, including language, hearing, as well as visual, face and word recognition. Planum temporale asymmetry emerged as especially susceptible to deletions and duplications of specific gene sets. Targeted analysis of common variants through genome-wide association study (GWAS) consolidated partly diverging genetic influences on the right versus left planum temporale structure. In conclusion, our gene-brain-behavior mapping highlights the consequences of genetically controlled brain lateralization on human-defining cognitive traits.

PB1864 Using RNA-sequencing to investigate the rhythmicity of chronic low back pain

Authors:

A. Zacharias[1], H. Gowdy[1], M. Knezic[1], D. Taccardi[1], E. Bisson[2], Q. Duan[1,3], N. Ghasemlou[1,4,5]; [1]Dept. of BioMed. and Molecular Sci., Queen's Univ., Kingston, ON, Canada, [2]Kingston Hlth.Sci. Ctr., Kingston, ON, Canada, [3]Sch. of Computing, Queen's Univ., Kingston, ON, Canada, [4]Dept. of Anesthesiology & Perioperative Med., Queen's Univ., Kingston, ON, Canada, [5]Ctr. for NeuroSci. Studies, Queen's Univ., Kingston, ON, Canada

Chronic low back pain (CLBP) is highly prevalent and contributes to the most years lived with disability worldwide. CLBP has been shown to vary in intensity throughout the day; however, these effects remain unclear at the molecular level. The aim of this study is to investigate how pain rhythmicity affects outcomes and its underlying mechanisms. Based on self-reported daily pain rhythmicity, 60 participants expressed 4 phenotypic pain patterns: constant low, constant high, rhythmic↑, and mixed. We sought to identify gene expression differences across the 4 clusters using RNA sequencing of peripheral blood cell samples taken at 8:00 and 20:00 (n=116). Sequencing reads were processed with *FastQC*/*MultiQC, Hisat2*, and *StringTie*. Normalization and outlier detection were performed using *edgeR* and *arrayQualityMetrics.* Transcripts were kept if their median absolute deviation was ≥ the 70th quantile (0.054), leaving 104,246 remaining transcripts. *edgeR* identified differentially expressed transcripts (DETs; Bonferroni-adjusted p-values < 0.05) between the rhythmic↑ participants vs. any other phenotypes, adjusted for sequencing batch, sex, and participant ID. Next, we used weighted gene co-expression analysis (*WGCNA* in R) to find co-expressed transcripts associated with pain rhythmicity. Finally, we performed pathway enrichment analysis on DETs and transcripts modules with *gprofiler2*. We identified 214 differentially expressed transcripts between rhythmic↑ and any other phenotype. These transcripts are enriched in the REAC neutrophil degranulation and GO:CC azurophil granule categories (adj. p-value < 0.05). Furthermore, 55 transcripts were differentially expressed in blood collected at day versus night in the rhythmic↑ cohort. These transcripts are enriched for GO categories related to podosomes and regulation of double-strand break repair via homologous recombination (adj. p-value < 0.05). Additionally, we identified 79 and 68 modules of co-expressed transcripts in the day and night networks, respectively. Of these modules, 2 day and 4 night modules were associated with the rhythmic↑ phenotype (GLM p-value < 0.05). These clusters were enriched in T-cell migration, neutrophil degranulation, and mRNA modification pathways (adj. p-value < 0.05). Results from our study suggest that neutrophils, among other immune cells, are important regulators of pain rhythmicity in people with CLBP. This supports previous findings that neutrophil activation contributes to pain chronicity and suggests that neutrophils may be a potential target for intervention in CLBP.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1865 Uterine fibroids causes and consequences: Using mendelian randomization to establish directionality between fibroids and associated genitourinary and neoplasm phecodes

Authors:

J. Piekos[1], H. M. Seagle[1], J. N. Hellwege[2], N. K. Khankari[2], T. L. Edwards[2], D. R. Velez Edwards[2]; [1]Vanderbilt Univ., Nashville, TN, [2]Vanderbilt Univ. Med. Ctr., Nashville, TN

Uterine fibroids (UF) are benign monoclonal tumors of the uterine myometrium that are present in 70 - 80% of biological females. Despite being the most common pelvic tumor in females, research has yet to fully uncover the etiology and the downstream consequences of UF. Previously, we have performed a phenome-wide association study (PheWAS) in Vanderbilt's BioVU to identify phecodes associated with UF in the clinical phenome. We identified 24 and 28 unrelated phecodes in the genitourinary and neoplasm categories respectively to focus on. Here was assign directionality to these relationships using two sample Mendelian Randomization (MR). Genetic instruments for MR were selected from the Finngen Cohort for UF and the genetic instruments for the tested associated phecodes were selected from the UK BioBank. SNPs for analysis were selected by linkage disequilibrium clumping genome-wide significant ($p < 5x10^{-8}$) variants using an r^2 threshold = 0.01. With UF as exposure, 10 genitourinary and 12 neoplasm phecodes were significant consequences of UF (P value < 0.05). The top phenotypes identified as consequences of genetic UF exposure were endometriosis OR = 1.30 (95% CI = 1.22 - 1.38, P value = $3.05x10^{-17}$) and ovarian cysts OR = 1.20 (95% CI = 1.14 - 1.26, P value = $1.81x10^{-12}$) from genitourinary and lipoma OR=1.16 (95% CI = 1.10 - 1.22, P value = $1.01x10^{-7)}$ and benign neoplasm of skin OR = 1.12 (95% CI = 1.07 - 1.16, P value=$1.19x10^{-7}$) from the neoplasm category. Two genitourinary phenotypes were found to be causal towards UF with MR. They were hemangioma and lymphangioma OR = 1.15 (95% CI: 1.10 - 1.21, P value=$1.86x10^{-10}$) and polyp of female genital organs OR = 1.34 (95% CI = 1.11 - 1.60, P value = 0.002). We observed horizontal pleiotropy between UF and breast conditions, congenital or related to hormones OR = 1.40 (95% CI = 1.13 - 1.74, P values = 0.003) using the MR Egger method. The egger intercept of the model was significant (P value = 0.01). Understanding the directionality of the relationships between UF and other phenotypes can be leveraged to help understand the etiology of disease, identify novel risk factors, assist in prioritizing females of UF interventions, and intervene to prevent downstream consequences.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1866 Utilizing genetically determined retinal thickness to link to the risk and Age-at-Onset of Alzheimer's disease.

Authors:

Q. Fan[1], J. La[2], X. Liu[3], E. Martin[4], Y-J. Li[2]; [1]Ctr. for Quantitative Med., Duke-NUS Med. Sch., Singapore, Singapore, [2]Duke Univ., Durham, NC, [3]Dept. of Statistics and Data Sci., Natl. Univ. of Singapore, Singapore, Singapore, [4]Univ. of Miami Miller Sch. of Med., Miami, FL

Objective: Retinal thickness, as measured by optical coherence tomography (OCT), has emerged as a potential non-invasive biomarker for Alzheimer's disease (AD). This study aims to investigate the association between genetically determined individual retinal layer thickness with both risk and age-at-onset (AAO) of AD. **Methods:** Genome-wide association studies were performed for 10 retinal thickness measurements obtained from spectral-domain OCT, including the retinal nerve fiber layer (RNFL), inner nuclear layer (INL), ganglion cell-inner plexiform layer (GCIPL), ISOS-RPE layer, and others from 67,280 European participants with both retinal layer thickness and genotype data from UK Biobank. The pooled AD dataset from 20 ADGC cohorts was used as the testing dataset (9,219 cases and 19,564 controls) (Li et al. 2023). Polygenic scores (PGS) for each retinal layer thickness were constructed using PRSice. The Association of PRS with AD risk was tested by the multivariable generalized linear mixed model. For AAO of AD, a multivariable linear mixed model was performed. Both models adjusted for sex, (age), and population structure (principal components 1-10) and accounted for the cohort with a random intercept. A significance threshold of P< 0.005 was used. **Results:** The PRS for thinner RNFL showed the strongest association with an increased risk of AD (OR(95% CI)=1.05 (1.02, 1.08), P=9.9E-04) and nominal association with decreasing AAO of AD (P=0.028). Interestingly, increasing INL thickness showed an association with early AAO of AD (beta(SE)=-0.24(0.07); P=9.3E -04) but not with the risk of AD (P=0.145). The thinner photoreceptor layer and ISOS-RPE layer were associated later onset of AD (beta(SE)=0.20(0.07), P=0.005) but the association with AD risk was not strong (P=0.018). **Conclusion:** Overall, genetic predictors of thickness in RNFL, INL, and ISOS-RPE layers demonstrated the most significant associations with AD or AAO of AD. These findings support the potential utility of retinal layer thickness as a non-invasive biomarker for AD risk assessment and early detection.

PB1867 Utilizing Long-read Sequencing to Decipher the Phenotypic Heterogeneity in Motor Neuron Diseases

Authors:

A. Jain[1,2], E. Udine[1,2], N. A. Finch[1], J. Wuu[3], A. Cooley[3], J. P. Hernandez[3], M. DeJesus-Hernandez[1], A. White[1], E. P. Pioro[4], J. Heckmann[5], T. Burns[6], J. Statland[7], J. Caress[8], J. Trivedi[9], J. Ravits[10], C. Jackson[11], L. Elman[12], C. McMillian[12], A. Swenson[13], S. Maiser[14], J. McCauley[3], R. Rademakers[1], G. Wu[15], E. Rampersaud[15], J. Myers[16], J. Taylor[17], M. Benatar[3], M. van Blitterswijk[1]; [1]Mayo Clinic, Jacksonville, FL, [2]Mayo Graduate Sch. of BioMed. Sci., Jacksonville, FL, [3]Univ. of Miami Miller Sch. of Med., Miami, FL, [4]Nothwestern Univ., Cleveland, OH, [5]Univ. of Cape Town, Cape Town, South Africa, [6]Univ. of Virginia, Charlotteville, VA, [7]Kansas Univ. Med. Ctr., Kansas city, KS, [8]Wake Forest Sch. of Med., Winston-Salem, NC, [9]UT Southwestern Med. Ctr., Dallas, TX, [10]Univ. of California San Diego, San Diego, CA, [11]Univ. of Texas Hlth.Sci. Ctr. San Antonio, San Antonio, TX, [12]Univ. of Pennsylvania, Philadelphia, PA, [13]Univ. of Iowa, Iowa City, IA, [14]Hennepin County Med. Ctr., Minneapolis, MN, [15]St Jude Children s Res. Hosp., Memphis, TN, [16]St. Jude Children's Res. Hosp., Memphis, TN, [17]St Jude Children's Res Hosp, Memphis, TN

Identifying determinants of selective upper motor neuron (UMN) and lower motor neuron (LMN) pathology is crucial for understanding the phenotypic variability in motor neuron diseases and predicting the disease course and outcome. While classic amyotrophic lateral sclerosis (ALS) is known for its variable degrees of UMN and/or LMN dysfunction, primary lateral sclerosis (PLS) and progressive muscular atrophy (PMA) represent extreme phenotypes characterized by pure UMN and LMN involvement, respectively. Given the role of splicing defects in motor neuron diseases, we obtain detailed RNA profiles by capturing full-length transcripts through long-read RNA sequencing. In this study, we used blood specimens from age- and sex-matched individuals clinically diagnosed with PLS (n=2), classic ALS (n=20), or PMA (n=17) from the PGB (Phenotype-Genotype-Biomarker, NCT02327845) study of the CReATe (Clinical Research in ALS and Related Disorders for Therapeutic Development) Consortium. RNA was extracted using the Qiagen PAXgene Blood RNA extraction kit, and specimens with an RNA integrity number (RIN) of more than 7 were included. Long-read RNA sequencing (Iso-Seq method) was performed on the Sequel II platform (Pacific Biosciences) at Mayo Clinic's Genome Analysis Core. Transcriptomic data was analyzed using a custom workflow that incorporates various tools (pbmm2, isoseq3, cDNA cupcake, SQANTI3, Integrative Genomics Viewer, etc.). In total, we obtained roughly one million reads per individual. The average read length was about 2.5 kb, demonstrating our ability to produce long reads. We detected over 18,000 genes with more than 300,000 unique transcripts. Transcripts were classified into major structural categories including full-splice matches, incomplete splice matches, and novel transcripts, among others. Our preliminary analysis of over 50 ALS-linked genes showed significant differences (e.g., *C9orf72* and *TARDBP*), providing insight into drivers of UMN and/or LMN dysfunction. Therefore, our novel long-read sequencing approach in a well-characterized clinical cohort of patients with PLS, classic ALS, and PMA should assist in identifying some of the biological underpinnings of the phenotypic heterogeneity of these diseases, which vary not only in the relative degree of UMN versus LMN pathology, but also with respect to rates of progression and survival. This can facilitate the search for much-needed biomarkers and/or disease modifying therapies.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1868 Validation study of the AD8 and Clinical Dementia Rating Scale for a Samoan speaking population.

Authors:

R. Hansen[1], J. Tavana[1], B. Vaitohi[1], C. S. Pakalani[1], T. D. Packard[1], A. T. Perez[1], F. Matthes[1], S. Polaapau[1], S. F. Funaki[1], T. N. G. Tavana[1], J. T. Tschanz[2], J. S. K. Kauwe[3], P. G. Ridge[1]; [1]Brigham Young Univ., Provo, UT, [2]Utah State Univ., Logan, UT, [3]Brigham Young Univ, Provo, UT

Alzheimer's Disease (AD) is the most common form of dementia, yet diagnosing AD is challenging, especially for individuals who are not native English speakers. Approximately 250,000 Samoans live in the USA (including many in American Samoa, an American territory) and are the second fastest-growing race in the USA. Yet, Samoans are underrepresented in virtually every medical dataset, including AD datasets. The Clinical Dementia Rating Scale (CDR) and the AD8 are standard tools for staging dementia. Many Samoans are bilingual but speak Samoan more comfortably than English, especially the elderly. There are no Samoan language AD diagnostic tools, and English-based assessments require a nuanced understanding of English, which is challenging for non-native speakers. This work aimed to develop Samoan versions of the CDR and the AD8.

A professional translator translated the CDR and AD8 into Samoan. We administered the tests to a focus group of 10 Samoans to evaluate cultural relevance and clarity, and measured the semantic equivalence to the validated English versions of the CDR and AD8. Finally, a second professional translator and bilingual psychologist back-translated the tests. Each of the validation steps supported the quality of the translations.

Next, we are determining if the Samoan tests accurately determine dementia status. We recruited 50 Samoans, including bi- and monolingual Samoans. The AD8 is complete for all participants, and the CDR and NACC (National Alzheimer's Coordinating Center) neuropsychological battery assessments are ongoing. A neuropsychologist and neurologist independently evaluate the assessments to determine the presence or absence of dementia. Consistent outcomes from the different tools and the evaluators confirm the accuracy of the Samoan language versions. So far, our data demonstrate that the Samoan versions are effective. We will present the final results at the conference.

Our broad objective is to build more ethnically diverse AD cohorts and reduce the health disparities in Samoans and Pacific Islanders. This study is an essential first step.

PB1869 Variant-enhancer-gene mapping at the 9p21 locus in smooth muscle cells reveals new enhancer-gene pairs for coronary artery disease

Authors:

M. Ramste[1], C. Weldy[1], D. Li[1], D. Sharma[1], A. Ranta[1], D. Amgalan[2], E. Jagoda[3], G. Qin[1], A. Gschwind[4], T. Nguyen[1], J. Engreitz[5], C. Park[1], T. Quertermous[1]; [1]Div. of Cardiovascular Med., 300 Pasteur Drive, Falk CVRC, Stanford, CA 94305, USA, Stanford, CA, [2]Dept. of Genetics, Stanford Univ. Sch. of Med., Stanford, CA, USA, Stanford, CA, [3]Harvard Univ, Cambridge, MA, [4]Dept. of Genetics, Stanford Univ. Sch. of Med., Stanford, CA, USA, Stanford, Switzerland, [5]3Dept. of Genetics, Stanford Univ. Sch. of Med., Stanford, CA, USA, Stanford, CA

The majority of variants identified by genome-wide association studies (GWAS) that influence coronary artery disease (CAD) risk reside in noncoding regions of the genome. Thus, it is challenging to link them with the genes they regulate and the gene regulatory networks that they form. A deeper understanding of how genetic variation in noncoding regions, and especially in enhancers, can be linked to causal genes will help uncover fundamental mechanisms in coronary artery disease. Enhancers are cell type specific, and vascular smooth muscle cells (SMC) are known to have the highest heritable risk in CAD and play a major role in the atherosclerotic plaque formation. The 9p21.3 locus is the most impactful genetic risk locus for CAD. Although some studies have shown that SMC are the causal cell type for CAD risk at this locus, the causal gene and molecular mechanism of genetic risk are poorly understood.

Here, we report efforts to systematically map SMC specific enhancers to neighboring genes within the 9p21.3 locus in human immortalized SMC by implementing single cell CRISPRi enhancer screens.First, we intersected CAD GWAS loci with human coronary artery SMC (HCASMC) ATAC-seq and H3K27ac ChIP-seq datasets to focus on the disease relevant SNPs that fall within active enhancer regions in SMC. This analysis identified 27 SNPs in 11 enhancers, and single guide RNAs were designed to target the summit of each enhancer using the CRISPRiTiling tool. Pooled lentiviral guides, including negative and positive controls were introduced into animmortalized HCASMC line stably expressing dCas9-KRAB. Perturbed cells were collected at 5- and 10- days post transduction. To enable detection of weak effects and lowly expressed genes, we employed the targeted Perturb-seq (TAP-seq) approach for library generation and sequencing.

We identified several enhancer-gene -pairs, including a strong enhancer-gene connection to both *CDKN2A* and *CDKN2B*. Additionally, we identified multiple enhancer regions that control *MTAP* expression, with smaller but significant effects. We followed up with individual validation of enhancer-gene pairs through qPCR. Furthermore, these results are consistent with chromosomal interaction data obtained from our previous HiChIP.Our results identify new variant to gene links and how the genetic risk in 9p21 is mediated in the vascular wall, provides new understanding of enhancer-gene pairs regulating *CDKN2A* and *CDKN2B*, suggests a novel mechanism of 9p21.3 disease risk through *MTAP* and provides an important discovery platform through which CRISPRi screens can be used to discover causal mechanisms of disease.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1870 Variants Detected in Mitochondrial DNA D-loop in Iranian Patients with Non-alcoholic Fatty Liver Disease

Authors:

S. Kamfar; Pediatric Congenital Hematologic Disorders Res. Ctr., Res. Inst. for Children's Hlth., Shahid Beheshti Univ. of Med. Sci., Tehran, Iran, Tehran, Iran, Islamic Republic of

Background: Non-alcoholic fatty liver disease (NAFLD) is a growing chronic liver disease with unknown etiology which in advanced stages, can be life-threatening. There is a substantial body of evidence that mitochondrial dysfunction due to its impact on hepatic lipid homeostasis, cytokine release, ROS production, and cell death, contributes to the pathogenesis of NAFLD. Therefore, we aimed at comparing mitochondrial D-loop sequence variations in liver tissue samples of Iranian patients with NAFL and NASH. **Methods**: Liver tissue samples from 38 NAFLD patients (16 patients with NAFL and 22 patients with NASH) were collected. Polymerase chain reaction and direct sequencing were performed to detect sequence variation in two hypervariable regions, HVR1 and HVR2 of the mtDNA D-loop region. Sequences of all individuals were compared with the MITOMAP Database. **Results**: Overall, 87 somatic mutations (32 mutations in HVR2 and 55 mutations in HVR1) were identified in mtDNA D-loop, including 85 single-base substitutions, two deletions, and one single nucleotide insertion. The result showed that the variant numbers in NAFLD patients ranged between 1-14. In this case, the comparison between NAFL and NASH groups showed that the numbers were higher in the NASH group (109 mutations) compared with NAFL (101 mutations), but this difference was not significant ($P > 0.05$). C to T and T to C transitions were the most prevalent single-base substitutions among patients (31 and 38 single-base substitutions, respectively, in the NAFL group). C258T, C271T, A335G, C431A, T482C, C497T, C530T, T16093C, C16111T, A16127C, A16160G, A16163G, A16171T, C16186T, C16218T, A16220C, A16227G, C16239T, C16260T, C16291T, T16298C, T16304C, C16344T, T16362C, G16390A were seen only in NASH group. Furthermore, A16180del and G16035C were detected as novel mutations in the NAFL group and 16220-16221ins C in both groups. Also, no important difference was found in mtMSIs, including D310, mt514-523 (CA)n between NAFL and NASH groups. **Conclusions:** Our results indicate that 16220-16221ins C could be a candidate as a potential new biomarker for NAFLD diagnosis.

PB1871 Variation in mushroom body morphology in cocaine preferring Drosophila Genetic Reference Panel lines

Authors:

A. Ummet, T. Mackay, R. Anholt; Clemson Univ., Greenwood, SC

The mushroom body is a central structure in the Drosophila brain which plays a key role in sensorimotor integration and experience dependent behaviors, including olfactory behavior and memory formation. Kenyon cells and their projections are organized as the alpha, beta, and gamma lobes of the mushroom bodies. Variation in the structure of mushroom body lobes correlates with variation in multiple traits, including sleep, aggression, and lifespan. In this study, I am investigating how naturally occurring genetic variation among lines of the Drosophila Genetic Reference Panel results in variation in mushroom body morphology and whether this variation is correlated with cocaine preference. I use an anti-fasciclin II antibody to visualize the mushroom body and ellipsoid body by confocal microscopy in 20 brains for each genotype, sexes separately. Analysis of three-dimensional reconstructions of mushroom bodies from three cocaine preferring lines and three controls reveal variation in dimensions of the mushroom body lobes. Together with transcriptomic analyses this study will give insights into the relationship between genomic variation, variation in gene expression, brain morphology, and cocaine preference behavior. Based on evolutionary conservation of fundamental cellular processes, insights from the fly model may lead to a deeper understanding of the neurogenetic underpinnings responsible for cocaine addiction in human populations.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1872 Vitamin D genetics: inclusion of residence-based UV exposure reveals novel independent loci in genome-wide association and interaction analyses.

Authors:

R. Shraim[1], J. van Geffen[2], M. van Weele[2], R. McManus[1], L. Zgaga[1]; [1]Trinity Coll. Dublin, Dublin, Ireland, [2]Royal Netherlands Meteorological Inst., De Bilt, Netherlands

Sun exposure has long been established as the major determinant of vitamin D levels in humans. Recent genome-wide studies have identified up to 143 genetic variants linked to vitamin D status, independently and in interaction with sun exposure. The common approach relies on season of blood sampling, dichotomized as summer/winter, as a proxy for UV exposure. In this study, we explore the aetiology of vitamin D status in the UK Biobank cohort, using an exact measure of ambient UV. To capture UV exposure over a period of time, we calculated a weighted UV dose for each participant based on their residence and date of blood sampling. UVB was isolated as the relevant wavelength for vitamin D production, adjusted for cloud cover and the rate of decay of vitamin D in the body. We first carried out a genome-wide association study (GWAS) of 25-hydroxyvitamin-D (25OHD) in 408,820 White British individuals. In addition to age, sex, supplement intake, and population structure (principal components), the regression model was adjusted for the calculated UVB dose. We then carried out a genome-wide gene-environment interaction analysis (GxE) in the same sample where the model additionally included a GxUVB interaction term. The GWAS results identified 54 novel independent variants significantly associated with 25OHD concentration and the GxE analysis identified 37 novel variants. Downstream functional analysis of these variants supports vitamin D involvement in metabolic pathways and hormone and skin phenotypes. Overall, our findings support the importance of accurate environmental exposure measures and accounting for gene-environment interactions in uncovering the genetic architecture of complex traits like vitamin D status.

PB1873 *VRK2* is implicated in stuttering, beat synchronization, and language decline.

Authors:

D. Pruett[1], A. Scartozzi[2], J. Eissman[3], Y. Mekki[1], H. Polikowsky[2], T-C. Wang[2], X. Bledsoe[4], S. Kraft[5], E. Gamazon[6], L. Dumitrescu[1], T. Hohman[1], R. Gordon[1], J. Below[1]; [1]Vanderbilt Univ. Med. Ctr., Nashville, TN, [2]Vanderbilt Univ., Nashville, TN, [3]Vanderbilt Memory & Alzheimer s Ctr., Nashville, TN, [4]Vanderbilt Univ., Pleasant View, TN, [5]Wayne State Univ., Detroit, MI, [6]VUMC Clare Hall, Univ. of Cambridge, Nashville, TN

Stuttering is a neurological speech condition characterized by syllable repetitions, prolongations, and involuntarily pauses. Although the etiology of stuttering is unknown, familial and population-based studies show a strong genetic influence on stuttering risk. A recent study performed eight ancestry- and sex-specific GWAS of self-reported stuttering (n = 99,776 cases; 1,123,019 controls) and found *VRK2* to span the top two hits in the European-ancestry male cohort. *VRK2* was also recently implicated in independent GWAS investigating musical beat synchronization, functional language connectivity, and language decline in Alzheimer's Disease (AD). These findings are especially compelling considering the role rhythm perception and language play in stuttering: rhythm discrimination is below average in adults and children who stutter and a recent meta-analysis found that children who stutter exhibited significantly lower language scores.

Given the overlapping GWAS findings implicating *VRK2* and the involvement of rhythm and language in the development of stuttering, our study examines how *VRK2* may be related to speech, language, and musicality phenotypes.

Sentinel SNPs mapping to *VRK2* varied across studies: rs11898834 ($p = 9.990 \times 10^{-10}$) in female AD-related language decline GWAS; rs35609938 ($p = 5.84 \times 10^{-12}$) and rs1040225 ($p = 1.82 \times 10^{-11}$) in the male stuttering GWAS; and rs848293 ($p = 9.23 \times 10^{-18}$) in beat synchronization GWAS. We examined effects at significant SNPs across studies and found alleles associated with increased risk of stuttering were associated with poorer beat synchronization and decreased risk of language decline ($p < .003$ Bonferroni correcting for 4 SNPs across 4 studies). To evaluate the neurophysiological consequences of variation in genetically regulated gene expression of *VRK2*, we utilized NeuroimaGENE, a publicly accessible catalog of neuroendophenotypes derived from transcriptome-wide association studies in 33,000 individuals from UK Biobank. NeuroimaGENE findings revealed that the thalamus and somatosensory cortex, areas involved in processing sensory information, are associated with *VRK2* expression ($p <$ Benjamini-Hochberg correction threshold). Phenome-wide association study of genetically regulated VRK2 expression revealed suggestive associations with neurological and hormonal clinical outcomes, including anxiety, and major depression, and a significant association with congenital anomalies of female genital organs (p = .0000235996). Together, findings from this study may highlight biological mechanisms and implications for VRK2 in speech, language, and musicality related phenotypes.

PB1874 White matter microstructure associations with polygenic risk score for essential tremor in healthy adults

Authors:

A. Pastor[1,2], M. Medeiros[3,4], Z. Schmilovich[2,4], P. A. Dion[4,2], G. A. Rouleau[1,2], A. Dagher[1,2]; [1]Montreal Neurological Inst.-Hosp., Montreal, QC, Canada, [2]McGill Univ., Montreal, QC, Canada, [3]McGill, Montreal, QC, Canada, [4]Dept. of Human Genetics, Montreal, QC, Canada

Intro

Essential tremor (ET) is a common neurological disorder characterized by involuntary upper limb rhythmic movements. ET has a strong genetic basis that may develop via the additive contribution of risk variants of varying frequencies. About 20% of ET liability can be explained by common variants which are incorporated in polygenic risk scores (PRS) that quantify individual risk level (Liao et al. 2022). Separately, white matter tractography, a technique utilizing diffusion-weighted magnetic resonance imaging (DTI) can be used to map the connectivity and integrity of white matter tracts in the brain. In this study we probe the vulnerability of healthy subjects to ET by investigating the association of white matter microstructure with ET PRS

Methods

We paired genetic and imaging data from the UK Biobank to model the associations of ET PRS on brain structure changes. Individual-level genotyping data as well as neuroimaging measures on 31,386 healthy adults were used to correlate genetic risk scores to brain morphometric outcomes. PRS-CS was used to infer SNP posterior effects, which were then combined to generate a PRS for each subject in the cohort using PLINK. Principal component analysis (PCA) was performed to determine ancestry using the 1000 Genomes Project as reference, and those of European descent were retained to limit population stratification. DTI mean diffusion measures (DM) fractional anysotropy, FA, mean diffusivity, MD, and free-water, FW were obtained across 73 anatomically curated tracts in the ORG fiber clustering white matter atlas (Zhang et al., 2018). We performed multiple regression analysis with glmnet (R) for variable selection and cross-validation, and conducted a white matter to grey matter tract crossing and volume analysis

Results

We observed negative associations of ET PRS with FA in motor tracts including the posterior limb of the internal capsule, the corticospinal tract, the motor region of the corpus callosum and the intracerebellar input and Purkinje tracts. We also found converse positive associations with MD and FW for these tracts. Grey matter associations included mainly subcortical structures and the cerebellum. The bilateral putamen, ventral diencephalon, medulla and brainstem were negatively associated with ET PRS after correction by intracraneal volume. Distinct cerebellar regions were also specifically associated with ET PRS (e.g somato-motor, limbic networks)

Summary

These results suggest an involvement of white matter motor tract associations with ET PRS with prevalence of subcortical regions typically involved in motor processing including known cerebellar tracts belonging to distinct motor networks

PB1875 † Whole genome burden testing in 333,100 individuals identifies novel rare non-coding aggregate associations with height that impact *HMGA1* and miRNA expression

Authors:

G. Hawkes[1], R. Beaumont[1], Z. Li[2], R. Mandla[3], X. Li[4], J. Locke[1], N. Owens[1], A. Murray[1], TOPMed Anthropometry - Adiposity Working Group, K. Patel[1], T. Frayling[1], C. Wright[1], A. Wood[1], X. Lin[4], A. Manning[5], M. Weedon[1]; [1]Univ. of Exeter Med. Sch., Exeter, United Kingdom, [2]Dept. of Biostatistics and Hlth.Data Sci., Indiana Univ., Indiana, IN, [3]Programs in Metabolism and Med. And Population Genetics, Broad Inst., Cambridge, MA, [4]Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, [5]Massachusetts Gen. Hosp., Boston, MA

Background/Objectives: Most sequence-based association studies for common human phenotypes have focussed on rare variants that reside in the coding regions of the genome. However, the recent release of whole-genome-sequence (WGS) data in 100,000s of individuals from several studies provides an unprecedented opportunity to examine rare, non-coding variants and their contribution towards the genetic architecture of common traits.
Methods: We performed the largest WGS-based analysis for height using 333,100 individuals from three studies: UK Biobank (UKB, N=200,003), TOPMed (N=87,652) and All of Us (N=45,445). We developed a generalised analytical pipeline with the aim of finding novel rare (<0.1% minor-allele frequency) non-coding genetic associations. We tested 75,311,546 variants which had at least 20 carriers in the UK Biobank, and performed 52,749,161 genomic aggregates tests split into gene-centric (e.g. proximal-regulatory) and non-gene-centric (e.g. intergenic-regulatory), and grouped by measures of conservation, constraint and deleteriousness. Finally, we performed a hypothesis-free 2kbp sliding window analysis. We then assessed the capacity of novel non-coding regulatory variants to modulate transcription factor binding through in-silico motif analysis and confirmation of binding potential with ChIP-Atlas.
Results: We observed evidence ($p<1e-10$) for non-coding aggregate associations proximal to *HMGA1* and *GH1*, and an association downstream of *C17orf49* overlapping mRNA sequence , all of which showed evidence of replication in TOPMed and UKB. Variants in the *HMGA1* aggregate were predicted to impact *FOX* and *CTCF* binding, with effects up to 5cm. We show that leading miRNA aggregate variants lie in crucial binding sites for miRNA-497 and miRNA-195, which have previously been linked to chondrogenesis and bind to *IHH*, which regulates bone growth. We additionally identified rare genetic variants within pri-miR-497 which may affect miRNA expression by regulating the miRNA host-gene (*MIR497-HG*). We also observed 30 independent novel rare variants associated with height, after conditioning on more than 13,000 previously reported loci. We observed effect sizes range from -7cm to +2cm, and replicated three rare single variant associations.
Conclusions: Our approach found novel non-coding associations for height with evidence of impact on gene regulation. Our work provides a template for the analysis of non-coding rare variants for common human phenotypes, and ushers in the next era of genome association studies.

PB1876 Whole Genome Sequencing (WGS) in COVID-19 persistent chemosensory dysfunction: assessing the role of Loss of Function variants (LoFs) in a highly characterized Italian cohort.

Authors:

G. G. Nardone[1], B. Spedicati[1,2], A. Pecori[2], A. Santin[1], A. Morgan[2], M. P. Concas[2], P. Gasparini[1,2], P. Boscolo-Rizzo[1], G. Girotto[1,2]; [1]Dept. of Med., Surgery and Hlth.Sci., Univ. of Trieste, Trieste, Italy, [2]Inst. for Maternal and Child Hlth.– I.R.C.C.S. "Burlo Garofolo", Trieste, Italy

Background: Chemosensory dysfunction can be caused by several pathogens, including common respiratory viruses (i.e. rhinovirus, adenovirus), cytomegalovirus, Zika virus, HIV, and, more recently, SARS-CoV-2. Despite all the knowledge gathered in the last years, to date, the biological and genetic mechanisms underlying COVID-19-derived long-lasting chemosensory alteration are still widely unexplored. In this light, WGS analysis of a large cohort of fully characterised Italian individuals previously diagnosed with COVID-19 was carried out to identify candidate genes involved in persistent chemosensory alterations.
Methods: Olfactory and taste function of 201 individuals (164 cases; 37 controls) was assessed with the extended Sniffin Sticks test and validated Taste Strips. Chemosensory alterations were assessed via self-reporting questionnaires and Visual Analog Scale. All individuals underwent WGS and data was filtered for LoFs with two gene lists obtained, respectively, by literature review and using Ingenuity Pathway Analysis Compare tool: 1) 209 genes known to be involved in olfactory perception/smell loss; 2) 26 genes involved both in recessive immunodeficiencies and COVID-19. Linear and logistic regression models for three groups (males, females, sex-combined) and burden tests were performed to investigate the association between LoFs and chemosensory phenotypes.
Results: Our preliminary analyses highlighted the association of several genes involved in immune response with odor discrimination: *CD3G* (p-value: 0.048) in the sex-combined group, *IFNGR2* (p-value: 0.046) and *PPARG* (p-value: 0.046) in the female group and *CFI* in both the sex-combined (p-value: 0.048) and the female (p-value: 0.046) groups. Moreover, complement factor *C3* (p-value: 0.046) and olfactory receptor *OR4E1* (p-value: 0.044) genes were significantly associated, respectively, with olfactory and taste alteration in the male group. Finally, burden test highlighted the association of List 1) genes with taste alteration (p-value: 0.046) and nasal patency (p-value: 0.031) in males, while genes List 2) genes were significantly associated with parosmia in the sex combined (p-value: 0.049) and in the female group (p-value: 0.025).
Conclusions: Here, for the first time, a large cohort of patients, fully characterised through a comprehensive psychophysical evaluation of smell and taste, have been analysed using WGS. The results of this study highlight the unexplored role of LoFs in the determination of COVID-19-derived long-lasting chemosensory alteration, pointing out possible candidates to be targeted in future personalized treatments.

PB1877 Whole Genome Sequencing (WGS) Meta-analysis identifies Loci Associated with Non-alcoholic Fatty Liver Disease (NAFLD) across ancestries

Authors:

C. Raut[1], Y. Chen[1], A. Oliveri[1], M. F. Feitosa[2], J. R. O'Connell[3], K. A. Ryan[3], J. I. Rotter[4], S. S. Rich[5], K. A. Young[6], A. Hakim[7], P. A. Peyser[8], L. F. Bielak[1], M. T. Long[9], C-T. Liu[10], E. K. Speliotes[11], N. D. Palmer[12], NHLBI Trans-Omics for Precision Medicine (TOPMed)Consortium, Genetics of Obesity and Liver Disease (GOLD) Consortium; [1]Univ. of Michigan, Ann Arbor, MI, [2]Washington Univ Sch Med., Saint Louis, MO, [3]Univ. of Maryland-Baltimore, Baltimore, MD, [4]Lundquist Inst., Harbor-UCLA Med Ctr, Torrance, CA, [5]Univ. of Virginia, Scottsville, VA, [6]Univ. of Colorado Anschutz, Aurora, CO, [7]Brigham and Women's Hosp. and Harvard Med. Sch., Boston, MA, [8]Univ Michigan, Ann Arbor, MI, [9]Boston Univ. Sch. of Med. and Novo Nordisk a/S, Boston, MA, [10]Boston Univ. SPH, Boston, MA, [11]Univ. of Michigan Med. Sch., Ann Arbor, MI, [12]Wake Forest Sch. of Med., Winston-Salem, NC

Background: Non-alcoholic fatty liver disease (NAFLD) affects about 30% of individuals in the United States. There are few effective treatments for the disease due to a lack of understanding on its causes. NAFLD is heritable and previous genome-wide association analyses mostly in individuals of European ancestry have identified multiple common variants that associate with the disease. These common variants however explain about 20% of the heritability of the disease suggesting that more variants that affect the disease exist and remain to be discovered. NAFLD prevalence is also higher in individuals of Hispanic/Asian ancestry than in European or African ancestries. This difference in prevalence is mostly due to genetic differences in these groups. To better understand the genetic underpinnings of NAFLD, we conducted the largest-to-date multi-ancestry whole genome sequencing (WGS) association study of NAFLD.
Methods: We carried out study-, ethnic/race- and sex-stratified association analyses in six cohorts with imaging-measured hepatic steatosis using SAIGEgds adjusted for age, sex (where appropriate), alcoholic drinks per week, and principal component estimates of admixture. Study results were meta-analyzed overall and through male- and female-only using a fixed-effects meta-analysis in METAL. Cochran's Q test and the I^2 metric were used to identify and quantify heterogeneity.
Results: The overall meta-analysis included 16,664 individuals including individuals of European, African American, Hispanic, and Chinese American ancestries with imaging-measured hepatic steatosis. The overall meta-analysis identified three variants significantly associated ($P \leq 5E-08$) with NAFLD, i.e. *PNPLA3, HAPLN4, PPP1R3B.* An additional 12 variants trended toward association ($P \leq 5E-07$). The sex-stratified meta-analysis revealed that the PNPLA3 and PPP1R3B variants were more strongly associated in females. In addition, variants in HAPLN4 and TMTM120B were identified in male- and female-only analyses, respectively.
Conclusions: In a large, multiethnic analysis of imaging-measured hepatic steatosis, we replicated loci previously associated with NAFLD and identified new sex-specific loci. Several variants were trending toward association and will benefit from ongoing analyses to include 6,492 additional samples with imaging-measured steatosis.

PB1878 Whole Genome Sequencing Analysis of Weight Loss in Chronic Obstructive Pulmonary Disease in Trans-Omics for Precision Medicine

Authors:

A. Rocco[1], J. Chiles[1], W. Labaki[2], E. Wan[3], M. Han[2], R. Bowler[4], S. Christenson[5], L. Lange[6], Y. Gao[7], B. Psaty[8], S. Gharib[9], X. Guo[10], S. Rich[11], G. O'Connor[12], M. Wells[1], R. Patel[1], R. Casaburi[13], H. Rossiter[10], H. Tiwari[14], M-L. Mcdonald[15]; [1]Univ. of Alabama at Birmingham, Birmingham, AL, [2]Univ. of Michigan, Ann Arbor, MI, [3]Brigham & Women's Hosp, Boston, MA, [4]Natl. Jewish Hlth., Denver, CO, [5]Univ. of California, San Francisco, CA, [6]Univ Colorado Denver, Aurora, CO, [7]Univ. of Mississippi Med. Ctr., Jackson, MS, [8]Univ. of Washington, Seattle, VA, [9]Univ. of Washington, Seattle, WA, [10]The Lundquist Inst., Torrance, CA, [11]Univ. of Virginia, Scottsville, VA, [12]Boston Univ., Boston, MA, [13]Univ. of California, Los Angeles, CA, [14]Univ Alabama at Birmingham, Birmingham, IN, [15]Univ. of Alabama of Birmingham, Birmingham, AL

RATIONALE: Weight loss (WL) in chronic obstructive pulmonary disease (COPD) is associated with increased mortality. Identifying genetic variants associated with WL in COPD may help identify causal pathways as possible therapeutic intervention targets. Our prior genome-wide association study of WL in COPD utilized affinity chip data, but whole genome sequencing (WGS) data is now available for analysis, yielding opportunities for increased cohort size and genomic resolution.
METHODS: We utilized data from seven studies within the Trans-Omics for Precision Medicine initiative: the Cardiovascular Health Study (CHS); Genetic Epidemiology of COPD (COPDGene); Evaluation of COPD Longitudinally to Identify Predictive Surrogate End-points (ECLIPSE); Framingham Heart Study (FHS); Jackson Heart Study (JHS); Multi-Ethnicity Study of Atherosclerosis (MESA); and the SubPopulations and InteRmediate Outcome Measures In COPD Study (SPIROMICS). All analyses were conducted in 8,628 participants with COPD, where COPD was characterized using spirometry and smoking history. Of these participants, 29.6% had WL of 5% or more between study visits or a body mass index (BMI) of less than 20 kg/m2. WGS analyses, adjusted for age, sex, and principal components of ancestry, were performed using the GENESIS BioData Catalyst pipeline, with participants of African-American (AA) and non-Hispanic white (NHW) ancestries analyzed separately. Fixed-effects meta-analysis was performed using METAL.
RESULTS: Across nine ancestry- and study-stratified cohorts of research participants with COPD, we identified eight variants that reached significant association with WL in COPD across five distinct loci. In COPDGene NHW participants with COPD, two chromosome 12 variants intergenic to LINC02426 and CCDC59 were associated with increased WL risk (OR = 5.74, p = 2.0 x 10-8 for both). In ECLIPSE, two intronic variants in SEPTIN7 on chromosome 7 were associated with increased WL risk (OR = 5.35, p = 3.3x10-8 for both). In FHS, one 3' untranslated region chromosome 1 variant in NR5A2 was significantly associated with WL (OR = 0.136, p = 3.0x10-8). In JHS, one chromosome 2 variant between DOCK10 and NYAP2 was associated with increased WL risk (OR = 15.5, p = 7.7x10-9). Finally, in CHS, two chromosome 3 variants intronic to HHATL were associated with increased WL risk (OR 4.4, p = 2.7x10-8 and OR = 5.1 and p = 3.2x10-8). None of the identified associations remained significant after meta-analysis.
DISCUSSION: We identified five novel loci associated with unintentional weight loss in COPD. Additional efforts are being directed at fine mapping and replication analyses in larger biobanks with genomic data.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1879 † Whole genome sequencing analysis reveals structural variants in the H1/H2 haplotype region and new susceptibility loci associated with progressive supranuclear palsy.

Authors:

H. Wang[1], T. Chang[2], B. Dombroski[1], U. Kumar[2], Y. Leung[1], C. Dalgard[3], D. Dickson[4], L-S. Wang[1], G. Schellenberg[1], D. Geschwind[2], W-P. Lee[1]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Univ. of California, Los Angeles, Los Angeles, CA, [3]Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, [4]Mayo Clinic, Jacksonville, FL

Background: Progressive supranuclear palsy (PSP) is a neurodegenerative disease characterized by the buildup of tau protein in neural cells. Studies have shown that the H1/H2 haplotype region, including microtubule associated protein tau (MAPT), is associated with an increased genetic risk of PSP. But it is challenging to identify new variants and genes or even causal variants and genes in H1/H2 for PSP. **Method:** We analyzed whole-genome sequencing data from 4878 subjects (N_{case} = 1767, $N_{control}$ = 3111). Single nucleotide variants (SNVs) and small insertions and deletions (INDELs) were identified by GATK while structural variants (SVs) were first called using Manta and Smoove and then joint-genotyped using Graphtyper2. Then, an association analysis was conducted on SNVs, INDELs, and SVs to identify variants associated with PSP. Furthermore, we analyzed complex structure of H1/H2 and examined various variants within the haplotype to gain a deeper understanding of the association of H1/H2 and PSP. **Results:** Our analysis of SNVs and INDELs confirmed the association of *MAPT*, *MOBP*, and *STX6* with PSP and revealed two novel genes, *APOE* and *FCHO1*/*MAP1S* ($P < 5 \times 10^{-8}$). Notably, *APOE E2* and *E4* alleles exhibited opposite effects in PSP compared to Alzheimer's disease. In our analysis, *E2* emerged as a risk allele, while *E4* displayed a protective effect against PSP. Additionally, six loci are suggestive of significance ($P < 1 \times 10^{-6}$) in *SLCO1A2*, *DUSP10*, *SP1*, *KIF13A*, *TRIM24* and *TNXB*. Regarding SV, six high-quality SVs showed a significant association with $P < 5 \times 10^{-8}$, including three deletions tagging the H2 haplotype, two insertions in *UCMA* and *RBMS2*, and one deletion in *PCMT1*. Notably, individuals with a homozygous deletion (chr6:149762615-149763234, $P = 6.62 \times 10^{-11}$) in *PCMT1* show an odds ratio of 8.68. Within the H1/H2 haplotype region, we identified 28 CNVs ranging from 80 bp to 47 kb. Six out of seven common CNVs are covered by transposable elements (SVAs, L1s, or Alus), indicating the crucial role of transposable elements in shaping the landscape of this region. The remaining 21 rare CNVs displayed a significantly higher burden in individuals with PSP ($P = 7.94 \times 10^{-4}$). One singleton deletion (chr17:45993882-45993970), which covers exon 9 of *MAPT*, is identified in an individual with PSP. Overall, we helped resolve the genetic basis of PSP by identifying novel variants associated with the disease and potential causal variants within the H1/H2 haplotype region. These findings provide valuable insights for future research into disease mechanism and therapeutic targets.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1880 Whole genome sequencing and proteomic analysis of mucus plugging in COPDGene

Authors:

K. Kim[1], H. Nath[2], S. Grumley[3], J. Orejas[4], W. Dolliver[4], S. Mettler[1], A. Yen[3], K. Jacobs[3], P. P. Manapragada[2], M. Abozeed[2], M. Aziz[2], M. Zahid[2], S. Sonavane[5], Trans-Omics in Precision Medicine (TOPMed), E. Silverman[1,6], R. Bowler[7], A. Diaz[4], M. Cho[1,6]; [1]Channing Div. of Network Med., Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, [2]Dept. of Radiology, Univ. of Alabama at Birmingham, Birmingham, AL, [3]Dept. of Radiology, Univ. of California San Diego, San Diego, CA, [4]Div. of Pulmonary and Critical Care Med., Brigham and Women's Hosp., Boston, MA, [5]Dept. of Radiology, Mayo Clinic, Jacksonville, FL, [6]Div. of Pulmonary and Critical Care Med., Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, [7]Natl. Jewish Hlth., Denver, CO

Introduction:Mucus plugs in smokers with and without COPD are associated with worse lung function and may represent an important treatable trait in airways disease. While genetic risk factors have been identified for symptomatic syndromes associated with mucus plugging (e.g. bronchiectasis), genetic risk factors for CT-identified mucus plugs, which are often asymptomatic, have not been identified. Methods:We performed a whole genome sequencing association study of mucus plugs in 3,433 non-Hispanic white (NHW) and 1,021 African American (AA) individuals in the Genetic Epidemiology of COPD (COPDGene) using data generated from the Trans-Omics in Precision Medicine (TOPMed) study. We calculated lung mucus plugging scores using chest CT scans. We analyzed a dichotomized overall score after adjusting for age, gender, smoking pack-years, current smoking status, sequencing center, and genetic ancestry. We also performed a secondary analysis using the value in each lobe. We investigated genome-wide single variants, loss-of-function rare variants within genes and candidate associations in genes with reported associations for related phenotypes (cough, phlegm, bronchiectasis). We considered a P-value of 5x10-8 for genome-wide significance. We also used SomaScan 1.3k data in a subset of 518 individuals to investigate the association between the trait and proteins. Results:We found no significant associations in the single variant, rare variant, and protein analyses using the binary score for whole mucus plugging. Our top findings in single variant associations were near FAM80B and SLC2A13 (P = < 2 x10-7). In rare variant analysis, the top association for high-confidence loss-of-function rare variants was in HAL (P = 3.84x10-6), while our top protein association was CXCL13 (P = 2.29x10-4). Notably, we did not identify any associations with previously described associations with cough, phlegm, or in other candidate genes associated with bronchiectasis. In a secondary analysis of lobar mucus plugging binary scores, we identified 4 genome-wide significant regions; our top finding was near ZNF407 (8.02x10-9) with other less significant associations near ZNF816, CCSER1, and L3HYPDH. Conclusions: In a whole genome sequencing and proteomic study of mucus plugging, we did not identify genome- or proteome-wide significant associations; nor did we find associations in a set of candidate genes and variants. In a secondary analysis, we did identify associations with lobe-specific values, though their clinical significance remains unclear. Future work will include analysis of quantitative phenotypes and in additional samples.

Session Title: Complex Traits and Polygenic Disorders Poster Session III

PB1881 Whole-exome-widerarevariants analysis detectedgenesassociatedwithpediatric sepsisphenotypewith severe outcome

Authors:

Y. Qin[1], K. Kernan[2], J. Carcillo[2], H. Park[1]; [1]Univ. of Pittsburgh, Pittsburgh, PA, [2]UPMC children Hosp., Pittsburgh, PA

Pediatric sepsis is leading to a global health burden in children. The unavoidable heterogeneity within the patients has hindered the performance of regular treatment. As one of the potential sources contributing to disease heterogeneity, the role of rare variants has not been fully understood. Our previous study identified four phenotypes showing distinct clinical characteristics, cytokine patterns, outcomes, and responses to therapies (PedSep-A, B, C, and D). In this study, we collected whole-exome-wide sequencing data from pediatric sepsis patients from the same cohort and conducted a gene-based analysis to aggregately testassociations between rare variants and pediatric sepsis phenotypes. One whole-exome-wide significant gene (LTBP4) and two suggestive significant genes (PLA2G4E, CCDC157) showed association with PedSep-D, one of the pediatric sepsis phenotypes with the most severe outcomes. Since the genes are implicated for inflammation, immune cell activation, these results implied the influence of rare variants in pediatric sepsis subgroups, enhanced genetics basis of critically ill patients with the disease, and assisted informing more tailored application in precision medicine.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1882 Whole-genome Sequencing Analysis of Body Mass Index in the Trans-Omics for Precision Medicine (TOPMed) Program Identifies Novel African Ancestry-specific Risk Allele

Authors:

X. Zhang[1], J. Brody[2], M. Graff[1], H. Highland[1], N. Chami[3], L. Lange[4], C-T. Liu[5], R. Loos[6,3], K. North[1], A. Justice[7]; [1]Univ North Carolina at Chapel Hill, Chapel Hill, NC, [2]Univ of Washington, Seattle, WA, [3]Icahn Sch. of Med. at Mount Sinai, New York, NY, [4]Univ Colorado Anschutz Med. Campus, Aurora, CO, [5]Boston Univ. SPH, Boston, MA, [6]Univ. of Copenhagen, Copenhagen, Denmark, [7]Geisinger, Danville, PA

Background: Obesity is a global public health crisis associated with high morbidity and mortality rates. Previous genome-wide association studies (GWAS) investigating body mass index (BMI) have primarily relied on imputed data from European individuals. Consequently, most BMI risk variants identified to date are common and in primarily European ancestry populations exhibiting small effect sizes, leaving low and rare variants with potentially large effects largely unexplored.
Methods: This study leveraged whole-genome sequencing (WGS) data from 88,873 participants from the Trans-Omics for Precision Medicine (TOPMed) Program, of which 51% belonged to non-European population groups. We performed GWAS of BMI adjusting for age, age^2, sex, study, population group, principal components, sequencing center, sequencing phase, and project (TOPMed vs. Centers for Common Disease Genomics). We subsequently conducted replication analyses, stepwise conditional analyses, rare variant (MAF $\leq$ 1%) aggregate association analyses, and fine-mapping.
Results: We discovered a total of 18 BMI-associated signals ($P < 5 \times 10^{-9}$), including a novel low-frequency single nucleotide polymorphism (SNP), rs111490516, in *MTMR3* that was common in individuals of African descent (minor allele frequency [MAF] = 13% in African and Barbadian population groups). We successfully replicated this novel SNP and observed directionally consistent associations across replication studies of similar background. In the meta-analysis of 198,621 individuals from both discovery and replication studies, the estimated effect of rs111490516 was 0.037 kg/m^2 with a SE of 0.006 ($P = 4.19 \times 10^{-9}$). Using our diverse study population, we additionally identified two potentially novel secondary signals in known BMI loci (rs2206277 in *TFAP2B* and rs3838785 in *BDNF*) in our conditional analyses and pinpointed two likely causal variants in the *POC5* (rs2307111, posterior probability [PP] = 0.99) and *DMD* loci (rs1379871, PP = 1.00) in our fine-mapping analyses. Finally, we successfully replicated previous gene-based associations with the well-known *MC4R* gene ($P = 8.47 \times 10^{-8}$) by aggregating 111 alleles across 37 sites within coding regions, enhancers, and promoters.
Conclusion: Our work shows the benefits of linking WGS in diverse cohorts for discovering new variants and genes that confer risk for obesity. Ultimately, our study brings us one step closer to understanding the complex genetic underpinnings of obesity, translating these leads into mechanistic insights, and developing targeted preventions and interventions to address this global public health challenge.

Session Title: Complex Traits and Polygenic Disorders Poster Session II

PB1883 Whole-genome sequencing analysis of IgG4-related disease in the Japanese population

Authors:

Y. Zhang, T. Iwasaki, T. Kawaguchi, I. Yamaguchi, M. Takahashi, S. Kawaguchi, F. Matsuda, for the Japanese Research Group of IgG4-Related Disease; Kyoto Univ., Kyoto-city, Japan

Introduction: IgG4-related disease (IgG4-RD) is a rare autoimmune disorder characterized by organ enlargement, tissue infiltration by IgG4+ plasma cells, storiform fibrosis, and elevated serum IgG4 levels. Previously, we identified the *HLA-DRB1* and *FCGR2B* regions as susceptibility loci for IgG4-RD via a genome-wide association study (GWAS) with a single-nucleotide polymorphism (SNP) array. However, the potential involvement of the rare variants and copy number variations (CNVs) in IgG4-RD has not been investigated. **Method:** We performed a GWAS in the Japanese population using whole genome sequencing data (cases, n=732; controls, n=3,148). Associations with the risk of IgG4-RD subtypes, Mikulicz's disease (MD) and autoimmune pancreatitis (AIP), were analyzed. For complement component 4 (C4) CNV analysis, a depth-oriented tool from GATK was utilized to estimate the total copy number (CN) of C4. The estimated CN was further calibrated using known C4 CN data. Next, we determined the ratio of isotypes, C4A and C4B, based on the relative read depths of five C4A/C4B-specific SNPs. We further investigated the association of C4 CNV with IgG4-RD and evaluated its independence from the human leukocyte antigen (HLA) risk alleles. **Result:** We identified a novel locus close to the *PTCH1* region in MD patients. The variant with the lowest *p*-value (the lead variant) was rs66917126, where the presence of the alternative T allele was associated with an increased risk of IgG4-RD (odds ratio (OR), 2.12; $p = 5.18 \times 10^{-9}$). Additionally, the external expression quantitative trait loci (eQTL) data suggested that the T allele of rs35474521, which is in linkage disequilibrium (LD) with the second lead SNP ($r^2 = 0.79$), increased *PTCH1* expression (beta = 0.28, $p = 9.32 \times 10^{-39}$). In patients with AIP, we identified an association of a rare variant (rs544522470) located in the intron of the *DPY19L3* gene. Its alternative A allele increased the risk of IgG4-RD (OR, 7.31; $p = 4.38 \times 10^{-8}$). As for the CNV of C4, we found that individuals with a lower C4A CN and a higher C4B CN had a higher risk of IgG4-RD (p = 0.0047, 0.0145, respectively). We also confirmed their independence from two previously identified HLA risk alleles (*DRB1*04:06* and *DRB1*09:01*) using logistic regression models. **Conclusion:** Based on the whole genome sequencing data, we identified two susceptibility loci and one risk copy number variation for IgG4-related disease. Our findings nominate candidate genes for further exploration and provide novel insights into the etiology of IgG4-RD.

Session Title: Complex Traits and Polygenic Disorders Poster Session I

PB1885 “Age-in-a-dish” model of astrocytes - Can directed differentiation do the trick?

Authors:

M. Carless, U. Bhaskar; Univ. of Texas at San Antonio, San Antonio, TX

Age is undeniably a major risk factor for neurodegenerative diseases, including Alzheimer’s disease (AD), Parkinson’s disease (PD), and other neurological disorders such as epilepsy and stroke. Current estimates predict that at least one in six people will be aged 60 or over by 2030. Astrocytes, the largest group of cells in the brain, and regulators of CNS homeostasis, exhibit dysfunctional synapse regulation, ion dyshomeostasis, neuronal atrophy, synapse loss, and upregulation in neuroinflammatory and oxidative stress response genes with age. Such reactive phenotypes also occur in response to pathological stimuli, and as such, astrocytes are prime candidates in contributing to disease progression. However, few, if any, studies have investigated the relevance of astrocytes to age-related disorders. This is, in part, due to a lack of efficient human model systems that can capture age-associated disease progression. Prior research in neurons has demonstrated that age-associated methylome and transcriptome patterns can be retained following direct conversion from fibroblasts, which bypasses the stem-cell state. Similar strategies in astrocytes have shown inefficient conversion when transforming ***adult*** human fibroblasts. Here, we have developed an efficient direct conversion strategy employing a combination of small molecules to induce trans-differentiation of human adult fibroblasts to astrocytes. We demonstrate that this method produces mature GFAP+/S100B+ cells at high efficiency (40-45%) that are enriched for markers of astrocyte functionality, including ion-channel buffering, gap-junction communication and glutamate uptake; and that these cells exhibit astrocyte-like calcium signaling and neuroinflammatory phenotypes. RNA-Seq analysis indicates an adult rather than fetal astrocytic gene expression signature, with higher relative expression of forebrain-specific markers as compared to hindbrain, ventral, or spinal cord markers. We see evidence of an aged phenotype in our fibroblast-derived astrocytes compared to induced pluripotent stem cell-derived astrocytes via increased reactive oxygen species ($p<0.001$) and increased senescence ($p<0.001$). Future studies will focus on further validation of an aged phenotype through assessing DNA methylation and evaluating "epigenetic age". Our method of generating fibroblast-derived induced astrocytes, provides a useful tool in understanding age-associated disease processes and will be an asset in the study of late-stage brain disorders.

Session Title: Genetic Therapies Poster Session I

PB2001 A case study of a female infant with primary hypertrophic osteoarthropathy demonstrates that early initiation of celecoxib slows but does not prevent symptom progression.

Authors:

K. Zehr[1], M. Buckley[1], J. Owens[2], A. Shillington[3]; [1]Univ. of Cincinnati Coll. of Med., Cincinnati, OH, [2]Cincinnati Children's Hosp., Cincinnati, OH, [3]Cincinnati Children's Hosp., Cincinnatti, OH

Primary Hypertrophic Osteoarthropathy (PHO) is characterized by digital clubbing, periostosis, and pachydermia. HPGD encodes 15-prostaglandin dehydrogenase, which catalyzes the first step of prostaglandin degradation. Loss of function *HPGD* variants cause Primary Hypertrophic Osteoarthropathy Autosomal Recessive 1 (PHOAR1) due to insufficient prostaglandin degradation. Recognizing that PHOAR1 pathology is driven primarily by increased Prostaglandin E2 (PGE2) levels has led to multiple clinical trials exploring the impact of selective COX-2 inhibitors in adults with PHO. Many studies have demonstrated that selective COX-2 inhibitors improve digital clubbing, joint swelling, pachydermia, joint pain/mobility, and inflammatory markers in adults with PHO. In this case study we present a female patient incidentally diagnosed with PHOAR1 due to a likely pathogenic homozygous *HPGD* c.218-1G>A variant at 5 months of age. At presentation, she was noted to have a diffuse erythematous rash secondary to hyperhidrosis, symmetric clubbing of her fingertips, and relatively mild decreased range of motion of bilateral knees and wrists for her age group. By 20 months of age, the bilateral clubbing was more notorious, she had flexion contracture of the knees (~15 degrees), and general signs and symptoms of significant joint pain that limited her ability to play. Six months later, the patient was started on celecoxib, a selective COX-2 inhibitor, and showed improvement but not resolution of her symptoms. This patient's early PHOAR1 diagnosis allowed for a better understanding of the clinical course of PHOAR1 with early initiation of celecoxib, in contrast to previously treated patients who started treatment at an older age with established chronic symptoms. Her case could demonstrate that starting celecoxib early in the course of disease delays but does not stop disease progression, suggesting that fully resolving PHO-related symptoms may go beyond normalizing PGE2 levels through COX-2 inhibition alone.

Session Title: Genetic Therapies Poster Session II

PB2002 A drug repurposing screen reveals dopamine signaling is important for the rare disease DPAGT1-CDG.

Authors:

H. Dalton; Univ. of Utah, Salt Lake City, UT

Glycosylation encompasses a wide class of biological pathways involving co- and post-translational sugar modifications. Mutations in glycosylation genes underlie Congenital Disorders of Glycosylation (CDGs) - ultra-rare disorders that can cause seizures, developmental delay, and early death. There are few treatment options available for CDGs, and small patient populations make clinical trials difficult. Thus, there is a great need for alternative approaches to finding treatments for these rare diseases. One such alternative is the use of drug repurposing screens that utilize libraries of small molecules with established safety profiles in humans, allowing for potentially faster turnaround for patients.

DPAGT1-CDG is caused by mutations in the gene *DPAGT1*, which encodes the essential first enzyme for N-linked glycosylation. We created a model of DPAGT1-CDG in *Drosophila* via *DPAGT1* knockdown in the fly eye to cause a small, rough eye phenotype. This model can be screened for new therapies by quantitatively measuring improvements to its eye size. To find such therapies, we performed a drug repurposing screen using 1,520 small molecules that are 98% FDA/EMA-approved (Prestwick Chemical Library). Drugs were mixed into fly food, flies were exposed until early adulthood, and eye size was compared to control, DMSO-treated flies. The top candidate drugs that rescue, resulting in a larger eye, were validated by dose-response or genetic analyses.

The screen has a 3% hit rate for drugs capable of rescuing the DPAGT1-CDG model eye size ($Z \geq 1.5$). Top drug categories are dopamine receptor D2 (D2R) antagonists, COX inhibitors, and ion transporter-related drugs. Three D2R antagonists were strong hits (Z>1.8, 20%+ eye size). Confirming the role of this pathway, knockdown of the D2R-encoding gene *DRD2*/*Dop2R* could recapitulate this effect (20%+ eye size). This represents a potential new avenue for therapy - especially as seizures and movement disorders are common in DPAGT1-CDG patients. In addition, we genetically validated COX inhibitors through knockdown of the COX-like gene *Pxt* (17%+ eye size), as well as an ion transporter inhibitor through its target encoded by *NKCC1*/*Ncc69* (+12% eye size). All three pathways reveal novel biology related to *DPAGT1* mechanisms, and they may represent new therapeutic, FDA-approved options for DPAGT1-CDG.

Session Title: Genetic Therapies Poster Session III

PB2003 A values typology of underpinning responses to gene editing compared to other means of enhancement

Authors:

c. castelyn[1], W. Van Staden[1], M. Pepper[2]; [1]Univ. of Pretoria, Pretoria, South Africa, [2]Univ Pretoria, Lynnwood, South Africa

Gene editing tools such as CRISPR may be limited to genetic abnormalities that cause disease, however it is inevitable that these technologies will be extended to non-medical applications. This study aimed to uncover what would be perceived as being good, bad, wrong or right about gene editing not only for therapeutic purposes but also for enhancement purposes. The study moves beyond the knee jerk reactions of uneasiness to identify the underpinning value judgements and consequent kinds of values.Data was collected through individual in-depth interviews with eight purposively selected participants. Values-based practice guided the study in recognising the underpinning values. Data was analysed by searching for the value words in the responses, typological coding allowed for the data to be coded according to pre-identified types of values such as good and bad, wrong or right, deontological, societal, cultural and aspirational values.The findings that emerged differentiated between individual and societal perceptions. There was overlap between perceptions about therapeutic and enhancement purposes of gene editing. Gene editing for enhancement could be perceived as being good for personal fulfilment and for humanity's improvement. It would be bad if gene editing were to repeat the past and if some were enhanced at the expense of others. Gene editing would be right if human dignity was upheld. It would be wrong if universal access was unattainable and if it led to people not having the freedom to choose whether to gene edit themselves or their offspring. To account for a wide variety of kinds of values underpinning perceptions of gene editing not only for therapeutic but also enhancement purposes is important so as to inform regulations, frameworks and commissions.

PB2004 Advancing Recombinant Adeno-Associated Virus Vector Integration Analysis through Next-Generation Sequencing Optimization

Authors:

B. Niu, H. Latif, Y. Fan, Y. Zhang, C. Goswami, D. Corney, A. O'Hara, L. Turner, G. Zhou; Azenta US, South Plainfield, NJ

Recombinant adeno-associated viral (rAAV) vectors have seen widespread application as a gene therapy delivery platform in preclinical and clinical studies. Though rAAV largely remains episomal after transduced into the nucleus of host cells, data has shown that rAAV does integrate into the host genome in an undefined, non-homologous manner. The frequency of rAAV integration has been estimated at 0.1 to 10% in hepatocytes. In consideration of the theoretical risk of tumorigenesis associated with rAAV integration in humans, assessment of rAAV integration in *in vitro* studies, animal models and patient samples are recommended by FDA for preclinical and clinical studies and long term follow up studies (LTFU). rAAV integration analysis presents several challenges, including the random nature of rAAV integration sites and low expected integration frequency. To address this, Next-Generation Sequencing (NGS) for rAAV integration analysis has been adopted as a highly sensitive assay. Here we conducted a comparative study analyzing multiple NGS-based methodologies to study rAAV integration, including hybrid capture-based target enrichment sequencing, as well as amplification-based sequencing such as Quantitative Shearing Linear Amplification Mediated-PCR (qsLAM-PCR) and Shearing Extension Primer Tag Selection Ligation-Mediated PCR (S-EPTS/LM-PCR). In addition, we assessed multiple approaches for episomal rAAV genome removal to improve the sensitivity of NGS-based methods. The studies described will drive greater insights into rAAV integration and its impact on patient safety, as well as contribute to improvement and standardization of analysis methods.

Session Title: Genetic Therapies Poster Session II

PB2005 AI for Next-Generation Gene Design

Authors:

D. Gaddes[1], D. Cirillo[2], A. Edwards[1], A. Hott[1]; [1]CFD Res. Corp., Huntsville, AL, [2]The Ohio State Univ., Columbus, OH

To support enhanced healthcare in a post-pandemic landscape, it is scientifically and economically imperative to maximize the expression of protein therapeutics or mRNA vaccines. In pursuit of this objective, we present a codon harmonization technique, powered by AI, resulting in a more than 400% increase in protein expression. In modern healthcare, genomic tools like synthetic plasmids or mRNA are employed to synthesize proteins for therapeutics and vaccines. The design of genes for plasmids or mRNA vaccines involves precisely configuring the nucleic acid sequence to achieve desired outcomes. Traditionally, gene and mRNA design has relied on codon optimization, a computational technique aimed at maximizing protein expression and improving translational efficiency. Codon optimization achieves this by integrating the most frequently utilized codons of the host organism into the synthesized gene or mRNA. However, concerns have emerged regarding the efficiency of codon optimization, leading to the proposal of codon harmonization as an alternative approach. The primary goal of codon harmonization is to reduce protein misfolding while simultaneously improving protein yields. This approach achieves its objective by incorporating host organism-specific codons in the synthetic gene in a proportional manner, resulting in a gene design that closely aligns with the codon utilization of the host organism. Towards creating synthetic genes more like the host organism's, we have developed a generative AI tool to design genes based on learning how the host organism typically encodes DNA for protein production. By employing a transformer model, we successfully uncovered the correspondence between genes from *E. Coli* and highly expressed proteins. Our dataset consisted of over 20,000 gene-protein pairs, enabling the model to learn this relationship. Notably, our AI achieved a 73% accuracy in codon prediction and demonstrated 100% accuracy in amino acid prediction, without any mutations or changes in protein length. A comparative analysis with a commercial codon optimization tool revealed remarkable outcomes for our generative AI. Specifically, our tool yielded a striking 428% increase in COVID nucleocapsid protein expression when using instant induction media. These initial findings provide a glimpse into the potential of AI-driven manufacturing, which holds significant promise in reducing development time and treatment costs. Moving forward, our focus will be on further enhancing protein expression and folding across different host organisms, including CHO cells, while also exploring the application of generative AI in mRNA therapeutics.

Session Title: Genetic Therapies Poster Session III

PB2006 An *in vivo* screen identifies small molecule modulators of the endoplasmic reticulum stress response.

Authors:

K. Beebe, H. Evans, K. Hope, A. Berman, C. Chow; Univ. of Utah, Salt Lake City, UT

Misfolded protein accumulation in the endoplasmic reticulum (ER) induces ER stress. Cells respond to ER stress by initiating the unfolded protein response (UPR) that upregulates chaperone protein expression, increases the degradation of misfolded proteins, and inhibits protein translation. Failure to effectively manage ER stress and restore homeostasis results in cellular dysfunction and ultimately apoptosis, a process implicated in numerous human diseases such as retinal degeneration, Alzheimer's disease (AD), Parkinson's disease (PD), Huntington's disease (HD), and amyotrophic lateral sclerosis (ALS), among others. Identifying small molecules that modulate ER stress may be effective therapeutics for human diseases caused by misfolded protein accumulation. Here, we used a *Drosophila* model of retinitis pigmentosa (RP) that expresses misfolded rhodopsin protein, $Rh1^{G69D}$, in the developing eye. $Rh1^{G69D}$ expression induces chronic ER stress and apoptosis, resulting in a degenerative eye phenotype. We took a drug repurposing approach and used the Prestwick Chemical Library, consisting of 1520 small molecules, the majority of which are FDA-approved, to identify compounds that modulate neuron cell death in $Rh1^{G69D}$ expressing flies. We identified multiple classes of drugs that enhance or suppress the degenerative eye phenotype, including compounds acting through monoamine neurotransmitters, folate metabolism, sodium channels, and the renin/angiotensin pathway. Degeneration-enhancing compounds may reveal novel ER stress pathways, while compounds that suppress degeneration are potential therapeutic candidates for RP. We are using an RNAi approach to identify the mechanism of action for the top enhancers and suppressors. Additionally, we will present data showing that compounds that rescue cell death in the RP model can also rescue disease-associated phenotypes in other *Drosophila* models of protein misfolding diseases, such as PD, HD, and ALS. This work identified potential therapeutic drugs for RP and possibly other human diseases that result from misfolded protein accumulation and ER stress.

Session Title: Genetic Therapies Poster Session I

PB2007 † Androgen and mineralocorticoid receptor signaling are drivers of - and therapeutic targets for - pubertal vascular rupture in Vascular Ehlers-Danlos Syndrome (VEDS) mice.

Authors:

E. Juzwiak[1,2], C. Bowen[1,2], A. Zeng[1,2], H. Dietz[1,2]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Howard Hughes Med. Inst., Chevy Chase, MD

Background: In contrast to females, male patients with VEDS are at particularly high risk of spontaneous death due to arterial rupture during puberty. Our VEDS mouse model (*Col3a1*$^{G938D/+}$) recapitulates this sexually dimorphic vulnerability during puberty, with 49% vs. 66% survival of males vs. females by the end of puberty (60 days of age), respectively.
Methods: Given the male bias, we hypothesized that vascular rupture involved androgen-dependent perturbations of cellular function. We treated *Col3a1*$^{G938D/+}$ mice with the potent and selective AR antagonist (ARa) bicalutamide from weaning until 60 days of age. We also utilized a conditional (floxed) allele for the Ar gene in combination with a globally expressed Cre recombinase allele to create a genetic knock out for the AR in *Col3a1*$^{G938D/+}$ mice. *Col3a1*$^{G938D/+}$ mice were also treated with the dual ARa and mineralocorticoid receptor antagonist (MRa) spironolactone from weaning until 60 days of age. Many VEDS patients only come to medical attention post puberty, so we initiated spironolactone treatment of adult *Col3a1*$^{G938D/+}$ mice that had survived puberty and monitored subsequent survival. Finally, we treated *Col3a1*$^{G938D/+}$ mice with a selective MRa (finerenone or eplerenone) from weaning until 60 days of age.
Results: Deletion of the Ar gene affords improved survival at 60 days of age in male *Col3a1*$^{G938D/+}$ mice compared to their unmanipulated counterparts (80% vs. 49%), a protective performance similar to that observed upon treatment with bicalutamide (70% survival). Notably, male *Col3a1*$^{G938D/+}$ mice treated with spironolactone showed the best performance (88% survival at 60 days). Interestingly, use of either finerenone or eplerenone also afforded significant protection (74% male survival at 60 days with either treatment). The residual enhancement of risk for vascular death during puberty seen with isolated pharmacologic AR or MR antagonism in male VEDS mice is only abrogated upon dual AR/MR blockade, as achieved by spironolactone. Female *Col3a1*$^{G938D/+}$ mice are not afforded protection with isolated AR or MR antagonism; however, they do experience near-complete survival through puberty with spironolactone. Postpubertal treatment with spironolactone afforded complete and durable protection in both sexes.
Conclusions: These data document that pubertal vascular catastrophe in *Col3a1*$^{G938D/+}$ mice of both sexes is dependent on both AR and MR signaling with dramatic protection afforded by dual antagonism. There is therapeutic potential for isolated MR antagonism that will maintain normal sexual development in males transitioning through puberty.

Session Title: Genetic Therapies Poster Session II

PB2008 Cell-based functional assays for screening of drug candidates for Free Sialic Acid Storage Disorder.

Authors:

P. Leoyklang[1,2], M. Hackbarth[1,2], M. S. Sabir[2], K. Dobrenis[3], C. Lion[4], V. Rigolot[4], C. Biot[4], L. Wolfe[2], D. R. Adams[5], W. A. Gahl[1,2], M. C. V. Malicdan[1,2], M. Huizing[1]; [1]MGB, NHGRI, NIH, Bethesda, MD, [2]NIH Undiagnosed Diseases Program, NIH, Bethesda, MD, [3]Dept NeuroSci., Albert Einstein Coll. of Med., Bronx, NY, [4]Université de Lille, CNRS, UGSF, Lille, France, [5]OCD, NHGRI, NIH, Bethesda, MD

Background: Free sialic acid storage disorder (FSASD) is a progressive neurodegenerative disease caused by biallelic mutations in *SLC17A5,* which encodes sialin, the lysosomal sialic acid (SA) exporter. Affected cells exhibit lysosomal storage of free SA. FSASD manifests as a spectrum of clinical severity, and biochemical findings include increased urinary excretion and lysosomal accumulation of free SA. Despite extensive research on SA metabolism, membrane transport, and lysosomal biology, the underlying pathobiology remains poorly understood, and no approved therapies are available. **Methods:** We developed FSASD-specific cellular functional assays to identify potential therapeutic strategies. The primary assay involves live incorporation of alkyne-labeled SA into cells. Alkyne-SA is endocytosed to lysosomes, exported through sialin into the cytosol, and incorporated into glycoconjugates in the Golgi; these are detected using fluorescent click-chemistry and imaging. Secondary assays utilize immunofluorescence to examine distribution of lysotracker, LAMP1, LAMP2, and GM2. Tested FSASD cell lines include mouse embryonic fibroblasts, either deficient in sialin or carrying the prevalent p.Arg39Cys variant, as well as human FSASD primary skin fibroblasts with different *SLC17A5* variants. To further validate the assays, disease cells transfected with *GFP-SLC17A5* were also used. Additional testing was performed with candidate small-molecule drugs known to be applicable for other lysosomal storage diseases, including arimoclomol, genestein, and mercaptoethyguanidine. **Results:** Control cells efficiently incorporated alkyne-SA into glycoconjugates, while FSASD cells showed absent or markedly reduced incorporation due to defective sialin-mediated release of SA from lysosomes. Secondary assays showed increased numbers of small endo-lysosomes, elevated LAMP1, LAMP2, and lysotracker signals, as well as lysosomal GM2 accumulation in FSASD cells. Gene replacement with *GFP-SCL17A5* restored the wild type phenotype. Preliminary testing of candidate small molecule drugs yielded encouraging results, warranting further investigation. **Conclusion:** The FSASD-specific functional assays that we developed demonstrated their utility across different FSASD genotypes and cell types. Gene correction and selected small molecule drugs showed promise in rescuing the cellular phenotype and will be further investigated in our p.Arg39Cys knock-in mouse model. These functional assays hold potential for high-throughput drug screening, offering a valuable tool for identifying disease-modifying therapies for FSASD patients.

Session Title: Genetic Therapies Poster Session III

PB2009 Characterization of a novel mouse model with 35 bp deletion in *Champ1* gene and exploration of AAV gene therapy to correct phenotypic consequences arising from *CHAMP1* mutations

Authors:

T. Carneiro, B. Strenkowski, M. Bakay, H. Hakonarson; Children's Hosp. of Philadelphia, Philadelphia, PA

Introduction: Chromosome alignment maintaining phosphoprotein 1 (CHAMP1) is crucial for kinetochore-microtubule attachment during metaphase in mitosis and for chromosome segregation, process known to be important for neurodevelopment (Hempel et al., 2015; Isidor et al., 2016). Mutations in *CHAMP1* were recently associated with global developmental delay, Intellectual disability, hypotonia and dysmorphic features (Hempel et al., 2015; Tanaka et al., 2016). Reported mutations results in a premature stop codon, loss of protein c-terminal region which is essential for CHAMP1 localization and protein dysfunction. Until now, variants are predicted to cause loss of function resulting in haploinsufficiency (Garrity et al., 2021). We propose a gene therapy treatment using animal model to rescue the phenotype developed due to *CHAMP1* mutations. **Methodology:** In order to mimic *CHAMP1* disfunction, an animal model was created through CRISPR/Cas9 gene editing technology in mouse zygotes where a 35bp deletion was made in *CHAMP1* exon 2. The mouse model was developed using the C57BL/6NCrl strain by the mutant mouse resource and research center at UC Davis. Phenotype characterization is executed through behavior tests (mice with 8-10 weeks old), divided in two batteries: Motor and reactivity battery and cognitive battery. In the first one, information about motor delay, muscular strength and overall health of the mice is obtained with the results from open field, rotarod and catwalk gait test. The second battery provides information about learning ability, memory, and social impairment through the performance of Novel object recognition, acoustic startle response (ASR) and social choice. Upon completion of comprehensive phenotyping of the Champ1 mice, a new cohort is treated with AAV9 vector (Penn vector Core, University of Pennsylvania, Philadelphia, PA, USA) carrying the wildtype copy of *CHAMP1* gene. **Results:** To perform the phenotype characterization, 4 cohorts were submitted for behavioral testes, with 2 cohorts (20 mice) per battery. The offspring that composes those cohorts was generated by a breeding trio (a male heterozygous for *Champ1* deletion and two wildtype B6J females obtained from Jax Lab). Champ1 mice present delay in motor development and impairment in memory and learning abilities. Once this phonotype is confirmed by our studies, a gene therapy using AAV9 will be administered in an attempt to rescue the impairments observed, with the behavioral tests repeated in new cohorts. Molecular measurement of CHAMP1 both at gene and protein levels will be conducted for disease confirmation.

Session Title: Genetic Therapies Poster Session I

PB2010 Characterizing novel *in vitro* systems for the investigation of human post-traumatic fibrosis.

Authors:

J. Palmer[1], N. Cubbage[1], E. Rentschler[2], J. Ferreira de Vasconcellos[1]; [1]James Madison Univ., Harrisonburg, VA, [2]Blue Kick, Westerville, OH

Dangers of modern life, such as automobile crashes, severe burns and orthopedic surgery yield large numbers of traumatic neuromuscular injuries closely associated with the development of post-traumatic fibrosis. Modulation of the local inflammatory response following injury is essential for wound healing, however, severe traumatic injuries initiate an exacerbated response that compromises efficient tissue regeneration and leads to the formation of fibrotic tissue. TGFβ plays an essential role in tissue fibrosis and is highly expressed in human muscle after injury. However, robust *in vitro* systems to investigate the molecular mechanisms underlying human post-traumatic fibrosis are still needed. Here we investigated two *in vitro* culture systems used in a novel way in the investigation of the molecular mechanisms associated with human post-traumatic fibrosis. Bone marrow mesenchymal stem cells (BM-MSCs) were cultured in (i) nanofiber plates, comprised of a 700 nm diameter electrospun polycaprolactone nanofiber matrix randomly oriented and (ii) the Petaka™ cell culture system, designed to perform cell culture in an environment protected from external conditions. BM-MSCs were treated with TGFβ [10 ng/mL] for 48 h as a fibrotic model. Gene expression analysis for the fibrotic genes *ACTA2*, *VIM*, *COL1A1* and *COL3A1* was performed by q-RT-PCR. BM-MSCs treated with TGFβ and cultured in the nanofiber plates demonstrated no changes on *ACTA2* (control: 1.0 ± 0.0; TGFβ: 1.1 ± 0.1) and *VIM* (control: 1.0 ± 0.0; TGFβ: 1.0 ± 0.1), and down-regulation of *COL1A1* (control: 1.1 ± 0.1; TGFβ: 0.6 ± 0.4) and *COL3A1* (control: 1.0 ± 0.0; TGFβ: 0.6 ± 0.1). BM-MSCs treated with TGFβ and cultured in the Petaka™ system demonstrated up-regulation of *ACTA2* (control: 1.0 ± 0.0; TGFβ: 1.6 ± 0.4), *VIM* (control: 1.0 ± 0.0; TGFβ: 1.3 ± 0.2) and *COL3A1* (control: 1.2 ± 0.3; TGFβ: 4.7 ± 4.1), while *COL1A1* (control: 1.4 ± 0.5; TGFβ: 0.8 ± 0.4) was down-regulated. For comparison, BM-MSCs treated with TGFβ and cultured in a regular tissue culture plate demonstrated the up-regulation of the fibrotic genes *ACTA2* (control: 1.0 ± 0.0; TGFβ: 2.1 ± 1.4), *COL1A1* (control: 1.0 ± 0.0; TGFβ: 2.4 ± 1.0) and *COL3A1* (control: 1.0 ± 0.0; TGFβ: 1.4 ± 0.5), while *VIM* (control: 1.0 ± 0.0; TGFβ: 0.9 ± 0.1) remained unchanged. Additional studies need to be performed to validate these systems and understand the biological significance of these findings. Altogether, our current results support the notion that the Petaka™ cell culture system may be used for the *in vitro* investigation of human post-traumatic fibrosis and may be a useful culture system for future translational studies.

Session Title: Genetic Therapies Poster Session II

PB2011 Characterizing the role of the *IGF2BP1-3* genes during human osteogenic differentiation.

Authors:

E. Melton, L. Robinson, H. Cole, X. Yin, N. Omandan, N. Cubbage, J. Palmer, J. Ferreira de Vasconcellos; James Madison Univ., Harrisonburg, VA

Hazards of modern life, such as automobile crashes associated with a bone fracture or dislocation yield large numbers of traumatic neuromuscular injuries closely associated with the development of post-traumatic ectopic bone, where extraskeletal bone is formed in muscle and soft tissues. *Let-7* miRNAs are known to be upregulated in the muscle tissues of patients that formed ectopic bone compared to patients who did not develop ectopic bone after injury. Here we characterized the expression of *let-7* miRNAs and the insulin-like growth factor 2 binding protein genes (*IGF2BP1*, *IGF2BP2* and *IGF2BP3*), known targets of the *let-7* miRNAs, during human *in vitro* osteogenic differentiation and hypothesized that the *IGF2BP1-3* genes may play a role in human bone formation. Bone marrow mesenchymal stem cells (BM-MSCs) were induced to osteogenic differentiation for 14 days. BM-MSCs cultured in conventional growth media were used for comparison. RNA was harvested at the timepoints day 0 (before osteogenic differentiation), and days 7 and 14 of osteogenic differentiation. Gene expression was investigated by q-RT-PCR. *Let-7a*, *let-7d* and *let-7f* were upregulated at osteogenic differentiation day 14 to levels that did not reach statistical significance (p=.281, p=.200 and p=.192, respectively). *IGF2BP1* and *IGF2BP2* were significantly downregulated at osteogenic differentiation day 14 (p=.002 and p=.015), while *IGF2BP3* remained unchanged (p=.319). As expected, the osteogenic marker *ALP* was upregulated at days 7 and 14 (p=.007 and p=.012, respectively) during osteogenic differentiation. Knockdown of the *IGF2BP1* (BP1-KD), *IGF2BP2* (BP2-KD) and *IGF2BP3* (BP3-KD) genes were performed in BM-MSCs followed by 14 days of osteogenic differentiation. A scramble control was used for comparison. RNA was harvested at timepoints day 0 (48 h after transfection, but prior to osteogenic differentiation), and days 7 and 14. Gene expression was investigated by q-RT-PCR and alizarin red staining was performed to identify calcium deposits at day 14. Knockdowns were confirmed 48 h after transfection. Following BP1-KD and BP2-KD, the osteogenic gene *ALP* was upregulated at day 7 (p=.03 and p=.49, respectively) and day 14 (p=.09 and p=.10, respectively) compared to controls. Following BP3-KD, no significant effects were observed in the expression of osteogenic genes (osteocalcin, *ALP* and *CBFA1*) at days 7 and 14. Finally, we observed more calcium deposits in the BP1-KD compared to controls, while no differences were observed in the BP2-KD and BP3-KD compared to controls. Overall, these results support the notion that the *IGF2BP1* gene may play a role during human osteogenic differentiation.

Session Title: Genetic Therapies Poster Session III

PB2012 Clinical and translational studies in in-vitro and an *in-vivo* mouse model of a unique HSPB8 associated vacuolar myopathy.

Authors:

A. Shmara[1], L. Weiss[1], P. Pal[1], B. Tedesco[2], H. Zhang[1], P. Farahat[1], V. Boock[1], M. Wu[1], A. Panchagatti[1], S. Metwali[1], A. Villalta[1], X. Xu[1], A. Poletti[2], V. Kimonis[1]; [1]Univ. of California, Irvine, Irvine, CA, [2]Università degli Studi di Milano, Milano, Italy

HSPB8 associated autosomal dominant rimmed vacuolar myopathy is caused mainly by frameshift (fs) mutations. Patients develop a distal myopathy in their thirties, with progressive generalized weakness. Muscle biopsies show fatty replacement, fibrosis, rimmed vacuoles, and aggregates. We have shown that the mutant HSPB8 protein causes increased aggregation and secondary loss of activity of the normal HSPB8. We propose that microRNAs against the toxic Hspb8 mutation in addition to replacement of total endogenous HSPB8 is a logical therapeutic approach. We have generated stem cells from patient skin fibroblasts and transformed them into myoblasts to study the pathogenesis of the disease, and for translational studies. We found reduced HSPB8 protein, increased TDP-43, increased autophagy, as well as aggregations in patient fibroblasts. Using CRISPR technology, a knock-in *Hspb*8 mouse model was made of the c.515dupC fs variant seen in two families. The mice showed muscle weakness starting at 6 months of age. Muscle pathology revealed central nuclei, muscle degeneration, fatty replacement, reduced HSPB8, increased TDP-43, autophagy pathology, and amyloid fibril aggregates recapitulating the clinical phenotype. For our proof of principle gene therapy delivery studies, we have (1) transfected patient iPSC-derived myoblasts with wild-type HSPB8 and found the increase in HSPB8 protein as well as improved TDP-43 pathology; (2) dosed *Hspb*8 c515/+ mice with myotropic AAVmyo-CAG-EGFP by systemic delivery to check the muscle tropism effect. Results showed strong expression of the AAVmyo at 1E+12vg dose in all muscle groups vs. AAV9-CAG-EGFP control. Currently, the *Hspb*8 c515/+ mice are being treated with the AAVmyo-CBH-hHSPB8 construct that incorporates the normal *Hspb8*. Muscle specific promoters (CK8 and MHCK7) are also tested to select the most potent promoter for muscle delivery. Our next step is treating the animals with the best combination of microRNA and/or normal *Hspb8* constructs using AAVmyo with the most effective promoter. This will be followed by evaluating the amelioration of muscle weakness and pathology. Results of our studies holds promise for treatment of HSPB8 associated myopathy in patients.

Pollard[11], R. Reimer[12], M. Sabir[13], S. U. Walkley[3], R. Wang[14], M. Wasserstein[15], L. Wolfe[16], R. Zoncu[17], FSASD Consortium, M. Huizing[13]; [1]NIH, Bethesda, MD, [2]Office of Rare Disease Res., NCATS, NIH, Bethesda, MD, [3]Dept. of NeuroSci., Albert Einstein Coll. of Med., Bronx, NY, [4]NHGRI (NIH), Bethesda, MD, [5]Université Paris, SPPIN, CNRS, Paris, France, [6]NIH Undiagnosed Diseases Program, Bethesda, MD, [7]NHGRI, Bethesda, MD, [8]NIH Undiagnosed Diseases Program, Severn, MD, [9]Neural Ctr. of Neuropsychology, Neural Ltd, Oulu, Finland, [10]Dept. of Pharmacology, Univ. of Oxford, Oxford, United Kingdom, [11]Greenwood Genetic Ctr., Greenwood, SC, [12]Dept. of Neurological Sci., Stanford Univ., Palo Alto, CA, [13]NIH, Bethesda, MD, [14]CHOC Children's Specialists, Orange, CA, [15]3Dept. of Pediatrics and Genetics, The Children's Hosp. at Montefiore,, Bronx, NY, [16]NIH - NHGRI, Bethesda, MD, [17]Dept. of Molecular and Cell Biology, Univ. of California Berkeley, Berkeley, CA

Background: Free sialic acid storage disorder (FSASD) is an extremely rare, autosomal recessive, neurodegenerative, multisystemic disorder caused by defects in the lysosomal sialic acid (SA) exporter SLC17A5 (sialin). FSASD presents a broad clinical spectrum, ranging from mild neurodevelopmental disease to severe infantile forms with fatal outcomes. This study highlights the significant progress achieved in therapeutic development for FSASD through collaborative research efforts. **Methods:** To address the challenges in FSASD research, a highly collaborative multidisciplinary research consortium composed of clinicians, researchers from various specialties, and an FSASD patient advocacy group (S.T.A.R.) was formed. The consortium implemented parallel clinical and preclinical efforts to advance understanding and therapeutic development for FSASD. **Results:** The collaborative research consortium achieved remarkable advances in expanding our understanding of FSASD and identifying potential therapeutic strategies. By leveraging the collective expertise of clinicians, researchers, and patient advocates, a comprehensive approach to FSASD research was established. A pilot Natural History study and a Patient Registry were initiated to gather valuable data and biobank on the disease. A knock-in mouse closely resembling the Finnish *SLC17A5* founder variant (R39C) was generated, faithfully replicating key features of the human FSASD condition and providing valuable insights into disease pathology. Primary cells from FSASD patients and FSASD model mice were utilized to explore various approaches, including gene complementation, base editing, and candidate small drug screenings, which showed promise in ameliorating the cellular FSASD phenotype. Pilot studies investigating adeno-associated virus tropism in mice, a critical step for gene therapy design, yielded encouraging results. **Conclusion:** The collaborative research efforts, driven by the expertise of clinicians, researchers, and patient advocates, have yielded significant progress in data collection and therapeutic development for FSASD. Through the collaborative framework, scientific, clinical, and financial challenges have been overcome, leading to a deeper understanding of the disease and the identification of potential therapeutic strategies. The success of the collaborative model serves as an inspiring example for accelerating therapeutic advancements in rare diseases like FSASD, offering new hope for improved treatments and better outcomes for individuals affected by this condition.

Session Title: Genetic Therapies Poster Session II

PB2014 Developing a framework for precision therapy for rare and genetic diseases

Authors:

S. Kerr[1], J. Zschocke[2], J. Berg[3]; [1]Univ. of Dundee, Dundee, United Kingdom, [2]Med Univ Innsbruck, Innsbruck, Austria, [3]Univ Dundee, Dundee, United Kingdom

Introduction. The identification of the majority of genes that cause monogenic disorders in humans over the past 30 years has led to the possibility of developing highly specific therapies that truly modify disease progression. Multiple different approaches have been developed that are effective in different genetic disorders, and an exponential increase in highly specific therapies (that address a specific gene activity or even a specific pathogenic variant) is expected. A conceptual framework for classifying precision therapies is required to improve understanding amongst all healthcare professionals, and to facilitate design of therapies for new rare indications.
Methods. We identified newly emerging therapies for rare and genetic diseases through a journalistic review and from online clinical trials databases. Common mechanisms of action were identified and mapped to the central dogma of protein production. ***Results.*** We identified 10 specific mechanisms of action.
I. Gene Replacement, II. Gene Editing, III. Epigenetic Modification, IV. RNA Knockdown, V. RNA Editing, VI. Translation (stop codon readthrough), VII. Post Translational Modification, VIII. Protein Interaction, IX. Protein Replacement, X. Environmental Modification
This framework supports a common understanding of the place of action of different therapeutic interventions. It also provides a structure for teaching about emerging new classes of therapeutic agents. Such therapies are currently largely restricted to the precise treatment of rare disease, but application of the same technologies to the treatments of a wide range of common medical disorders is already emerging.

Session Title: Genetic Therapies Poster Session III

PB2015 Developing an approach to screening rare genetic diagnoses for amenability to bespoke genetic therapy development.

Authors:

D. Cheerie[1,2], M. C. Lauffer[3], M. Synofzik[4,5], D. Beijer[4], N=1 Collaborative, M. Szego[2], K. Amburgey[1,2], B. Kalish[1,2], J. J. Dowling[1,2], G. Costain[1,2]; [1]The Hosp. for Sick Children, Toronto, ON, Canada, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Dutch Ctr. for RNA Therapeutics, Leiden, Netherlands, [4]Hertie-Inst. for Clinical Brain Res., Tübingen, Germany, [5]German Ctr. of Neurodegenerative Diseases, Tübingen, Germany

Background: Rare genetic diseases are major contributors to pediatric morbidity and mortality, but there are few genetic therapies that target the underlying pathomechanism(s) at a DNA or RNA level. Proof-of-concept exists for precision genetic therapies like antisense oligonucleotides (ASOs) that are customized for an individual's specific genetic variant and/or ultra-rare condition. A recent analysis of public databases suggested that ~50% of pathogenic variants may have a disease mechanism tractable to amelioration with an ASO. However, this preliminary study did not account for key molecular genetics, clinical, and ethical considerations, and was restricted to one kind of genetic therapy. We hypothesize that less than 5% of genetic diagnoses in real-world patient cohorts offer the realistic prospect for precision therapy development, based on our current understanding of the associated pathomechanisms, natural history, and contemporary treatment methods. **Objective and Methods:** Our study aims to develop and apply a reproducible multi-factorial approach to screening rare genetic diagnoses for amenability to bespoke genetic therapy development. Via modified Delphi techniques, we aim to define clinical, molecular genetics, and bioethical principles that can inform suitability for precision treatment. We will then apply our approach to two well-characterized pediatric cohorts that underwent clinical genome sequencing (total n~1000).**Preliminary Results:** Using a preliminary workflow defining amenability to ASO therapies, 1 of the first 43 diagnosed pediatric patients qualified for exon skipping ASOs on a molecular basis. Despite being the sole ideal candidate based on its molecular principles, the condition is non-progressive and may respond to standard anti-epileptic medication, mitigating the need for developing a precision genetic therapy for this variant. Therefore, as expected, no patients from our preliminary cohort have a realistic prospect for precision therapy development.**Conclusion:** Our initial findings underscore the importance of considering molecular, clinical, and bioethical factors to better reflect the number of genetic diagnoses amendable to genetic therapy. Our proposed methodologies and results promise to help inform large-scale translational research initiatives and healthcare system policies related to the development and provision of precision genetic therapies.

Session Title: Genetic Therapies Poster Session I

PB2016 Development of a human genetics-guided priority score for 19,365 genes and 347 drug indications

Authors:

A. Duffy[1], B. Petrazzini[1], D. Stein[1], J. Park[1], I. Forrest[1], K. Gibson[1], C. Marquez-Luna[1], M. Mort[2], A. Schlessinger[1], Y. Itan[1], D. Cooper[2], D. Jordan[3], G. Rocheleau[1], R. Do[1]; [1]Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]Cardiff Univ, Cardiff, Wales, United Kingdom, [3]Icahn Sch. of Med. at Mt Sinai, New York, NY

Studies have shown that human genetic data can inform clinical trial outcomes. The development of drug prioritization frameworks that leverage the vast array of genetic data is necessary to aid the selection of effective drug targets at the preclinical stage of drug discovery.

In this study, we developed an *in silico* genetic priority score (GPS) for 19,365 protein-coding genes and 347 drug indications to inform drug target prioritization. We constructed an integrated drug genetics dataset using the Open Targets database for drug indications and leveraged eight genetic features which encompassed clinical variants, coding variants and phenome-wide association studies. Using Firth logistic regression with five-fold cross-validation, we built the GPS as the weighted sum of the effects of each of the 8 genetic features with drug indication. We further incorporated the direction and mechanism of the drug indication into a complementary version of the GPS. Hence, this framework prioritizes genes as suitable drug targets based on the number and strength of each predictor with genetic support.

First, we stratified the GPS into bins of 0.3 to confirm that gene-phenotypes with increased genetic support were associated with an increased likelihood of having a drug indication. A GPS in the top 4%, 0.3% and 0.2% conferred a 5.2-, 8.3- and 8.8-fold increased effect of having an indication, respectively. Importantly, the top scores were driven by multiple genetic features (mean=3.1). We validated the results using an independent drug database, SIDER and observed similar results. We demonstrated in a prioritization framework, that gene-phenotype observations with a GPS in the top 0.2% were 4.2-fold more likely to be a therapeutic target compared to a random selection. Furthermore, we showed that targets with a score in the top 0.2% were 1.3, 4.5 and 7.8-fold more likely to advance from phase I to phase II, III and IV, respectively.

Next, we ascertained the GPS for 19,365 genes and 347 phenotypes. We note that the great majority of observations (98.7%) linking a gene to a phenotype with a high GPS score were not found in either the Open Targets or SIDER resources, indicating potential new drug targets. Finally, we highlight both known and novel examples of gene targets supported by a high GPS that are consistent with the direction and mechanism of action of the drug.

In conclusion, we have developed an *in silico* GPS that can be used to inform the prioritization of gene targets for a large number of genes and diseases in drug development.

Session Title: Genetic Therapies Poster Session II

PB2017 Development of an myotropic adeno-associated virus (AAV) for VCP related myopathy

Authors:

L. Weiss, P. Pal, H. Zhang, F. Philip, A. shmara, V. Boock, C. Cheng, S. Metwaly, G. Wu, A. Villalta, X. Xu, V. Kimonis; Univ. of California, Irvine, Irvine, CA

Pathogenic variants in Valosin Containing Protein (VCP) gene cause a unique autosomal dominant disease characterized by inclusion body myopathy, Paget disease of bone and frontotemporal dementia, also known as multisystem proteinopathy (MSP). VCP pathogenic variants lead to hyperactive enzymatic activity, suggesting a gain-of-function. To ameliorate the gain-of-toxicity of VCP mutant proteins, an ideal approach is to silence the mutant gene in an allele-specific manner and to leave the wildtype allele intact which is challenging. We therefore propose co-expression of VCP silencing with rescue vectors to replace endogenous VCP with exogenous functional human VCP. We have designed (1) 3 artificial microRNA against VCP, (2) a codon-optimized wildtype VCP, both tested in HEK293T cells, (3) muscle trophic AAV9 variant: AAVmyo-CAG-EGFP vector, tested in 8 weeks old C57BL/6 and VCP R155H/+ mice. The results show: (1) The best microRNA, mirVCP2 (2µg, ratio of hVCP: mirVCP2 = 1:5, transfection efficacy >70%), achieved the reduction of 75 % VCP mRNA and 55% VCP protein expression in HEK293T cells. (2) The codon-optimal WT VCP was not targeted by mirVCP2 in HEK293T cells. (3) In both WT, VCP mice infected with $4x10^{12}$vg of AAVmyo-CAG-EGFP, the EGFP protein expression is convincingly higher in muscle-specific AAVmyo vector compared to AAV9 in skeletal and cardiac muscles. We then use mirVCP2 and AAVmyo for virus packaging and inject in a well-established VCPR155H/R155H mice at 4 days old. Currently, VCP mice are injected systematically by retro-orbital injection with 1e12 vector genome of virus to determine the safety and efficiency including specific muscle tropism, effective virus dosage, viral immune response, and toxicity. Success in these preclinical studies holds potential for promising therapeutic benefits in patients with VCP disease.

Session Title: Genetic Therapies Poster Session III

PB2018 Dose-ranging pre-clinical studies of systemic AAV9 with codon-optimized reduced size ATP7A (cors-ATP7A) plus subcutaneous Cu-Histidinate in a Menkes disease model

Authors:

S. Kaler[1], L. Venkataraman[1], T. Kaniganti[1], B. Kennedy[1], M. Gelb[2], J. Reese[3], D. Goldstein[4], P. Sullivan[4]; [1]Ctr. for Gene Therapy, Nationwide Children's Hosp., Columbus, OH, [2]Dept. of Chemistry, Univ. of Washington, Seattle, WA, [3]Sentynl Therapeutics, Solana Beach, CA, [4]NINDS/NIH, Bethesda, MD

Menkes Disease (MD) is an infantile onset, X-linked recessive disorder of copper transport characterized by rapidly progressive neurodegeneration, seizures, and failure to thrive caused by mutations in *ATP7A*, a copper transport gene. Prior studies have shown that early intervention with CuHis alone improves survival and clinical outcomes, yet the overall burden of disease remains considerable. Based on the multi-tasking character of ATP7A, MD infants may benefit from viral gene therapy that provides working copies of *ATP7A*. *Mo-br* mice harbor a deletion in *Atp7a*, the murine homolog, and recapitulate salient features of MD, including low serum copper levels, neurodegeneration, and early death (postnatal day 13). We previously documented 23% and 53% respective rescues of this model with CSF-directed AAV5- or AAV9- mediated transfer of human *ATP7A*, in combination with copper. Here, we evaluated a systemic gene therapy approach and performed dose-ranging preclinical studies of intravenous AAV9 delivering a codon-optimized, reduced size version of *ATP7A* (cors*ATP7A*) plus 30µg clinical grade CuHis by subcutaneous injection. AAV biodistribution in 12-day wildtype and *mo-br* mice revealed efficient transduction in various organs except the renal medulla, reflecting inability of AAV particles to effectively traverse renal glomeruli and reach the distal nephron. Safety, efficacy, and toxicological studies identified two doses, $2.6x10^{12}$ and $2.6x10^{13}$ vg/kg body weight + CuHis as highly promising, with combined long-term survival of 89% (n=36) versus 60% in mice receiving CuHis alone (n=10) and 0% for AAV9-cors*ATP7A* alone. Overall outcomes (serum and brain copper, brain neurochemical ratios, growth, neurobehavior) appear superior in the $2.6x10^{13}$ vg/kg + 30µg CuHis cohort survivors (n=19). Administration of a higher dose, $2.6x10^{14}$ vg/kg, was initially well-tolerated, but sudden death occurred in 5 of 6 animals after CuHis administration on P4 or P5. Postmortem analyses showed no evidence of brain, or liver toxicity however acute renal tubular necrosis and high renal copper levels were noted and considered the cause of death. These studies in the *mo-br* mouse represent important steps toward a future pilot gene therapy clinical trial for individuals with this illness. Development of newborn screening for MD, based on detection of metabolites in the catecholamine biosynthetic pathway in conjunction with *ATP7A* variant detection by whole genome sequencing, both from dried blood spots, is also underway. In combination, the potential impact of this progress on clinical practice is high since the largest barriers to good health for patients with MD will be circumvented.

Session Title: Genetic Therapies Poster Session I

PB2019 Endogenous expression of *AGBL5* or reduction of *TTLL5* expression rescues the cellular disease phenotype in *AGBL5*$^{-/-}$ human retinal pigment epithelium cells.

Authors:

S. Villa Vasquez[1], R. Ewing[2], R. Pengelly[1], D. I. Wilson[1], D. Baralle[1], G. Wheway[1]; [1]Univ. of Southampton, Faculty of Med., Southampton, United Kingdom, [2]Univ. of Southampton, Faculty of Environmental and Life Sci., Southampton, United Kingdom

AGBL5 is a dual function deglutamylase that regulates functional tubulin glutamylation levels in cilia. Mutations are associated with a form of autosomal recessive Retinitis Pigmentosa, for which there are no known treatments or cures. This study investigated *AGBL5* CRISPR knockout ARPE19 cells, to further elucidate the mechanism causing retinal dysfunction and investigate opportunities for rescue of the cellular disease phenotype.
AGBL5$^{-/-}$ cells have reduced levels of *AGBL5* mRNA and AGBL5 protein, show hyperglutamylation, significantly shorter cilia, and a lower percentage of ciliated cells than WT cells ($p<0.001$). Whole transcriptome RNA-seq analysis showed that genes differentially expressed in *AGBL5*$^{-/-}$ cells are associated with nervous system development, neuron apoptotic process, cell adhesion, protein localisation to microtubule, photoreceptor cell maintenance, and other ciliopathies.
To counter the glutamylation imbalance due to loss of AGBL5, *TTLL5* which encodes tubulin tyrosine ligase like 5 and functions as an alpha tubulin polyglutamylase, was considered for further experiments. We hypothesised that knockdown of *TTLL5* could rescue the cellular disease phenotype in *AGBL5*$^{-/-}$ cells. Indeed, we found that WT AGBL5-eGFP expression in mutant cells, or CRISPR knockout of *TTLL5* robustly rescued the ciliary phenotype and glutamylation levels in *AGBL5*$^{-/-}$ cells.
This work reports a clear phenotype in *AGBL5*-deficient human retinal cell lines consisting of hyperglutamylation, short cilia and reduced ciliogenesis. It provides functional and transcriptomic data and protein interaction data from this cell model as a resource to the ciliopathy research community. Crucially, the demonstrates the potential effectiveness of therapy to treat *AGBL5*-associated cilia deficiency with endogenous expression of AGBL5 or reduction of *TTLL5* expression.

Session Title: Genetic Therapies Poster Session II

PB2020 Epigenome Editing Durability Varies Widely Across Cardiovascular Disease Target Genes

Authors:

X. Wang, M. N. Whittaker, L. C. Testa, A. Quigley, I. Jindal, S. V. Cortez-Alvarado, P. Qu, Y. Yang, M-G. Alameh, K. Musunuru; Univ. of Pennsylvania, Philadelphia, PA

Background: Hepatic knockdown of the proprotein convertase subtilisin/kexin type 9 (*PCSK9*) gene or the angiopoietin-like 3 (*ANGPTL3*) gene has been demonstrated to reduce blood low-density lipoprotein cholesterol (LDL-C) levels, and hepatic knockdown of the angiotensinogen (*AGT*) gene has been demonstrated to reduce blood pressure. Genome editing can productively target each of these three genes in hepatocytes in the liver, offering the possibility of durable "one-and-done" therapies for hypercholesterolemia and hypertension. However, concerns around making permanent gene sequence changes via DNA strand breaks might hinder acceptance of these therapies. Epigenome editing offers an alternative approach to gene inactivation, via silencing of gene expression by methylation of the promoter region, but the long-term durability of epigenome editing remains to be established.
Objectives and Results: We assessed the ability of epigenome editing to durably reduce the expression of the human *PCSK9*, *ANGPTL3*, and *AGT* genes in HuH-7 hepatoma cells. Cells treated with the CRISPRoff epigenome editor and *PCSK9* guide RNAs were maintained for up to 124 cell doublings and demonstrated durable knockdown of gene expression and increased CpG dinucleotide methylation in the promoter, exon 1, and intron 1 regions. In contrast, cells treated with CRISPRoff and *ANGPTL3* guide RNAs experienced only transient knockdown of gene expression. Cells treated with CRISPRoff and *AGT* guide RNAs also experienced transient knockdown of gene expression; although initially there was increased CpG methylation throughout the early part of the gene, this methylation was geographically heterogeneous—transient in the promoter, and stable in intron 1.
Conclusions: This work demonstrates precise and durable gene regulation via methylation, supporting a new therapeutic approach for protection against cardiovascular disease via knockdown of genes such as *PCSK9*. However, the durability of knockdown with methylation changes is not generalizable across target genes, likely limiting the therapeutic potential of epigenome editing compared to other modalities.

Session Title: Genetic Therapies Poster Session III

PB2021 Establishing predictive models for cystic fibrosis gene editing therapeutic development

Authors:

J. Conte, A. Bell, M. Armstrong, M. Chado, N. Allaire, A. Sivachenko, M. Mense, C. Cotton, H. Valley; Cystic Fibrosis Fndn., Lexington, MA

Gene editing and gene therapy are promising approaches to cure cystic fibrosis (CF) and there is intense, ongoing research and development in this area. Primary human bronchial epithelial (hBE) cells are considered the "gold standard" for demonstration of efficacy of small molecule CFTR modulators. However, hBEs have limited expansion potential and available genotypes; therefore, other cell models are frequently used for early-stage gene editing research and development. HEK-293 cells are a widely used immortalized cell model for gene editing, but do not express CFTR. 16HBE cells, an immortalized cell model, are a valuable tool for CF-specific research. Inducible pluripotent stem cells (iPS), a cell model that can be programmed to differentiate into multiple tissue lineages, are also actively used in early-stage CF research. It is not known whether results obtained in these cell models will translate to cultured primary CF hBEs and ultimately in vivo. The overall goal of this project is to establish if gene editing outcomes in CFTR are correlated between HEK-293, 16HBE, iPS, and primary hBE cells.

We used next generation sequencing to assess indel formation frequency caused by Spy-Cas9:gRNA at eighty unique targets in WT genomic CFTR in each of these four cell models. We designed eight guide RNAs for each of ten genomic CFTR regions: the -20.9 kb regulatory element (RE), 5' UTR, intron 1 RE, the 3' end of intron 1, exon 1, intron 11, exon 12, intron 12 RE, exon 23, and the 3' UTR. Guide RNAs were complexed with Cas9 to form a ribonucleoprotein complex, which was delivered by nucleofection. Following nucleofection, cells were plated and allowed to recover for 72 hours before genomic DNA was harvested. Targeted, next generation sequencing for each of the regions was performed. We compared indel frequency for each of these 80 guides between HEK-293, 16HBE, hBE, and iPS cells.

These data provide robust, quantitative comparisons of the four cell models and inform whether HEK-293, 16HBE, and/or iPS cells are predictive of indel editing outcomes in CFTR in primary hBE cells. There is a strong correlation of indel editing frequency for the guides tested between all 4 cell models tested with R^2 values ranging from 0.39-0.70. The best correlation between hBE cells and another cell model is seen with 16HBE, R^2 = 0.65. The lowest correlation between hBE cells and another cell model is seen with iPS cells, R^2 = 0.48. While there are exceptions, evaluation of guides in HEK, 16HBE, and iPS cells can be used to select guides that are likely to be highly successful in primary hBE cells for CFTR.

Session Title: Genetic Therapies Poster Session I

PB2022 Evaluating anti-diabetic drugs for protection against Alzheimer's disease by integration of genetics, genomics and drug-induced transcriptomic signatures.

Authors:

X. Zhong[1,2], Q. Wei[3,2], Y. Tan[4,2], B. Li[5,2], N. Cox[6,2]; [1]Vanderbilt Univ. Med. Ctr., Nashville, TN, [2]Vanderbilt Genetics Inst., Nashville, TN, [3]Vanderbilt Univ, Nashville, TN, [4]Vanderbilt Univ. - Nashville, TN, Nashville, TN, [5]Vanderbilt, Nashville, TN, [6]Vanderbilt Univ Med Ctr., Nashville, TN

Alzheimer's disease (AD) is the leading cause of dementia with very limited therapeutics. Several anti-diabetic drugs (e.g. Semaglutide) have shown some protection against cognition decline in recent clinical trials. Repurposing existing approved drugs for novel uses can expedite drug development. Drugs with support from human genetics are twice more likely to succeed to the market. In this study, we use our (previously developed) iRIGS framework to infer AD risk genes through integration of genetics, functional genomics and gene-gene networks. We then use these risk genes together with AD-associated direction of perturbation to construct a genetic perturbation signature. By examining the drug-induced perturbation signatures with more than 8700 perturbagens, we identified Sitagliptin, a DPP4 inhibitor, that ranked top (top 0.1%) for reversing the AD disease signature. Analyzing single cell RNAseq data from human AD brains, we identified cell-cell communications among microglia, excitatory neurons, inhibitory neurons, endothelial cells, and pericytes through formation of ligand-receptor pairs between *ADAM17* (a known AD risk gene) and *ITGB1* (a receptor). Given that *ITGB1* directly interacts with *DPP4*, this suggests that Sitagliptin may act to influence AD risk through disruption of the *ADAM17-ITGB1* interaction. In conclusion, we present a strategy for repurposing existing drugs for AD, identify a DPP4 inhibitor as a top candidate and provide further support from single-cell transcriptomics for the potential mechanism of action of the prioritized drug.

Session Title: Genetic Therapies Poster Session II

PB2023 Evaluating antisense oligonucleotides in spinocerebellar ataxia type 15/16.

Authors:

B. Masser, H. S. McLoughlin; Univ. of Michigan, Ann Arbor, MI

Spinocerebellar ataxias (SCAs) encompass a diverse group of dominantly inherited neurodegenerative ataxias, with over 50 SCAs identified to date. Over 40 genes are directly implicated in SCA pathogenesis, underlying their genetic and clinical heterogeneity. However, growing evidence suggests that neuronal calcium (Ca^{2+}) signaling perturbation plays a central role among SCAs. Various polyglutamine SCAs (SCA 1, 2, 3, 6, 7, and 17) have been reported to exhibit cerebellar Ca^{2+} signaling dysfunction, primarily attributed to the inositol 1,4,5-triphosphate receptor, type 1 (IP_3R1). IP_3R1 is a Ca^{2+} channel situated in the membrane of the endoplasmic reticulum. It performs a crucial function in ensuring the survival of Purkinje neurons, the cerebellum's sole output cells. Macrodeletions resulting in haploinsufficiency of the gene encoding IP_3R1 (*ITPR1*) cause SCA15/16, a slowly progressive, pure cerebellar ataxia. To date, no treatment options are available for SCA15/16 patients. Traditional gene replacement strategies are not applicable to SCA15/16 due to the considerable size of *ITPR1* (~10 kb coding sequence), which exceeds viral delivery packaging capacities. Here, we propose utilizing antisense oligonucleotides (ASOs) to obstruct endogenous gene-silencing mechanisms, specifically microRNAs (miRNAs), to increase the expression of IP_3R1 via the remaining functional allele. We hypothesize that ASO binding to active miRNA recognition elements (MREs) within the *ITPR1* 3' untranslated region (UTR) will prevent miRNA-mediated silencing and restore IP_3R1 channel expression and function. Utilizing a dual luciferase reporter construct containing the *ITPR1* 3' UTR, we have validated several predicted *ITPR1*-miRNA interactions. We then designed "miR-masking" ASOs, complementary to these validated MREs and the flanking sequences. These miR-masks showed target site protection in our reporter system. Ongoing studies are evaluating the efficacy of the miR-masking ASOs to protect endogenous *ITPR1* transcripts and safety *in vitro* and *in vivo*. These studies have the potential to provide a promising therapeutic strategy for not only the treatment of SCA15/16 but also for other channelopathies caused by haploinsufficiency, as miR-masking allows for restoration rather than overexpression and upregulation of channel function.

Session Title: Genetic Therapies Poster Session III

PB2024 Experience with maintenance therapy of carglumic acid in patients with organic acidemia

Authors:

Ctr., Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [3]Asan Inst. for Life Sci., Asan Med. Ctr., Seoul, Korea, Republic of, [4]Dept. of Genetic Counseling, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of

Background: Organic acidemias including propionic acidemia (PA) and methylmalonic acidemia (MMA) are associated with secondary hyperammonemia, leading to poor neurological outcomes. Carglumic acid (N-carbamylglutamate) has been considered a therapeutic option for hyperammonemia.
Aim: This study aims to evaluate the efficacy, safety, and impact on hospitalizations of carglumic acid in patients with organic acidemias and concomitant hyperammonemia.
Methods: Three patients with organic acidemias (2 PA, 1 MMA) have received carglumic acid in a dose of 50 mg/kg/day along with standard therapy. The primary outcome was hospitalization days due to hyperammonemia. Secondary outcomes included the number of emergency room (ER) visits, peak concentration of ammonia, duration of hyperammonemia, other biochemical markers, growth, and developmental assessment. Safety was assessed throughout the study.
Results: The patients (median age 0.9 years; range 0.2-4.0) were followed for a median of 1.1 years. Median hospitalization days per year decreased from 35 (range 15-259) to 12 (range 0-25) days compared to before carglumic acid treatment. Annualized rates of admission and emergency room visits were also reduced by 70% and 50%, respectively. Peak ammonia level decreased from 411 (range 232-615) to 69 (range 63-75) μmol/L. Duration of hyperammonemia was reduced by 83%. Other biochemical markers remain stable. No further deteriorations of growth and development were observed. There were no drug-related adverse events throughout the study.
Conclusions: Maintenance therapy with carglumic acid for organic acidemias was efficacious and generally tolerable with reductions in hospitalization days. Longer-term observation with more patients is necessary to validate this efficacy.

PB2025 Exploring the potential of readthrough compounds on nonsense mutation, R132* of *MMACHC* gene responsible for cobalamin C defect

Authors:

G. Kaur, R. Kaur, S. V. Attri, I. Verma, A. G. Saini, R. Gupta; Postgraduate Inst. of Med. Ed. & Res. (PGIMER), Chandigarh, India

Background: Cobalamin-C defect is the most common inborn error of intracellular cobalamin metabolism. Nonsense mutations account for majority of inherited genetic diseases. The nonsense-mutation, c.394C>T (R132*) in *MMACHC* gene results in truncated protein and is most common in North Indian population. Based on the location of this mutation, it can be targeted for readthrough drug therapeutics for restoring the MMACHC activity. We evaluated a range of readthrough compounds including aminoglycosides and non-aminoglycosides, to assess their ability to suppress PTC recognition. **Methods:** To check the efficacy of readthrough compounds like Geneticin (G418), PTC124 and Amlexanox, the stable mammalian cell lines expressing wildtype (WT) and mutant (R132*) MMACHC protein were created. WT cDNA clone of *MMACHC* gene was purchased and mutant clone (R132*_MMACHC) was prepared by site-directed mutagenesis. WT and R132*_MMACHC constructs were subcloned into mammalian expression vector (pcDNA5FRT) along with eGFP sequence. Vectors were transfected into Flp-In CHO cell line and selected using hygromycin antibiotic and GFP positive cells. Flp-In CHO cells carrying R132* variant was treated with different readthrough compounds at different concentrations and checked for protein expression by confocal microscopy and western blot. **Results:** Western blot showed good expression in transfected cells carrying WT MMACHC clone; however, no expression of GFP tagged protein was observed in mutant (R132*) cells suggesting no expression of MMACHC with this mutation. On treating R132* Flp-In CHO cells with different concentrations of G418 for 24 hrs, protein expression was restored at 15 µg/ml with relatively higher band intensities at 100-750 µg/ml of G418. PTC124 treatment for 24 hrs also restored the full length expression of MMACHC in the range 3-50 µM. Amlexanox showed restoration of MMACHC protein expression within the range of 50-250 µM. These results were also in concordance with the fluorescence analysed using confocal microscopy. **Conclusion:**The readthrough compounds (G418, PTC124 and Amlexanox) have the potential to restore the full-length functional protein from truncated MMACHC protein with nonsense mutation, R132* in stable cell lines. ***Keywords:*** *Cobalamin-C defect, readthrough compounds, MMACHC, nonsense mutation, stable cell lines*

Session Title: Genetic Therapies Poster Session II

PB2026 Genotype and phenotype analysis of individuals with nano-rare genomic variants considered for experimental antisense oligonucleotide therapy.

Authors:

C. Ngongang Tekendo[1], T. Cole[1], J. Carroll[2,1], J. Douville[1], A. Williford[1], S. Glass[1], J. Gleeson[1,3,4], C. Bennett[5,1], S. Crooke[1]; [1]n-Lorem Fndn., Carlsbad, CA, [2]Dept. of Neurology, Univ. of Washington, Seattle, WA, [3]Dept. of NeuroSci.s, Univ. of California, San Diego, La Jolla, CA, [4]Rady Children's Inst. for Genomic Med., San Diego, CA, [5]Ionis Pharmaceutical, Carlsbad, CA

Recent advances in OMICS technologies allow for the identification of an increasing number of individuals with diseases caused by extremely rare genetic variants. Because nano-rare variants (worldwide prevalence of <30) are so rare, these difficult-to-diagnose individuals are uniquely disadvantaged and pose significant challenges to healthcare systems and the society in large. Despite having diseases caused by actionable single genes variants in many cases, there is no commercial path for treatments for such a small patient population. Since antisense oligonucleotide (ASO) technology has proven to be suited to address the needs of a meaningful portion of these individuals, we have established an industrialized approach that couples detailed genotypic and phenotypic data to the immediate potential for ASO therapy. Here, we leverage our experience in assessing the causality of nano-rare genetic variants and associated proximal molecular pathological events to attempt a correlation between detailed genetic data with patient specific phenotypic observations in 173 nano-rare patients from diverse age groups evaluated for experimental ASO therapy. We found that the time required to achieve a molecular diagnosis varies from 1 month to 36 years, with the mean and median times from symptom onset to diagnosis estimated to be 4.37 years and 2 years respectively. There is a significant bias toward Neurological diseases, with diverse genes and functional families involved and a marked preponderance of variants in ion channels proteins. The variability in phenotypic expression associated with nano-rare variants in genes such as *H3F3A*, *GBE1*, *GNAO1*, *UBTF*, *PACS1* or *PACS2* clearly support previous observations that phenotypes associated with same variants in the same gene can vary. We equally observe that different, but functionally equivalent variants can result in both similar (e.g., *TARDBP*) and different phenotypes (e.g., *CACNA1A*, *KCNQ2*, or *MED13L*). Despite the relatively small size of the patient population investigated, our findings enable a variety of insights into the genotype and phenotype relationships in nano-rare conditions. Moreover, our data show that this unique patient population presents a remarkable opportunity to apply modern OMICS approaches to begin to understand the various homeostatic, compensatory, and secondary effects of these genetic variants on the networks that result in expression of their unique phenotypes.

Session Title: Genetic Therapies Poster Session III

PB2027 Hermansky-Pudlak Syndrome: Exploring the therapeutic effect of gene therapy for HPS-1 pulmonary fibrosis

Authors:

G. Nieto-Alamilla[1], M. Behan[2], S. Abudi[1], M. Hossain[1], W. Gahl[3], M. Malicdan[1]; [1]NIH, Bethesda, MD, [2]NHGRI, Bethesda, MD, [3]NHGRI (NIH), Bethesda, MD

Background: Hermansky-Pudlak Syndrome type 1 (HPS-1) is a rare autosomal recessive multisystemic disease caused by biallelic loss-of-function mutations in the *HPS1* gene. HPS1 is characterized by oculocutaneous albinism, a bleeding diathesis, and progressive restrictive lung disease known as pulmonary fibrosis (HPS-PF). Current treatment options for HPS-PF, such as lung transplantation, have limitations and significant risks, emphasizing the need for alternative therapeutic approaches. Gene therapy, which aims to correct the underlying genetic defect, holds promise for the treatment of HPS-PF. Here, we present a rationale and preliminary findings for HPS1 gene complementation as a potential therapeutic strategy.**Methods:** To assess the feasibility of gene therapy for HPS1 we utilized knockout and a knockin mouse models (Hps1-KO, and Hps1-KI) generated in our laboratory. We employed adeno-associated virus (AAV) vectors to deliver either the enhanced green fluorescent protein (eGFP) open reading frame, as well as the mouse (mHps1) or human *HPS1* (hHPS1) genes, either locally (intranasal) or systemically (intravenous). Tropism analysis was conducted to evaluate the distribution of GFP in multiple tissues. To evaluate if the effect of gene complementation on PF, we induced PF using bleomycin through osmotic subcutaneous delivery.**Results:** Tropism analysis revealed robust AAV expression in the lungs, including alveolar epithelial type 2 cells (AEC2), indicating effective targeting of AAV vectors to HPS1-deficient cells. Overexpression of the mHps1 gene in Hps1-KO mice showed no adverse effects. Notably, Hps1 mice treated with mHps1 exhibited some improvement in pulmonary compliance and stiffness, suggesting a promising therapeutic effect. Human HPS1 expression was present in the lungs of both Hps1 mouse models following hHPS1 delivery. The therapeutic effects of hHPS1 gene therapy are currently under assessment and will be the subject of further investigation.**Conclusion:** Our current results underscore the progress made in gene therapy for HPS1-PF. Successful generation of animal models, including a humanized mouse model and knockout model, has provided valuable tools for studying the disease and evaluating therapeutic interventions. In vivo studies showed encouraging results, highlight the potential of gene therapy as a transformative treatment for HPS1-PF, and pave the way for further research and clinical translation. Continued investigations are necessary to optimize the gene therapy approach and validate its long-term safety and efficacy for the benefit of HPS1-PF patients.

PB2028 † High frequency AAV integration into Cas9-induced DSBs: implications as a gene therapy vector in the brain

Authors:

H. Bazick[1], M. J. Zylka[1,2,3], H. Mao[4], J. K. Niehaus[1], J. M. Wolter[5]; [1]UNC NeuroSci. Ctr., UNC Chapel Hill, Chapel Hill, NC, [2]Carolina Inst. for Dev.al Disabilities, UNC Chapel Hill, Chapel Hill, NC, [3]Dept. of Cell Biology and Physiology, UNC Chapel Hill, Chapel Hill, NC, [4]Life Edit, Durham, NC, [5]Univ. of Wisconsin Madison, Madison, WI

Angelman Syndrome (AS), a severe neurodevelopmental disorder caused by disruption of the maternally-inherited ubiquitin protein ligase E3A (UBE3A) allele, is characterized by severe sleep dysfunction, seizure disorders, impaired cognition and speech, motor deficits, and microcephaly. Due to epigenetic silencing of the paternal allele of UBE3A (patUBE3A) by a long non-coding antisense RNA (*UBE3A-ATS*) in neurons, mutation or deletion of maternal *UBE3A* results in near complete loss of UBE3A protein in the brain. Our previous study revealed that adeno-associated virus (AAV)-CRISPR/Cas9 gene therapy targeted to 75-repetitive *SNORD115* sequences along *UBE3A-ATS* leads to integration of the AAV vector into Cas9 target sites, trapping *UBE3A-ATS*, unsilencing patUBE3A, and alleviating AS phenotypes in mice with a dual embryonic/post-natal day 1 injection. Based on this mechanism of unsilencing, we hypothesized that integration of AAV at a single unique site should sufficiently block *UBE3A-ATS* transcription to unsilence patUBE3A. Thus, we designed 25 guide RNAs (gRNAs) single sites within *UBE3A-ATS*. When delivered in an AAV vector with Cas9 to primary neuron cultures, the best gRNAs individually achieved only 46% knockdown (KD) of *UBE3A-ATS*. This contrasted with 80% KD when a single gRNA was used that targeted 78 *SNORD115* genes. Examination of comprehensive editing profiles following AAV/Cas9 treatment in neuron cultures using modified Anchored Multiplex PCR (AMP)-seq revealed that AAV integration accounts for approximately 80% of all editing events, while insertions/deletions (indels) account for only 20%. Using a reporter assay, we found that the most frequent indels failed to block gene transcription, while integration of AAV-derived elements disrupted downstream gene expression. Our study shows that AAV integration is a frequent outcome of AAV/Cas9 therapy in neurons, suggests that AAV-derived elements are capable of disrupting genes, and that AAV integration may be the primary mechanism of *UBE3A-ATS* knockdown in the treatment of AS. Our work has implications for AAV/Cas9 as a gene therapy vector and in considering the risks versus benefits of utilizing an active nuclease and integrating viral genomes in the brain.

PB2029 Inhibition of chemokine expression declines cancer cells proliferation and migration in vitro

Authors:

M. Abo-Zeid[1,2], M. Abo-Elfadl[2,3], S. Mostafa[2,3]; [1]Genetics and Cytology Dept., Biotechnology Res. Inst., Natl. Res. Ctr., Dokki 12622, Cairo, Egypt, [2]Cancer Biology and Genetics Lab., Ctr. of Excellence for Advanced Sci., Natl. Res. Ctr., Dokki 12622, Cairo, Egypt, [3]Biochemistry Dept., Biotechnology Res. Inst., Natl. Res. Ctr., Dokki 12622, Cairo, Egypt

Background: The role of silencing chemokines to lose their function promotes initiation of cell cycle arrest and inhibits cell division, proliferation and migration. Therefore, knocking down chemotactic gene markers of metastatic cancer cells obstacle their migration and invasion to new loci. **Methodology**: In the present study, different types of cancer cells were transfected with specific chemokine inhibitor silencing CXCR4 gene. The low observed adverse effect level concentration of the siRNA was used to monitor DNA damage response by comet assay, gene expression by qRT-PCR for CXCR4 gene expression as well as related cell division, invasion and migration genes markers, protein expression by immunofluorescent assay and cell migration by wound healing procedure to record the delay in cell migration process. **Results:** When different cancer cell lines were transfected with the chemokine inhibitor for 48 h by the LOAEL concentration, the percentages of DNA damage were increased remarkably, and the gene expression of CXCR4 was downregulated extensively along with protein expression on the tested cancer cell lines. Also, the gene expression of cell division, proliferation and invasion were down regulated effectively when cancer cells transfected with that CXCR4 inhibitor. Moreover, the gap area of migration between non-transfected cells was smaller than that observed on transfected cells remarkably. **In conclusion**, target gene therapy based on silencing chemokines could contribute to down regulate other gene markers responsible for cell division, proliferation and migration, which consequently could diminish metastasis to new loci leading to secondary tumors.

Session Title: Genetic Therapies Poster Session III

PB2030 Investigation of gene transcription modifications associated with obesity in*Danio rerio* (zebrafish)

Authors:

K. Dobrinski[1], R. Stephenson[1], B. Alston[1], J. Gran[1], S. Desai[2], B. Ward[3], J. Kwon[4], Q. Zhu[4], C. Lee[4]; [1]Univ. of Tampa, Tampa, FL, [2]Coll. of Osteopathic Med. of the Pacific COMP-Northwest, Western Univ. of Hlth.Sci., Pomona, CA, [3]Moorehouse Med. Sch., Atlanta, GA, [4]The Jackson Lab. for Genomic Med., Farmington, CT

“We gratefully acknowledge the contribution the Genome Technologies Service at The Jackson Laboratory for expert assistance with the work described herein.” This study investigates transcriptional differences in the model organism, *Danio rerio* (zebrafish), associated with obesity. Zebrafish are an excellent model organism for obesity as they share 70% genetic identity with humans. Eighty-four percent of genes associated with human diseases are also found in zebrafish. Additionally, zebrafish have similar organ systems and store excess nutrients in their white adipocytes. The objective of this study is to use a zebrafish model to investigate early gene transcription changes associated with obesity. These changes may lead to downstream effects resulting in disease such as diabetes and non-alcoholic fatty liver disease. To create a model of obesity in zebrafish, two separate diets were used to raise obese fish and control fish for liver dissection. Control fish were fed a normal diet of 0.006 grams frozen artemia while obese fish were fed with 0.06 grams frozen artemia per day. Body Mass Indexes between obese and controls were analyzed using ANOVA (p value = 1.04e-11). Furthermore, histological analysis indicated that obese zebrafish had more and greater sized adipocytes which are a marker of increased adipose tissue. After 8 weeks fish were sacrificed, and livers dissected for DNA and RNA extraction. RNA sequencing was used to generate short read sequences and transcription differences were evaluated using the following bioinformatic tools: Trim Galore, STAR, Docker, and Stringtie. Preliminary analyses showed that genes overexpressed in obese fish included: preproinsulin, fatty acid binding proteins, amnionless, and cubilin. These genes along with others found to be overexpressed in obese fish are involved in increased production of insulin, increased receptors for insulin, increased fatty acid transport and increased inflammation. Some genes found to be under expressed in obese fish include pathogen binding proteins, MHC class I genes, and G-protein coupled receptors. Inactivating mutations in G-protein coupled receptors have been described to be associated with endocrinological related diseases. Overall, genes under expressed in obese fish are involved with a reduced immune system and reduced signaling pathways. This work has demonstrated that an obese zebrafish model can be used to investigate obesity related gene expression to uncover genes associated with human disease.

Session Title: Genetic Therapies Poster Session I

PB2031 In-vitro evaluation of CRISPR/Cas9-mediated excision of the Spinocerebellar Ataxia 27b repeat expansion in *FGF14*.

Authors:

G. Spurdens[1], A. Rebelo[1], M. Danzi[2], C. Yanick[1], D. Pellerin[3], B. Brais[3], M. Saporta[1], S. Zuchner[1]; [1]Univ. of Miami Miller Sch. of Med., Miami, FL, [2]Univ. of Miami, Dakota Dunes, SD, [3]McGill Univ., Montreal, QC, Canada

Spinocerebellar ataxia 27b (SCA27b) is a rare, autosomal dominant disorder caused by an expanded GAA repeat located deep in intron 1 of *FGF14*. SCA27b has been recently identified as one of the most common inherited late-onset forms of cerebellar ataxia, exhibiting episodic features, downbeat nystagmus, and cerebellar degeneration. In patients with repeat expansions exceeding 250 repeats, we see a significant decrease in the amount of FGF14 protein. FGF14 is highly expressed in the brain and is an important regulator of sodium channels and neuronal excitability. Due to locational restraints, neurodegenerative disorders have proven difficult to treat. However, with the continuous advancements in gene therapy, targeted approaches to treat neurodegenerative disorders are now a possibility. Here, we explore a corrective approach using CRISPR/Cas9 to excise the SCA27b repeat expansion. A dual-guide RNA (gRNA) strategy was used to precisely target the 5' and 3' regions flanking the repeats. Guide RNA validation and evaluation of cutting efficiency was performed in HEK293 Cas9-stable cells to screen for the best-performing gRNA pairings. Additional in-vitro testing was executed in patient fibroblasts and patient-derived iPSC motor neurons containing the repeat expansion. An adeno-associated virus (AAV) dual-vector approach was utilized to deliver all CRISPR/Cas9 components. Our results demonstrate efficient excision of the SCA27b repeat expansion in-vitro. The objective of our study is to successfully rescue FGF14 protein expression with minimal off-target effects to provide a promising therapeutic approach for SCA27b.

Session Title: Genetic Therapies Poster Session II

PB2032 JB2 therapy for a mouse MEF2C haploinsufficiency model of human autism in Mali

Authors:

M. kouyate; ACE-USTTB, Street 171/ Door 85, Mali

The MEF2C transcription factor regulates many genes related to autism spectrum disorders (ASD) and human MEF2C haploinsufficiency leads to ASD, intellectual disabilities, and epilepsy. However, the molecular mechanisms underlying the MEF2C haploinsufficiency syndrome remain poorly understood. We report here that Mef2c+/-(Mef2c-het) mice show behavioral deficits resembling those of human mice. behavioral deficits resembling those of human patients. Gene expression analyses of these mouse brains show changes in genes associated with neurogenesis, synapse formation and neuronal cell death. For example, Mef2c-het mice show decreased neurogenesis, increased neuronal apoptosis, and increased numbers of dead neurons. Neuronal apoptosis and an increased ratio of excitatory to inhibitory neurotransmission (E/I) Importantly, neurobehavioral deficits, E/I imbalance, and histological lesions are all ameliorated by treatment with JB2 . by treatment with JB2, a novel dual-acting compound related to memantine, JB2 regulates the phosphorylation of postsynaptic autism risk factors an FDA-approved drug. JB2 is an FDA-approved, non-competitive/rapidly deactivating antagonist of NMDA-type glutamate receptors. These results suggest that MEF2C haploinsufficiency leads to abnormal brain development, E/I imbalance, and neurobehavioral dysfunction, which can be mitigated by pharmacological intervention.

Session Title: Genetic Therapies Poster Session III

PB2033 Literature-based predictions of treatments for genetic disease pathology

Authors:

C. Deisseroth[1], W-S. Lee[1], J-Y. Kim[1], H-H. Jeong[1], J. Wang[2], H. Zoghbi[3], Z. Liu[1]; [1]Baylor Coll. of Med., Houston, TX, [2]Univ. of Pennsylvania, Philadelphia, PA, [3]Baylor Coll. of Med./HHMI/NRI, Houston, TX

Most debilitating genetic disorders caused by deficiency or excess of a specific protein are currently treated only at the symptomatic level—such as anti-epileptics for seizures and laxatives for constipation. Treatments that target the underlying molecular cause would provide greater therapeutic benefit, and reduce the risk of polypharmacy. Candidate drugs that might accomplish this goal must be tested individually, but a systematic analysis of molecular pathways is a promising method to prioritize these drugs for testing. Using known drug-gene and gene-gene interactions, one can predict drugs that are likely to modulate a protein of interest. These can treat haploinsufficiency conditions caused by loss-of-function genetic variants, as well as diseases caused by protein excess or toxic gain-of-function variants.

Existing pathway analyses rely on manually curated pathway databases to make predictions. With the exponentially growing body of medical literature, keeping these databases up to date with the latest discoveries is not sustainable. However, natural language processing (NLP) methods have made major advances in recent years, and enable us to extract this information automatically from the literature itself.

To find candidate drugs that correct protein imbalances without relying on manual pathway curation, we developed an artificial intelligence tool called PARsing ModifiErS via Abstract aNnotations (PARMESAN). This tool uses NLP to automatically identify gene-gene and drug-gene relationships from PubMed and PubMed Central. It then assembles a pathway database, and uses known relationships to predict undiscovered ones. It assigns a score to each hypothesis based on the amount of evidence supporting and opposing it.

We compare the drug-gene relationship predictions to the relationships displayed by the Drug-Gene Interaction Database (DGIdb), and the gene-gene predictions to the functional interactions in Reactome. PARMESAN's drug-gene predictions scoring above 7 (of which there are 264,980) are 23 times more likely to be supported by DGIdb than contradicted by it. Likewise, the gene-gene predictions scoring above 10, of which there are 325,379, are 21 times more likely to be confirmed than contradicted by Reactome.

PARMESAN is a free, open-source tool, and its source code. curated knowledgebase, and predictions will be made publicly available upon publication. This tool sustainably updates its knowledgebase, and allows researchers to prioritize tests for drugs that correct protein imbalances. This will save a tremendous amount of time and resources in drug screens, and pave the way to making many severe genetic disorders treatable.

Session Title: Genetic Therapies Poster Session I

PB2034 Monthly intravitreal enzyme replacement in classic late-infantile CLN2 disease slows decline in visual acuity: a case report.

Authors:

C. Courage[1], E. M. Maier[2,3], O. Ehrt[4], H. Pudritz[5], G. Rudolph[4], M. Gerhardt[4], C. Priglinger[4]; [1]Med. Genetics Ctr. (MGZ), Munich, Germany, [2]Dr. von Hauner Children's Hosp., Ludwig-Maximilians-University, Munich, Germany, [3]Labor Becker MVZ GbR, Newborn Screening Unit, Munich, Germany, [4]Dept. of Ophthalmology, Ludwig-Maximilians-Univ., Munich, Germany, [5]Pharmacy, Ludwig-Maximilians-Univ., Munich, Germany

Late infantile neuronal ceroid lipofuscinosis type 2 (CLN2) is a rare fatal neurodegenerative disorder characterized by deficiency of the lysosomal enzyme tripeptidyl peptidase-1 (TPP1). The autosomal-recessively inherited disorder is caused by pathogenic variants in the *TPP1* gene. The initial symptoms typically manifest between 2-4 years of age with epilepsy and speech delay, followed by rapid loss of motor and language function, vision loss, and early death. Intracerebroventricular enzyme replacement therapy (ERT) with recombinant human (rh) TPP1 (Cerliponase alfa©) has shown to slow the neurologic decline but has no effect on ongoing retinal degeneration in affected children. Intravitreal administration of rhTPP1 was shown to slow retinal degeneration in canine model of CLN2. A first-in-man use of intravitreal rhTPP1 has been started in the UK in 8 individuals in 2021 undergoing 8-weekly intravitreal injections of rhTPP1. We report on a 6-year-old male patient with classical CLN2 receiving monthly intravitreal rhTPP1 injections. The patient started ERT with 3 years and 4 months, being symptomatic with epilepsy. The patient was genetically confirmed with the known homozygous pathogenic variant c.509-1G>C in the *TPP1* gene. Intravitreal injections of rhTPP1 (0.2mg in 0.05ml BSA for the first 8 injections, following 0.4mg in 0.05ml) into the right eye (RE) have been started at the age of 5 years. The left eye (LE) was left untreated as a paired control. Until June 2023 the patient has undergone 10 intravitreal injections. At baseline best corrected visual acuity (BCVA) was 0.5 decimal in both eyes. Upon fundoscopy beginning bull´s eye maculopathy was evident. Optical coherence tomography (OCT) revealed perifoveal photoreceptor outer segment (OS) reduction with subfoveal sparing and diffuse thinning of the outer nuclear layer (ONL). The average of VA over the last 6 months was 0.3 in the treated RE and 0.2 in the control LE. In OCT volume scans a thin subfoveal OS band was still preserved in the RE. In the LE no volume scans were possible due to poor fixation. Line scans demonstrated perifoveal loss of outer nuclear layer and OS. No adverse reactions have been observed. Monthly general anaesthesia required for the intravitreal injections was well tolerated. In the observation period intravitreal ERT slightly delayed but did not stop retinal degeneration. BCVA in the treated eye remained better preserved during the first ten months when compared to the untreated eye, but slowly declined. Dose finding studies and clinical trials exceeding one year and are required to determine whether intravitreal ERT is able to significantly attenuate CLN2-associated retinopathy.

Session Title: Genetic Therapies Poster Session II

PB2035 Observational registry study of treatment practices and long-term outcomes of children with neurofibromatosis type 1 and plexiform neurofibromas initiating selumetinib in real-world practice in the United States: Study design and methodology

Authors:

R. de la Rosa Rodriguez[1], A. J. Waanders[2], K. Yohay[3], S. Fang[1], S. Wahlstrom[4], M. Bornhorst[5], J. Meade[6,7], K. Vallance[8]; [1]Alexion, AstraZeneca Rare Disease, Boston, MA, [2]Ann & Robert H. Lurie Children's Hosp. of Chicago, Chicago, IL, [3]Comprehensive Neurofibromatosis Ctr. at NYU Langone Hlth., New York, NY, [4]AstraZeneca, Wilmington, DE, [5]Children s Natl. Hosp., Washington, DC, [6]UPMC Children's Hosp. of Pittsburgh, Pittsburgh, PA, [7]Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA, [8]Cook Children's Med. Ctr., Fort Worth, TX

Selumetinib (ARRY-142886, AZD6244) is an oral, allosteric MEK1/2 inhibitor approved in the United States (US) for children aged ≥2 years with neurofibromatosis type 1 (NF1) and symptomatic, inoperable plexiform neurofibromas (PN), based on results from the pivotal SPRINT study. Aims of the US Selumetinib Registry study [NCT05683678] include understanding treatment practices and assessing short- and long-term safety and effectiveness outcomes of selumetinib treatment in children with NF1-PN in real-world US practice. Clinical and non-clinical factors affecting outcomes will also be explored.This observational registry study of pediatric patients with NF1-PN will be conducted in up to 22 US centers. Eligible patients will be 2-18 years old at the time of selumetinib initiation (on/after April 10, 2020), and not currently participating in a clinical trial. Patients will be divided into three cohorts: Cohort 1 - treatment discontinued before enrollment, Cohort 2 - treatment initiated before enrollment and currently on treatment, Cohort 3 - treatment initiation intended within 3 months of enrollment. Patients will be followed for ≥36 and up to 60 months. Primary objectives are to describe patient demographics and disease characteristics (including diagnosis criteria and related manifestations, diagnostic tests and results, and PN-related morbidities), selumetinib treatment course, short- and long-term effectiveness and safety, and disease course and treatment following discontinuation. Key secondary objectives include measures of quality of life, pain and physical functioning before, during, and after selumetinib. Target enrollment is 200 patients with a 24-month enrollment period and will begin in 2023.The US Registry study will facilitate understanding of treatment practices and assess short and long-term outcomes of selumetinib for NF1-PN in a real-world setting.

Session Title: Genetic Therapies Poster Session III

PB2036 PEG-PLGA Polymersomes as a Delivery Mechanism for CRISPR-Cas9 in HEK293-GFP Cells.

Authors:

A. Harley[1], V. Kanduri[1], C. Argenti[1], D. LaVigne[1], C. Ennis[1], C. Forenzo[1], S. Edgecomb[2], D. Larsen[1]; [1]Clemson Univ., Clemson, SC, [2]Univ. of Mississippi, University, MS

The increasing prevalence of genetic diseases is a global concern. However, current treatments for many genetic diseases are limited to managing symptoms instead of correcting the cause. The gene-editing tool CRISPR-Cas9 (clustered regularly interspaced short palindromic repeats-associated protein 9) can be used to target specific DNA sequences and has shown potential as a possible therapeutic treatment for genetic diseases by enabling gene correction. The delivery of CRISPR-Cas9 into specific cells can be difficult to achieve due to immune system responses and specific biological barriers in place to prevent foreign materials from infiltration. To enable CRISPR-Cas9 delivery into cells, we investigate the use of self-assembling polymer-based nanoparticles (polymersomes) as an effective encapsulation and delivery method for the Cas9 ribonucleoprotein (RNP) to support non-viral gene editing. Film rehydration was used to synthesize polyethylene glycol and poly(lactic-co-glycolic acid) (PEG-PLGA) polymersomes, which were then optimized using sonication and filtration and characterized through dynamic light scattering (DLS). A TAT peptide was added to the polymersomes to provide a positive charge and improve endocytosis and endosomal escape. The human embryonic kidney cell line (HEK293-GFP) was selected for study because it contains a green fluorescence protein (GFP) which can be targeted for knockdown. First, sgRNA was designed to target GFP and made into an RNP that was tested via electroporation. Findings supported that the RNP was effective in GFP knockdown and was confirmed via fluorescence microscopy and flow cytometry. Treatment of HEK293-GFP cells with the RNP using sgRNA (CCATGGCACGGGCAGCTTGC) resulted in an average fluorescent knockdown of 64 ± 4.9% following a 72-hour incubation resulting in the selection of the RNP for encapsulation within polymersomes**.** The average size of polymersomes created via film rehydration was 84 nm ± 9.6 nm with an average PDI of 0.19 ± 0.03. Bicinchoninic acid (BCA) assay determined the average loaded content to be 5µg ± 1µg RNP for a total concentration of 2.5 µg/mg of Cas9 per polymer. Initial knockdown studies are ongoing using polymersomes, but preliminary fluorescent images are promising, demonstrating a decrease in GFP expression 72 hours after incubation. In conclusion, RNP was found to be effective in fluorescent knockdown. Future directions include in depth *in vitro* analysis in which encapsulated RNP is delivered to HEK293-GFP cells and then progressing to *in vivo* testing in Zebrafish.

Session Title: Genetic Therapies Poster Session I

PB2037 Quantitative characterization of on-target and off-target variation induced by CRISPR+Cas9 systems at the single-cell resolution.

Authors:

I. Salas-Gonzalez, V. Weigman; BioSkryb Genomics, Durham, NC

Introduction: Genome editing using CRISPR-Cas9 has revolutionized biomedical research by enabling the modification of DNA at targeted locations. The capacity of these systems to modify specific loci is dependent on the ability of Cas9 to induce DNA cleavage at genomic sites that exhibit precise base pairing with designed single guide RNAs (sgRNA). CRISPR/Cas systems are, conceptually, targeted editing tools, but the prevalence DNA edits that occur beyond the targeted gene (off-target effects) are increasingly observed. *In silico* tools have been developed to identify sgRNA guide-specific genome-wide potential off-target sites. Existing limitations of single cell genome enrichment have limited ability to confirm these in vitro, urging the need of unbiased methods of detection and validation. The goal of our study was to develop a bioinformatics workflow that could identify and prioritize on- and off-target gene editing events from single-cell whole genome sequencing data. Methods: We leveraged previously published data in which CD34+ cord blood cells and U2OS sarcoma cells were transfected with by two previously described sgRNAs (EMX1 and VEGFA) and Cas9. Mock treated and Cas9-only transfected cells served as a control. Single cells were isolated and primary template-directed amplification was used to amplify genomes from single cells. Libraries were created and deep sequencing (~20X coverage) was performed. Secondary bioinformatics analysis was performed using the WGS pipeline available in BaseJumper (BioSkryb Genomics). We called CNV events using Ginkgo, translocations were called using an ensemble approach overlapping events called by Manta and GRIDSS. *In silico* prediction of off-target events was done with Cas-OFFinder allowing up to 7 mismatches and 1 indel. Results: The EMX1 sgRNA induced more on-target mutations versus VEGFA sgRNA (5/5 vs 3/5 CD34+ cells and 5/5 vs 1/5 U2OS cells). Both guides exhibited heterogeneity in their on-target induced changes. Further, we characterized ~3200 reproducible off-target indels and 18 translocations from which only ~15% could be predicted in silico. Additionally, we identified ~150 mega bases across both cell types that exhibited significant fluctuation in their ploidy when exposed to the CRISPR+Guide treatments. Conclusions: We have developed a single-cell whole genome sequencing workflow for detecting indels, CNV, and SV alterations gene-edited cells. Overall, the data presented showcase the hidden heterogeneity of on-target modifications induced by CRISPR-Cas9 systems and the emergence of prevalent genome-wide off-target events impossible to determine with *in silico* approaches.

Session Title: Genetic Therapies Poster Session II

PB2038 † Rationale synthetic design of a broadly expressed NRF1-array mini-promoter for application to disease modeling and gene therapy.

Authors:

R. Nicholls[1], T. Zhang[1], J. Cheng-Zhang[2], W. Zhu[1], E. Hundertmark[2], M. Johnson[1], E. Koppes[1], D. Kemaladewi[3], G. Gittes[1]; [1]UPMC Children's Hosp, Pittsburgh, Pittsburgh, PA, [2]Univ. of Pittsburgh, Pittsburgh, PA, [3]Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA

Adeno-associated virus (AAV) has strict size limitations for packing into a viral particle, which previously limited the size of encoded therapeutic proteins or genome editing applications. To overcome this size limitation of AAV vectors and to provide a modular component for gene regulation, rather than the commonly used CMV promoter-enhancer (613-nt) or many cell-type specific promoters for gene expression, we rationally designed mini-promoters of length 34-nt to 210-nt. These mini-promoters are tandem arrays of 2-10 units in length of motifs (consensus is 5'-YGCGCANGCGCR-3') for a transcription factor (TF), NRF1, with 10-11 nucleotides spacing equal to one-turn of the DNA α-helix between binding sites to allow each NRF1-dimer to interact for potential cooperative binding (while an additional set of the vectors includes a TATA-box motif). Indeed, use of NRF1-arrays of 1, 2, 4, 6, 8 and 10 units displayed cooperative increases in luciferase expression within transfected SK-N-SH neuroblastoma cells. Subsequent characterization focused on the 4xNRF1 and 10xNRF1 promoters, with high levels of mNeonGreen expression from mammalian expression plasmids in cell lines including INS-1 β-cells, αTC1-6 α-cells, C2C12 mouse myoblasts, HEI-193 schwannoma, and mHippoE-2 hippocampal neurons. Next, robust expression was also demonstrated by fluorescence microscopy and luciferase assays using each of these two promoters in an AAV6-luc-GFP vector following viral transduction of rodent β- and α-cell lines, a human α-cell line, and by ductal infusion of each virus in wildtype mice with *in vivo* imaging of bioluminescence clear expression was observed in the pancreas. Critically, the 4xNRF1 mini-promoter was also utilized in a miniaturized CRISPR-activation (CRISPRa) AAV9 vector for therapeutic *Lama1* gene upregulation in a *Lama2*-deficient muscular dystrophy mouse model, resulting in reduced hindlimb paralysis, improved mobility, body weight, and survival. Previously generated synthetic promoters are based on random DNA motifs or utilize endogenous promoter fragments, but do not have the broad expression profile of the NRF1-array mini-promoters. Miniaturization of promoter and encoded functions will aid *in vitro* and *in vivo* disease modeling and gene therapy AAV applications.

Session Title: Genetic Therapies Poster Session III

PB2039 Retroelement analyses identify diagnostic and therapeutic opportunities in genetic disorders

Authors:

B. Zhao[1,2,3], M. A. Nguyen[1,2], S. Woo[4], J. Kim[4], T. W. Yu[1,2,3], E. A. Lee[1,2,3]; [1]Boston Children's Hosp., Boston, MA, [2]Harvard Med. Sch., Boston, MA, [3]The Broad Inst. of MIT and Harvard, Cambridge, MA, [4]KAIST, Daejeon, Korea, Republic of

Advances in clinical sequencing have dramatically accelerated the discovery of causal variants in genetic diseases; however, a substantial proportion of genetic cases remain unresolved as certain classes of genetic variation still escape detection in conventional analysis. Retroelement insertion is one such class, which has been increasingly reported as a cause of Mendelian diseases and may offer unique therapeutic implications.

To understand the contribution of retroelements to genetic diseases, we analyzed retroelement insertions in whole genome sequencing (WGS) data from 237 individuals with ataxia telangiectasia (A-T), a representative recessive Mendelian disorder. We identified 15 patients bearing retroelement insertions in the causative *ATM* gene, all but one of which landed in noncoding regions, highlighting the advantages of WGS over exome sequencing. Notably, 13 (~5.5%) patients carried one of five distinct pathogenic insertions. We found one exonic Alu insertion, as well as three intronic Alus that landed in close proximity (<50 nt) to exon-intron boundaries; the latter events led to different levels of exon skipping as validated by RNA sequencing, RT-PCR, and/or minigene splicing assays. Beyond Alu insertions, we also resolved a deep intronic *DUSP16* pseudogene insertion, which resulted in loss of ATM function by activating cryptic splice sites.

The discovery of splice-altering insertions may represent therapeutic opportunities with splice-switching antisense oligonucleotide (ASO). Previous work has shown that aberrant splicing caused by an SVA insertion could be corrected using ASOs—short, chemically modified RNAs—tailored to the aberrant splicing defects (Kim *et al.*, 2019, *NEJM*). For the *DUSP16* insertion, we developed proof-of-concept ASOs that suppress cryptic exonization, supporting the experimental amenability of some of splice-altering insertions with RNA-based ASO intervention.

Leveraging a well-phenotyped cohort of patients with A-T as a model, we provide a first systematic estimate of the contribution of retroelements to the genetic architecture of recessive Mendelian disorders as 5.5% (13/237 cases). Our study underscores the importance of retroelement insertions as an underexplored source of pathogenic genetic variation and therapeutic opportunities.

Session Title: Genetic Therapies Poster Session I

PB2040 Safety evaluation for CRISPR/Cas9-based PD-1 gene-editing products

Authors:

H. Kim; Natl. Inst. of Food and Drug Safety Evaluation, Cheongju-si, Korea, Republic of

CRISPR/Cas9 system is a versatile and specific gene-editing technique for applying to treat genetic diseases as well as intractable diseases. Despite the remarkable advances in CRISPR/Cas9 over the past decade, the assessment methods for CRISPR/Cas9-based human gene-editing products remain to be verified from regulatory perspectives. Here, we assessed the efficacy and safety of CRISPR/Cas9-based programmed cell death 1 (PD-1) gene-editing product by current 'on-target' and 'off-target' analysis methods. NGS-based analysis of insertion and deletion (Indel) showed that the Indel events occurred in 91% of transfected HEK293T cells. From the results of ELISA assay, the expression level of PD-1 protein was decreased by 44% in PD-1-targeted CRISPR/Cas-9 transfected Molt-4 cells, demonstrating that the CRISPR/Cas9 system disrupted the PD-1 gene in Molt-4 cells. Mycoplasma was not detected in PD-1 gene-edited Molt-4 cells. Next, the off-target effects were examined by using *in silico* prediction tool (Cas-OFFinder) and *in vitro* method (Digenome-seq). To perform Digenome-seq, we produced synthetic gRNA and Cas9-RNP complex *in vitro* followed by an assessment of DNA digestion efficiency using qPCR. The potential off-target sites of these Cas9-RNP were investigated by Whole Genome Sequencing. The results from targeted sequencing shows that the Indel events were hardly detected (<0.1%) among the highly ranked potential off-target sites obtained by Cas-OFFinder and Digenome-seq analysis. In this study, as a safety concern, we assessed off-target effects in CRISPR/Cas9-based PD-1 gene-editing products using *in silico* and *in vitro* off-target methods with comparative analysis. To increase the predictability of off-target effect, we suggest that integrated analysis would be necessary with orthogonal approaches using currently available and appropriate off-target methods depending on each CRISPR/Cas9-based gene-editing product.

Session Title: Genetic Therapies Poster Session II

PB2041 Safety of a reduced infusion time of Agalsidase Beta in the treatment of Fabry Disease: An Observational Study

Authors:

D. GERMAIN[1,2], A. EL MOUDEN[1], W. TRANG[1]; [1]Div. of Med. Genetics, APHP, GARCHES, France, [2]Div. of Med. Genetics, Univ. of Versailles, Montigny, France

Background: Fabry disease is an X-linked inborn error of metabolism caused by the deficiency of the lysosomal alpha-galactosidase A. Enzyme Replacement Therapy (ERT) with agalsidase beta was approved in 2001 and has demonstrated clinical benefits. Very few studies have explored the optimal duration of agalsidase beta infusions and many patients over the world are still infused during 3 hours every other week, in a lifetime way, significantly impairing their quality of life. In this work, the safety and tolerability of high speed agalsidase beta infusions were investigated.Patients and Methods: The safety of an optimized infusion time of 90 minutes (specified in the Summary of Product Characteristics) for the administration of 70 mg of agalsidase beta (diluted in 250 mL of NaCl 0.9%) was studied in 29 consecutive adult patients (15 males, 14 females) with Fabry disease (23 different *GLA* pathogenic variants) for a total of 53 infusions. The study population included 8 patients naïve to the enzyme and 17/29 patients with significant comorbidities. Physical examination was performed and vital signs were measured before and after each infusion. Results: Agalsidase beta was infused without premedication a constant rate of 0,77 mg/min (46,7mg/h) in all 53 infusions. None of the 29 patients complained of any discomfort. No adverse effect was reported. Vital signs remained stable in all patients during all infusions. Three patients received 105 mg of agalsidase in 90 minutes (1,16 mg/min - 70mg/h) with no side effects. Discussion: The infusion of 70 mg of agalsidase beta in 90 minutes (0,77mg/min) was well-tolerated with no report of discomfort or adverse effect. The optimized regimen reduces the burden of biweekly infusions, and improves patients quality of life in patients with Fabry disease.

Session Title: Genetic Therapies Poster Session III

PB2042 Short peptides targeting MECP2 Rett syndrome mutations through phage display

Authors:

J. Vincent[1], S. Pastore[2], T. I. Sheikh[1], J. Ausio[3], T. T. Madanagopal[1]; [1]Ctr Add/Mental Hlth, Clarke Div, Toronto, ON, Canada, [2]Ctr. for Addiction & Mental Hlth., Toronto, ON, Canada, [3]Univ. of Victoria, Victoria, BC, Canada

Background Mutations in MECP2 (methyl CpG binding protein 2) have been found to cause Rett syndrome (RTT). About 33% of all RTT patients have missense mutations, and mainly in the methyl-CpG-binding domain (MBD) that binds to DNA and forms a chromatin-associated protein complex. These mutations interfere with DNA binding and/or disrupt the clustering of chromatin. A similar proportion of RTT patients have nonsense mutations that truncate the MECP2 protein, leading to protein degradation resulting in insufficient levels in the cell. Studies have suggested this rapid degradation/insufficiency might also be true for missense mutations. Stabilizing the mutant protein could be a key to reverse the symptoms caused by insufficient levels of MECP2 and in-turn RTT. **Methods** T158M and R111G mutations were introduced to a MECP2/MBD vector construct by site directed mutagenesis with a GST tag. Wild type and mutant MECP2 vectors were over expressed in BL21 cells, and the resulting protein was used as the bait for phage display. After four rounds of selection, clones were sequenced by next generation sequencing, and peptides selected for MECP2 mutant binding over WT, or GST. Following this selection, a reverse approach using GST-tagged selected peptide as bait was used to pull down the MECP2-GFP protein using GST pull-down kit, as validation of the peptide-MECP2 binding. The peptides selected from this step were then synthesized with a Rhodamine B-tag. These peptides were then transfected into C2C12 cells using d-Arg8 (cell penetrating peptide). Only the peptides that co-localized with MECP2 were used for further analysis. The selected peptides will be used for cellular studies, to explore ability to bind MECP2 and stabilize and/or increase the bioavailability of mutant MECP2 protein. **Results** From the phage display experiment 11 peptides for wild type MECP2, 13 for T158M mutant and 13 for R111G mutant were selected. These peptides were then used for the reverse prey/bait GST pull down, and only 6 peptides for wild type and 5 peptides for T158M mutant were confirmed for binding to MECP2. No peptides were confirmed for the R111G mutant. These 11 peptides were then co-transfected in to C2C12 cells along with MECP2-GFP. The peptides that co-localized with MECP2 will be further analyzed for MECP2 protein stability and bioavailability with ELISA, cycloheximide chase assay and FRAP. **Conclusion** The selection of peptides that binds and stabilize MECP2 with specific RTT mutations through this approach may help develop personalized therapeutic approaches for RTT, and the approach may also be extended to other genes and diseases.

Session Title: Genetic Therapies Poster Session I

PB2043 Single-cell RNA Sequencing Data-based Drug Repurposing for Alzheimer's Disease Using Gene Expression data of ROSMAP Cohort

Authors:

T. Wang, C. Wang, D. Wu; Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Alzheimer's disease (AD) and related dementias currently affect 50 million individuals worldwide. Only 6 drugs, including four symptom relief agents and two disease-modifying agents, have been approved for AD. Drug repurposing (DR) offers a cost-effective and readily available strategy to address the need for new AD treatments. In this study, we employed the ASGARD (A Single-cell Guided Pipeline to Aid Repurposing of Drugs) algorithm to define a novel predictive drug score that considers all cell types and evaluates drug efficacy across multiple cell types. We applied ASGARD to publicly available single-cell RNA sequencing (scRNA-seq) data from the Religious Orders Study and Memory and Aging Project (ROSMAP). The ROSMAP is a large longitudinal clinical-pathologic cohort study of aging and AD, and the dataset includes snRNA-seq data obtained from post-mortem brain samples of 48 individuals, including 24 participants with AD and 24 participants without AD as controls. The analyzed tissue originated from the Brodmann area 10 prefrontal cortex. From the AD cases (26,049 cells) and controls (44,281 cells), we collected scRNA-seq data of 27,737 genes from brain tissues, analyzing 6 out of the 8 main cell types: excitatory neurons, inhibitory neurons, astrocytes, oligodendrocytes, microglia, and oligodendrocyte progenitor cells. Pericytes and endocytes data were excluded due to lower cell counts. Differential gene expression analysis using the Wilcoxon rank-sum test in Seurat identified differentially expressed genes between cases and controls. The ASGARD computed a drug score for each drug, quantifying the reverse of expression levels in the L1000 drug response dataset (GSE92742, GSE70138). Applying ASGARD, we predicted 6 drugs (FDR < 0.1 and overall drug score > 0.75 quantiles) to be potentially effective for AD, including dasatinib, vorinostat, sirolimus, dopamine, dexamethasone, and testosterone, ranked by decreasing drug score. Dasatinib, currently approved for chronic myeloid leukemia, is being investigated in phase I and II trials as a DR candidate for AD (SToMP-AD, STAMINA). Vorinostat, the second-best candidate, is an approved drug for T-cell lymphoma and is undergoing a phase I trial as a DR candidate for AD (VostatAD01). Sirolimus, approved for preventing kidney transplant rejection, is being evaluated in a phase II clinical trial as a DR candidate for AD (REACH). The predicted drug candidates will undergo validation through pharmacoepidemiologic analyses using real-world data (US Medicare claims) to assess their effectiveness in preventing incident dementia and slowing the progression of AD.

PB2044 Single-cell RNA sequencing reveals novel cellular factors for response to immunosuppressive therapy in aplastic anemia

Authors:

J. Jang[1], H. Kim[1], S-S. Park[2], M. Kim[3], Y. Min[3], H-o. Jeong[1], S. Kim[1], T. Hwang[1], D. W. Choi[1], H-J. Kim[2], S. Song[4], S. Lee[1], C. Lee[3], J. Lee[2]; [1]Ulsan Natl. Inst. of Sci. and Technology, Ulsan, Korea, Republic of, [2]Seoul St. Mary's Hosp., Seoul, Korea, Republic of, [3]Korea Res. Inst. of Chemical Technology, Daejeon, Korea, Republic of, [4]Chungnam Natl. Univ. Sch. of Med., Daejeon, Korea, Republic of

Aplastic anemia (AA) is a lethal hematological disorder; however, its pathogenesis is not fully understood. Although immunosuppressive therapy (IST) is a major treatment option for AA, one-third of patients do not respond to IST and its resistance mechanism remains elusive. To understand AA pathogenesis and IST resistance, we performed single-cell RNA sequencing (scRNA-seq) of bone marrow (BM) from healthy controls and patients with AA at diagnosis. We found that $CD34^+$ early-stage erythroid precursor cells (EPCs) and $PROM1^+$ hematopoietic stem cells (HSCs) were significantly depleted in AA, which suggests that the depletion of $CD34^+$ early-stage EPCs and $PROM1^+$ HSCs might be one of the major mechanisms for AA pathogenesis related with BM cell hypoplasia. More importantly, we observed the significant enrichment of $CD8^+$ T cells and T cells-activating intercellular interactions in IST responders, indicating the association between the expansion and activation of T cells and the positive response of IST in AA. Taken together, our findings represent a valuable resource offering novel insights into the cellular heterogeneity in the BM of AA and reveal potential biomarkers for IST, building the foundation for future precision therapies in AA.

Session Title: Genetic Therapies Poster Session III

PB2045 Small molecule inhibition of *Plasmodium AP2-I*&*BDP1* genes in *P. berghei*-infected mice

Authors:

D. O. Oladejo[1,2], D. O. Anzaku[1,2], C. O. Mamudu[1,2], T. M. Dokunmu[1,2], E. E. J. Iweala[1,2]; [1]Covenant Univ., Ota, Nigeria, [2]Covenant Applied Informatics and Communication Africa Ctr. of Excellence, Ota, Nigeria

Plasmodium transcription factors (TFs), along with other proteins in a complex, control gene expression during the intraerythrocytic development cycle of the parasites. We predicted *in silico*, the binding of a small molecule 7-[(7-methoxy-4,5-dihydro-1H-benzo[g]indazol-3-yl)carbonyl]-2-phenyl-5,6,7,8-tetrahydropyrazolo[1,5-a]pyrido[4,3-d]pyrimidin-9(1H)-one (MCL) to the active sites of *Pf*AP2-I and *Pf*BDP1 thereby inhibiting their actions. This study validated experimentally the inhibitory effects of MCL against *Pb*AP2-I and *Pb*BDP1 *in vivo* after due ethical approval. Forty mice were inoculated with 0.2 mL infected blood suspension having 1.0×10^7 parasitized erythrocytes intraperitoneally. Three days post-infection, mice were treated with 1, 10, 20, 30, 40, and 50 µM/kg body weight of MCL compound, respectively, and 10.00mg/kg chloroquine (control) for 7 days. Blood samples were obtained from the treated mice for analysis. RNA was extracted, and reverse-transcription PCR of AP2-I and BDP1 genes was carried out. Data were compared using ANOVA at $P<0.05$, and the relative gene expression of AP2-I and BDP1 genes was expressed as $2^{-\Delta\Delta Ct}$ of the untreated and treated relative to GAPDH (control). Relative gene expression results after a 7-day single oral dose shows MCL inhibited the expression of *Pf*AP2-I (by 4.52 and 8.08 folds) and *Pf*BDP1 (by 37.92 and 79.07 folds) at 40 and 50µM doses. Our findings validate that MCL inhibits *Pf*AP2-I and *Pf*BDP1 significantly by reducing its expression in treated mice, hence representing potential new targets of antimalarial therapy and for control of malaria parasite invasion.

Session Title: Genetic Therapies Poster Session I

PB2046 Suppression of dominant-negative *SPTAN1* allele in patient-derived cell lines via antisense oligonucleotide therapy

Authors:

C. Wang, S. Li, S. Zhao, J. Sinson, N. T. Ho, B. Vuocolo, G. Clark, S. Nagamani, P. Liu; Baylor Coll. of Med., Houston, TX

Spectrins are a family of cytoskeletal proteins that support positioning and stabilization of ion channels, cell adhesion molecules, and membrane proteins. Pathogenic variants in four out of six spectrin genes in humans have been discovered to cause neurodevelopmental disorders. Pathogenic variants in *SPTAN1* encoding αIIspectrin cause developmental and epileptic encephalopathy 5 (DEE5). SPTAN1, like other spectrins, comprises alpha and beta heterodimers that form tetramers in a head-to-head arrangement. Heterozygous pathogenic variants in the heterodimerization domain of *SPTAN1* (e.g., p.D2303_L2305dup) are suspected to cause dominant-negative aggregation of the thermolabile heterodimers, leading to more severe clinical phenotypes. Previous work has demonstrated accumulation of αII-spectrin aggregates in glutamatergic neurons derived from induced pluripotent stem cells (iPSCs) generated from patient-derived fibroblasts with the p.D2303_L2305dup variant. Targeting such dominant-negative variants from a therapeutic standpoint is made challenging by the presence of in-tandem spectrin repeats in the heterodimerization domain. We hypothesized that using a specific strategy with anti-sense oligonucleotides (ASO) to induce RNase-mediated cleavage of mRNA from the pathogenic allele can be of potential therapeutic value. We have obtained samples from three individuals, two of whom are monozygotic twins, with the p.D2303_L2305dup pathogenic variant. Here, we present a research grade ASO design strategy that successfully targets the p.D2303_L2305dup variant of *SPTAN1* in iPSCs and iPSC-derived neural progenitor cells and neurons generated from the three individuals with this particular variant. Expression analysis using qPCR revealed that the ASO led to a significant knockdown of mutant *SPTAN1* expression in iPSCs. Ongoing work is aimed at exploring off-target effects, as well as confirming reduction in the aggregation of thermolabile heterodimers in neurons and neural progenitor cells using fluorescent microscopy. Our approach would be an important first step in designing ASO and performing validations for DEE5 in patient-derived cell lines, and if successful, could help in the development and validation of therapeutic strategies for other neurodevelopmental disorders.

Session Title: Genetic Therapies Poster Session II

PB2047 Suppressors of TAZ-mediated cellular dysfunction identified through genetic interaction screening

Authors:

S. Masud[1], D. Thomson Taylor[1], N. Mikolajewicz[1], J. Wei[2], P. Mero[2], K. Chan[2], K. Brown[2], A. Habsid[2], O. Sizova[2], A. Quaile[3], J. Chan[3], J. Montenegro Burke[3], C. Boone[3], J. Moffat[1]; [1]Univ. of Toronto, Hosp. for Sick Children, Toronto, ON, Canada, [2]Hosp. for Sick Children, Toronto, ON, Canada, [3]Univ. of Toronto, Toronto, ON, Canada

The genotype-to-phenotype relationship in health and disease is complex, influenced by environmental and genetic factors. Unmasking the non-trivial pairwise genetic interactions on a genome-wide scale remains an active area of investigation in many prominent disease models. The diverse spectrum of phenotypes observed in Barth Syndrome (BTHS), caused by mutations in the gene *TAZ* is consistent with such complex genotype-to-phenotype interplay, however, systematic efforts to understand these interactions remain lacking. Furthermore, numerous mutations in the *TAZ* gene have been documented in BTHS patients, including frameshift, point mutations, as well as mutations that disrupt alternative splicing of *TAZ*. This diverse pattern of *TAZ* mutations suggest that several independent mechanisms contribute to a loss or altered function of Tafazzin, the protein product of *TAZ*, which may account for the pleiotropic nature of BTHS. We address this by leveraging our expertise in genome-wide CRISPR screens, mapping the genetic interactions between mutations in *TAZ* and all other genes in a systematic manner using a HAP1 cellular model. Our work has identified suppressing interactions with *TAZ* loss-of-function, restoring the critical lipid species cardiolipin, and rescuing *TAZ*-mediated mitochondrial dysfunction. Using several cell lines and animal models, we integrate functional genomics, proteomics, and the development of novel biologics that can lead to clinical/commercially relevant outcomes with the potential to greatly impact BTHS and expand on biological pathways critical in physiological and pathological mitochondrial conditions.

Session Title: Genetic Therapies Poster Session III

PB2048 Transforming a pathogenic dominant-negative variant into a benign loss-of-function variant: *ATAD3A* as a paradigm

Authors:

S. Ezer[1,2], S. Yanovsky-Dagan[1], L. Omari[1,2], A. Saada-Reisch[1], T. Harel[1]; [1]Hadassah Med. Ctr., Jerusalem, Israel, [2]Hebrew Univ. of Jerusalem, Jerusalem, Israel

Introduction *ATAD3A* is a nuclear gene that encodes a protein with various roles in the mitochondria. Among the pathogenic variants reported in this gene is a recurrent dominant-negative variant NM_001170535.3 (*ATAD3A*): c.1582C>T (p.Arg528Trp). Information available from families who carry deletion variants in *ATAD3A* confirms that carriers of one deletion with one wild-type allele are healthy. Thus, we assume that nullifying the dominant-negative allele using allele-specific targeting approach with antisense oligonucleotides (ASOs) could provide a therapeutic option. **Methods** We designed ten ASOs spanning the pathogenic variant and transfected these into patient-derived fibroblasts carrying the monoallelic variant. ASO specificity and efficiency was evaluated by several methods: RNA was sequenced followed by Synthego ICE analysis for measuring the relative change in expression of the mutant transcript triggered by each ASO; reverse transcriptase quantitative PCR was performed to measure the effect of ASO on reduction in total *ATAD3A* expression and C>T allele expression, and to test for normalization of the expression of selected genes we have previously shown to be affected by the dominant negative variant (e.g., *MFN2*). Mitochondria function was assessed by reactive oxygen species (ROS) production and cytochrome c oxidase (COX) activity. **Results** Several ASOs were found to improve the c.1582 wild-type/mutant allele ratio at the expression level, and accordingly improved mitochondrial function i.e. COX/citrate synthase ratio, normalize gene expression and decrease ROS production compared to untreated fibroblasts. At least one ASO consistently seemed to be harmful to the variant-carrying cells. Finally, ASOs that reduce the C>T allele drastically are also less specific and cause damage by also reducing the wild-type allele. **Conclusion** Allele-specific ASOs can be used to induce a shift in the relative expression of mutant/wild-type alleles, while improving mitochondrial function in cells with the *ATAD3A* recurrent pathogenic variant. While none of the ASOs studied resulted in a complete knockdown of the C>T allele, it is possible that improvement can be achieved by shifting the stoichiometry towards the wild-type allele. Non-specific targeting of the wild-type allele is harmful, even if there is a strong shift towards knockdown of the other allele. Further research in neuronal cells and animal models may provide further validation of this allele-specific therapeutic approach in monoallelic *ATAD3A*-associated disease. Moreover, this approach is generalizable to other disease genes with both dominant and recessive inheritance patterns.

Session Title: Genetic Therapies Poster Session I

PB2049 Understanding the role of Curcuma caesia Roxb. in *PIN1* degradation using SKOV3 ovarian cells.

Authors:

T. Patel[1], K. Mukunthan[2], P. Bhattacharya[3], N. Hempel[4]; [1]VIT Univ., Vellore, India, [2]Manipal Inst. of Technology, Manipal Academy of Higher Ed., Manipal, India, [3]Scientist, Neuberg Ctr. for Genomic Med., Neuberg-Supratech, Ahmedabad, India, [4]Faculty Member, Cancer Biology Program, UPMC Hillman Cancer Ctr., Pittsburgh, PA

Peptidyl-prolyl isomerase (*PIN1*) is over-expressed in many cancers and is known to contribute to the expansion of cancer stem cells. All trans retinoic acid (ATRA) induced down-regulation of *PIN1* reduces cancer cell proliferation especially using the slow releasing formulation of ATRA. Hence, it is employed in the treatment of ovarian cancer, bladder cancers, Kaposi sarcoma, squamous cell carcinoma, and neuroblastoma. However, its usage is limited by a very short half-life and so search for newer ATRA-like compounds is ongoing. C. caesia, also known as Black Turmeric (BT) is a bitter spice predominantly found in India and other south-east Asian countries. Our study was aimed to explore the protective role of Curcuma caesia Roxb. against cancer cell proliferation and *PIN1* over-expression. Computationally, we show that compounds from the hexane rhizome extract (HRE) of C. caesia have drug-like properties especially, Compound 3 that docks to PIN1 protein with optimum affinity and can be a novel PIN1 inhibitor. We carried out *in vitro* studies using SKOV3 ovarian cancer cells to compare the efficacy of ATRA and hexane extract. The MTS assay determined an IC_{50} value of 2.09 µg/mL and 12.77 µg/mL respectively for ATRA and HRE in SKOV3 cells. Clonogenic assay showed that hexane extract reduced the survival fraction of SKOV3 cells as compared to ATRA albeit not significantly. Furthermore, a significant increase in HRE induced cellular apoptosis was established as compared to ATRA with Annexin V assay. The relative mRNA expression for *PIN1* was significantly ($p<0.001$) reduced with HRE and was comparable to ATRA which also down-regulated *PIN1* drastically. In contrast, Western blot analysis showed a significant increase in PIN1 degradation using hexane extract as compared to ATRA treatment in SKOV3 cells. The mechanisms which may lead to PIN1 degradation by HRE needs to be elucidated in future studies. Our pilot study thus demonstrates that hexane extract from C. caesia may harbor molecules that can target cancer cells and may contain potential PIN1 inhibitors.

Session Title: Genetic Therapies Poster Session II

PB2050 † Weight loss in individuals with 16p11.2 deletion syndrome receiving GLP-1 receptor agonists and/or SGLT-2 inhibitors for type 2 diabetes treatment.

Authors:

H. Shimelis[1], C. Wood[1], L. K. Walsh[1], B. Finucane[1], S. M. Myers[1], J. E. Franceschelli[1], S. D. Christopher[1], M. T. Oetjens[1], L. H. David[2], C. L. Martin[1]; [1]Geisinger, Danville, PA, [2]Univ. of Florida, Jacksonville, Jacksonville, FL

Obesity is a common feature affecting 75-95% of adults with 16p11.2 deletion syndrome (16p11.2DS), a condition caused by a recurrent proximal deletion involving breakpoints 4-5. GLP-1 receptor agonists (GLP1-RA) and SGLT-2 inhibitors (SGLT-2-I) have shown benefit for weight management in patients with or without type 2 diabetes (T2D), however, there has been limited research on the effectiveness of these medications in adults with 16p11.2DS. This study compares weight loss and glycemic control among Geisinger MyCode participants with 16p11.2DS versus matched variant-negative controls who received GLP1-RA, SGLT-2-I, or co-treatment for T2D. Of 160 adults with 16p11.2DS, 19 (12%) were prescribed GLP1-RA (N=6), SGLT-2-I (N=6), or GLP1-RA and SGLT-2-I (N=7) and were compared with matched variant-negative controls (N=149). One-year percent total weight loss (TWL) and hemoglobin A1c (HbA1c) were assessed with linear mixed model. At baseline, the 16p11.2DS and control cohorts were similar for mean age (±SD): 51.9±10.3 years / 53.3±9.2 years; body mass index (44.3/42.9), gender, and T2D diagnosis (100%/100%), respectively. After one year, TWL among those treated with GLP1-RA alone was not significantly different between 16p11.2DS and controls, with each group experiencing ~2% weight loss. By contrast, SGLT-2-I monotreatment was far less effective for weight reduction in adults with 16p11.2DS compared to controls (-0.96% vs 3.23%), a mean difference of 4.19% (p=0.047). Co-treatment with both drugs did not significantly boost the effectiveness of GLP1-RA or SGLT-2-I monotherapy in controls. However, in the 16p11.2DS cohort, the combined use of both drugs resulted in significantly greater weight reduction than SGLT-2-I alone (6.46% vs. -0.93%), with a mean TWL difference of -7.43% (p=0.023); and GLP1-RA alone (6.46% vs. 2.08%), although the mean difference between co-treatment and GLP-RA only trended toward significance (p=0.15). Furthermore, the use of SGLT-2-I in the control group resulted in a significant HbA1c reduction (-1.08%), while the effects of GLP-1RA or co-treatment (-0.86%, -0.42%) were not significant. By contrast, in those with 16p11.2DS, monotherapy with SGLT-2-I or GLP-1RA did not show significant HbA1c reduction (-0.71%, -0.70%), however the effect of co-treatment (-1.82%) trended toward significance (p=0.09). Our findings suggest that adults with 16p11.2DS may derive significantly more benefit from co-treatment with GLP1-RA and SGLT-2-I than from SGLT-2 alone. Additional research is needed to confirm our findings, which may inform medication strategies for obesity treatment in adults with 16p11.2DS.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2051 A comprehensive genetic analysis unravels the impact of *PVRL1* in the risk of nonsyndromic cleft lip with or without cleft palate across ethnically diverse populations.

Authors:

J. Park[1], G. Kang[2], S-H. Baek[3], Y. Kim[4], D-H. Kim[5]; [1]Dept. of Med. Genetics, Hallym Univ. Coll. of Med., Chuncheon, Korea, Republic of, [2]Hallym Univ. Coll. of Med., Chuncheon, Korea, Republic of, [3]Dept. of Orthodontics, Sch. of Dentistry, Seoul Natl. Univ., Seoul, Korea, Republic of, [4]Dept. of Orthodontics, The Inst. of Oral Hlth.Sci., Samsung Med. Ctr. , Sungkyunkwan Univ. Sch. of Med., Seoul, Korea, Republic of, [5]Dept. of Social and Preventive Med., Hallym Univ. Coll. of Med., Chuncheon, Korea, Republic of

Nonsyndromic cleft lip with or without palate (NSCL/P) is a prevalent congenital anomaly, affecting approximately 135,000 infants worldwide each year. However, inconsistent replication of genetic effects, including the poliovirus receptor-related 1 (*PVRL1*) gene, in previous studies, suggests the presence of genetic heterogeneity across different ethnic groups. To address this, we initially performed a transmission disequilibrium test and evaluated parent-of-origin effects using 10 tagging single nucleotide polymorphisms (tSNPs) in 142 Korean families with NSCL/P. To validate our findings, we conducted replication analyses using publicly available data from 245 Asian families and 487 European families (dbGaP accession: phs000774.v2.p1). Additionally, case-control analyses were performed within each ethnic group. Our results demonstrated robust evidence of transmission disequilibrium at rs7940667 (allelic $p = 0.007$), which was consistently replicated in both Asian ($p = 2.96\times10^{-7}$) and European families ($p = 1.82\times10^{-11}$). Furthermore, the initial observation of marginal evidence for maternal over-transmission of the A allele at rs10790330 (PO-LRT $p = 0.044$) in Korean families was exclusively replicated in European families (PO-LRT $p = 0.0009$). Notably, all ten SNPs displayed significant transmission disequilibrium in European families, whereas five SNPs exhibited this effect in Asian families. In terms of parent-of-origin effects, distinct patterns of maternal over-transmission were observed for different SNPs, specifically rs7129848 in Asian and rs10790330, rs3935406, and rs10892434 in European families. Our findings provide robust evidence of transmission disequilibrium and highlight the impact of maternal over-transmission within the *PVRL1* gene on NSCL/P risk. The replication of these effects in both Asian and European families, along with larger family sizes, strengthens the statistical associations and supports the presence of a shared genetic basis across different ethnic groups. These results contribute to our understanding of the role of the *PVRL1* gene in NSCL/P risk and shed light on genetic heterogeneity underlying this condition.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2052 A longitudinal study on the maternal blood transcriptome during the early phase of onset of labor

Authors:

T. Leung, S-C. CHIM, R. Wang, W. Ding, K-W. WONG, E-L. KO; The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

BACKGROUND: The mechanism that instigates human parturition remains incompletely understood. Hence we investigated the changes in transcriptome of maternal blood before and after onset of labor.METHODS: Healthy singleton-pregnant women who were indicated for induction of labor (IOL) were invited to participate this longitudinal study. The maternal whole blood samples collected just before IOL and after latent phase of labor onset (cervical dilation <3 cm) were subjected to RNA-seq and RT-qPCR validation. To gain insights into molecular functions of the differentially expressed genes, gene functions from the Gene Ontology (GO) Consortium were analyzed.RESULTS: In the RNA-seq dataset, 913 mRNA transcripts were changed by >2-fold after the onset of labor, compared with before onset. The fold-change values showed the same direction of change between the RNA-seq and validation datasets. For instance, the maternal blood levels of CLEC4E and LIG4 mRNAs were increased after labor onset in both datasets. Women with high (>95th percentile) blood levels of CLEC4E mRNA underwent labor earlier (4.8 h vs 30 h, Logrank p =0.04) and delivered sooner (13 h vs 44 h, p =0.01) than their counterparts with low levels. Women with high (>median) blood levels of LIG4 mRNA underwent labor earlier (4.3 h vs 7.3 h, p =0.02) and delivered sooner (11 vs 14 h, p =0.02) than their counterparts with low levels. In the gene list with increased maternal blood RNA levels after labor onset, among other GO terms, regulation of neutrophil degranulation (7.4- fold), leukocyte aggregation (5.4-fold), production of molecular mediators involved in inflammatory response (5.3-fold) were enriched. In contrast, in the list of genes with decreased blood RNA levels after labor onset, no GO terms related to the immune system was found.Conclusion: During the early phase of labor onset, the maternal blood transcriptome is drastically changed, characterized with the upregulation of many genes in the immune system. The roles and potential of these genes in the prediction of a successful IOL (i.e. ending in spontaneous labor) warrants further investigation in a cross-sectional study along with women who failed IOL (i.e. ending in Cesarean delivery).

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2053 A molecular autopsy of fetuses with cerebral abnormalities and description of PLAT as a new putative hydrocephalus gene

Authors:

K. Uguen, M-A. Delrue, E. Lemyre, C. Maftei, A. Karalis, A-M. Laberge, J-F. Soucy, S. Perreault, C. Fallet-Bianco, J. Michaud; CHU Sainte-Justine, Montreal, QC, Canada

Purpose. Central nervous system (CNS) anomalies represent an important group of birth defects, occurring in approximately 0.3% of newborns. We hypothesized that fetal CNS anomalies may involve a distinct genetic landscape than that observed in children with homologous anomalies, as the former group includes a subset of cases that are so severely affected that they cannot survive beyond the perinatal period. In order to characterize the genes associated with these anomalies, we investigated fetuses with CNS anomalies from interrupted pregnancies by performing whole-exome sequencing (WES).
Methods. We recruited 85 fetuses with structural cerebral anomalies. They had negative array-CGH and no history of environmental factors that would explain their condition. All fetuses underwent autopsy with deep neuropathological examination. We also included cases with fetal akinesia as this disorder can be caused by severe CNS impairment. We performed WES in 62 of these trios while the sequencing of the remaining cases (n=23) is underway.
Results. WES revealed a genetic etiology in 31% of fetuses. The diagnostic yield was higher in fetuses with anomalies of the corpus callosum (6/14, 43%) and cortical defects (2/4, 50%), but lower in those with cerebellar hypoplasia (3/8, 38%) and isolated ventriculomegaly (3/10, 33%). Pathogenic variants were de novo in 63% and inherited in 37% cases. Interestingly, we describe the occurrence of a severe form of obstructive tetraventriculomegaly in two siblings from a consanguineous union. WES revealed the presence of a homozygous stopgain variation in the PLAT gene (NM_000930.5:c.85C>T, p.(Arg29Ter)), which encodes the tissue plasminogen activator. This finding and the previous description of hydranencephaly in two siblings with another homozygous truncating variant (NM_000930.5:c.102_103del)1 in PLAT strongly support the involvement of this gene in severe ventriculomegaly.
Conclusion. Our study highlights the diagnostic utility of WES in fetuses with cerebral anomalies. Moreover, the description of a second family with a homozygous truncating variant in PLAT emphasizes the potential role of this gene in severe ventriculomegaly, .

PB2054 A naturally occurring variant of *MBD4* causes maternal germline hypermutation in primates.

Authors:

A. Stendahl[1], R. Sanghvi[2], S. Peterson[1], K. Ray[1], A. Lima[1], R. Rahbari[2], D. Conrad[1]; [1]Oregon Hlth.& Sci. Univ., Beaverton, OR, [2]Wellcome Trust Sanger Inst., Cambridge, United Kingdom

As part of an ongoing genome sequencing project at the Oregon National Primate Research Center, we identified a rhesus macaque with a rare homozygous frameshift mutation in the gene Methyl-CpG binding domain 4 (*MBD4*). MBD4 is responsible for the repair of C>T deamination mutations at CpG dinucleotides and has been linked to somatic hypermutation and cancer predisposition in humans. We show here that MBD4-associated hypermutation also affects the germline: the 6 offspring of the *MBD4*-null dam have a 4-6-fold increase in *de novo* mutation burden. This excess burden was predominantly C>T mutations at CpG dinucleotides consistent with *MBD4* loss-of-function in the dam. There was also a significant excess of C>T at CpA sites, indicating an important, unappreciated role for MBD4 to repair deamination in CpA contexts. The *MBD4*-null dam developed sustained eosinophilia later in life, but we saw no other signs of neoplastic processes associated with *MBD4* loss-of-function in humans, nor any obvious disease in the hypermutated offspring. This work provides the first evidence for a genetic factor causing hypermutation in the maternal germline of a mammal, and adds to the very small list of naturally occurring variants known to modulate germline mutation rates in mammals.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2055 A novel basic carrier test for all ethnicities using long read sequencing and an artificial intelligence platform.

Authors:

C. Kyriakidis[1], M. Garrido Navas[2], G. Madjarov[3], L. Krych[4], A. Schack[5], K. Alapont Celaya[1], M. Chaushevska[1], Z. Velkoski[1], D. Galevski[6], A. Nikov[6], G. Nowicki[7]; [1]gMendel ApS, Copenhagen, Denmark, [2]Genyo Ctr., Alcalá la Real, Jaén, Spain, [3]Univ. Ss Cyril & Methodius, Skopje, Macedonia, The Former Yugoslav Republic of, [4]Univeristy of Copenhagen, Copenhagen, Denmark, [5]Univ. of Copenhagen, Copenhagen, Denmark, [6]Netcetera AG, Zurich, Switzerland, [7]GenXone S.A., Poznan, Poland

The prevalence of genetic disorders in the global population is expected to continue increasing. Through development of technologies for early detection, including for carriers of genetic disorders, advancement can be made in efforts to contribute to better disease management. In this presentation, we will focus on Basic Carrier Test, which, as recommended by the American College Obstetricians Gynecologists (ACOG) and the American College of Medical Genetics (ACMG) identifies adult carriers of all ethnicities of genetic disorders Fragile X, Spinal Muscular Atrophy (SMA), and Cystic Fibrosis (CF). We developed an Artificial Intelligence (AI) platform for real-time and automated simultaneous analysis and detection of genetic diseases. It enables extensive numerical and visualization analysis and accurate, systematic and timely diagnosis significantly improving disease management. This platform can be applied directly on the stream of base-called DNA reads generated by the Nanopore device. It exceeds the limits of the real-time monitoring and analysis per DNA sample, which can significantly reduce the overall cost. The calculated throughput of the analysis pipeline is 4120 reads per sec measured on a referent hardware architecture using thread parallelism of 10. This platform managed to correctly identify CF, SMA and Fragile X. Following testing and validation on a mix of real and synthetically prepared samples, the sensitivity and specificity exceeded 90% in patients from Denmark and Spain. This work is a groundbreaking proof of concept that the nanopore low-cost sequencing platform can serve as a certified diagnostic tool with AI-based disease classification for mass-screening significantly reducing time and cost of future diagnostics for any genetic disorder. At the same time, this work opens an opportunity to substitute older diagnostic tools with more accurate, faster and cost-effective technology, and therefore will contribute to improvement of life for people with genetic disorders by improving the current practices in healthcare.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2056 *Abca2* depletion associated with gastrulation and neurological defects in *Xenopus tropicalis.*

Authors:

F. Aslam[1,2], E. Mis[1], A. Acharya[1], W. Hwang[1], S. Naz[2], M. Khokha[1], S. Lakhani[1]; [1]Yale Univ., New Haven, CT, [2]Univ. of the Punjab, Lahore, Pakistan

ABCA2 is a member of membrane associated transport proteins known to transport molecules across extracellular and intracellular membranes. *ABCA2* encoded protein, highly expressed in the brain tissue, maintains the homoeostasis of lipids, especially sphingolipids, and sterols. *Abca2* knockout mice have neurological defects due to aberrant myelination. We identified recessively inherited frameshift variants of *ABCA2* in individuals of consanguineous families with neurological disease. Patients presented with developmental delay, intellectual disabilities, ataxia and seizures. In order to understand the molecular mechanism of ABCA2, we depleted *Abca2* in *Xenopus tropicalis* (*X. tropicalis*) by targeting the gene with CRISPR Cas9 using three nonoverlapping guide RNAs. Depletion of *Abca2* caused severe gastrulation defects. Embryos that survived past gastrulation had motility problems in later embryonic stages. We assayed motility in *X. tropicalis Abca2* depleted tadpoles by stimulating stage 45 tadpoles near the head and measuring the distance traveled. Spontaneous seizures were also observed in the form of a 'C' shaped curve in the tails of embryonic stage 45^{+} tadpoles. Human wild-type *ABCA2* overexpression rescued the gastrulation, motility and seizure phenotypes in *Abca2* depleted embryos but patient variants failed to do so, verifying the detrimental nature of the variants. Hence, *X. tropicalis* knockout of *Abca2* recapitulated the human phenotypes and also demonstrated an important role of the gene in early development. This work was supported by NIH/NICHD (R01hd102186) and IRSIP funding to FA from HEC, Pakistan.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2057 Aberrant landscapes of maternal meiotic crossovers contribute to aneuploidies in human embryos

Authors:

R. McCoy[1], D. Ariad[2], S. Madjunkova[3], M. Madjunkov[3], S. Chen[3], R. Abramov[3], C. Librach[3]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Johns Hopkins Univ., Balitmore, MD, [3]CReATe Fertility Ctr., Toronto, ON, Canada

Meiotic recombination is a fundamental source of human genetic diversity and is also critical for ensuring the accuracy of chromosome segregation. Understanding the landscape of meiotic recombination, its variation across individuals, and the processes by which it goes awry are long-standing goals in human genetics. Current approaches for inferring the landscape of recombination either rely on population genetic patterns of linkage disequilibrium (LD)—capturing a time-averaged view—or direct detection of crossovers in gametes or multi-generation pedigrees, limiting the scale and availability of relevant datasets. Here, we introduce an approach for inferring sex-specific landscapes of recombination from retrospective analysis of data from preimplantation genetic testing for aneuploidy (PGT-A) based on low-coverage (<0.05×) whole-genome sequencing of biopsies from *in vitro* fertilized (IVF) embryos. To overcome the sparsity of these data, our method exploits its inherent relatedness structure, knowledge of haplotypes from external population reference panels, as well as the frequent occurrence of chromosome loss in embryos, whereby the remaining chromosome is phased by default. Based on simulation, we show that our method retains high accuracy down to coverages as low as 0.02×. Performance is affected by the local density of SNPs and sequencing reads, as well as ancestry matching between the reference panel and the target samples. Applying this method to low-coverage PGT-A data from 18,967 embryos, we mapped 70,660 recombination events at an average resolution of ~150 kbp. The resulting sex-specific maps of crossovers generated by our method were strongly correlated with published sex-specific genetic maps based on prospective whole-genome sequencing of living parent-offspring trios, in support of the accuracy of our method. However, we observed that the total length of the female genetic map is reduced for trisomies compared to disomies, while the genomic distribution of crossovers is also altered in a chromosome-specific manner. These observations include a depletion of crossovers near the centromere for trisomies compared to disomies of chromosome 16. Based on haplotype configurations in regions surrounding the centromeres, our data additionally indicate that individual chromosomes possess unique propensities for different mechanisms of meiotic error ($\chi 2[2, N = 2540] = 489.2$, $p = 1.6 \times 10^{-77}$). Together, our results provide a detailed view of the role of aberrant meiotic recombination in the origins of human aneuploidies, as well as a flexible tool for mapping crossovers in low-coverage sequencing data from multiple siblings.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2058 † Application of single-cell multiomics technology to establish an effective screening method for identifying fetal nucleated red blood cells suitable for non-invasive prenatal genetic testing.

Authors:

N. Ito[1], T. Fujii[1], K. Taniguchi[1,2], K. Hata[1,2], H. Sago[1], K. Nakabayashi[1]; [1]Natl. Ctr. for Child Hlth.and Dev., Tokyo, Japan, [2]Gunma Univ. Graduate Sch. of Med., Gunma, Japan

Non-invasive prenatal genetic testing (NIPT) based on cell-free DNA (cfDNA) in maternal plasma has prevailed worldwide. However, low levels of the fetal DNA fraction may lead to false-negative results. In contrast, since fetal cells in maternal blood represent a pure source of fetal genomic DNA, they are expected to be ideal for NIPT if successfully isolated. We have previously established a protocol to efficiently isolate fetal nucleated red blood cells (fNRBCs) from maternal blood using fluorescence-activated cell sorting with erythrocyte-associated surface antigen markers (Ito N et al. 2021). However, the efficiency of the whole genome amplification in the single isolated cells was not consistent enough for subsequent genomic diagnostics. The quality of genomic DNA may have deteriorated due to enucleation and/or apoptosis in most isolated fNRBCs. In this study, we tested whether multiomics technology effectively overcame this problem. We adopted a single-cell multiomics technique, G&T-seq , which can obtain parallel sequencing data of single-cell genomes and transcriptomes. Using umbilical cord blood as a model, we isolated 12 single lymphocytes and 69 single NRBC candidate cells from two samples and obtained their genomic and transcriptomic data. As expected, we could distinguish lymphocyte and NRBC candidate groups based on gene expression patterns. When plotted using multi-dimensional scaling (MDS), three NRBC-candidate cells were clustered separately and located between the lymphocyte cluster and the other 66 NRBC-candidate clusters along the dimension-1 axis. Based on the expression levels of the marker genes for the primitive, intermediate, and mature stages of NRBC maturation, three NRBC-candidate cells from the separate group were classified as those in the primitive stage and the other 66 NRBC-candidate cells as those in the mature stage. We subsequently assessed the quality of the genomic sequencing data based on their library yield and mapping rate for all cells. Two out of three cells in the primitive stage showed high library yields and mapping rates comparable with those of lymphocyte cells, suggesting the intactness of their nuclear genome when the two cells were isolated. Therefore, G&T-seq effectively identified NRBC cells in the primitive stage among NRBC candidates. Applying single-cell multiomics technology is expected to facilitate the development of fNRBC-based NIPT.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2059 Bioinformatic identification of small X chromosome CNVs in 46, XY pregnancy loss cases suggest novel male lethal candidate genes.

Authors:

J. Cao[1], K. Hatchell[2], S. Aguilar[2], M. Aminbeidokhti[3], C. Tise[4], A. Rajkovic[3,5,6], J. Bernstein[7], S. Yatsenko[8,9,10,11], M. Snyder[1], S. Aradhya[2,12], R. B. Dept. of Pediatrics, Stanford, CA, [5]Univ. of California San Francisco Inst. of Human Genetics, San Francisco, CA, [6]Univ. of California San Francisco Dept. of Obstetrics, San Francisco, CA, [7]Stanford Univ. Sch. of Med. Dept. of Pediatrics, Stanford, CA, [8]Univ. of Pittsburgh Dept. of Pathology, Pittsburgh, PA, [9]Magee-Womens Res. Inst., Pittsburgh, PA, [10]Univ. of Pittsburgh Dept. of Obstetrics, Pittsburgh, PA, [11]Univ. of Pittsburgh Dept. of Human Genetics, Pittsburgh, PA, [12]Stanford Univ. Dept. of Pathology, Stanford, CA, [13]Stanford Univ. Dept. of Obstetrics and Gynecology, Stanford, CA

Background: Human reproduction is inefficient, with ~70% of all conceptions not progressing to live birth. While large chromosome abnormalities are commonly seen in pregnancy losses, nearly half of pregnancy losses remain unexplained by standard of care chromosome analysis. An overrepresentation of karyotypically normal 46, XY conceptions among pregnancy losses suggests many X-linked genes may be essential for development and survival of male fetuses. Currently, only ~30% of X-linked genes have been linked to specific genetic conditions, while the clinical importance of the remaining 70% is undetermined. The objective of this study was to identify copy number variations (CNVs) on the X chromosome to assess possible correlations with male pregnancy loss and identify novel genes and their functions that may be essential for embryonic development. **Methods:** We analyzed anonymized high-resolution chromosomal microarray data and reported test results from 12,506 pregnancy loss samples, referred for genetic testing at a single clinical laboratory. We examined the clinically reported chromosomal analysis results and CNVs for each sample. We then performed blinded de novo bioinformatic analysis, independent of clinical laboratory processes, to enrich for and characterize smaller CNVs of unknown significance on the X chromosome of male samples. **Results:** Among the 12,506 pregnancy loss CMA results we examined, 7,428 cases were euploid, including 4,214 (56.7%) males and 3,214 (43.3%) females. Clinically reportable CNVs were present in 1,269 (30.1%) of XY euploid conceptions, including 75 X chromosome CNVs, consistent with results reported to referring physicians. We further identified ~400 samples with CNVs on the X chromosome of uncertain clinical significance, including many <1Mb CNVs that were not reported clinically. Within these abnormal regions, we identified CNVs involving several genes (*NKRF, SEPTIN6, SRPK3, IDH3G, BRCC3*) which have not been reported in live born males and currently have no known OMIM phenotype or disease association. **Conclusion:** In this analysis of >7,000 46,XY pregnancy loss cases, we demonstrate an enrichment of male losses and numerous incidences of small X chromosome CNVs that are not typically sought out or reported during clinical testing. These findings provide critical and new information about specific genes and point to genomic regions on the X chromosome that may be lethal when copy number is disrupted. This work and similar studies of this magnitude have the potential to identify novel gene alterations associated with human lethality, and improve the understanding of embryonic and fetal development.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2060 Can first trimester prenatal samples be used to functionally assess Noonan syndrome variants?

Authors:

N. Zjacic[1], G. Siegel[1], I. Ivanovski[1], A. Bahr[1], M. Mocera[1], P. Krejci[1], B. Oneda[1], T. Burkhardt[2], A. Rauch[1]; [1]Inst. of Med. Genetics, Univ. of Zurich, Schlieren, Switzerland, [2]Univ. Hosp. Zurich, Univ. of Zurich, Zurich, Switzerland

Noonan syndrome (NS) is a congenital disorder that affects 1 in 1000-2500 births and is most commonly caused by gain-of-function variants in genes of the essential Ras-mitogen-activated protein kinase (Ras/MAPK) pathway. This results in pleiotropic developmental problems of varying severity such as cardiac defects and neurocognitive deficits, as well as increased predisposition to childhood malignancies. After exclusion of chromosomal aberrations, NS and other RASopathies are the most common differential diagnosis in fetuses with increased nuchal translucency detected by first trimester screening. There are currently no routine functional tests available for parents expecting a child with a variant of unknown significance (VUS) in a RASopathy gene that would allow them to make informed decisions after genetic screening or prepare for post-pregnancy. Our goal was therefore to create a direct, patient cell-based analysis pipeline that would provide functional information on VUS in NS genes in a short enough time frame for critical pregnancy-related decisions. We tested Ras/MAPK pathway functional readouts from established overexpression studies in HEK293 and Cos-1/7 cells, as well as a novel approach, for direct functional assessment of cultured chorionic villi sample (CVS) cells obtained during invasive prenatal sampling. Five patient CVS lines containing one unclear and four (likely) pathogenic variants in the most common NS disease genes, *PTPN11* and *SOS1*, were compared to five healthy control lines. We found no significant differences between patient and control activation of ERK1/2 via Western blot or activation of RAS via ELISA analysis of whole cell lysates. This contrasts the published HEK293 and Cos-1/7 overexpression studies which showed increased and prolonged activation of pathway components. In addition to the established readouts for individual components of the Ras/MAPK pathway, we tested a commercially available serine/threonine kinase assay to compare the activity of 144 kinases from multiple pathways in patient and control cells. The assay did not produce robust enough results to select biomarkers that distinguish between patients and controls. Overall, our data show that cultured CVS cells from invasive first trimester prenatal testing may not suitably reflect the increased Ras/MAPK pathway activity underlying NS when analyzed using conventional functional assays from the literature or a novel kinase assay approach. A different cell type or an entirely different strategy will therefore be required for creating a functional pipeline for VUS in NS genes.

PB2061 Cell-type specific methylome-wide significant associations for adverse neonatal outcomes detected in blood.

Authors:

T. Campbell[1], L. Xie[1], C. Hultman[2], E. Van den Oord[1], K. Aberg[1]; [1]Virginia Commonwealth Univ., Richmond, VA, [2]Karolinska Inst., Stockholm, Sweden

Adverse neonatal outcomes such as small birth size, early gestational age, low APGAR score, and neonatal jaundice have been associated to an increased risk of physical and mental health conditions. A potential mechanism by which neonatal outcomes may lead to these conditions, is via epigenetic variation, such as DNA methylation (DNAm). DNAm is often cell-type specific, requiring the need to control for cell-type composition when studying bulk tissue. However, even with such adjustments, standard bulk analyses represent an average value across the cell-types present, often preventing differences in specific cell-types to be detected. Here we use sequencing-based MBD-seq data, from nearly 28 million CpGs, from 332 neonatal blood samples. Next, we use statistical deconvolution to performed cell-type specific methylome-wide association studies (MWAS) of neonatal outcomes. In addition to investigating 9 individual neonatal outcomes, we used an exploratory factor analysis that identified two factors, which represents shared effects mainly from size related (size factor) and disease related (disease factor) outcomes. We also regressed out these factors from the outcomes allowing us to study outcome specific effects. We identified methylome-wide significant ($q<0.1$) associations for the disease and size factors and for APGAR. The significant findings for the size factor were detected for B cells (N=5), granulocytes (N=10), monocytes (N=12), cytotoxic T cells (N=27) and bulk (N=13). Of note, the top findings in granulocytes ($P=3.35x10^{-9}$, $q=0.0694$) and monocytes ($P=1.12x10^{-11}$, $q=0.0003$) were the same CpG, but with different direction of effect, located in the *BLNK* gene, highlighting the importance of cell-type specific analysis. For the disease factor, findings included monocytes (N=2), cytotoxic T cells (N=28), T helper cells (N=216) and bulk (N=2). Here, we detected the same three significant CpGs in cytotoxic T and T helper cells ($P<6.10x10^{-8}$, $q<0.0922$) that overlapped *SLC12A7,* which has been identified as a biomarker for childhood cancers. For APGAR, findings were detected for granulocytes (N=1), natural killer cells (N=1) and bulk (N=10). This included five CpGs ($P<1.08x10^{-8}$, $q<0.0374$) overlapping *ASRGL1,* which has been identified as a biomarker for spontaneous preterm birth. To our knowledge, this is the first time that cell-type specific methylation patterns have been studied in relation to neonatal outcomes. Our results suggest that most outcomes are linked to two distinct processes (i.e., from different factors) which provide valuable insights into the cell-type specific role DNAm plays for these neonatal outcomes.

PB2062 Clinical significance of cell free DNA screening positive trisomy 15: Cohort study and literature review.

Authors:

R. Choy[1], S. Xue[1], D. Lam[2], S. Cheung[2], Y. Zhao[1], Y. Zheng[1], C. Chung[1], Y. Kwok[1], X. Zhu[3], T. Leung[1], X. Kong[3]; [1]Chinese Univ. of Hong Kong, Hong Kong, China, [2]NIPS Dept., NGS lab, Xcelom Limited, Hong Kong, China, [3]Genetics and Prenatal Diagnosis Ctr., Dept. of Obstetrics and Gynaecology, The First Affiliated Hosp. of Zhengzhou Univ., Zhengzhou, China

Cell free DNA (cfDNA) testing has expaned to include rare autosomal trisomies. Trisomy 15 is one of the most common imprinted chromosome aneuploidies identified in cfDNA test and fetuses with trisomy 15 positive result may be at risk not only of fetal trisomy but also of fetal uniparental disomy (UPD) 15 responsible for Angelman/Prader-Willi syndrome. Currently, the positive predictive value (PPV), risk of fetal UPD 15 and the clinical significance of trisomy 15 positive cases are largely unknown. This study aims to investigate the clinical significance of cfDNA positive for trisomy 15. We prospectively studied the performance of cfDNA for testing trisomy 15 in 36,466 pregnant women in a single center. The incidence, PPV, and risk of UPD 15 were assessed based on amniocentesis results by cytogenetic, molecular analysis and reported clinical outcomes. Eleven of 36,466 cases were reported positive for trisomy 15 in our cohort, yielding a cfDNA screen-positive rate of 0.030% (11/36,466). Invasive diagnostic testing results revealed the PPV for trisomy 15 was 36.4% (4/11) and 3 of 9 (33.3%) cases were confirmed with maternal UPD 15. We further conducted a systematic review of cfDNA cohort studies that have reported the detection of trisomy 15 to generate a large cohort. The incidence, diagnostic accuracy as well as pregnancy outcomes of trisomy 15 positive cases were studied. We generated a large cfDNA cohort of 826,601 pregnancies and identified 130 cases (0.016%) that were screened positive for trisomy 15. In total, 18 of 75 cases with diagnostic results were confirmed in the fetuses, including 8 full trisomy 15 and 10 true fetal mosaicism, with an overall PPV of 21.6% (18/75, 95% CI, 3.9-44.9). Among 46 cases with UPD testing, 13 (28.3%) were identified to be maternal UPD 15, and 8 of them had normal fetal karyotypes. 70.0% (49/70) of the patients experienced adverse pregnancy outcomes, including 32.9% fetal loss, 24.3% selective termination of pregnancy, and 12.9% with other pregnancy complications. The overall PPV of cfDNA positive trisomy 15 is 21.6%, and fetuses with cfDNA-positive trisomy 15 results showed a high risk (28.3%) of Prader-Willi syndrome resulting from maternal UPD 15. Our data suggests that amniocentesis should be recommended for cfDNA positive trisomy 15 case and exclusion of both UPD and true fetal mosaicism are highly warranted.

PB2063 Convergent coexpression of autism-associated genes implicates early immune dysfunction

Authors:

F. Segato Dezem[1], C. Cheng[2], J. Plummer[3], K. Aldinger[4]; [1]St Jude Children s Res. Hosp., Los Angeles, CA, [2]Boston Univ. Sch. of Med., Boston, MA, [3]St Jude Children s Res. Hosp., Memphis, TN, [4]UW/Seattle Children s Res. Inst., Seattle, WA

Autism spectrum disorder (ASD) is a highly variable neurodevelopmental disorder diagnosed based on a core set of social communication impairments and repetitive sensory-motor behaviors. Individuals with ASD often also exhibit a wide range of clinical features that vary in severity and parallel the heterogeneity among the common and rare genetic variants associated with ASD etiology. Despite this clinical and genetic complexity, pathway enrichment among ASD-implicated genes has suggested some functional commonalities, including impairments in synapse function and chromatin modification. However, most prior studies focused on the potential impact of genetic variants on brain development even though the genetic changes occur in all cells of the body and their impact is expected to contribute to both brain and non-brain clinical phenotypes. Here, we examined the expression of high-confidence ASD-associated genes (345 curated from SFARI high-confidence gene list) across multiple organs during human development to more comprehensively investigate the tissues and cell types that are vulnerable to ASD pathophysiology. Paired enrichment analysis revealed ASD genes enriched in the thymus, cerebellum, cerebrum, eye, and kidney ($P<0.05$). We employed an empirical binary classifier (ROCit) of the ASD gene set against single-cell gene expression profiles from the Descartes Atlas of human gene expression during development which profiled 4 million cells from 15 prenatal tissues. Partitioning cell type identities revealed a set of ASD genes (SCAI, MBD5, CASK) with enriched expression in the thymocytes. Immune dysfunction has been implicated in ASD etiology and the thymus is a critical site for T cell development. Our results suggest there may be an early primary role for immune-mediated dysfunction in ASD pathogenesis. Understanding ASD genetics in the context of body-wide single-cell gene expression during development provides a framework for understanding which genetic perturbations could lead to the complex clinical features recognized among individuals diagnosed with ASD.

PB2064 Correlation between maternal copy number variations and preterm birth in Indian women: A pilot study

Authors:

D. Charan[1], D. Chandel[2], T. Patel[3]; [1]Vellore Inst. of technology, Vellore, Vellore, India, [2]Sch. of Sci.s, Gujarat Univ., Ahmedabad, India, [3]VIT Univ., Vellore, India

Preterm birth (PTB) is a condition of spontaneous parturition before the completion of 37 weeks of gestation. PTB causes multiple birth complications, lifelong disabilities and can be frequently fatal to the neonates. India has the highest number of preterm births second only from African countries. Multiple factors like maternal malnutrition, inflammation/infection, endocrinological or genetic causes could be attributed to PTB. In this study we performed certain biochemical and molecular analysis for three patients [Institutional Ethical Committee of - GU (GUJIEC_03_2017)/GMERS-(GMERSMCS/IEC/37/2018).The preliminary survey showed they belong to the lower economy strata indicating maternal malnutrition as one of the reasons. Besides this, the ROS biochemical panel showed an increased oxidative stress, along with increased micronuclei. These outcomes can be a result of inadequate nourishment, unhygienic living environment and/or genotoxic exposures. Pan-genome copy number variation study (Illumina) in these 3 maternal samples showed that one of the samples had only three CNVs (Sample 2) while the other two sample have 46 and 83 CNVs (Sample 1/3) respectively. Few genes showed loss of heterozygosity while some showed increase in the copy number across all the samples studied. STRING analysis did not give us any common genes among the three samples establishing that more sample size is required to conclude the involvement of specific genes in PTB. We conducted in silico gene enrichment studies. Most of the genes for sample 1 were clustered under infection, inflammation, physiologic conditions like hypertension and endocrinological disturbances. Sample 2 with not many variations in gene copy number, showed genes clustered only around viral infection. Sample 3 had genes clustered under infections and a few other genes under non-heritable genetic conditions. More sample size is required to conclude the outcomes of preterm births. However, the primary data suggest that malnourishment and unhygienic living environment which leads to infections could be one of the early causes of PTB. This could be elevated by fragile genetic makeup and variations in copy number due to molecular events in genes involved in cellular, biologic, and molecular functions.

PB2065 Detection of fetal RhD status on SNP-based prenatal cell-free DNA screening

Authors:

T. Wang[1], Y. Altug[1], S-C. Kuo[1], X. Wang[1], N. Avent[2], S. Vege[3], H. Pawar[1], R. Swenerton[1], G. Heilek[1], B. Zimmermann[1], J. Babiarz[1]; [1]Natera, Inc., San Carlos, CA, [2]Consultant, Bristol, United Kingdom, [3]New York Blood Ctr., Long Island City, NY

Background: Rhesus D (RhD) alloimmunization can occur if a RhD negative (RhD(-)) individual is exposed to RhD positive (RhD(+)) blood. In the US, antenatal prophylaxis with anti-RhD immunoglobulin at 28 weeks gestation and after a potential sensitizing event is standard of care for RhD(-) pregnant people unless the father of the baby is also Rh(-) or the pregnant person is already RhD alloimmunized. In some countries, quantitative PCR (qPCR)-based NIPT for fetal RhD status in D(-) patients is used to avoid unnecessary treatment with anti-RhD immunoglobulin and to guide pregnancy management in RhD alloimmunized patients. Here, we establish the proof of concept of testing fetal RhD as a part of an SNP-based NIPT (Panorama^{TM}) that utilizes massively multiplex PCR (mmPCR) to screen for common chromosomal aneuploidies and microdeletions.
Methods: A set of primers for targeted amplicons covering regions differing between the *RHD* and *RHCE* genes were designed and incorporated into the NIPT assay. *RHD* and *RHCE* can be directly detected by targeting the differences between these two highly similar genes. To assess sensitivity of the approach, we developed models from cell lines with known RhD status to mimic RhD(-) pregnancies, carrying either an RhD(+) or RhD(-) fetus over a range of fetal fractions from 1% to 15%. Additionally, the method was tested on 996 de-identified pregnant patient plasma samples using qPCR for concordance analysis.
Results: Cell line mixture experiments that modeled RhD(-) pregnancies, including minor RhD(-) genotypes, showed the mmPCR approach was able to determine fetal RhD status. These experiments also demonstrated accurate detection of RhD status across a range of fetal fractions, even below the current 2.8% threshold for aneuploidy calling. Among 996 pregnant patient samples, all 110 RhD(-) were correctly identified, with 40 RhD(-) fetuses and 70 RhD(+) fetuses. These results were confirmed with qPCR. This yielded a Negative Percent Agreement (NPA) of 100% [95% CI: 91.2-100%] and a Positive Percent Agreement (PPA) of 100% [95% CI: 94.9-100%]. Importantly, the addition of RhD targets did not interfere with overall NIPT performance.
Conclusions: mmPCR and sequencing allows for the direct observation and quantification of fetal *RHD* alleles, enabling the accurate prediction of fetal RhD status, even at low fetal fraction. Our results established the proof of concept for adding RhD detection to the Panorama^{TM} NIPT assay to screen for fetal Rh status as early as 9 weeks gestation. Information about fetal RhD status has potential to be incorporated into the management of RhD(-) pregnancies.

Background: Differences of Sex Development (DSD) are a spectrum of conditions with atypical sex chromosomes and/or anatomical or gonadal development. While accurate diagnosis is difficult even in high-income countries, little is known about DSD in low-resource settings, specifically the Democratic Republic of Congo (DRC). High cost of and limited access to care, and lack of trained specialists are obstacles to optimal care for rare diseases in the DRC. Standard karyotyping and other tests necessary to distinguish DSD conditions with different management are unavailable locally. To address these gaps we established a care network with local and foreign experts in genetics, pediatrics, gynecology, surgery, endocrinology, psychology. **Methods:** Health professionals were sensitized to the recognition of DSD in newborns, children, and adults through social media and clinical visits. Patients' clinical evaluations were standardized using an adaptation of the DSD-Translational Research Network (DSD-TRN) forms. To assess etiology, saliva was sent to Children's National in Washington, DC for exome (n=23 for 10 probands) or genome (n=43 for 20 probands) sequencing. **Results:** Thirty-one participants (2 months to 26 years) and their bio-relatives were recruited from December 2021 to May 2023: 17 had a male sex-of-rearing, 12 female, and 2 had experienced a change from female to male. All were brought to medical attention because of genital atypia. The 10 exomes identified only one possible etiology, a sex chromosome aneuploidy. Genome sequencing identified 6 causative variants. An intronic variant in *AR* established a diagnosis of partial androgen insensitivity in a 22 year-old XY male, raised as a female until age 5. Trisomy 21 explained the hypospadias in an XY boy. A recurrent homozygous *SRD5A2* variant described in the historical cases of 5α-reductase deficiency in the Dominican Republic was found in a family with two XY females and an unrelated individual. Others were a de novo stop gain in *NR5A1* and, *NR5A1* and *AR* missense variants. No definitive diagnosis could be made in the 8 individuals where short-read sequencing suggested XX sex complement. A single *CYP21A2* Gln319* variant was found in an XX male, but a diagnosis of Congenital Adrenal Hyperplasia could not be established as short-read sequencing is inadequate to identify the gene conversions responsible for most pathogenic alleles in this gene. **Conclusion:** This experience of DSD multidisciplinary clinic in DRC showed local challenges for the diagnosis and optimal management of these complex conditions. Collaborations between international and local experts may help advance diagnosis in low resources settings.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2067 † Early commitment to neuroectoderm is reduced in Down Syndrome iPSCs due to dysregulation of a Primary Cilium-Autophagy-Nrf2 (PAN) axis

Authors:

M. Chaklader, B. Rothermel; UT Southwestern Med. Ctr., Dallas, TX

Down syndrome (DS), caused by trisomy of human chromosome 21, is the most common genetic cause of intellectual disabilities and is associated with an increased risk for a wide range of developmental and degenerative processes. Analyses both in human and mouse models have shown delays in cortical neurogenesis during the development of DS embryos. The underlying cause of this defect has yet to be fully understood. We have found that iPSCs derived from individuals with DS (3S-iPSCs) are intrinsically less capable of committing to a $PAX6^+$ neuroectodermal lineage (NE) when compared to isogenic, diploid iPSCs controls (2S-iPSCs), both under conditions of spontaneous differentiation and when subjected to directed differentiation protocols. The primary cilium is a threadlike projection that extends from the cell membrane of many cell types, acts as a signaling hub, and is involved in many developmental and adaptive processes. Other investigators have proposed that the primary cilium helps direct stem cells toward a neuroectodermal fate during normal development by increasing autophagic activity to reduce NRF2-dependent transcription. Because the cilium grows during G_1/G_0 of the cell cycle, rapidly dividing cells are disfavored for signaling through this pro-neurogenic Primary Cilium-Autophagy-Nrf2 (PAN) Axis. Interestingly, DS cells have previously been noted to have abnormal primary cilia, be deficient in autophagy, and have elevated NRF2 activity. We provide evidence that 3S-iPSCs proliferate more rapidly than 2S-iPSCs leading to the suppression of PAN signaling. This suggests that the neurogenic deficiency of DS may be initiated during the earliest steps of lineage commitment. Studies are ongoing to test whether inhibitors that lengthen the G1 phase of the cell cycle can increase cilia formation and, thus, neuroectoderm differentiation in 3S-iPSCs. Because primary cilia impact various organs and organ systems, we postulate that defects in this signaling axis may contribute to other DS-associated pathologies.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2068 Early post-zygotic mutations are inherited by the germline and reveal its polyclonal origin in humans

Authors:

Y. Jang[1], L. Tomasini[2], A. Szekely[3], F. Vaccarino[2], A. Abyzov[1]; [1]Mayo Clinic, Rochester, MN, [2]Yale Univ., New Haven, CT, [3]Yale Univ. Sch. of Med., Hamden, CT

Little is known about the origin of germ cells in humans. We previously leveraged mutations to reconstruct zygote-rooted cell lineage ancestry trees in a phenotypically normal woman, termed NC0. Here, by sequencing the genome of her children and their father, we analyzed the transmission of early pre-gastrulation lineages and corresponding mutations across human generations. We found that the germline in NC0 is polyclonal and consists of at least two clones descending from each of the first two blastomeres. Our results, complemented by public data from multi-children families, also show that previously detected unbalances in early lineages allocation in the soma are not detected in the germline, suggesting a fundamental difference in mechanisms of lineage allocation between the soma and the germline.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2069 Epigenetic regulator *Tet2* modulates ovarian dysfunction in a model of the Fragile X premutation

Authors:

K. Shelly[1], S. Call[1], P. Jin[2], E. Allen[1]; [1]Emory Univ., Atlanta, GA, [2]Emory Univ Sch Med, Atlanta, GA

Fragile X-associated Primary Ovarian Insufficiency (FXPOI) is the clinical diagnosis given to roughly 20% of women who carry a premutation (PM) allele. This disease is driven by the expansion of a CGG-repeat tract in the 5' untranslated region (UTR) of the *FMR1* gene to 55-200 repeats. Limited availability of primary tissue and patient cohorts with elevated FSH levels and cessation of menses for 4-6 months prior to age 40 mean the molecular mechanism of FXPOI is understudied. We utilize mouse models of FXPOI with an ectopically expressed tract of CGG_{99} repeats capable of producing expanded repeat RNA (RNA-only) or rCGG and a non-canonically translated polyglycine product (FMRpolyG+RNA) from the *Rosa26* locus. Previous work demonstrated that follicular development, steroidogenesis, and ovulation were perturbed. Using untargeted metabolomics on FXPOI and control women we found that 2-oxoglutarate was altered in FXPOI women plasma. By crossing the PM mice with the mice haploinsufficient for the 2-oxoglutarate dioxygenase-dependent enzymes *Tet1* and *Tet2*, we observed that female mice expressing RNA-only alleles with haploinsufficiency of *Tet2* display reduced breeding compared to controls, which is not seen in mice only expressing CGG RNA. Decreased progeny results from a combination of reduced litters and pups per litter. Surprisingly, FMRpolyG+RNA;$Tet2^{+/-}$ females are not significantly different from controls or FMRpolyG+RNA females in producing progeny, suggesting a partial, but not complete, rescue of ovarian function. While the intraindividual variation seems to blunt a significant change from FMRpolyG+RNA itself, half of FMRpolyG+RNA;$Tet2^{+/-}$ females do not exhibit the consistent cessation of breeding observed in all FMRpolyG+RNA females. Ovaries collected reveal that corpora lutea are also present in the ovaries of FMRpolyG+RNA;$Tet2^{+/-}$ females in contrast to the FMRpolyG+RNA group, supporting that loss of ovulation was corrected. This work adds to the growing body of human omics data and previous mouse studies, that point to impaired ovulation as central to FXPOI. We are currently determining whether the role of Tet2 in demethylating ovulation-associated genes drives this phenotype using transcriptomic- and 5hmC-profiling data and whether these markers may be detected in human patients, enabling their use as biomarkers of FXPOI.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2070 Establishment of Nepal's first Non-Invasive Prenatal Testing (NIPT) Service Laboratory

Authors:

S. Thapa[1], N. Thakur[1], G. Joshi[1], S. Khanal[1], U. Thakur[2], A. Jang Kunwar[1]; [1]Kathmandu Ctr. for Genomics and Res. Lab. (KCGRL), Lalitpur, Nepal, [2]Nova Intl. Diagnostics, Lalitpur, Nepal

Design: Non-Invasive Prenatal Testing (NIPT) for fetal aneuploidies using cell-free DNA (cfDNA) has been widely adopted in clinical practice due to its improved accuracy. Several NIPT tests have been developed and validated. The core goal of cell-free based prenatal testing is to provide minimally invasive, clinically accurate screening for fetal chromosomal aneuploidies in the early stages of pregnancy. The purpose of this study was to establish a validated NIPT workflow for cell-free fetal DNA (cffDNA) sequencing from maternal plasma for the detection of trisomy 13, 18, and 21 on a semiconductor sequencing instrument. A total of ninety-one standard samples from healthy pregnant women were provided by Yourgene Health; their cfDNA library was prepared and loaded on the Ion 540 chip for sequencing. The sequencing output data was analyzed by using the bioinformatics pipeline of Yourgene Health. **Results:** Eighty-one samples were successfully validated out of a total of 91 samples. However, 3% of samples did not meet quality, and 3% of sample libraries had low reads and failed validation. Moreover, the validation of NGS workflow on the Ion Genestudio S5 for fetal aneuploidy detection would allow us to build up a reference database. Based on the validated database 224 clinical samples were analyzed out of which 43 samples failed QC and the 37 samples were analyzed for chromosomal aneuploidy risks, all had Z-score below 2.
8. **Conclusion:** This research aims to introduce and set up Nepal's first NGS laboratory for NIPT, utilizing the Ion Torrent technology to provide a complete in-house solution for pregnant women in Nepal. The establishment of this prenatal test signifies a significant advancement in prenatal care and reproductive health.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2071 Evaluating Gene Expression Profiles in Clinically Accessible Tissues for Prenatal Diagnostic Testing of Genetic Disorders

Authors:

M. Vladoiu[1], R. Zemet[1], C. Parobek[1], S. Zhao[1], J. Sinson[1], S. Tankersley[2], I. Van Den Veyver[1], P. Liu[1]; [1]Baylor Coll. of Med., Houston, TX, [2]Baylor Genetics, Houston, TX

Next generation sequencing (NGS) assays such as whole exome sequencing (WES) have considerably improved diagnostic yield in invasive prenatal testing particularly for monogenic disorders and after negative cytogenetic results. While approximately 40% of fetal abnormalities are diagnosed prenatally by conventional cytogenetic assays, WES has an incremental diagnostic yield of 31% across various prenatally detected malformations. With the advent of NGS technologies and the increasing number of variants detected in prenatal samples, there is a pressing need for confirmatory assays to promote accurate interpretation. RNAseq using whole blood and skin biopsies is expanding variant detection and provides functional evidence for variant interpretation. Our study aims to investigate the utility of RNAseq in prenatal diagnosis using chorionic villus sampling (CVS) and amniotic fluid (AF) samples. To determine clinically relevant expressed genes in prenatal samples, we performed RNAseq using polyA library preparation and standard RNAseq pipeline of 21 prenatal, 10 fibroblast and 10 blood samples. We reviewed the literature and queried existing databases (OMIM, HPO, PanelApp) to identify genes whose disruption leads to a prenatal phenotype. Gene expression profile comparisons were conducted between prenatal/postnatal samples and the prenatal phenotypes gene list, GTEx and single-cell RNAseq fetal datasets. Our results demonstrate an important overlap between the prenatal expression profiles and genes associated with prenatal phenotypes. A trend for a higher proportion of genes associated with urogenital, stillbirth, hydrops and central nervous system disorders was observed among AF samples, versus musculoskeletal and cardiovascular associated genes among CVS samples. Differential gene expression also revealed unique gene differences between CVS and AF samples. Some examples include LHX1, KCNJ16 and HNF1B showing higher expression levels in AF samples, and GATA4, PITX1 and GPC3 in CVS samples. Comparison between expression profiles of prenatal samples with fetal tissue-specific single-cell RNAseq data and GTEx database shows gene expression overlap with multiple organ types, particularly for AF samples suggesting that this sample type can provide a broader overview of genes associated with specific organ development. In conclusion, prenatal RNAseq in clinically accessible tissues reveals the detection of variety of unique genes with implications for prenatal conditions as well as fetal organ development. Our findings highlight the potential of RNAseq as a valuable assay supporting NGS variant interpretation in the prenatal setting.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2072 † Genetic Ancestry, Exome Sequencing and Classification of Variants Identified in Genes Associated with Inborn Errors of Metabolism

Authors:

J. Najera[1], Y. Mavura[1], A. Adhikari[2], M. Kvale[1], N. Risch[1], F. Chen[1], R. Gallagher[3]; [1]Inst. for Human Genetics, Univ. of California San Francisco, San Francisco, CA, [2]Illumina Corp., San Diego, CA, [3]Div. of Med. Genetics, Dept. of Pediatrics, Univ. of California San Francisco, San Francisco, CA

Background Newborn screening (NBS) plays a crucial role in identifying and treating inborn errors of metabolism (IEMs), a group of largely recessive genetic diseases. Traditional NBS methods, such as tandem mass spectrometry (MS/MS), have been successful in identifying IEMs, but the use of genetic screening pipelines could increase the positive predictive value. While the role of exome sequencing (ES) in NBS is promising, the pipeline approach is highly dependent on variant pathogenicity curation. Consequently, information disparity across populations related to pathogenicity of variants could lead to reduced accuracy of variant classification in patients of non-European descent. In this study we examine ES for IEMs and the relationship of genetic ancestry to diagnostic outcomes. **Methods** The California Department of Public Health provided dried blood spots from 1,728 neonates who screened positive by MS/MS for one of 48 IEMs between July 2005 and December 2013, including all individuals with a confirmed diagnosis. ES was performed and 833 confirmed true positive cases passed QC for further analysis. A variant annotation pipeline was created that analyzed 78 genes underlying the 48 IEMs, which included previously documented pathogenic variants, CNVs, and all protein altering variants with a global minor allele frequency <0.5%. The true positive individuals who were homozygous or with two annotated variants in a matching gene were considered exome positive (diagnosed), all others were considered exome negative. We characterized the genetic ancestry of exome positive (N=668) and exome negative (N=165) cases. Individual admixture was estimated from the exome data using HGDP WGS data as reference and the program ADMIXTURE. Differences in ancestries for positive and negative cases were assessed by linear regression. **Results** Overall genetic ancestries were: 7.5% African, 11.2% East Asian, 46.4% European, 8.5% Middle Eastern, 20.5% Native American, 5.6% South Asian. Native American ancestry was positively associated (P<0.02) with an exome positive diagnosis (22.7% in positive, 16.9% in negative); all other ancestries showed no association, either positive or negative. **Conclusion** Diagnostic yield of IEMs by ES was positively associated with Native American ancestry, and not negatively associated with any non-European genetic ancestry. While we found numerous ancestry-specific founder variants of varying frequency, there was no preferential bias in terms of diagnosis. These results suggest ES diagnosis of recessive IEMs is not negatively impacted by non-European genetic ancestry.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2073 † Genetic determinants of spontaneous preterm birth in Indian women: Transethnic and population specific markers.

Authors:

E. Bhattacharjee[1], R. Thiruvengadam[2], *. Ayushi[3], GARBH-Ini study group, P. Kshetrapal[3], S. Bhatnagar[3], P. P. Majumder[4], A. Maitra[1]; [1]Natl. Inst. of BioMed. Genomics, Kalyani, India, [2]Pondicherry Inst. of Med. Sci., Puducherry, India, [3]Translational Hlth.Sci. and Technology Inst., Faridabad, India, [4]John C. Martin Ctr. for Liver Res. and Innovation, Kolkata, India

Preterm birth (PTB), or live birth before 37 weeks of gestation, is the major cause of neonatal deaths and adverse health severities. Prevalence of PTB varies widely across countries and is considerably high in India and other South-Asian countries. To investigate whether such variation is due to genetic differences, we derived weighted genetic risk score (GRS) using the genomewide significant SNPs from the 23andMe spontaneous PTB (sPTB) genome-wide association study (GWAS) summary statistics and tested it on 4682 Indian women from GARBH-Ini cohort. We tested GRS prediction using Nagelkerke's pseudoR^2 adjusting for age, BMI, parity, occupational status and top 10 PCs. The European-derived GRS performed poorly in Indian women, explaining 0.9% of sPTB risk (p=0.44). Hence, to identify SNPs that can robustly predict risk of sPTB in Indian women, we conducted GWAS using genotype data of these 4682 women adjusting for above mentioned covariates. We found 38 SNPs with p<1e-5, and one genomewide significant SNP, rs57480735 (OR=1.57, p= 2.78e-8), which was also associated with gestational length (B= -0.16, p=2.05e-3). Of these 39 SNPs, 15 were also associated with early sPTB (<33 weeks). Additionally, from the cross-ancestry meta-analysis with 23andMe sPTB GWAS summary statistics, we identified 199 transethnic SNPs, of which rs35760881 was the most significant (p=8.45e-7). Functional investigation revealed that rs57480735 is a cis-eQTL of *NR2F2* which participates in maternal placenta development. Using placental single cell RNA sequencing data we found its high expression in the cells of maternal origin. Further, integrating genotype data with clinical data from the cohort, we found that preterm delivering women who carried minor allele at rs57480735 had higher uterine arterial pulsatility index, suggesting poor placental development. Interestingly, the transethnic SNP, rs35760881 is a cis-eQTL of *AKIP1,* which via inflammation may cause early myometrial contraction. Several immune cells in the placenta showed high expression of *AKIP1*. Moreover, we found that women who delivered preterm and carried minor allele at rs35760881 had high systemic mean arterial pressure, suggesting early myometrial contraction. Finally, from the AUROC analysis, we found that the 39 significant SNPs along with 199 transethnic SNPs have high predictive ability for sPTB (AUC 0.8). Our findings thus suggest that inflammation may result in sPTB in a population independent manner, while, poor placental development might be a population specific event. The significant SNPs and transethnic SNPs may help to stratify at-risk group of women for interventions leading to reduction of sPTB.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2074 Genetics services are an integral part of interdisciplinary care of individuals with disorders of sex development.

Authors:

C. Keegan, M. Hannibal, **L. Mohnach**; Univ Michigan, Ann Arbor, MI

Disorders of sex development (DSD) include conditions involving anomalies of the sex chromosomes, gonads, reproductive ducts and genitalia. Patients and families with DSD are faced with complex medical and psychosocial needs and benefit from an interdisciplinary care team composed of specialists from urology, endocrinology, gynecology, psychology, and genetics. A clinical diagnosis is often made using karyotype analysis, hormone testing, imaging, and physical examination. However, a specific genetic diagnosis helps to tailor management by providing more insight into fertility potential, gonadal tumor risk, and response to surgery. Many DSD conditions have phenotypic overlap, which can confound management and inheritance counseling. A genetic diagnosis is important for families to understand recurrence risks, reproductive options, and identify at-risk relatives. Further, some conditions have an increased risk for tumor development, but their diagnosis may be missed or not clinically recognized until later in life. Lastly, gene-specific identification allows a better understanding of the phenotypic variability and natural history of these distinct conditions. We evaluated the diagnostic rate of genetic testing in our DSD patient population to determine the utility of genetic testing in this clinic. Patient records from 2011-2023 were reviewed. Since the inception of the program, 256 patients have been evaluated in our DSD clinic. Common referral indications include: 46,XY phenotypic female, 46,XY undervirilized phenotypic male, atypical genitalia, congenital adrenal hyperplasia, sex chromosome abnormalities, and complex cloacal/urogenital malformations. Genetic evaluation differed by phenotypic presentation but most often included a DSD gene panel or whole exome sequencing. A genetic diagnosis was made in 100% of patients with a 46,XY female phenotype with absent uterus and in 54% of patients with 46,XY karyotype and female phenotype, with a uterus present. Our diagnostic rate was the lowest (29%) in those presenting with 46, XY male phenotype, most likely due to the diversity of etiologies associated with hypospadias and cryptorchidism. Genetic testing in the DSD patient population has a high yield, especially in those with 46,XY female phenotype without a uterus. Genetic services are valuable for all patients seen in the DSD clinic as a genetic diagnosis provides the family and interdisciplinary team with more details to formulate multisystem medical management decisions. Genetic providers are integral to the DSD team to provide genetic testing and serve a key role in patient education and psychosocial support.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2075 Genome-wide investigation reveals significant interaction of *FURIN* with maternal vitamin intake on orofacial cleft risk.

Authors:

Z. Erdogan-Yildirim[1], N. Mukhopadhyay[1], J. C. Carlson[2], J. R. Shaffer[2,1], S. M. Weinberg[1], M. L. Marazita[1,2,3]; [1]Ctr. for Craniofacial and Dental Genetics, Dept. of Oral and Craniofacial Sci., Sch. of Dental Med., Univ. of Pittsburgh, Pittsburgh, United States, Pittsburgh, PA, [2]Dept. of Human Genetics, Sch. of Publ. Hlth., Univ. of Pittsburgh, Pittsburgh, United States, Pittsburgh, PA, [3]Clinical and Translational Sci., Sch. of Med., Univ. of Pittsburgh, Pittsburgh, United States, Pittsburgh, PA

Nonsyndromic orofacial clefts (NSOFC) are congenital defects affecting the lip and/or the palate. NSOFC have a multifactorial etiology involving genetic factors and intrauterine environmental exposures. Hence, exploring gene-environment (GxE) interactions may elucidate the complex biological mechanisms of NSOFC. Previous research, including our own, has investigated GxE interactions in multiethnic or European cohorts using both trios and case-control designs.In this study, we explore the genome-wide GxE interactions between genetic variation and intrauterine exposures to maternal smoking, alcohol or vitamin intake within ± 3 months of conception.Our study cohort consists of 547 Filipinos with cleft lip or cleft lip and palate (CL/P) and 264 unrelated controls with no family history of clefting. Genotyping was done via the Illumina GDA-8v1-0 array and additional genotypes were imputed using TOPMed reference panel via minimac4. Variants with imputation rsq &lt 0.8 were excluded.We conducted a two-stage design GxE analysis on a total of 5,245,942 variants. We used logistic regression models accounting for the first five principal components of ancestry (PCA), and assuming an additive genetic model in PLINK v1.9. In the first stage, we screened for genetic and/or GxE associations with a p &lt 0.05 using a joint 2 degree of freedom test (*2df*). In the second stage, we tested the GxE effect alone while applying a significance threshold accounting for the dependence between the joint test and the GxE test (as determined via simulation) and further adjusted by the number of independent loci (p_{GE} &lt 0.00275/716).Preliminary findings revealed a significant interaction effect influencing CL/P between variants on 15q26.1 and maternal vitamin intake. The strongest signal was obtained at rs881431 ($p_{2df} = 8.23 \times 10^{-6}$ and $p_{GE} = 3.55 \times 10^{-6}$) in the intergenic region between *VPS33B* and *SV2B*. It locates about 170kb distal from *FURIN* encoding a serine protease involved in the cleavage of protein precursors including growth factors, their receptors, and extracellular matrix proteins. Furin is vital in very early embryonic development. Germline knockout mouse embryos lacking *FURIN* cannot survive beyond 11 days. Folic acid impacts the proteolytic activity of furin. Additionally, mutations in *GDF11* that prevent cleavage by furin are known to cause CL/P. In summary, our study identified a significant interaction near *FURIN* with maternal vitamin intake associated with risk of CL/P in Filipinos. Notably, several loci showed suggestive interaction with alcohol use and smoking. Further follow-up analyses and validation are critical to strengthen and corroborate the findings.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2076 Genotype - phenotype identification in a case of genetically described (5p inversion deletion and duplication syndrome) developmental epileptic encephalopathy.

Authors:

E. Yaman[1], Y. Ataş[2], G. Şen[2], D. E. Toprak[2], S. Kanmaz[2], E. Şimşek[3], T. Atik[3], S. Yılmaz[2], H. Tekgül[2]; [1]Ege Univ. Faculty of Med., Izmir, Turkey, [2]Ege Univ. Faculty of Med., Dept. of Pediatric Neurology, Izmir, Turkey, [3]Ege Univ. Faculty of Med., Dept. of Pediatric Genetics, Izmir, Turkey

Background:
The inverted duplication with deletion of 5p, shortly known as *inv dup del 5p*, is a rare chromosomal rearrangement disorder that has been described in detail by only a handful of cases in the literature. The resulting phenotype, which was first described by Sreekantaiah et al in 1999, is a complex one, differing depending on both the size and the position of the deletion and duplication in each case; generally presents with development delay accompanied with cardiac, neurocranial and musculoskeletal anomalies and varying dysmorphic facial features.

Introduction:
Here we report a case of a 15 month old male presenting ***minor facial dysmorphologies***, ***developmental delay***, and ***epileptic encephalopathy***. The patient was receiving dual anti-seizure treatment for behavioral pause and automatism seizures and presented to us with focal motor status epilepticus. Microarray analysis for the genetic etiology-specific identification of developmental and epileptic encephalopathy showed a **large partial deletion** (**2.7 Mb**) located at 5p15.33 and **a much larger duplication** (**22.9 Mb**) located at 5p15.33p14.1. The family segregation study had normal karyotypes indicating that the rearrangement was **de novo**.

Methods:
Cranial magnetic resonance imaging, metabolic tests, electroencephalography, genetic tests (microarray and karyotyping) and karyotyping of the family were performed to investigate the etiology of developmental epileptic encephalopathy and the de novo status of genetic rearrangement.

Case Discussion:
The patient was noted *not* to have the characteristic findings of 5p deletion syndrome (Cri-du-chat) and cat-like-cry was *not* observed. Consistent with the variable clinical findings associated with 5p duplication, no anomalies or system findings were detected, except for developmental delay, minor dysmorphic findings, and epilepsy. The patient was characterized by ***focal motor*** and ***non-motor seizures*** and ***developmental epileptic encephalopathy*** with EEG characteristics. *Focal epileptiform activities* were present on initial presentation and control EEG monitoring.

Conclusion:
To the best of our knowledge, **our patient is the eighth reported case in the literature and the fifth reported case of postnatal pure 5p inversion duplication deletion syndrome.** The genotype-phenotype and electro-clinical description of this rare case of developmental epileptic encephalopathy caused by this dual rearrangement is presented. *Describing the clinical and genetic features of such cases, collecting and detailing information on genotype-phenotype correlations will have great prognostic value and will be an important contribution to the literature.*

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2077 GWAS meta-analysis on heavy menstrual bleeding in three large biobanks reveals 28 loci suggesting multiple contributing pathways

Authors:

A. Johnson[1,2], J. Cunha[1,2], J. Huffman[3], P. Wilson[4,5], K. Cho[6], J. Johnsen[7], M-H. Chen[1,2], F. Thibord[1,2]; [1]Natl. Heart Lung and Blood Inst., Bethesda, MD, [2]The Framingham Heart Study, Framingham, MA, [3]Palo Alto Veterans Inst. for Res., Boston, MA, [4]Emory Univ., Atlanta, GA, [5]Atlanta VA Med. Ctr., Decatur, GA, [6]VA Boston Hlth.care System, Boston, MA, [7]Univ. of Washington, Seattle, WA

Background: Heavy menstrual bleeding (HMB) is the most prevalent global clinical bleeding issue and contributes to various medical complications and negative quality-of-life outcomes. Large biobanks such as UK Biobank (UKBB), the VA Million Veteran Program (MVP), and FINNGEN could help discover HMB genetic risk loci using a well-powered genome-wide association study (GWAS). To our knowledge, this is the first study to report a GWAS focused specifically on HMB in the general population.**Methods**: ***Study Population***: Data from individuals with HMB ICD-9/10 codes were sourced from UKBB (13,500 cases/247,045 total), FINNGEN (19,024 cases/119,687 total), and MVP (7,550 cases/56,898 total). ***GWAS and Meta-Analysis***: UKBB, MVP, and FINNGEN used generalized mixed effects models implemented in SAIGE and REGENIE that account for relatedness and population structure with adjustments for age, genetic principal components, and cohort-specific covariates. For the meta-analysis, we applied a fixed-effects approach using METAL. Transcriptome-wide association studies (TWAS) were conducted using FUSION and selected relevant GTeX tissues, followed by *coloc* analysis.
Results: ***Multi-population meta-analysis***: GWAS signals (p<5E-8) were identified in regions previously associated with uterine fibroids (UFs) (e.g. *CDC42/WNT4*, *GATA2*, *TP53*, *SYNE1*), coagulation (*FV*), and several relevant cancers (e.g., ovarian, uterine, breast). Some novel candidate genes were highly expressed in uterine tissues according to GTeX (e.g., *GMNC*, *STK26*). The strongest associations were a protective effect of the Factor V Leiden variant (OR=0.69, P=1.8E-33), and a protective regulatory region variant near *FSHB* (follicle-stimulating hormone B) (OR=0.88, P=1.35E-28), a gene pivotal in regulating menstrual cycles. Conditional analyses revealed multi-SNP independent signals only at 2 loci (chr1, chr10). TWAS revealed several additional loci including several with high co-localization probabilities (CALCRL, CDK2AP1, CCDC170) in hematological and genitourinary tissues (spleen, liver, vagina).
Conclusions: Variants were identified in loci with genes highly expressed in the uterus, or identified in prior UF or malignant female growth loci, suggesting major enrichment of these in HMB. Aside from *FV* Leiden and *GATA2*, there were relatively few overlaps with genetic signals for platelet phenotypes, anemia, hemostasis, or coagulation loci as had been hypothesized. This suggests that at least in older women the additional genetic drivers of HMB may be more related to regulation of hormones and menstrual cycles, and abnormal growth in female genitourinary tissues.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2078 Identification of novel genes for Coloboma using single cell RNA-Sequencing

Authors:

E. Boobalan[1], D. M. McGaughey[1], U. Neelathi[1], D. Sanchez-Mendoza[1], T. D. Fufa[2], R. B. Hufnagel[3], B. P. Brooks[1]; [1]Pediatric, Dev.al & Genetic Ophthalmology Section, Ophthalmic Genetics & Visual Function Branch, NEI, NIH, Bethesda, MD, [2]Div. of Genome Sci., NHGRI, NIH, Bethesda, MD, [3]Med. Genetics and Ophthalmic Genomics Unit, Ophthalmic Genetics & Visual Function Branch, NEI, NIH,, Bethesda, MD

Uveal coloboma is a congenital disorder of ocular development caused by failure of optic fissure closure (OFC) beginning around the 5th week of human gestation. Although rare (0.5-2.6 cases/10,000 live births), it is estimated to cause up to 10% childhood blindness. Although significant progress has been made in identifying genes for coloboma in humans, many cases remain unsolved molecularly. To identify genes important for optic fissure closure we used single cell RNA-sequencing of wild-type C57BL/6J eyes at E11.5—the time point at which the optic fissure is closing.

Single cells were made by digesting eyes with Trypsin for 10-20 minutes at 37^{o}C. Libraries were made with 10x Chromium controller using Chromium Next GEM Single Cell 3' Reagent Kits v3.1 (Dual Index). After quality control filtering, we recovered 4034 cells across 11 cell types, including 418 cells from the optic fissure/stalk, 1598 presumptive neural retina (pNR), 538 presumptive RPE (pRPE), and 1017 fibroblasts. We identify a cluster of cells on enriched genes from previously known to occur in the optic fissure (e.g., Adamts16, Ntn1, Pax2, Vax1) as well as potentially novel genes (e.g., Afapl2, Sox1, Lrrn1, Shtn1). Immunohistochemistry (IHC) and In Situ techniques were used to evaluate the temporal and spatial expression of genes of interest in mouse embryonic eye sections. Morpholino knock down assays were done on to assess the role of genes in zebrafish ocular development.

Sox1 expression was confirmed in the ventral pNR and pRPE at the optic fissure and lens by IHC at E11.5 and found to be significantly down regulated in the optic fissure (but not the lens) at E12.5. A similar pattern of expression was noted in zebrafish by ISH and morpholino knockdown causes coloboma like phenotype in zebrafish. Similarly, Lrrn1 and Shtn1 mRNA expression were noted by RNAScope assay in the distal naso-ventral retinal neuroblasts, proximal ventral pRPE and weaker expression in dorsal pNR as well as at the extra ocular regions for Lrrn1; and ventral pNR and pRPE for Shtn1 at E11.5 and significantly downregulated at E12.5. These data provide further insight into the molecular mechanisms of OFC and may identify candidate genes for human disease.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2079 Illuminating Prenatal Diagnosis: Enhancing Clinical Relevant Variant Interpretation via Transcriptome Analysis in Amniotic Fluid Cells.

Authors:

Y. Cao[1], S. Ketkar[2], H. Dai[2], M. Shi[1], Y. Zheng[1], Z. Liu[1], Y. Kwok[1], Z. Dong[1], P. Liu[2], T. Leung[1], B. Lee[2], R. Choy[1]; [1]The Chinese Univ. of Hong Kong, Hong Kong, China, [2]Baylor Coll. of Med., Houston, TX

Transcriptome analysis has garnered significant interest as it can offer additional information about aberrant expression and splicing that complements DNA-based genetic testing. It aids in clinically relevant variant interpretation as well as helps detect variants that may otherwise go unnoticed with genetic testing alone. RNA sequencing (RNA-seq) has been shown to improve the diagnostic rate by 8-36% for postnatal patients with suspected Mendelian disorders but inconclusive genetic investigations. However, its use in prenatal diagnosis is currently limited. Our study aimed to assess the feasibility and utility of RNA-seq supplementing prenatal genetic testing analysis. We retrospectively recruited 50 prenatal subjects with amniotic fluid cells samples, which includes 4 cases with normal live birth, 6 cases with known pathogenic variants and two deletions, 40 cases with various fetal structural abnormalities but inclusive genetic testing results. RNA libraries of AF samples are formed via polyA capture and rRNA removal and reverse transcription of cDNA. PE150 technology is employed to sequence the RNA extracted from AF samples. Principle complement analysis showed clustered and unique gene expression of expression in these amniotic fluid cells compared with published dataset of fibroblasts and whole blood. Outlier-Based differential gene expression analysis of the reads counts/genes flagged a Lissencephaly case with an outlier *PAFAH1B1* gene which matched its 1.9Mb deletion on 17p13.3, including *PAFAH1B1* gene. Alternative splicing analysis detected another positive case with a single-exon deletion of the *PIEZO2* gene by showing in-frame exon skipping in transcripts without obvious decrease in expression. Allele-specific expression analysis reveals no dominant transcripts with four heterozygous missense variants or abnormal splicing events. Additionally, we examined the alternative transcript/s generated by genome-wide rare variants with a spliceAI delta score>0.2 in 30 cases using 30x genome sequencing data. The higher the score, the greater the likelihood that the variant could result in transcript changes, while commonly occurring in a leaky pattern, suggesting that PVS1 Strength evidence be used with caution. Our study highlights the great potential of transcriptome analysis through RNA sequencing as a promising prenatal diagnostic tool.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2080 Inferring the number of founding primordial germ cells in humans from *de novo* mutation data

Authors:

Z. Gao; Univ. of Pennsylvania, Philadelphia, PA

Primordial germ cells (PGCs), the precursors of mature germ cells, are established around the gastrulation stage during embryogenesis in mammals. Extensive research has shed light on the developmental process of germ cells in mice, but studying the corresponding process in humans presents practical challenges. Moreover, the distinct morphological structure of the post-implantation epiblast in humans and mice raises questions regarding the generalizability of knowledge acquired from mice to human development. To address these questions, I propose a genetic approach to learn about germ cell development in humans, leveraging the recently available genomic sequencing data of pedigrees. Deep sequencing of human families with multiple children reveals a considerable fraction of *de novo* mutations to be shared among siblings. The presence or absence of these sibling-shared mutations in each child is informative about the genotype of the corresponding diploid germ cell in the parent. Based on this rationale, I developed an algorithm to determine the *minimum* number of founding cells at the time of PGC specification. Analysis of existing human pedigree datasets indicates that least 2-7 cells commit to the germ cell fate in each individual. This finding aligns with previous observations in mice, suggesting that germ cells are not monophyletic relative to somatic cells. The estimates do not significantly differ between sexes, consistent with the timing of PGC specification before sex determination in mammals. Additionally, the estimate is not influenced by the number of offspring in a family but correlates with the number of informative mutations detected, indicating that detecting more sibling-shared mutations, such as those at short tandem repeats, can further refine the lower bound estimate. Next, I developed a formula to estimate the *expected* number of founding PGCs, under a model of synchronized, symmetric division during germ cell proliferation. Analysis of human pedigree data suggests a small number (<50) of founding cells at PGC specification. Although this estimate seems surprisingly small, it is consistent with observations from live imaging of developing mouse embryos. Alternatively, if germ cell proliferation involves asymmetric division, asynchrony, or cell death, the actual number might exceed the estimate. Overall, our study provides refined estimates of the number of founding PGCs that contribute to the gamete pool in humans. More generally, the new genetic approach developed in this study, combined with classical anatomical, molecular, and developmental approaches, promises to uncover a more detailed model of germ cell development.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2081 Integrative analysis of transcriptome dynamics during human craniofacial development identifies novel candidate disease genes

Authors:

J. Cotney[1], T. Yankee[1], S. Oh[1], E. Winchester[1], A. Wilderman[1], K. Robinson[2], T. Gordon[3], J. Rosenfeld[3], J. VanOudenhove[1], D. Scott[4], E. Leslie[5]; [1]UConn Hlth., Farmington, CT, [2]Emory Univ., Decatur, GA, [3]Baylor Coll. of Med., Houston, TX, [4]Baylor Coll. Med, Houston, TX, [5]Emory Univ., Atlanta, GA

Craniofacial disorders are among the most common of all congenital defects. A majority of craniofacial development occurs early in pregnancy. To fully understand how craniofacial defects arise, it is essential to observe gene expression during this critical time period. To address this, we performed bulk and single-cell RNA-seq on human craniofacial tissue obtained from 4 to 8 weeks post conception, establishing the most comprehensive profile of the transcriptome in the early developing human face to date. We identified 239 genes that were expressed more strongly in craniofacial tissues relative to dozens of other human tissues and stages. We found that craniofacial specific enhancers are enriched within 400 kb of these genes, establishing putative regulatory interactions. To further understand how genes are organized in this program, we constructed coexpression networks and show that disease candidates are likely genes that are coexpressed with many other genes, serving as regulatory hubs within these networks. We leveraged large functional genomics databases including GTEx and gnomAD to reveal hub genes that are more strongly expressed in craniofacial tissue and genes which are resistant to mutation in the normal healthy population. We validated our network findings using sequencing data from orofacial clefting trios and single-nucleus gene expression from the developing human face. Our unbiased methods revealed dozens of novel disease candidate genes that warrant further study.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2082 † Making a human specific model: Maternal Immune Activation and Neuroinflammation.

Authors:

B. Spiegelberg; Johns Hopkins Univ., Baltimore, MD

The human placenta is essential for the development and survival of a developing fetus. It is the main communicator between fetus and mother and is responsible for producing hormones and growth factors for correct fetal development during pregnancy. Maternal Immune Activation (MIA) plays a role in antagonizing the placenta and increasing risk of neurodevelopmental disorders, by causing a proinflammatory state. This information is known from human epidemiological studies and animal models, but the human placenta is a severely understudy. There is a gap in the scientific field for a human specific placenta model to better understand the interplay of MIA and neurodevelopmental disorders.
Primary human trophoblast stem cells (hTSC) and human pluripotent stem cells (hPSC) differentiated to hTSC can potentially model placental processes in vitro. Yet, it remains controversial how the differentiation of human pluripotent stem cells to trophectoderm relates to in vivo development and the factors required for this differentiation. Here, we demonstrate that the primed pluripotent state retains potency to generate trophoblast stem cells by activating EGF and WNT and inhibiting TGFb, HDAC and ROCK signaling without exogenous BMP4 (named TS). We map this specification by temporal single cell RNAseq compared to activating BMP4 or activating BMP4 and inhibiting WNT. TS conditions generate a stable proliferating cell type that is highly similar to six-week placental cytotrophoblasts with activation of endogenous retroviral genes and without amnion expression. Multiple primed iPSC and ES lines differentiate to iPS-derived-TSCs that can be passaged for at least 30 passages and differentiate to pure populations of multinucleated syncytiotrophoblasts (STB) and extravillous trophoblast cells. Having establish that primed IPSC and ES lines can be used to make an in vivo model of TSC, we were able to use this to create a model to study MIA and neuroinflammation with, specifically, STB as the mediator. We show that by exposing STBs to a RNA viral analog, they produce proinflammatory cytokines, mimicking MIA.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2083 Mutational and gene expression profiles of early-onset preeclampsia.

Authors:

N. Guo, H. Chavez, M. Huang, C. Mason, K. K. Nelson, M. Meads, O. Aisagbonhi, M. Parast, M. Horii, K. M. Fisch; UC San Diego, La Jolla, CA

Preeclampsia affects 3-8% of pregnancies and is a leading cause of severe maternal morbidity and mortality. Early-onset (EO) preeclampsia, defined as preeclampsia with an onset of <34 weeks gestation, is characterized by placental dysfunction and fetal growth restriction. The role rare genetic mutations play in placental dysfunction observed in preeclampsia is unexplored although widespread placental mosaicism has recently been described. To address this, we investigated rare genetic variants and gene expression from healthy pregnancies (>34 weeks gestation and <34 weeks gestation) and those affected by preeclampsia (late-onset (LO) >34 weeks gestation and EO <34 weeks gestation). We analyzed RNA sequencing data of 112 human placentas with detailed clinical adjudication and histopathological review. We identified variants (SNPs and INDELs) using the GATK Best Practices Workflow for RNAseq short variant discovery implemented in bcbio-nextgen and annotated variants with VEP. We implemented stringent variant quality filters including DP >50 and then prioritized rare variants by filtering for allele frequency in gnomAD v3.1.2 < 0.05, removed non-exonic variants, filtered out INDELs that were not present in gnomAD v3.1.2 or dbSNP, and removed frequent variants (>70% of individuals) and genes (>50% of individuals), which resulted in a total of 8,127 variants in 2,736 genes. We performed clinical enrichment analysis with a Fisher's Exact Test in maftools to identify genes significantly enriched for variants in each clinical subset (Preeclampsia vs Healthy; Preeclampsia LO vs EO; Healthy >34 weeks vs <34 weeks; Preeclampsia LO vs Healthy >34 weeks; Preeclampsia EO vs Healthy <34 weeks), which identified 6 genes differentially mutated in Preeclampsia EO vs Healthy <34 weeks (UCHL5, CFLAR, GOGLB1, SH3D21, DVL1 and CSHL1) and 5 genes differentially mutated between Preeclampsia LO and EO (UCHL5, CSHL1, COL6A2, CFLAR and CD36; FDR < 0.05). We also uncovered significantly higher mutational burden in Preeclampsia EO relative to all other groups (p.adj < 0.05). Differentially expressed genes were identified after TMM-normalization using the limma-voom method, resulting in 538 differentially expressed genes between EO Preeclampsia compared to Healthy <34 weeks (adj-p < 0.05 and |log2FoldChange| > 1), which were significantly enriched for PI3K-Akt signaling, Calcium signaling, and cytokine-cytokine receptor interactions using g:Profiler (p-value < 0.05). This study has characterized rare variants, differentially expressed genes and increased mutational burden in placentas associated with early-onset preeclampsia warranting further investigation.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2084 NGS based Genetic Analysis of Embryos for Chromosomal Abnormalities in Nepal

Authors:

S. Khanal, S. Thapa, G. Joshi; Kathmandu Ctr. for Genomics and Res. Lab. (KCGRL), Lalitpur, Nepal

Introduction: Chromosomal abnormalities occurring in embryos can result in various reproductive and developmental disorders. Preimplantation Genetic Screening (PGS) is a method employed to detect chromosomal abnormalities in embryos before their implantation. This research entails an examination of the genetic data obtained from embryos of multiple patients in order to ascertain the prevalence of chromosomal abnormalities and their impact on embryo viability.**Methods:** Genetic analysis was performed on embryos from a cohort of patients using NGS. The embryos were assigned unique Patient IDs and Embryo IDs. Chromosome abnormalities were identified and categorized based on the impacted chromosome. The results were interpreted to determine whether the embryos were euploid (normal), aneuploid (abnormal), or Mosaic. **Results:** A total of 312 embryos from 78 patients were analyzed. Among them, 80 embryos were identified as euploid and 92 embryos were identified as aneuploid. The most common chromosomes impacted by abnormalities were 1 and 16. Mosaicism was observed in 128 embryos.**Interpretation:** The high occurrence of aneuploidy in this patient cohort suggests that chromosomal abnormalities are prevalent in embryos. These abnormalities can lead to a heightened risk of implantation failure, miscarriage, and developmental disorders. The presence of mosaicism indicates the possibility of both normal and abnormal cell populations within an embryo, potentially influencing overall embryo viability. These findings underscore the significance of genetic analysis through PGS, which enables the selection of euploid embryos for successful implantation and healthy pregnancies.**Conclusion:** This study provides valuable insights into the genetic characteristics of embryos within a patient cohort, revealing a substantial prevalence of chromosomal abnormalities and mosaicism. The identification of such abnormalities through PGS facilitates the selection of euploid embryos, thereby improving the success rates of assisted reproductive technologies and reducing the risk of genetic disorders in offspring. Further research and larger-scale studies are necessary to validate these findings and optimize the clinical application of PGS.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2085 Non-immune hydrops fetalis is associated with autosomal recessive variants in the MYB Binding Protein 1a (*MYBBP1A*) gene

Authors:

J. Tenorio[1], E. Mansilla[2], G. Fe Amalia[1], R. Reojo[3], P. Arias[1], A. Parra[4], P. Pascual[4], N. Gallego[4], M. Cazalla[4], R. Rodriguez-González[5], J. Nevado[6], P. Lapunzina[6]; [1]Inst. of Med. and Molecular Genetics (INGEMM) - La Paz Univ. Hosp. - CIBERER, Madrid, Spain, [2]Inst. of Med. and Molecular Genetics (INGEMM) - La Paz Univ. Hosp.-CIBERER, Madrid, Spain, [3]Dept. of Pathology, La Paz Univ. Hosp., Madrid, Spain, Madrid, Spain, [4]Inst. of Med. and Molecular Genetics (INGEMM) - La Paz Univ. Hosp., Madrid, Spain, [5]Div. of Maternal and Fetal Med., Dept. of Obstetrics and Gynecology, Hosp. Univ.rio La Paz. IdiPAZ, 28046 Madrid, Spain., Madrid, Spain, [6]INGEMM-HULP-CIBERER, Madrid, Spain

Non-immune hydrops fetalis (NIHF) is an extremely infrequent entity usually characterized by an excessive accumulation of fetal fluid within the fetal extravascular compartments and body cavities. The etiology of NIFH is highly variable with a proportion of idiopathic unknown cases, or associated with syndromic disorders. Here we present a fetus died at 27+3 weeks with a NIHF presenting with oligohydramnios, cystic hygroma, pleural effusion, and generalized hydrops with predominance of subcutaneous edema. The fetus also presented with ascites, severe and precocious IUGR and some skeletal anomalies. Trio whole exome sequencing was applied in order to screen for a possible genetic pathogenic variant. Variant prioritization according to a custom in-house algorithm allowed to identify two variants in *MYBBP1A*, one nonsense (NM_001105538.2:c.238G>T:NP_001099008.1:p.Gly80Ter) and one canonical splice-site variant (NM_001105538.2:c.3196-2A>G:NP_848696.1:p.Leu177Argfs*20), each inherited from a healthy parent. A previous report (PMID: 28425981) described another case with similar phenotype with a compound heterozygous variant in MYBBP1A (one identical to our patient). The two variants are predicted to be damaging by the *in silico* bioinformatic tools applied. The protein encoded by *MYBBP1A* play a role in many cellular processes including response to nucleolar stress, tumor suppression and synthesis of ribosomal DNA. Therefore, we suspect that *MYBBP1A* can be a strong candidate gene associated with the development of hydrops fetalis. It is necessary to collect more cases and further studies to understand the role of this gene and the mechanism associated with the development of the prenatal malformation.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2086 Noninvasive Preimplantation Genetic Testing for Aneuploidy from Spent culture Media in infertile couples.

Authors:

A. Patel[1], S. S. Chettiar[1], D. Jhala[2]; [1]Genexplore Diagnostics and Res. Ctr. Pvt. Ltd., Ahmedabad, Gujarat, India, [2]Sch. of Sci., Gujarat Univ., Ahmedabad, India

Preimplantation genetic testing for aneuploidy (PGT-A) is a primary method utilized to select euploid embryos for transfer and have supported numerous couples with infertility worldwide. PGT includes methods that allow embryos to be tested for Chromosomal aneuplodies and inherited conditions, relevant to embryo viability. PGT-A helps patients who have advanced maternal age, recurrent pregnancy loss, male infertility, or recurrent implantation failure to enhance ART outcomes. However, in order to obtain embryonic genetic material to perform PGT-A, a biopsy is required, involving the removal of one or more cells from Day 3 or Day 5 of cultured embryos. This invasive procedure requires highly sophisticated instruments, biopsy skills and also there have been concerns about mechanical damage to the developing embryos as embryo viability could be compromised in some cases. Recent development of technology using cell free DNA present in Spent culture media (SCM) overcomes requirement of embryo biopsy and has potential to detect chromosomal abnormalities termed as Noninvasive Preimplantation Genetic Testing for Aneuploidy (niPGT-A). niPGT-A is a novel approach to the genetic analysis of embryos allow clinicians to select embryos with normal genomic content without damaging embryos. Here, we are presenting niPGT-A testing of 3400 embryos from 624 females. Subjects included in the study were both women and men who were then sub-grouped based on four major reasons viz. 1) advanced maternal age, 2) more than three IVF failures, 3) low sperm count and 4) genetic indications. Culture medium in which an embryo had grown from day 3 until the day of last day of culture (Day5) was collected. After a blastocyst was removed from its culture dish,15-20 µL of its SCM was collected in PCR tubes. Total 3400 SCM were collected from 624 females undergoing IVF treatment. These collected SCMs were subjected to whole genome amplification using a picoplex WGA kit. Amplified product was then taken up for customized NGS based chromosomal aneuploidy analysis where a lower mark of 10MB of deletion duplication was taken for reporting and a mosacisim of minimum 25% was reported. NGS data revealed that 816 (24%) embryos had segmental or whole chromosomal aneuploidy. Whereas, 484(14.2%) embryos showed low mosaicism. 74 (2.17%) samples exhibits low DNA and were not be able to analyzed. Euploid reported embryos were evaluated for morphology score and AI score and are consistent with the invasive PGT-A testing. However, embryos with low mosaic is of concern but progress of niPGT-A will overcome challenges and become a choice of method to detect chromosomal abnormalities in developing embryos.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2087 Novel application of NIPT to indirectly diagnose paternal sex chromosome aneuploidy via parent-of-origin analysis

Authors:

A. Zalesny[1], A. Boyd[2], B. Polendo[1], S. Whitehead[1], R. Higgins[2], M. D. Maxwell[1]; [1]Univ. Hlth.System, San Antonio, TX, [2]Univ. of Texas Hlth.Sci. Ctr. at San Antonio, San Antonio, TX

In 2011, non-invasive prenatal testing (NIPT) was introduced as the first maternal screen for fetal sex chromosome abnormality (SCA). It has since been shown to incidentally detect maternal SCA, microduplications, and malignancy. Turner syndrome (TS) is the most common chromosomal abnormality in first-trimester miscarriage and often results from sporadic paternal nondisjunction, making recurrence unlikely. Possible explanations for recurrence include undiagnosed parental SCA or gonadal mosaicism. Here we present two consecutive 45,X intrauterine fetal demises (IUFDs) in which NIPT's maternal cell-free DNA background was applied to determine X chromosome inheritance and thereby the monosomy's parent of origin.

A G4P1 28-year-old female and her 28-year-old partner had one first-trimester miscarriage at age 24 followed by a term pregnancy, delivering a live-born male. At ages 26 and 27, they had two second-trimester IUFDs, both with cystic hygromas, monosomy X risk on single nucleotide polymorphism (SNP)-based NIPT, and 45,X karyotypes on amniocentesis. Given her two consecutive pregnancies associated with SCA, a maternal karyotype was performed on peripheral leukocytes which revealed 46,XX(20). To further investigate potential 45,X mosaicism, the patient consented to comparative analyses of maternal and fetoplacental SNP profiles from each IUFD to determine X chromosome inheritance, which confirmed both to be maternally inherited and suggested mosaic paternal SCA. A paternal karyotype was then performed on peripheral leukocytes, which revealed 46,XY(20), and supplemental X-/Y-centromere FISH of 200 cells was also normal, suggesting paternal 45,X gonadal mosaicism. Paternal fibroblast and semen analyses have not been performed due to logistic limitations.

While somatic mosaicism is unconfirmed, paternal 45,X gonadal mosaicism is suspected within the context of consecutive fetal TS, SNP-based NIPT comparisons, and Y-chromosome constitution of the couple's only viable pregnancy. The data support paternal 45,X gonadal mosaicism as another, possibly more likely differential diagnosis for their first fetal loss and consecutive fetal TS than recurrent sporadic meiotic error. To our knowledge, this is the first case of NIPT applied to indirectly diagnose paternal SCA via parent-of-origin analysis.

PB2088 Optical genome mapping for detection of chromosomal aberrations in prenatal diagnosis

Authors:

Q. Zhang, Y. Wang, Z. Xu, P. Hu; Women's Hosp. of Nanjing Med. Univ., Nanjing Maternity and Child Hlth.Care Hosp., Nanjing, China

Introduction: Chromosomal aberrations are the most important etiological factors for birth defects. Optical genome mapping is a novel cytogenetic tool for detecting a broad range of chromosomal aberrations in a single assay, but relevant clinical feasibility studies of OGM in prenatal diagnosis are limited. **Material and methods:** We retrospectively performed optical genome mapping analysis of amniotic fluid samples from 34 fetuses with various clinical indications and chromosomal aberrations detected through standard-of-care technologies, including karyotyping, fluorescence in situ hybridization, and/or chromosomal microarray analysis. **Results:** In total, we analyzed 46 chromosomal aberrations from 34 amniotic fluid samples, including five aneuploidies, 10 large copy number variations, 27 microdeletions/microduplications, two translocations, one isochromosome, and one region of homozygosity. Overall, 45 chromosomal aberrations could be confirmed by our customized analysis strategy. Optical genome mapping reached 97.8% concordant clinical diagnosis with standard-of-care methods for all chromosomal aberrations in a blinded fashion. Compared with the widely used chromosomal microarray analysis, optical genome mapping additionally determined the relative orientation and position of repetitive segments for seven cases with duplications or triplications. The additional information provided by optical genome mapping will be conducive to characterizing complex chromosomal rearrangements and allowing us to propose mechanisms to explain rearrangements and predict the genetic recurrence risk. **Conclusions:** Our study highlights that optical genome mapping can provide comprehensive and accurate information on chromosomal aberrations in a single test, suggesting that optical genome mapping has the potential to become a promising cytogenetic tool for prenatal diagnosis.

PB2089 Optical genome mapping versus chromosomal microarray analysis and karyotyping in prenatal diagnosis

Authors:

P. Hu, Y. Xu, Q. Zhang, Y. Wang, Z. Xu; Women's Hosp. of Nanjing Med. Univ., Nanjing Maternity and Child Hlth.Care Hosp., Nanjing, China

Background: Emerging studies demonstrate that optical genome mapping (OGM) is able to detect nearly all classes of structural variations in a single assay with high concordance with standard of-care methods. However, the application and evaluation of OGM in prenatal diagnosis remains limited.**Objectives:**This study aimed to evaluate the feasibility, efficacy, and incremental yield of OGM compared with chromosomal microarray analysis (CMA) and karyotyping for routine prenatal diagnosis.**Study design:**In this prospective study, a total of 200 singleton fetuses with ultrasound abnormalities were recruited. OGM and CMA plus karyotyping were performed in each sample in parallel. Triploidies, aneuploidies, copy number variations and microscopic balanced translocations and inversions were detected and analyzed in blinded fashion. Small (< 50 kb) insertions, deletions, duplications and submicroscopic translocations and inversions that beyond the detection range of CMA and karyotyping were validated by long-rang PCR plus Sanger sequencing, multiplex ligation-dependent probe amplification or fluorescence in situ hybridization.**Results:**Overall, 41 (20.5%, 41/200) cases with chromosome aberrations were identified by OGM, including one with triploidy, 22 with aneuploidies, 15 with pathogenic or likely pathogenic copy number variations and three with balanced translocations. Compared with CMA plus karyotyping, OGM provided an additional detection of one case with pathogenic intragenic duplication and two cases with cryptic balanced translocations (one translocation resulted in the disruption of OMIM gene associated with dominant disorders), but failed to identify one case with pericentric inversion. Additionally, OGM added information of orientation and location for eight duplication segments and identified eight (4.0%, 8/200) cases with repeat contraction disorders.**Conclusions:**Compared with CMA and karyotyping, OGM provided a more comprehensive detection of structural variations at a higher resolution in prenatal diagnosis. In addition, OGM revealed the location and orientation of duplication segments, refined breakpoints of structural variations and identified specific repeat contraction disorders. Our results suggest that OGM has the potential to be an alternative technology to CMA and karyotyping for prenatal evaluation of fetuses with ultrasound abnormalities.

PB2090 Optimization of preimplantation genetic testing workflow for a higher percentage of euploid embryos

Authors:

Y. Goikhman, S. Avdeichik, I. Mirzalimova, A. Kullyev; Israeli Med. Ctr., Tashkent, Uzbekistan

Upon establishing preimplantation genetic testing for aneuploidy (PGT-A) laboratory in a new location in Tashkent, Uzbekistan, AB-PGT (AB Vector) kit was chosen as the PGT-A sample preparation method.
With this setup, 62.8% of embryos were diagnosed as euploid, consistent with published data for euploidy rate among younger patients (the average patient's age is 31.9 years).
As the number of samples grew we switched to the EmbryoMap PGT-A kit to streamline the sample processing. EmbryoMap sample processing reduces hands-on time in half. It also reduces the chance of human errors in sample processing and results interpretation due to the following measures: The order of samples with unique Sample IDs is locked at the beginning of processing in the eMap Laboratory Planner. Primers for the library come pre-mixed for every sample. Data analysis and reporting are performed using eMap software with automated calling for whole chromosome aneuploidy, segmental changes, and mosaic changes.
The euploidy rate with the EmbryoMap is 48.2%, 23% lower relative to AB Vector. The percentage of embryos with mosaic and segmental aneuploidy is 60% higher with EmbryoMap (22.3% with EmbryoMap compared to 13.9% AB Vector).
IVF clinic with clinicians performing ovarian stimulation, embryologists performing a biopsy, IVF laboratory setting, genetic laboratory personnel, and clinical geneticist reading and interpreting results remained the same for all the samples processed. All samples were sequenced on the Illumina MiSeq Sequencing System. The lower euploidy rate could be due to false positive results. To improve calling accuracy we are cataloging artifacts specific to EmbryoMap. To reveal false positive results we established a practice of routinely re-testing the inner cell mass (ICM) of embryos diagnosed as abnormal. Any discrepancies found during re-testing are used to improve the accuracy of PGT-A.
Conclusions: The sample processing kit in PGT-A impacts both probability of human errors and the percentage of embryos recommended for transfer. The percentage of euploid embryos among younger patients is a useful reference point to compare against published data. Results interpretation should be tailored to each PGT-A workflow. Diagnosis for embryos not recommended for transfer should be routinely reconfirmed by analyzing ICM, as part of PGT-A quality control.

PB2091 High-Resolution and Non-Invasive Prenatal Exome Screening

Authors:

M. Duyzend[1,2], H. Brand[1,2], C. Whelan[2], J. Lemanski[1], M. Salani[1], S. Hao[1], I. Wong[1], E. Valkanas[1,2], C. Cusick[2], C. Genetti[3], L. Dobson[4], C. Studwell[4], K. Gianforcaro[4], L. Wilkins-Haug[4], S. Guseh[4], B. Currall[1], K. Gray[4], M. Talkowski[1,2]; [1]Massachusetts Gen. Hosp., Boston, MA, [2]Broad Inst., Cambridge, MA, [3]Boston Children's Hosp., Boston, MA, [4]Brigham and Women's Hosp., Boston, MA

Non-invasive prenatal screening (NIPS) involves the assessment of circulating cell-free fetal DNA extracted from maternal plasma. While screening for chromosomal aneuploidies is now routine in clinical practice and advances have enabled detection of some targeted single gene conditions, current NIPS approaches capture only a small fraction of genetic variants relevant to prenatal diagnosis. Building on earlier efforts that relied on deep sequencing of cell-free and parental DNA, our studies demonstrate the feasibility of a high-resolution non-invasive prenatal screen that can capture most pathogenic coding variation (single nucleotide variant (SNV), indel, copy number variant (CNV)), including *de novo* variation, from a maternal blood draw alone. To demonstrate the feasibility of our method, we performed a study on 51 pregnancies with gestational ages ranging from 9 to 40 weeks and benchmarked our method against 11 of these samples with gold-standard germline exome sequencing from cord blood or amniocentesis. We prepared cell-free DNA (cfDNA) libraries from maternal plasma, enriched for exonic regions, and generated an average 211x exome-wide short-read sequencing coverage. We detected small variants using a customized pipeline built to filter out candidate variant sites generated by sequencing or mapping artifacts and genotyped sites using a Bayesian Gaussian mixture model which simultaneously estimates fetal fraction and considers features such as the DNA fragment sizes supporting each allele. We identified CNVs using read-depth techniques. Our methods demonstrate a high median sensitivity/precision for SNV (92.9% / 93.3%) and indel (77% / 71.6%) genotyping from cfDNA. Prior to filtering, median sensitivity is 99.6% for SNVs and 94% for indels, indicating that most coding variants are captured, but opportunities remain to optimize filtering and genotyping. We assessed utility across 14/51 pregnancies referred for diagnostic genetic testing and discovered all clinically identified variants (n=4), including a likely pathogenic splice variant in *COL2A1* (associated with Stickler syndrome) and a 4MB terminal deletion on chr7 (in a fetus with multiple congenital anomalies). Because maternal cfDNA is also sequenced, our approach has added value as a maternal carrier screen with high median sensitivity / precision for maternal SNVs (98.4% / 95.9%) and indels (86.2% / 81.9%), and we found at least one reportable variant in over half of pregnant individuals assessed. This method represents a substantial increase in the resolution of NIPS techniques and suggests that the complete non-invasive prenatal exome is accessible at scale.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2092 Performance of a genome-wide association study of neural tube defects allows an unbiased search for genetic contribution.

Authors:

F. Pangilinan[1], J. L. Mills[2], A. M. Molloy[3], L. C. Brody[1]; [1]Natl. Human Genome Res. Inst., NIH, Bethesda, MD, [2]Eunice Kennedy Shriver Natl. Inst. of Child Hlth.and Human Dev., NIH, Bethesda, MD, [3]Sch. of Med., Trinity Coll., Dublin, Ireland

Neural tube defects (NTDs) occur during if the neural tube, which gives rise to the brain and spinal cord, fails to close completely in the first month post fertilization. NTDs are among the most common major birth defects, causing severe morbidity and mortality. The etiology involves genetic and environmental components. Periconceptual folic acid supplementation has been shown to prevent 50-70% of NTDs, suggesting that susceptible genetic factors negatively affect folate related processes at the time of neural tube closure.

To date, researchers have largely used a candidate gene approach to uncover the genetic component of NTDs, where known developmental genes or known folate pathway genes have been tested for association with increased risk. This approach has been less successful than anticipated, with many reported associations not found to be replicable. Although valuable, candidate gene studies are limited because the only genes selected are those known a priori by researchers.

A genome-wide association study (GWAS) has the advantage of being an unbiased by assumptions. For this study, nearly two million genetic markers will be genotyped by the Center for Inherited Disease Research using an array that is the equivalent of the Global Diversity Array (Illumina). Designed to capture common and low frequency variants in global populations, as well as incorporate functional variants, this array will be used in a genome-wide screen of association with NTDs. An exceptional number of participants is required to reach a sufficient sample size to correct for multiple comparisons in the primary GWAS and to replicate positive signals.

The International Consortium on the Genetics of Neural Tube Defects is a collaborative effort to perform an NTD GWAS. Study participants have been drawn from the National Birth Defects Prevention Study (USA) and the Baby Biobank (UK), and will also involve NTD-specific cohorts, including a large, established cohort from the Republic of Ireland. Additional participants originate from cohorts collected in New York, Texas, Chile, the Netherlands, and Malaysia. After pooling, more than 1400 NTD cases and their parents from the US and Europe will be available for an initial GWAS of NTDs. Case-control and family-based tests of association will be used to evaluate genetic risk of offspring developing an NTD or mothers developing an NTD affected pregnancy. Over 1200 NTD cases and their parents are available for replication testing of positive signals. This study is expected to reveal new sources of genetic contribution to NTDs, thereby illuminating its etiology and potentially its treatment and prevention.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2093 Perinatal detection of HPV infection using a wearable device: Prevention of genomic instability using DNA editing.

Authors:

E. McGhee[1], A. Bahmani[2], J. LIllard[3]; [1]Martin Luther king Jr. Community Hlth.Hosp., Los Angeles, CA, [2]Stanford Univ., Palo Alto, CA, [3]Morehouse Sch. of Med., Atlanta, GA

The observation of infants showing signs from receiving perinatal transfection of human papillomavirus (HPV)-induced genomic instability has been demonstrated in several small studies. The direct contact of HPV infection carried by a pregnant woman can be perinatally transferred to the unborn baby. Wearable devices may be important for detecting HPV Infection in pregnant women and may be helpful in halting the perinatal transmission of the virus by this detection. However, HPV DNA has been detected in umbilical cord blood, and HPV can spread to amniotic cells that are then ingested by the fetus. Cells involving p53 and Rb, gate keeper proteins protect against DNA damage, if not degraded by E6/E7 HPV complex. This research will investigate the possibility for Mendelian mutations, associated with increased chromosomal instability through Robertsonian aberrations. Robertsonian translocations are common constitutional abnormalities in humans but are considered rare occurrences in cancer cells. Research is sparse surrounding Robertsonian translocations in viral infected cells; therefore, we examined *in vitro*, whether HPV-E6/E7 transfection will facilitate the formation of Robertsonian aberrations. We used single nucleotide polymorphism (SNP) spectral karyotyping (SKY) and array-comparative genomic hybridization (array-CGH) to score Robertsonian aberrations in cells, we analyzed metaphases to determine the types of Robertsonian translocations present in cells. The results showed non-homologous Robertsonian translocations in 100% of metaphases scored and homologous acrocentric rearrangements-isochromosome types in 75% of metaphases scored. We studied two types of Robertsonian translocations: der(13;14), the non-homologous type, and i(13), the homologous isochromosomes type. The results showed that HPV E6/E7 oncoproteins induce genomic instability, causing Robertsonian translocations on chromosomes 13 and 14. This research may provide a reliable detection method for future research involving HPV infection using wearable devises.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2094 Pleiotropic effect of de novo variants in structural birth defects and neurodevelopment disorder

Authors:

W. Gao[1,2], H. Jake[3,1], Q. Lu[1], Z. Guojie[2], C. Shu[1], Y. Shen[4], W. Chung[5]; [1]Dept. of Pediatrics, Columbia Univ. Irving Med. Ctr., New York, NY, [2]Dept. of System Biology, Columbia Univ. Irving Med. Ctr., New York, NY, [3]Dept. of Systems Biology, Columbia Univ. Irving Med. Ctr., New York, NY, [4]Columbia Univ., New York, NY, [5]Dept. of Pediatrics, Columbia Univ., New York, NY

Structural birth defects like congenital diaphragmatic hernia (CDH), orofacial cleft and sex development disorders have heterogenous genetic causes. Previous studies suggest that hundreds of genes can contribute to risk of these conditions through de novo variants. Many genes involved in core developmental pathways may have pleiotropic effect in contributing to risk of multiple birth defects and neurodevelopmental disorders. The statistical power of identifying new risk genes is typical low in studies of birth defects without large sample size. In this work, we aim to estimate the degree of pleiotropic effect of de novo variants across these conditions and to identify pleiotropic risk genes that have a new role in birth defects. We obtained genome data of a comprehensive set of birth defects from the NIH Gabriella Miller Kids First (GMKF) Pediatric Research Program, including 1078 CDH trios, 204 orofacial cleft birth defect trios, 218 Kidney and Urinary Tract trios, 107 nonsyndromic craniosynostosis, 44 sex development disorders trios, 185 Esophageal Atresia and Tracheoesophageal Fistulas (EA/TEF) trios. We called de novo coding variants from the GMKF affected individuals. We also obtained published de novo coding variants from studies on congenital heart disease (The Pediatric Cardiac Genetics Consortium, N~3000) and NDD (N~30,000). Consistent with previous studies, there are significant enrichment of de novo protein truncating variants in all GMKF conditions, especially among constrained genes (gnomAD pLI≥0.5). The enrichment of de novo missense variants is marginal; its significance depends on sample size, as expected. To estimate pleiotropic effect, we applied a simple Poisson test of damaging variants (PTV and missense variants with CADD phred-scale score≥25), in the combined data of all the conditions, and identified 219 genes with exome-wide significance (p-value<2.5e-6). Among these genes, 90 have at least one damaging variants in at least two conditions, including 85 estimated NDD genes and five putative novel risk genes. A notable gene is *ZFHX3* (*p*=7.8e-9), with damaging variants in individuals with NDD, CHD, or CDH, and a previously reported individual with orofacial cleft (not included in our data). Finally, we focused on CDH. Overall, the population attributable risk (PAR) of de novo coding variants to CDH is estimated to be 27%, including 7.5% from established CDH genes by human or mouse studies and an additional 6.5% from known NDD and CHD risk genes, most of which have not been implicated with CDH. These results provide new insight of finding new risk genes for rare birth defects through methods that leverage pleiotropic effect.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2095 Preimplantation genetic testing data from 129,479 IVF embryos reveals the landscape of haplo- versus triplo-sensitivity prior to blastocyst formation

Authors:

S. Carioscia[1], A. Biddanda[1], I. Vogel[2], E. Hoffman[2], R. McCoy[1]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Univ. of Copenhagen, Copenhagen, Denmark

Less than half of all human conceptions survive to live birth. Extra or missing chromosomes (aneuploidies) are the primary cause of pregnancy losses, many of which occur during the preimplantation stages. Data from preimplantation genetic testing for aneuploidy (PGT-A) from trophectoderm biopsies of blastocyst-stage in vitro fertilized (IVF) embryos offers a unique view into the origins of aneuploidy and the landscape of dosage sensitivity during the first five days after fertilization.

Here we report detailed patterns of chromosome abnormalities detected in biopsies of 129,479 day-5 blastocyst-stage IVF embryos from 20,900 sets of patients. Using genome-wide array-based genotyping of embryo biopsies, as well as DNA from parents, we infer transmission of individual parental homologs and assign parental origins of aneuploidies. The scale of the data offers unique insight into the origins of rare abnormalities in genome-wide ploidy. This includes the observation that triploidy nearly exclusively involves an extra copy of the maternal genome (1365 cases of maternal triploidy vs. 66 cases of paternal triploidy) and that haploidy/genome-wide uniparental isodisomy (GW-isoUPD) nearly exclusively involves the sole presence of a maternal genome (224 cases of maternal haploidy/GW-isoUPD vs. 35 cases of paternal haploidy/GW-isoUPD).

Gains and losses of all individual chromosomes were observed among the blastocyst-stage embryos. Maternal meiotic-origin trisomies were strongly enriched on chromosomes 15, 16, 21, and 22, consistent with previous literature. Because the predominant mechanisms of maternal meiotic error produce equal ratios of monosomies and trisomies (via reciprocal gain and loss in the egg and polar body, or vice versa), imbalance in this ratio offers insight into lethality of gains versus losses during cleavage-stage embryonic development. While all chromosomes were enriched for trisomies compared to monosomies, the magnitude of enrichment was greater for larger chromosomes with more protein-coding genes (Pearson $r = 0.683$, $p = 4 \times 10\text{-}4$). The enrichment was strongest on chromosomes 1 (89.3% trisomies; binomial test, $p < 1 \times 10\text{-}10$) and 9 (87.6% trisomies; binomial test, $p < 1 \times 10\text{-}10$) and weakest on chromosomes 21 (56.4% trisomies; binomial test, $p = 1.3 \times 10\text{-}26$) and 22 (56.2% trisomies; binomial test, $p = 6.8 \times 10\text{-}40$). These observations support a model whereby the cumulative burden of dosage effects of numerous genes, as opposed to few genes of large effect, drives embryonic mortality in response to aneuploidy. Our results offer insight into the strong and recurrent forces of purifying selection that shape the first days of human development.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2096 Prenatal CMA using exon-level coverage for 'disease gene' CNV interrogations in the era of non-invasive prenatal testing

Authors:

W. Bi[1,2], S. Anderson[2], R. Song[2], S. Cheung[1], A. Breman[1], J. Lupski[1], A. Beaudet[1], P. Ward[1,2], I. Van Den Veyver[1,3], C. Bacino[1,2], N. Owen[1,2], J. Smith[1], C. Settler[2], R. Rigobello[2], M. Chau[1,2]; [1]Dept. of Molecular and Human Genetics, Baylor Coll. of Med., Houston, TX, [2]Baylor Genetics, Houston, TX, [3]Dept. of Obstetrics and Gynecology, Baylor Coll. of Med., Houston, TX

Background: Non-invasive prenatal testing (NIPT) with cell-free DNA is widely accepted as standard of care to screen for common aneuploidies, and some platforms also include screening for microdeletions/duplications. This shift in clinical practice affects the use of chromosomal microarray analysis (CMA) in the prenatal setting. In addition, microarrays with exon-by-exon coverage for disease genes enable detection of intragenic copy number variants (CNVs) leading to increased sensitivity to postnatal diagnosis but such arrays are rarely used in prenatal CMA. This study investigated the role of prenatal CMA in the era of NIPT based on a single laboratory's experience.

Methods: We retrospectively reviewed the results of all the amniotic fluid or chorionic villus samples that were analyzed by CMA using custom-designed Agilent arrays during last 11 years at Baylor Genetics. For 80% of samples, CMA was performed using arrays that include exon-by-exon coverage for >1,700 genes. Parental samples were received concurrently to evaluate maternal cell contamination and to facilitate data interpretation.

Results: The overall CMA detection rate of clinically significant findings was 10.4% and the diagnostic rate for pregnancies with abnormal ultrasound findings was 13.7%. The diagnostic rate was highest (32.1%) for cases with abnormal or atypical NIPT results as primary indications. Among those, the most frequent NIPT findings were increased risk or positive result for autosomal aneuploidy with a diagnostic rate of 48.3%, followed by increased risk or positive result for sex chromosome aneuploidy, microdeletion/duplication, and inconclusive or nonreportable findings. Of the cases with increased risk for microdeletion/duplication, CMA confirmed the CNVs in 13% of cases including cases with increased risk of 22q11.2 deletion and cases with supernumerary/ring chromosomes of >14 Mb in size. Due to the increased probe coverage in genes for established rare disease traits, CMA detected clinically significant exonic CNVs involving nine different genes. The smallest one is a *de novo* 5.6 Kb deletion of the *ZIC2* gene in a fetus with multiple holoprosencephaly.

Conclusions: Prenatal CMA remains essential for the detection of microdeletions/duplications because NIPT is limited in screening for submicroscopic copy number changes. We also show that increased probe coverage of disease genes on prenatal microarrays enables detection of single gene copy number changes. Finally, this confirmation data demonstrates the importance of a diagnostic test such as CMA in follow up to NIPT results that are positive or increased risk for microdeletions/duplications.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2097 Products of Conception analysis by chromosomal microarray: a single center experience.

Authors:

J. Smith, N. Owen, W. Bi; Baylor Coll. of Med., Baylor Genetics, Houston, TX

Background: Missed abortions and fetal demises are often caused by chromosome aberrations detectable by conventional cytogenetics. However, chromosome analysis of products of conception (POC) may be unsuccessful or uninformative due to maternal cell contamination (MCC) of the sample and reduced viability of cells in culture. Chromosomal microarray (CMA) may circumvent such issues, as it does not require culturing, and MCC studies may be performed on extracted DNA prior to running CMA. **Methods:** Data from this clinical laboratory's offering of POC CMA over a 5-year period were reviewed specifically for aneuploidy/triploidy and compared to conventional cytogenetic results for the same period. CMA was performed on a custom designed Agilent 400k array with SNP probes. MCC was evaluated on CMA cases by comparative analysis of maternal and fetal DNA using multiple unlinked polymorphic markers when a maternal specimen was received. **Results:** Reportable data were obtained on 71% and 82% of POCs submitted for CMA and conventional cytogenetics, respectively. Unreportable CMAs were due to insufficient DNA quantity/quality or overwhelming MCC. Notably, 45% of cytogenetic studies were reported as 46,XX with no way to distinguish which were maternal vs. fetal in origin. Data review showing significantly more 46,XY results reported by CMA than by cytogenetics (31% vs. 12.6%) is evidence that a significant number of 46,XX results are maternal in origin. Discrepancies between CMA results (various aneuploidies and triploidy) and cytogenetics (46,XX) were noted in several cases. The use of MCC studies and avoidance of maternal cell overgrowth in culture by analysis of direct preparations gives CMA an advantage over conventional chromosome analysis. Among more than 100 CMA cases with abnormalities/incidental findings were 9 triploidies and 73 single chromosome aneuploidies including Monosomy X (18), trisomy 21 (15), trisomy 22 (9), trisomy 13 (8), trisomy 18 (7), trisomy 9 (4), trisomy 15 (4), trisomy 16 (2) and one case each of XXX, XXY and trisomies 4, 8, 14, and 20. Additional anomalies detected were 1 case of monosomy 3, 1 case of mosaic +X,+19, 8 other mosaic cases and 2 double aneuploidies (1 trisomy 15 and 16 and 1 trisomy 5 and 20). **Conclusions:** These data support the use of MCC studies and avoidance of maternal cell overgrowth in culture by analysis of direct preparations giving CMA an advantage over conventional chromosome analysis. Our CMA data are consistent with the literature in that autosomal trisomies as a group are the most common class of anomalies in pregnancy losses followed by monosomy X and triploidy; it does not support the published frequency of trisomy 16.

PB2098 Quantitative trait loci mapping: Identifying inbred strain-specific loci that modify cleft secondary palate expression in*Prdm16*^{csp1}mouse mutants.

Authors:

D. Melwani, M. Elibiary, B. Kimberly, E. Leslie, B. Bjork; Midwestern Univ., Lombard, IL

Cleft secondary palate (CP) is among the most common congenital craniofacial anomalies with complex inheritance. *Prdm16* is a zinc finger transcription factor whose loss in mouse embryogenesis results in CP resembling Pierre Robin complex. *Cleft secondary palate 1* mutant embryos *(Prdm16*^{csp1}*)* on a congenic FVB/NJ strain background (*csp1-FVB*) exhibit fully penetrant CP, whereas *csp1* mutants on a congenic C57BL/6J strain background (*csp1-B6*) do not exhibit CP. We hypothesize that quantitative trait loci (QTLs) that contribute to this phenotypic variation are present in these strains' genomes. To this end, we performed a F2 genetic modifier screen with genome-wide SNP analysis using the Mini Mouse Universal Genotyping Array (MiniMUGA) and Giga Mouse Universal Genotyping Array (GigaMUGA). *csp1-B6* carrier males were outcrossed to inbred FVB females to produce F1 B6.FVB-*csp1* carriers. Male and female F1 carriers were intercrossed to generate F2 homozygous *csp1* mutant pups on a mixed B6xFVB background. Resulting F2 mutants were placed in 3 distinct phenotypic classes (wide CP, narrow CP, and no CP), and whole-genomeSNP genotyping was carried out. QTL.gCIMapping.GUI software was utilized to identify putative QTLsthrough genome-wide composite interval mapping (GCIM) and likelihood of the odds (LOD) assessment. We also used r/QTL2 as an alternative method. We identified 6 significant QTL regions on 5 chromosomesassociated with variation in CP expression in *csp1* mutants with differing contributions of FVB and B6 alleles. Next, we performed secondary QTL analyses by adding high-resolution GigaMUGA SNPs on these 5 associated chromosomes to refine the QTL intervals. We are currently evaluating positional candidate genes for potential damaging sequence variants that may contribute to differences in CP phenotype between the *csp1* mutants on the FVB and B6 strains. In future studies we hope to employ existing mouse mutant alleles and/or CRISPR/Cas9 genome editing to introduce variant alleles to the FVB or B6 genomes to substantiate potential modifier loci identified in our screen. Our findings may contribute to a greater understanding of genetic factors that influence normal craniofacial development that may contribute to the complex etiology of cleft palate in humans.

Aston[10], D. Ježek[4], A. Katušić Bojanac[4], M. Barbalić[4], M. Laan[3], D. Conrad[1,2]; [1]Oregon Hlth.and Sci. Univ., Beaverton, OR, [2]Oregon Natl. Primate Res. Ctr., Beaverton, OR, [3]Inst. of Biomedicine and Translational Med., Univ. of Tartu, Tartu, Estonia, [4]Univ. of Zagreb Sch. of Med., Zagreb, Croatia, [5]Andrology Clinic, Tartu Univ. Hosp., Tartu, Estonia, [6]Andrology Dept., Univ.t Autònoma de Barcelona, Barcelona, Spain, [7]Univ. of Porto, Porto, Portugal, [8]Departamento de Genética Humana, INSA, Lisbon, Portugal, [9]Copenhagen Univ. Hosp., Copenhagen, Denmark, [10]Univ of Utah, Salt Lake City, UT

Non-obstructive azoospermia (NOA) is one of the more severe forms of male infertility, however many cases remain unexplained. DMRT1 is a transcription factor that is important in regulating development and sex determination. Disease-causing variants with autosomal dominant inheritance in *DMRT1* have been linked to many human infertility phenotypes, including disorders of sexual development and NOA. The connection between *DMRT1* variation and primary ovarian insufficiency (POI) in humans has not been determined. This study aimed to understand the effect of rare heterozygous *DMRT1* mutations in patients with spermatogenic failure (SPGF) and POI, and the genetic burden of carrying these mutations. We utilized whole exome sequencing (WES) from the GEnetics of Male INfertility Initiative (GEMINI) and Estonian Andrology (ESTAND) cohorts; n=1,940 SPGF, n=105 POI, and n=644 normozoospermic controls. To analyze causative *DMRT1* variants, a computational pipeline was developed to filter variants and ACMG guidelines were followed to determine variant pathogenicity. Gene-based burden testing was performed using the GEMINI+ESTAND cases and population-based controls from publicly available data in gnomADv2.1. We identified an excess of rare potentially pathogenic *DMRT1* variants in the combined male infertility cases (n=14), compared to normozoospermic controls (n=0, Fisher's Exact test $p<0.05$). Burden testing with the larger set of population controls from gnomAD with damaging *DMRT1* variants (n=519/141,456) compared to GEMINI+ESTAND was significant ($p<0.05$). Nine variants, including two in POI cases, clustered in the DNA binding (DM domain) of the DMRT1 protein. Six variants clustered together in two hotspot amino acid positions, both of which were highly conserved across species and previously reported as functionally important in the DM domain. We identified three rare *DMRT1* variants in POI cases, a significant enrichment compared to gnomAD (p=7.26E-03). One POI case with a substitution in the DM domain was also detected in two NOA cases. Phenotypes observed in patients with DM domain variants included smaller testes, spermatogenic arrest, and germ cell neoplasia in situ (GCNIS). These findings increase the understanding of the role of rare heterozygous *DMRT1* variants in male infertility, revealing how missense substitutions in the DM domain could be a dominant cause of male infertility. The connection between *DMRT1* mutations and POI in humans has not yet been determined and the shared positions between NOA and POI cases is a further avenue for investigation on *DMRT1* and POI.

PB2100 Recurrent spontaneous abortion related to balanced translocation of chromosomes - A case report

Authors:

N. DUKUZE; Univ. of Rwanda, Kigali, Rwanda

ABSTRACT INTRODUCTION: Recurrent spontaneous abortion (RSA) is defined as three or more consecutive pregnancy losses before the 20th week of gestation. RSA is often idiopathic, but structural chromosomal abnormality is an important cause. An unbalanced karyotype in the conceptus of a couple when one partner has a structural chromosomal abnormality may result in failure to implant, miscarriage, or pregnancy of a fetus with an unbalanced karyotype. CASE PRESENTATION: We report a rare case of RSA associated with balanced translocation of chromosomes. a woman who had four spontaneous abortions, all pregnancy loss happened before 12 weeks of gestation, no other known chronic diseases reported to the family nor medications taken during pregnancy. The karyotype was 46.XX, t(13p,21p) The abnormal karyotype was not found in any other chromosomes. Further spectral karyotyping was performed to rule out the involvement of any other chromosomal aberrations present in the genome.The cytogenetic analysis of the husband revealed a normal karyotype 46.XY. CONCLUSION: Couples with more than three miscarriages should be referred to the genetist for chromosomal analysis for possible hereditary etiology and chromosomal abnormalities responsible for miscarriages to plan prenatal diagnostics and genetic counseling for subsequent pregnancies.

PB2101 Residual risk of clinically significant copy number variations in fetuses with nasal bone absence or hypoplasia after excluding non-invasive prenatal screening-detectable findings

Authors:

Y. Wang[1], P. Hu[2], Z. Xu[1]; [1]Women's Hosp. of Nanjing Med. Univ., Nanjing Maternity and Child Hlth.Care Hosp., Nanjing, China, [2]Women's Hosp. of Nanjing Med. Univ., Nanjing Maternity and Child Hlth.Care Hosp., Nanjing, China, Nanjing, China

Objective: To evaluate the residual risk of clinically significant copy number variations (CNVs) in fetuses with nasal bone (NB) absence or hypoplasia after excluding theoretically non-invasive prenatal screening (NIPS)-detectable abnormalities, and to assess their clinical outcomes. **Methods:** This prospective study encompassed 400 fetuses with NB absence or hypoplasia undergoing chromosomal microarray analysis (CMA) testing between 2015 and 2022. Clinically significant CMA findings were categorized into three subgroups, including three-NIPS-detectable (trisomies 21, 18 and 13), five-NIPS-detectable (trisomies 21, 18 and 13 and sex chromosome aneuploidies) and genome-wide NIPS-detectable. We calculated the theoretical residual risk following the exclusion of NIPS-detectable findings and compared it with the results of a published control cohort of low-risk pregnancies. We further evaluated their clinical outcomes. **Results:** The overall diagnostic yield in our cohort was 7.8% (31/400). The modeled residual risk of clinically significant CNVs ranged from 3.1% (three-chromosome NIPS) to 1.7% (genome-wide NIPS) in fetuses with isolated NB absence or hypoplasia and 9.7% (three-chromosome NIPS) to 6.7% (genome-wide NIPS) in fetuses with non-isolated NB absence or hypoplasia. The theoretical residual risks were significantly higher in all NIPS models when compared with the control cohort. The normal infant rate in fetuses with normal CMA results was 97.9% (323/330). **Conclusions:** The residual risk of clinically significant CNVs in fetuses with NB absence or hypoplasia following the exclusion of theoretically NIPS-detectable findings was higher than that in low-risk pregnancies.

PB2102 Screening over 600 candidate genes for disease-causing variants in male factor infertility.

Authors:

K. Lillepea[1], A-G. Juchnewitsch[1], L. Kasak[1], A. Valkna[1], A. Dutta[1], K. Pomm[2], O. Poolamets[2], M. Punab[1,2,3], M. Laan[1]; [1]Inst. of Biomedicine and Translational Med., Univ. of Tartu, Tartu, Estonia, [2]Andrology Ctr., Tartu Univ. Hosp., Tartu, Estonia, [3]Inst. of Clinical Med., Univ. of Tartu, Tartu, Estonia

Failure to conceive a child affects 5-10% of men, and in most cases, it is due to spermatogenic failure (SPGF, $<39\times10^6$ sperm/ejaculate). Currently, >50% of SPGF patients remain idiopathic[1]. Although genetic factors are considered as a key etiology behind SPGF, today's clinical guidelines include limited genetic tests. Exome sequencing (ES) has led to the discovery of hundreds of candidate genes and variants for male factor infertility[2]. However, their added value in increasing the diagnostic yield and improving patient management in routine clinical practice is to be determined.

We performed ES to screen 519 idiopathic SPGF patients recruited to the ESTonian ANDrology (ESTAND) cohort for disease-causing variants in over 600 previously established and recently proposed candidate genes. Subgroups of patients with different andrological profiles were compared: non-obstructive azoospermia (NOA, 186 men), oligozoospermia (182), and patients with idiopathic cryptorchidism and SPGF (151). Rare disease-causing variants (MAF<0.01) were filtered, interpreted, and prioritized using available data for clinical and functional consequences, matchmaking with literature cases, and in silico predictions of variant pathogenicity. The final pathogenicity assessment was based on the ACMG guidelines[3] and gathered extended phenotype and pedigree data.

Molecular diagnosis was identified for >10% of ESTAND cases, and there was no significant difference between the three andrological subgroups for the proportion of patients with genetic findings. This is an important outcome with broad clinical consequences. Most of previously published ES studies in male infertility have focused only on NOA[2], whereas the fraction of idiopathic patients presenting oligozoospermia or cryptorchidism with SPGF is manifold higher compared to men with no sperm[1]. Although the screened gene panel comprised over 600 genes, the identified (likely) pathogenic variants were distributed only to 40 genes, including recurrently affected loci and recurrently detected disease-causing variants in more than one patient in ESTAND or overlapping with findings in other cohorts.

Our data suggest that gene panel-based ES could be included in the genetic testing of SPGF patients as it will contribute to the personalized management of patients' reproductive and overall health.

PB2103 Sex differences in placental gene expression in hypertensive versus normotensive pregnancies

Authors:

S. Plaisier[1], A. Abdulahad[2], T. Powell[2], L. Nordstrom[2], D. Coonrod[2], M. Wilson[1]; [1]Arizona State Univ., Tempe, AZ, [2]Valleywise Hlth.Med. Ctr., Phoenix, AZ

Preeclampsia is a pregnancy disorder characterized by gestational hypertension and proteinuria and is thought to be rooted in placental dysfunction. Many studies have reported fetal sex biases in the incidence of pregnancy complications including hypertension and preeclampsia, but the mechanisms underlying the relationship between fetal sex and pregnancy complications are poorly understood. Having previously demonstrated sex differences in placental gene expression in uncomplicated pregnancies, we sought to determine if gestational hypertension affects placental gene expression differently based on fetal sex. We performed RNA sequencing and sex-informed transcriptomics of placental tissue from full-term deliveries of ten hypertensive and ten normotensive pregnancies, each with half carrying a fetus assigned female at birth (XX) and half with assigned male at birth (XY). We found that XY male placentas had distinct gene expression profiles from XX female placentas and only XY males separated by hypertension status. XY male placentas showed differential gene expression of 540 genes between hypertensive and normotensive conditions, which were enriched for genes involved in metabolism, cell adhesion, angiogenesis, signaling and proliferation. In contrast, XX female placentas had only 303 differentially expressed genes between hypertensive and normotensive conditions, with little overlap to XY male placentas, and were enriched for spliceosome and immune functions. We found that the XY male placental hypertension gene signature had much higher correlation to published signatures of preeclampsia than XX female placentas. We used single cell deconvolution to show that specific immune cell types had different imputed cell fraction in XY male versus XX female hypertensive placentas, suggesting potential mechanisms by which sex differences in placental gene expression could lead to different health outcomes. In conclusion, our study demonstrates the importance of sex as a biological variable as there are large differences in the placental gene expression pattern of gestational hypertension based on the sex assigned at birth and that this may be due in part to different proportions of specific immune cell types in the placental tissue.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2104 Single cell RNA-seq processing pipeline and data integration method decisions impact significance of immune cell clusters in the uterus

Authors:

J. Garifallou[1], M. Simoni[2], S. Mani[2], M. Mainigi[2], S. M. Gordon[1]; [1]Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Dept. of Obstetrics and Gynecology, Univ. of Pennsylvania, Philadelphia, PA

Introduction: The diverse landscape of single cell RNA-seq technologies that have been developed have led to an ever-increasing number of pipelines and tools used to analyze these complex datasets. Initial data processing pipelines to call cells, map reads to a reference genome, and collapse UMIs, have been previously shown to produce variations in datasets while typically maintaining similar cell yields and mapping quality. Resultant cell by gene matrices are further analyzed in other software packages such as Seurat (Hao, 2021) and include mechanisms to integrate diverse libraries. Efficiency of the integration method across the libraries and proper accounting of unwanted sources of data variance are essential to elucidate the true, experimental biological heterogeneity of the dataset.
Methods: Sorted CD45+ immune cells from 1) endometrial biopsies obtained during the window of implantation (pre-pregnancy) and 2) the maternal decidua from first trimester elective terminations of pregnancy were collected. Single cell RNA-seq libraries were prepared using the 10x single cell library preparation and sequenced on the Illumina NovaSeq6000. Data was demultiplexed using the cellranger v6.0 pipeline (10x genomics). Cells were called and reads were then mapped to the same GRCh38 genome reference using the following pipelines: cellranger v6.0, Kallisto-Bustools, STARsolo, and Alevin. Separately, downstream mapped read matrices were analyzed using the seurat anchor integration and the harmony methods while regressing out differences between tissue source (Endo vs. FT) and UMI count. Post processing data quality was assessed for each of the pipelines regarding the number of molecules, number of genes, number of mapped reads per cell. To assess the effect of the initial processing pipeline choice on cell clustering and cell annotation, cells were automatically annotated using singleR package with a published literature dataset of an appropriate tissue reference. Finally, significance of cell type proportions was assessed using the propellor R package.
Results: Differing numbers of total cells per library and per dataset (all libraries integrated) were observed. Differences in the proportion of cell types were observed depending on the analysis pipeline. Examination of these differences hopes to yield insights into the optimal analytical methodology for this cell-tissue type.
Conclusion: Each data set has unique biological complexities that should be considered during analysis. Optimization and testing of multiple methods allows for maximizing biological data yield and subsequent analysis on a per sample and per data set basis.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2105 Single-cell analysis of the human neonatal infant airway epithelium reveals age-related changes in cellular composition and transcriptional programming

Authors:

S. Bhattacharya[1], B. Bera[2], C. Elizabeth[1], K. Salka[3], A. L. Welham[1], H. Morizono[4], M. J. Gutierrez[5], J. Jaiswal[1], N. Gustavo[1]; [1]Children s Natl. Hosp., Washington DC, DC, [2]Childrens Natl. Hosp., Washington DC, DC, [3]The State Univ. of New York at Buffalo, Buffalo, NY, [4]Children's Natl. Hosp., Washington DC, DC, [5]Johns Hopkins Univ. Sch. of Med., Baltimore, MD

The heterogeneous composition of the human airway epithelium may allow plasticity during early development and explain age-related differences in structure and function. How airway epithelial cell (AEC) populations change from the naïve neonatal state to the mature adult state is not well understood. Defining the early developmental differences in the airway epithelium is critical to understand the pathogenesis of respiratory disorders that begin to originate during this critical period of life. Here, we used single cell RNA seq analyses to define age-related changes in cellular composition and transcriptional programming comparing differentiated human neonatal infant AECs and adult AECs. We performed single-cell RNA sequencing of approximately 9990 nasal AECs from three neonatal infant donors and three adults. Primary AECs were differentiated at air-liquid interface (ALI), dissociated into a single-cell suspension (10X) and, followed by sequencing (Illumina) . For each sample, CellRanger, was used to estimate the gene expression per cell from the raw sequence files, Seurat and DoubletFinder to remove low quality reads, scTransform for normalizing the reads and Seurat for clustering and visualization. To estimate the differential expression (DE) between infants and adults, we integrate both groups using Seurat. Gene set enrichment analysis (GSEA) was used for functional annotation. Using single-cell RNA-sequencing and clustering based on known epithelial marker genes, we identified significant cell heterogeneity in primary human AEC populations, with 7 major clusters (basal, mitotic basal, basal-KRT15, rare cells, deuterosome and ciliated). Age-dependent differences observed included an overabundance of basal epithelial cells with mitotic markers(e.g. MKI67) and basal cells expressing KRT15 in Newborn infants, whereas Goblet/Secretory cells had overabundance in adults. Pseudobulk differential expression (DE) between infants and adults identified cell proliferation pathways in infants and immune-related pathways in adults. At cellular level there is higher expression of cell proliferation in infants whereas adults have higher expression of immune genes. Single-cell analysis of the human neonatal infant and adult airway epithelium revealed age-related changes in cellular composition and transcriptional programming. Additional studies are needed to further elucidate the early developmental program of the human airway epithelium, its environmental modifiers during infancy, and the functional consequences for the pathogenesis of respiratory disorders that begin during early life.

PB2106 SPEN deficiency contributes to the development of cleft palate in humans and mice

Authors:

B-J. Kim, A. Hernandez-Garcia, D. Scott; Baylor Coll. of Med., Houston, TX

Normal 0 false false false EN-US KO X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0in 5.4pt 0in 5.4pt; mso-para-margin-top:0in; mso-para-margin-right:0in; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0in; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif; mso-ascii-font-family:Calibri; mso-ascii-theme-font:minor-latin; mso-hansi-font-family:Calibri; mso-hansi-theme-font:minor-latin;} Deletions of chromosome 1p36 are the most common telomeric deletions in humans. Deletion/phenotype mapping suggests the existence of two critical regions that are sufficient to cause most of phenotypes seen in 1p36 deletion syndrome. *SPEN* is located in the proximal critical region and encodes a transcriptional repressor. Pathogenic *SPEN* variants have been shown to cause a new neurodevelopmental disorder, Radio-Tartaglia syndrome, characterized by anomalies of the brain, palate, and/or heart. SPEN deficiency also causes defects in the brain and heart in mouse models. However, malformations of the palate have not been described in SPEN-deficient animal models. Here we report that *Spen* null mouse embryos have a cleft palate. The palatal shelves are normally formed in wild-type and *Spen* null embryos at E13.5. At E14.5, the palatal shelves are elevated and ready to fuse in the middle line in wild-type embryos. In contrast, the palatal shelves are not elevated in *Spen* null embryos, which leads to cleft palate at E15.5. We conclude that loss of SPEN function contributes to the development of anomalies in the palate, including cleft palate, and that SPEN is required for normal palatal development in humans and mice.

PB2107 *SYCP2* variants present with variable age-related progressive SPGF and male infertility

Authors:

R. Hvasta[1], C. Pombar[1], M. Malizio[1], M. Olszewska[2], A. Malcher[2], M. Kurpisz[2], S. Qureshi[3], M. Khan[3], K. Hwang[1], A. N. Yatsenko[1]; [1]Dept. of Obstetrics, Gynecology, and Reproductive Sci., Magee-Womens Res. Inst., Sch. of Med., Univ. of Pittsburgh, Pittsburgh, PA, [2]Inst. of Human Genetics, Polish Academy of Sci., Poznan, Poland, [3]Dept. of Molecular Biology and Genetics, Inst. of Basic Med. Sci., Khyber Med. Univ., Peshawar, Pakistan

Infertility is a rising public health crisis with poorly understood foundations, affecting ~17.5% of the global population. Male infertility accounts for nearly half of the global burden and often presents with varying degrees of severity. Spermatogenic failure (SPGF) encompasses the variable presentation of defects in spermatogenesis from oligozoospermia to non-obstructive azoospermia (NOA). Considering many cases are due to genetic variation in meiotic genes, it is essential to investigate the breadth of these genes' impact on spermatogenesis and their pathogenicity. One such gene, *SYCP2*, a member of the synaptonemal complex, essential for meiotic recombination, has been reported to cause autosomal dominant SPGF. Our analysis has identified a potential age-related progression of dominant SPGF associated with loss of function (LoF) *SYCP2* variants in 3 siblings and 6 unrelated infertile patients.

Within our cohort, familial DNA (father, mother, proband with NOA, sibling with NOA, and sibling with reduced spermatogenesis [20 mil/mL]) and DNA from one sporadic patient with severe oligozoospermia (SO) (<5 mil/mL) were sequenced by Whole Exome Solution V1 (SOPHiA Genetics) and variants were analyzed via Fabric Genomics and SOPHiA DDM software.

In the family, a novel, single heterozygous, LoF *SYCP2* variant co-segregated with SPGF in the 3 brothers. At evaluation, the two brothers with NOA were 32 and 35, and the brother with reduced spermatogenesis was 25. In the sporadic case, a novel CNV deletion was identified. The patient was found to be normozoospermic at 28; however, at 41, the patient was revaluated and diagnosed with SO.

In conjunction with findings from published reports, it appears that *SYCP2* positive patients under age 30 typically present with less severe forms of SPGF or even clinically normal, whereas older patients appear to progress to more detrimental forms of SPGF. These variants could be insidiously inherited by offspring from females and notably, younger male carriers who were fertile at the time of conception, discretely passing on deleterious mutations through generations. We suggest that age-related accumulation of meiotic defects causes progressive SPGF, and potentially causes other cellular defect comorbidities such as cancer. To test our hypothesis, we will generate transgenic mouse models and evaluate their genomic instability, homologous recombination capacity, and perform fertility assessments at different time points. If confirmed, these findings could provide invaluable insight into the delicate balance required for meiotic preservation and propose a mechanism for dominant progressive onset of SPGF.

PB2108 Targeted exome sequencing in fetuses with ultrasound findings: A powerful tool in prenatal diagnosis.

Authors:

C. Pangalos, V. Chini, V. Velissariou; INTERGENETICS, Athens, Greece

One of the biggest challenges in prenatal diagnosis are the limitations of existing ultrasonographic tools regarding the true fetal phenotype. Even at an advanced gestation age, ultrasound findings may not be clear in many cases. Thus, prenatal genetic testing of syndromes *in utero* is a one-way approach. Following the initial publication (Pangalos *et al*, 2016), which presented a first approach on prenatal targeted exome sequencing at a cohort of fetuses with ultrasound anomalies and normal microarray results, this paper presents a retrospective analysis of a greater number of cases, in order to assess the potential diagnostic yield of this approach. In the period 2016-2022, 113 pregnancies with fetal ultrasound anomalies with normal prenatal microarray results were referred for additional molecular testing following genetic counseling. Only cases that underwent invasive prenatal sampling (chorionic villi sampling or amniocentesis) were included in this cohort. Fetal anomalies from this cohort were suspected by routine ultrasound scanning, mostly in the setting of second-trimester ultrasound screening. Twin pregnancies, where both fetuses had different anomalies and were both sampled, were counted as two separate cases. Targeted analysis through next-generation sequencing (NGS) of 874 genes associated to syndromes with fetal ultrasound findings was performed. Reporting and evaluating of findings followed the guidelines of ACMG (Monaghan *et al*, 2020). The advantage of this approach is that only pathogenic or likely pathogenic variants were reported avoiding complications within prenatal genetic counseling. In 34 out of 113 cases (30%), clinically relevant to the referred ultrasound findings, were detected. This agrees with the pooled incremental yield of exome sequencing (31%) reported (Mellis *et al*, 2022), while it seems to be 4-fold higher than the diagnostic yield of microarray analysis alone in fetuses with abnormal ultrasound scans (7%) (Callaway *et al*, 2013). It should be noted that a number of such cases result from parental inheritance, with parents being at risk for future pregnancies. By this approach, both diagnosis and prevention can be provided. Considering the aforementioned, prenatal targeted exome sequencing, following a normal chromosomal microarray, would notably increase the diagnostic yield in fetuses with ultrasound anomalies by ~30% and would allow early diagnosis of a genetic disorder, irrespective of the limited fetal phenotype.

PB2109 † Temporal changes in gene expression and chromatin accessibility in the mouse gut identify candidate postnatal modifiers of Hirschsprung disease (HSCR)

Authors:

H. Chubaryov[1], W. Hou[2], A. Chakravarti[3]; [1]NYU, New York, NY, [2]Columbia Univ., New York, NY, [3]NYU Sch. of Med., New York, NY

Introduction: The enteric nervous system (ENS) is established during embryonic development via the migration, differentiation, and proliferation of enteric neuronal crest cells (ENCCs) into the developing gut. Hirschsprung disease (HSCR) arises from developmental genetic defects in ENCC-derived neuronal and glial cells as well as cells in the supporting mesenchyme. Given that 30-50% of HSCR patients have persistent gastrointestinal symptoms after surgical repair, we hypothesized that postnatal genetic factors can modify HSCR. To unveil such genes, we studied gene expression changes, and the corresponding temporal *cis* regulatory elements that drive them, in wildtype mice across pre- and postnatal gut development. Methods: Bulk RNA-seq and ATAC-seq of the colon in the mouse were collected for E12.5, E14.5, P0, P07, P21, and 6-month-old mice. snRNA-seq was also conducted at P0 to identify the cell types contributing to these temporal changes. Results: Hierarchical clustering of bulk RNA-seq data revealed 10 distinct temporal patterns with many genes showing increased expression in postnatal development. The majority (13/20) of*temporally* varying known HSCR genes, including the genes most commonly mutated in HSCR, *Ret* and *Ednrb*, clustered together and decreased in expression in the postnatal gut. This cluster comprised genes enriched for RNA processing and chromatin modification (GO analysis). The remaining HSCR genes were distributed in clusters 2,7 and 9. Cluster 2, with *Eno3* and *Mmaa*, showed increased gene expression in the postnatal gut and was enriched for immune system and ribosomal biogenesis functions (GO). The ATAC-seq data similarly showed strong time dependent clustering by developmental stage (60% of total PCA variance). We observed that the *Ret* enhancer MCS+9.7, containing a common disease variant, is active during early development and corresponded to peak *Ret* gene expression but is absent later when *Ret* gene expression declined significantly. Similarly, for *Mmaa* we identified an enhancer that is first accessible at P0 and remained so throughout postnatal development, corresponding to its increased expression. Finally, snRNA-seq data were instructive of cell types with HSCR gene expression. *Eno3* and *Mmaa* are not restricted to the ENS: *Eno3* is expressed in epithelial cells and *Mmaa* across a wide variety of cell types. Conclusion: Gene expression profiles, including at single nucleus resolution, and chromatin accessibility identified enhancers of their cognate genes that vary across pre- and postnatal development provide specific coding and noncoding targets to search for variants affecting post-surgical persistence of HSCR.

Ctr., Dept. of Obstetrics and Gynaecology, The Chinese Univ. of Hong Kong, Hong Kong, China, [4]Maternal-Fetal Med. Inst., Shenzhen Baoan Women's and Children's Hosp., Shenzhen Univ., Shenzhen, China, [5]6. Dept. of Chemical Pathology, Faculty of Med., The Chinese Univ. of Hong Kong, Hong Kong, China, [6]The Chinese Univ. of Hong Kong-Baylor Coll. of Med. Joint Ctr. for Med. Genetics, Hong Kong, China

22q11.2 deletion syndrome (22q11DS) is commonly presented with immunodeficiency, hypoparathyroidism and congenital heart disease (CHD). However, the underlying mechanism is largely unknown. Currently, RNA-seq in cultured amniotic fluids (AFs) provides additional information of RNA aberration in assistance to disease investigation. Here, we applied single-cell RNA-seq and ATAC-seq to cultured AFs from 12 22q11DS fetuses [six with CHD diagnosed at Gestational Weeks (GW) of 20 by routine morphology scan (as later GW) and six at 16GW as (early GW)], and 10 GW-matched normal controls (5 from 20GW and 5 from 16GW). The single-cell analysis revealed consistent composition (adherent cells) of cell populations and expression profilings from different cultured passages of AFs from the same samples. As cardiac anomalies were identified in all six cases collected at 20GW, we first investigated the unique expression pattern from these six cases as reference. ScATAC-seq showed alteration of chromatin accessibility in cases not only in the deleted region, but also in 1Mb upstream region. In addition, inflammation fibroblast populations (*CCL2*$^{+}$) showed reduced expression of *CXC* gene-family in 22q11DS, suggesting a blunt hemostatic and inflammatory response. Further, a novel fibroblast subpopulation (*FTX*$^{+}$) presented with strong expression correlation with published fetal myocytes and cardiac fibroblast, but with significantly differential expressions detected in CHD related genes compared with controls. Lastly, we identified a subgroup mesenchymal stem cells in controls, the expression pattern of which showed activation of VEGF/EDN signaling pathways related to hemostasis and vasculature development, but it was absent in cases. In comparison, 22q11DS at 16GW showed a transient expression/chromatin-accessibility profiling different from that at 20GW; however, the subpopulations in fibroblast and mesenchymal stem cells showed mostly consistent expression patterns, indicating single-cell analysis in AFs in early 2nd trimester would be a potential source for phenotype prognosis for 22q11DS fetuses. Co-immunofluorescent staining confirmed the findings. Overall, our study demonstrates a phenotype-related single-cell profiling during fetal development by using 22q11DS as a model.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2111 The experience of one newborn sequencing study in evaluating potential clinical sequencing laboratory partners and genomic sequencing platforms

Authors:

K. Kucera[1], L. Milko[2], H. Cope[3], J. Berg[4], D. Bailey, Jr[1], C. Powell[5], H. Peay[3]; [1]RTI Intl., Research Triangle Park, NC, [2]Univ North Carolina at Chapel Hill, Chapel Hill, NC, [3]RTI Intl., Durham, NC, [4]UNC Chapel Hill, Chapel Hill, NC, [5]UNC - Chapel Hill, Chapel Hill, NC

Background: Early Check is a voluntary newborn screening research program available to birthing parents in North Carolina. Since 2018 Early Check has been offering screening for a small panel of conditions with targeted assays. In 2021, we began planning for the addition of genomic sequencing to screen for hundreds of genetic conditions that are actionable in early childhood. During the planning phase we sought to answer two vital questions: 1) What sequencing platform should be used - custom capture sequencing of only the genes of interest, or bioinformatic selection of genes of interest from exome sequencing (ES) or genome sequencing (GS) backbone? 2) Are commercial clinical sequencing laboratories interested in partnering to advance the field of newborn sequencing? This work provides insight to other groups that seek to conduct population-based sequencing studies.
Methods: Study leadership identified priority metrics to evaluate sequencing options including accepted specimen type, platform flexibility, turnaround time, throughput, and cost. Meetings were scheduled with eight clinical sequencing laboratories selected from an initial list of fifteen candidates to investigate interest and preferred approach.
Results: All eight interviewed laboratories were interested in newborn sequencing research and indicated ability to return results from standard clinical short read sequencing within ≤6 weeks for 150-200 specimens/week. Two laboratories had a validated pipeline that included DNA extraction from dried blood spots (DBS) and five indicated the capacity to validate within 6-9 months. All laboratories preferred informatic selection of gene panels from ES, GS, or large medical capture panel backbone quoting panel design flexibility, and time and costs associated with production and validation of custom capture panels. Five laboratories preferred ES and two preferred a large medical capture panel backbone. Three offered an option to design a custom capture panel. While GS was discussed as the ideal backbone for informatic panel selection, it was generally not considered feasible due to reagent costs. However, decreasing cost of GS, along with public-private partnerships make GS a feasible option. Motivations for laboratories to partner in newborn sequencing research included philanthropy, data use for technology development, and investment into research in clinical NGS for NBS.
Conclusions: Commercial clinical laboratories are interested in partnering on newborn sequencing research and prioritize informatic selection of gene panels. Cost, throughput, and TAT were identified as current limitations to large scale NBS.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2112 Transcriptome profiling during early postnatal development in humans

Authors:

V. Stranecky[1], L. Steiner Mrazova[1], A. Vrbacka[1], T. Kobets[2], P. Janovska[2], J. Kopecky[2]; [1]Dept. of Paediatrics and Adolescent Med., 1st Faculty of Med., Charles Univ. and Gen. Univ. Hosp., Prague, Czech Republic, [2]Inst. of Physiology, Czech Academy of Sci., Prague, Czech Republic

Premature birth and its complications are the number one cause of death among children < 5 years of age and could impose long-term developmental and health problems. To improve the prognosis of premature newborns, it is necessary to understand the causes of their insufficient postnatal adaptation that depends on the changes in energy metabolism and other mechanisms. However, this research is limited by the lack of clinical materials. Here we present results of RNA sequencing that we used to characterize perinatal and especially early postnatal development using a unique biobank of mostly extremely premature newborns (n=37) who died during first 2 months after birth from a number of different causes. We used two continuous variables (gestational age and length of survival after birth) to find differentialy expressed genes and other tools such as gene ontology, pathway enrichment analysis and protein-protein interaction networks to reveal the biological significance of these genes.*This project is supported by Ministry of Health of the Czech Republic (AZV* NU20-07-00026*).*

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2113 Trio-based exome sequencing incorporating deep phenotyping improves the diagnostic yield of prenatal skeletal dysplasia

Authors:

G. Li[1], Q. Qi[1], N. Wu[2], Y. Jiang[1], X. Zhou[1], Y. Lv[1], N. Hao[1], Z. Zhao[2], K. Xu[2], J. Cai[2], Q. Li[2]; [1]Peking Union Med. Coll. Hosp., beijing, China, [2]Peking Union Med. Coll. Hosp., Beijing, China

Prenatal skeletal dysplasia refers to a group of rare genetic disorders that disrupt fetal skeletal development, resulting in abnormal bone growth, morphology, and even prenatal death. In this study, we conducted trio-based exome sequencing on 198 Chinese pedigrees with prenatal skeletal dysplasia. Indications for testing included abnormal ultrasound findings, previous pregnancy abnormalities, and relevant family history. Through deep phenotyping by experienced obstetricians, we identified a positive gene testing rate of 73%. Employing two research strategies, we classified subgroups based on the phenotype of prenatal skeletal dysplasia and categorized skeletal dysplasia according to molecular diagnosis. Notably, we curated hot genes associated with prenatal skeletal dysplasia, including *COL1A1* (21/198), *FGFR3* (19/198), *COL1A2* (12/198), and *COL2A1* (10/198).Furthermore, we conducted a comprehensive review of postnatal patients with skeletal dysplasia who carried these hot disease-causing genetic mutations identified in our study, as well as those from the Deciphering disorders Involving Scoliosis and COmorbidities (DISCO) study (http://www.discostudy.org/). This analysis aimed to elucidate the phenotypic and genotypic distinctions between prenatal and postnatal patients with skeletal dysplasia.This study represents the largest cohort of prenatal skeletal dysplasia in China, with a high positive rate of gene testing. We recommend incorporating hot genes such as *COL1A1*, *FGFR3*, *COL1A2*, and *COL2A1* into prenatal skeletal dysplasia panels. Ultimately, the integration of trio-based exome sequencing and deep phenotyping improves diagnostic yield for prenatal skeletal dysplasia. The phenotypic and genotypic distinctions between prenatal and postnatal patients with skeletal dysplasia expand our understanding of skeletal dysplasia.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2114 Triploidy complicated with Hyperinsulinism hypoglycemia with an unusually long lifespan.

Authors:

R. Mendelson[1], K. Mezeivtch[1], A. Crichton[1], R. Saadeh-Haddad[2], L. Rubin[1]; [1]Medstar Georgetown Univ. Hosp., Washington, DC, [2]Georgetown Univ. Hosp., Mclean, VA

Triploidy has been estimated to cause up to 20% of spontaneous abortions and is an uncommon cause of premature birth and perinatal death. Reports of survival beyond several days is extremely rare. In the few known cases of liveborn triploid infants, the clinical phenotype may include severe intrauterine growth restriction, macrocephaly, total syndactyly of third and fourth fingers, and brain, heart, kidney anomalies.

We present a case of an unusually long-surviving infant with triploidy. The diagnosis was unsuspected during pregnancy. The newborn was delivered at 36 weeks gestational age to a 33 year-old G2P2 mother via cesarian section due to breech presentation. Birthweight was 2.14 kg. He was admitted to the birth hospital NICU for respiratory distress, requiring non-invasive support. His course was complicated by apneas and development of necrosis of a portion of the small bowel that required a 35 cm small bowel resection and subsequent presumed parenteral nutrition-associated cholestatic liver disease. At one month of age, he was transferred to our center for management of his short gut syndrome and evaluation for liver and potentially intestinal transplantation.

Upon arrival, he was intubated and hypotensive requiring dopamine and dobutamine infusions and hydrocortisone. During air transport, he had experienced new onset seizures treated with multiple anticonvulsants. He was growth restricted and had multiple dysmorphic features including downward slanting palpebral fissures, hypertelorism, a thick/short neck, low set and posteriorly rotated ears with underdeveloped helices, bilateral syndactyly of fingers, single palmar creases, talipes equinovarus of both feet, syndactyly of left 2nd-3rd toes, and generalized hypotonia. A chromosomal microarray revealed triploidy, 69, XXY. Karyotyping of two tissues did not show mosaicism. His subsequent hospital course included an inability to wean from respiratory support, hyperinsulinemic hypoglycemia, progressive liver failure, a bacterial bloodstream infection, and progressive edema. After increasing cardiac rythmn disturbances and discussions with his parents, he expired at two months of age. Autopsy confirmed cholestatic liver disease, visceromegaly, and a small brain with focal polymicrogyria.

This case adds to the range of phenotypes of neonates with triploidy. Our patient displayed several previously undescribed triploidy features including hyperinsulinemic hypoglycemia, enterocolitis, and liver failure. We believe he is the longest reported survivor having complete triploidy.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2115 Uncovering human specific gene regulatory elements in heart organogenesis by integrating primary tissues and organoid model

Authors:

s. oh, K. Child, J. Cotney; UConn Hlth., Farmington, CT

Organogenesis is highly conserved but ultimately results in distinct differences in tissue phenotypes across species. Changes in gene regulation have been suggested to be major contributors to phenotypic differences, and many studies have suggested that particular non coding regions known as enhancers have contributed to substantial human specific phenotypes. However, there is still a lack of complete understanding for human organogenesis itself at the comprehensive level of gene expression dynamics and their regulations. To address this gap in knowledge, we focused on uncovering human specific gene expression dynamics in organogenesis by integrating primary tissue data and *in vitro* organoid model. To figure out human specific gene expression dynamics in embryonic stages, we identified human biased gene regulatory landscapes for 15 developing organs by jointly comparing previously generated datasets from human and mouse. We initially focused on heart organogenesis, which is reported to have less conserved enhancers than other tissues at the sequence level. With gene expression, we figured out that heart development in human CS13(Carnegie Stage 13) to CS23 is most comparable to mouse E10.5(Embryonic 10.5 day) to E14.5. Interestingly, some heart genes such as MYL7, ACTC1 and TBX20 show different gene expression dynamics between human and mouse despite the overall expression levels in heart being high, suggesting that human specific enhancers contribute to the different trends of gene expression. From ChromHMM based genome segmentation analysis, we found that these genes have some species specific strong enhancer segments as well as conserved enhancer segments, which have the potential to affect the species specific expression pattern of these genes during organogenesis. To fully understand the effects of these enhancers on early organogenesis, we generated heart organoid models from H9 human Embryonic Stem Cells(hESCs), which successfully showed morphological and structural features of developing heart. Our organoid model also shows inducible expression of KRAB dCas9 early in differentiation, which allows us to suppress the activity of such regions. We also performed joint profiling of gene expression and chromatin accessibility in single nuclei (snMultiome) on both primary heart tissue and cardiac organoids, which allowed us to explore these findings at the cell type level. Taken together, it is expected to identify such regions that are important for understanding human specific features of heart development by giving human specific gene expression features in organogenesis.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2116 Understanding caudal developmental abnormalities using 5' end single-nuclei RNA sequencing data from wild type and Danforth's short tail mouse E9.5 tailbuds

Authors:

C. Zajac[1], R. D. Albanus[2], N. Manickam[1], E. Curka[1], C. Keegan[1], S. Parker[1]; [1]Univ. of Michigan, Ann Arbor, MI, [2]Washington Univ., St. Louis, MO

Background: Caudal embryo development is important for multiple organ systems arising from all three germ cell layers, including the gastrointestinal system, genitourinary system, and the lower spinal cord. Embryonic malformations associated with caudal birth defects affect 1 in 10,000 human live births, but their mechanisms are largely unknown. The Danforth's short tail (*Sd*) mouse exhibits cessation of the vertebral column at the lumbar level and malformations of urogenital and gastrointestinal organs and therefore provides a tractable model to study the etiology of human caudal birth defects. The *Sd* mutation is caused by an endogenous retroviral (ERV) insertion 12.5 kb upstream of the *Ptf1a* gene in the promoter region of the lncRNA gene *Gm13344*. This region is orthologous to a human pancreatic developmental enhancer, which provides motivation for the use of the *Sd* mouse as a translational model to study caudal dysgenesis. **Methods:** To better understand the cell-specific regulatory elements upstream of the promoter regions of the *Sd* mouse genome, we generated 5'end single nuclei RNA sequencing (5'end snRNA-seq) data from control (WT) and *Sd* E9.5 tailbuds. We used a custom pipeline for droplet QC before clustering. Then, we performed SCAFE (Single-Cell Analysis of Five-prime Ends) on this dataset to visualize gene expression and identify transcription start sites and transcribed cis-regulatory elements. **Results:** We obtained 5,804 (WT) and 9,768 (*Sd*) high-quality nuclei for joint clustering analyses. We found 18 clusters representing different cell types, some of which have differential chromatin accessibility and are linked to caudal embryonic developmental gene markers including *Ptf1a*, *Shh*, and *Gm13344*. In addition, we validated these findings using the SCAFE results from our 5'end snRNA-seq dataset, where we observed co-expression of Gm13344 and *Ptf1a* solely in a restricted subset of clusters in the *Sd* sample. **Future direction:** Preliminary results provide insights into cluster characterization. We identified a subset of cells that may represent the early cellular events that are causal to the *Sd* caudal phenotype. The next steps in this project involve further integration of the 5' RNA and chromatin accessibility modalities to identify transcription factors perturbed as a result of the *Sd* mutation. We expect these integrative analyses will improve our understanding of the causal cell types and regulatory networks that influence the *Sd* phenotype and, consequently, caudal developmental disorders in humans.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2117 † Understanding splicing regulation during human heart organogenesis

Authors:

K. Child, J. Cotney; UConn Hlth., Farmington, CT

Congenital Heart Defects (CHDs) are the most common congenital abnormality worldwide, affecting approximately 1% of all births. However, ~60% of these cases remain unexplained. Properly controlled gene expression during cardiac development, particularly at the initiation of organogenesis, is crucial for normal development. This can occur at multiple levels including chromatin state, transcription initiation, and RNA splicing, as well as many post-transcriptional mechanisms. Recent analysis of RNA splicing patterns across multiple species and organs revealed that dynamics and complexity of splicing of the developing heart are significantly greater than most tissues and on par with brain. These findings were based primarily on heart samples from fetal and adult stages with little data from the critical organogenesis phase. To address this gap in knowledge, our lab has directly examined both chromatin state and composite level gene expression ranging from Carnegie stages (CS) 13 to 23 (4 to 8 post-conception weeks of development). We identified a module of genes with dynamic expression through this period that significantly enriched for genes involved in RNA splicing and processing. Given the highly dynamic nature of splicing at later timepoints and a coherent module of genes directly related to regulation of splicing, we sought to examine splicing and isoform utilization during the organogenesis phase. When we compared alternative splicing (AS) between our 8 individual CS timepoints, we find 3,749 genes with AS events across the various stages of heart organogenesis. These are distinct from our previously reported differentially expressed genes but also enriched for genes related to cardiac development. In addition to these trends, we found evidence for splicing events which result in previously unannotated transcripts. To confirm these results, we performed Nanopore long-read sequencing of cDNA libraries from our samples. Using a combination of long- and short-read data we generated a comprehensive, novel cardiac-centric gene annotation. From this analysis we identified 13,137 novel transcripts including variants of well-known cardiac genes. One example is *TBX5*, a well-known cardiac gene implicated in Holt-Oram Syndrome. We discovered a novel TSS for *TBX5* which is highly conserved across species and constrained in human populations. Understanding transcript utilization and AS will lead to better screening for CHDs clarifying the unexplained CHD cases and provide a better understanding of gene expression dynamics during this critical period of development.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2118 Validation of low-pass genome sequencing as a replacement for chromosomal microarray in prenatal diagnostics

Authors:

E. Greenfeld[1], C. Mighton[2], N. Watkins[1], V. Di Gioacchino[1], J. Lerner-Ellis[3], E. Mukharryamova[1], N. Anggala[1], A. Noor[4]; [1]Mount Sinai Hosp., Toronto, ON, Canada, [2]St. Michaels Hosp. & Univ. of Toronto, Toronto, ON, Canada, [3]Mount Sinai Hosp., Sinai Hlth., Toronto, ON, Canada, [4]Mount Sinai Hosp, Toronto, ON, Canada

Background: Low-pass genome sequencing (LP-GS) is emerging as an alternative to chromosomal microarray (CMA) for the detection of copy number variants (CNVs). This study aimed to assess whether LP-GS can replace SNP-based CMA in prenatal diagnostics. **Methods:** A validation study was conducted to evaluate the performance of LP-GS at 10x compared to CytoSNP 859 (Illumina). 96 samples were included, of those, 40 positive samples with a range of abnormalities including CNVs of varying sizes, low-level mosaic aneuploidies, complex structural abnormalities (mosaic and non-mosaic), and AOH. 40 negative control samples were included. 14 samples were run by LP-GS at 5x and 10x for comparison. Concordance, sensitivity, specificity, reproducibility, repeatability, limit of detection, turnaround time, and cost-effectiveness were assessed. Tertiary analysis of LP-GS data employed the Genoox Franklin pipeline. Data from 34 samples were run through both the Illumina DRAGEN CNV pipeline and Genoox Franklin pipeline for comparison of two CNV analyses. **Results:** The results from all samples run by LP-GS at 10x and CMA were concordant with the exception of one false negative (69,XXX triploidy) which was missed by LP-GS. Sensitivity of LP-GS for detecting clinically relevant variants previously characterized by CMA was 97.5%, and specificity was 100%. Clinically relevant findings were concordant between the samples run at 10x and 5x, however, there were more failed and low confidence variant calls from the samples run at 5x, reflecting artefacts. There was 100% concordance between LP-GS results from 150 ng input and higher input. Reproducibility and repeatability experiments resulted in 100% concordance. Results were concordant between the Genoox Franklin and Illumina DRAGEN pipelines, however the calls from DRAGEN were fragmented, in particular for larger CNVs and whole chromosome aneuploidies. Workflow was shorter for LP-GS (1.5 days) than for CMA (2.5 days). Overall, the LP-GS turnaround time was comparable to CMA. LP-GS at 5x was cost-effective compared to the Illumina CytoSNP-850K array. LP-GS at 10x was almost cost neutral using S2 flow cell and 33 samples, and cost-effective with S4 flow cell. **Discussion:** LP-GS is a promising replacement for CMA in prenatal diagnostics. The one false negative case indicates that better integration of genotyping data to enhance CNV pipelines is needed. Strengths of LP-GS include a simplified protocol and faster turnaround time, gene content agnostic detection of variants, and integrated workflow for detecting single nucleotide variants and CNVs.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2119 Variants in DOK7 gene results in fetal akinesia deformation sequence

Authors:

A. TIWARI, D. Saxena, S. Phadke; Sanjay Gandhi Postgraduate Inst. of Med. Sci., Lucknow, India

INTRODUCTION: Fetal akinesis deformation sequence (FADS) is characterized by reduced fetal movements, joint contractures, facial anomalies, pulmonary hypoplasia and IUGR. DOK7 (Downstream of Tyrosine Kinase 7) gene was identified as a cause of FADS in 2009. Here, we report a case of FADS due to biallelic variants in DOK7 gene.

PATIENT DETAILS: At 24 weeks, antenatal scan showed 22 weeks fetus with subcutaneous edema, absent stomach, IUGR, arthrogryposis and polyhydramnios. Postnatally, fetus had facial dysmorphism (flat facies, depressed nasal bridge, upturned nose, microretrognathia), joint contractures (overlapping digits, flexion at elbow and hyperextension at knee joint, prominent calcaneum), short neck and subcutaneous edema on dorsum of hands and feet. On internal examination, lungs were hypoplastic. Whole exome sequencing identified compound heterozygous variants, c.68G>A (p.W23X) in exon 2 and c.1373dupC (p.Q460Pfs*59) in exon 7 of DOK7 gene (NM_173660). These are predicted to be likely pathogenic by ACMG/ AMP guidelines.

DISCUSSION AND CONCLUSION: First report of DOK7 related FADS concluded that complete loss of function due to variants in pleckstrin homology (PH) or phosphotyrosine binding domains result in a lethal fetal akinesia phenotype, whereas the variants associated with CMS are present in all domains. However, this was refuted by Radhakrishnan P, et al. who reported the 2nd case of DOK7 related FADS due to biallelic variant c.1263dupC, reported earlier in CMS. This is the third report of FADS due to biallelic DOK7 variants and further strengthens the association of DOK7 gene with this lethal phenotype and lack of genotype-phenotype correlation and further management of future pregnancy.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2120 Variants of uncertain significance identified with prenatal exome sequencing: to report or not to report?

Authors:

G. Santen, M. de Koning, M. Haak, E. Nibbeling, C. Ruivenkamp, M. Hoffer, M. Suerink; Leiden Univ. Med. Ctr., Leiden, Netherlands

Objectives: Congenital anomalies affect a substantial number of pregnancies and prognoses are greatly influenced by the presence of an underlying genetic disorder. Prenatal exome sequencing (pES) is increasingly being implemented in routine genetic diagnostic work-up. Diagnostic rates of pES are around 10%. In addition, variants of uncertain significance (VUS) are detected. Their interpretation is challenging due to lack of a complete clinical phenotype in a prenatal setting. Furthermore, the choice to report or not is a balancing act between reproductive autonomy and paternalism. VUS therefore provide a challenge for molecular and clinical geneticists, MFM specialists and future parents. We describe our experiences with reporting VUS in a prenatal setting.
Methods: In the Netherlands, pES is offered in pregnancies with a congenital anomaly detected by ultrasound screening. We retrospectively analyzed all consecutive pregnancies in which VUS identified by pES were reported to parents during pregnancy (n=20).
Results: VUS were mainly reported in genes associated with the detected fetal phenotype (n = 13). Most VUS were in genes associated with an autosomal dominant inheritance pattern and were de novo (n = 6) as well as inherited (n =6). Of the parents considering TOP (n = 14), four times the added uncertainty of the detected VUS contributed to pregnancy termination. In two cases, parents chose to continue the pregnancy either because the gene was not associated with intellectual disability or because the variant was inherited from a mildly affected parent. When TOP was not considered (n = 6), the VUS changed perinatal management in two cases: neonatologists were standby during labor in a case with increased risk of tracheomalacia due to a variant in *DCHS1,* and testing for metabolic acidosis was requested in a case with a variant in *UQCRC2*. Of the 13 live births, two probands were lost to follow-up and two demised at age of 1 and 15 months respectively. Of the other nine live born children, four have some degree of developmental delay.
Conclusions: Uncertain findings can be viewed as undesirable, especially in the prenatal setting with added stress of time pressure and incomplete phenotyping. Nevertheless, VUS might be helpful in guiding prenatal decision making or adjusting perinatal management. We advocate for future research to focus on patients' and clinicians' perspectives regarding VUS, in order to formulate much needed guidelines balancing reproductive autonomy and paternalism.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session II

PB2121 Whole exome sequencing in fetuses with abnormal ultrasound finding.

Authors:

D. Saxena, A. K. Tiwari, A. Moirangthem, K. Mandal, S. Srivastava, H. Sait, S. Phadke; Sanjay Gandhi Postgraduate Inst. of Med. Sci., Lucknow, India

Background: The incidence of major structural malformations is around 2-3%, which may be due to chromosomal abnormalities, single gene disorders, teratogens etc. Without molecular diagnosis, prenatal diagnosis in next pregnancy cannot be provided. Diagnostic yield of fetal karyotyping is around 8-10%. Use of cytogenetic microarray has further increased the diagnostic rate by around 6%. Still, around 80% of the cases remain undiagnosed. Use of next generation sequencing in prenatal cases had increased the diagnostic rate by around 20-30%. Objectives:To study the role of whole exome sequencing (WES) in fetuses with abnormal ultrasound findings.Methods: WES (trio/ solo) was performed on cases with fetal malformations detected on antenatal ultrasound, selected over a period of two years from September, 2020 to September, 2022. Results: A total of 50 families were included, comprising fetuses with skeletal defects (32%, 16/50), central nervous system malformations (22%, 11/50), hydrops (10%, 5/50), renal (10%, 5/50) and cardiac malformations (6%, 3/50), recurrent neural tube defects (8%, 4/50) and miscellaneous conditions including caudal regression syndrome (2 cases), severe oligohydramnios (2 cases), multiple pterygium and congenital diaphragmatic hernia (1 case each). Trio WES was done in 21 (42%) cases whereas solo fetal exome sequencing was done in 29 (58%) cases. Diagnostic yield was found to be 48% (24/50) and was highest in fetuses with skeletal dysplasia (81%, 13/16) and hydrops (80%, 4/5) followed by renal (40%, 2/5), CNS (36%, 4/11) and cardiac malformations (33%, 1/3). No causative variations were identified in fetuses with recurrent NTDs and other miscellaneous defects.We found pathogenic variants in 10 cases (CTSA, COASY, FGFR3, GNPTAB, PEX1, P3H1 in 2 cases, THSD1, TMEM67 and OBSL1), likely pathogenic variants in 9 cases (COL1A1, CREBBP, DOK7, KIF5B, L1CAM, LZTR1, PIEZO1, P3H1 and ZNF699) and variant of uncertain significance (VOUS) in 5 cases (MTOR, CHST3, COL2A1, COL6A1 and TRAPPC12). Most common disorder observed in our cohort was osteogenesis imperfecta, seen in 16.7% (4/24) cases. Most of the disorders detected (62.5%, 15/24) were autosomal recessive, 33.3% (8/24) had autosomal dominant disorder (de novo-4 and inherited - 2) and 4.2% (1/24) had an X-linked recessive disorder.Conclusion: Our study further emphasizes the role of whole exome sequencing in fetal abnormalities. Confirmation of molecular diagnosis improves pregnancy management, prenatal counselling, and assessment of recurrence risk in further pregnancies. Identification of novel variants further expanded the mutational spectrum of fetal disorders.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2122 Whole genome sequencing identifies very rare de novo and inherited pathogenic variants in European cleft case-parent trios.

Authors:

E. Aladenika[1], A. Alade[2], M. Olujitan[1], W. Awotoye[1], A. Oladayo[3], S. Miller[4], T. Busch[1], A. Butali[3]; [1]Univ. of Iowa, Iowa, IA, [2]Univ. of Iowa, Iowa City, IA, [3]Univ. of Iowa, Coralville, IA, [4]Univ Iowa, Iowa, IA

Introduction One in 700 infants worldwide is born with orofacial cleft (OFC). OFC etiology is multifactorial involving genetics and environmental factors. In the current study, we investigated the contributions of de novo and inherited (novel and rare) variants in craniofacial genes using whole genome sequencing data of European cleft case-parent trios. **Methodology** Whole genome sequencing was conducted on 15 case-parent trios (syndromic and non-syndromic). Called variants were annotated using GATK. Annotated variants were filtered based on genotype quality ≥20 and read depth ≥10. Novel (MAF=0) and very rare (MAF < 0.001) de novo and inherited protein-altering variants were identified. Deleteriousness of these protein-altering variants were predicted using polyphen, SIFT and a CADD score cutoff of ≥ 15. Variants predicted to be deleterious across polyphen, SIFT and CADD were prioritized. ACMG criteria was also used to assess pathogenicity using VARSOME. Amino acid changes effect on protein structure and function were identified using HOPE. The genes harboring these variants were assessed for contributions to craniofacial development using Mouse Genome Informatics (MGI), Online Mendelian Inheritance in Man (OMIM) and CleftGeneDB. Genes involved in craniofacial development in any of the 3 databases were prioritized. DECIPHER and thorough literature search were used to assess the implication of these prioritized genes in OFC. **Results and discussion** We identified 186 de novo variants in 141 genes. Eighteen of these genes harbor 19 deleterious variants. *VCAN* which is expressed in relevant craniofacial tissues contains a very rare pathogenic de novo variant rs781121274 (MAF= 0.0001). We also identified 684 inherited (novel and very rare) variants, among these, 84 were predicted to be deleterious. Eight of these deleterious variants were identified in genes that are expressed in craniofacial tissues, namely, *CFAP45*, *NISCH*, *CDKN1A*, *NOTCH1*, *FUZ*, *COL6A2*, *IL11RA*, and *AKAP6*. The resulting amino acid changes in *NOTCH1* and *COL6A2* are predicted to be likely damaging by HOPE. Patients with deletion of loci that contain *CFAP45, NISCH, NOTCH1, COL6A2* or *AKAP6* have OFCs as reported phenotypes. Similarly, there are reports that implicate these genes in OFC development. **Conclusions** Our study provides additional evidence for the role of *VCAN, CFAP45, NISCH, NOTCH1, FUZ, COL6A2* and *AKAP6* in OFC development. This is the first time *CDKN1A* and *IL11RA* will be implicated in OFC development. Identification of very rare variants (<0.001) in these genes could explain the missing heritability for OFC. Future functional experiments to validate these observations are needed.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session I

PB2123 Whole genome sequencing of fibroid samples identified potential novel loci associated with fibroid risk

Authors:

J. Jaworski[1,2], J. N. Hellwege[1,3], E. A. Jasper[1,4], T. L. Edwards[1,2], D. R. Velez Edwards[1,5,4]; [1]Vanderbilt Genetics Inst., Vanderbilt Univ., Nashville, TN, [2]Div. of Epidemiology, Dept. of Med., Vanderbilt Univ. Med. Ctr., Nashville, TN, [3]Div. of Genetic Med., Dept. of Med., Vanderbilt Univ. Med. Ctr., Nashville, TN, [4]Div. of Quantitative Sci., Dept. of Obstetrics and Gynecology, Vanderbilt Univ. Med. Ctr., Nashville, TN, [5]Dept. of BioMed. Informatics, Vanderbilt Univ. Med. Ctr., Nashville, TN

Uterine fibroids are benign smooth muscle growths affecting up to 75% of women by menopause. African American (AA) women have higher prevalence, earlier onset, and larger and more numerous fibroids than European American (EA) women. Genome-wide association studies have found numerous genetic loci associated with fibroids risk, however most of those studies were of European ancestry. Sequencing studies of fibroids to date have focused on somatic sequence changes. We performed whole genomic sequencing on AA and EA samples to determine the impact of rare variants on fibroid risk across populations. Samples from a de-identified electronic health record system linked to a DNA biorepository (BioVU) were selected using a previously described algorithm. A total of 548 AA (271 cases/ 277 controls) and 659 EA (371 cases/ 288 controls) samples were whole genome sequenced using the Illumina Dragen Germline application (v.3.10.4) on the Illumina Basespace sequence hub. EA and AA groups were joint called separately using the Dragen PopGen application (v.3.10.4). Sample and variant quality control was performed in PLINK2. The Ensembl Variant Effect Predictor was used for all annotation. Single variant and gene-based testing were performed using RVTESTS. Single variant analyses, adjusted for age and 10 principal components, were limited to variants with a minimum minor allele count (MAC) of 20. A cross-ancestry meta-analysis was completed using METAL. The gene-based tests were performed with the RVTESTS option SKAT-O, using rare, coding, and loss of function variants. For AA samples, the single variant association analysis showed nominally significant loci in 4p12 (p-value 1.5×10^{-8}) and 20q11.22 (p-value 1.4×10^{-7}). For the EA, there were variants close to significance on 12p13.33 (p-value 9.8×10^{-8}) in the gene *LINC02443*. Cross-ancestry meta-analysis detected a locus at 1p31.3 (p-value 4.9×10^{-8}) in the gene *ROR1*. The 4p12 locus was detected in the meta-analysis (p-value 5.6×10^{-7}) as well as the 12p13.33 (p-value 8.1×10^{-7}). For the gene-based tests, *SH2B3* (p-value 2.1×10^{-5}) and *EHD1* (p-value 2.4×10^{-5}) were nominally significant in the AA dataset. The top EA result was *SLC26A2* (p-value 5.2×10^{-6}). Whole genome sequencing of fibroid samples identified potential novel loci associated with fibroid risk within and across the AA and EA populations. Increasing the sample size with more sequencing and collaboration with existing datasets will further clarify these results.

Phelan-McDermid syndrome (PMS) is a neurodevelopmental disorder (NDD) caused by a loss of the distal part of chromosome 22 or by a pathological *SHANK3* variant. There is a wide variability of the mechanism and the size of the deletion among PMS patients ranging from less than 100 kb to over 9 Mb. Indeed, the distribution of the breakpoint position is mostly uniform along the 22q13 region, with the exception of a recurrent breakpoint within the *SHANK3* gene. PMS patients present with global developmental delay, intellectual deficiency, language impairment ranging from severe delay to absence of speech, neonatal hypotonia, minor morphological features and other nonspecific clinical features which differ from a patient to another leading to a high phenotypic heterogeneity. A number of studies have explored the clinical diversity observed in PMS patients which has led to the identification of correlation between the size of the deletion and the presence or severity of the PMS symptoms. In addition to deletion size, additional genetic variants could also contribute to the phenotypic difference existing between each patient with PMS. In order to identify such variants, we selected 90 *SHANK3*-related PMS patients carrying a 22q13 deletions or a pathogenic variant affecting *SHANK3* and collected their DNA (and the DNA from their parents when available) to perform whole genome sequencing. The analysis of *de novo* variants shows the presence of multiple hits in genes associated to NDD and predicted as deleterious. In particular, for some patients with epilepsy history, we could detect *de novo* deleterious variants in an HPO risk gene for epilepsy. We also found LoF and predicted deleterious missense variant in the 22q13 region on the intact chromosome 22 for patients with 22q13 deletion. The genetic and clinical profile of the PMS *SHANK3* patients will be described and compared with three other cohorts. In a next step, the common variants of *SHANK3*-related PMS will be also explored using PRS analysis.

Session Title: Prenatal, Perinatal, and Developmental Genetics Poster Session III

PB2125 Zellweger spectrum disorder: The case of a missing *PEX1* allele in a fetus with multiple congenital anomalies.

Authors:

T. Sneddon, K. Gilmore, E. Jalazo, B. Powell, N. Vora; Univ. of North Carolina, Chapel Hill, NC

PEX1 and *PEX6* encode ATPases that are essential for peroxisome biogenesis, maintenance, and prevention of peroxisome degradation. Biallelic variants in either gene are associated with the peroxisome biogenesis disorder known as Zellweger spectrum disorder (ZSD). This is an autosomal recessive disorder with a broad phenotypic spectrum where severity is inversely correlated with residual protein function.

Trio genome analysis was performed on a fetal sample from a patient enrolled in the Prenatal Genetic Diagnosis by Genomic Sequencing (PrenatalSEQ) multicenter study due to ultrasound findings that included cerebral ventriculomegaly, unilateral left clubbed foot, and a cardiac ventral septal defect. Analysis of filtered sequence variants identified a maternally-inherited pathogenic nonsense variant in *PEX1* [c.2614C>T; p.(Arg872Ter)] and a paternally-inherited pathogenic frameshift variant in *PEX6* [c.1314_1321del; p.(Glu439fs)]. Digenic inheritance has not been reported for ZSD, and the fetal phenotype was non-specific, so this result was non-diagnostic.

Postnatally the baby had severe hypotonia, respiratory distress, and dysmorphic features. At 2 weeks of life, the state newborn screening reported an elevated C26:0 ratio of 1.11 µM (cut off <0.15 µM) that resulted in diagnostic biochemical testing, confirming a diagnosis of a peroxisomal biogenesis disorder. Subsequent manual review of the trio genome sequence read alignments revealed a paternally-inherited 740 bp *PEX1* deletion variant (c.2719-251_2783+425del) that removes exon 17 of 24 and was confirmed by Sanger sequencing. These compound heterozygous *PEX1* variants were reported as consistent with a diagnosis of ZSD.

Concurrently, a peripheral blood sample sent to a commercial lab for clinical sequence analysis and deletion/duplication testing of an 18-gene ZSD panel, that included *PEX1* and *PEX6*, failed to identify the 740 bp *PEX1* deletion. Communication with the lab resulted in an update to their bioinformatic pipeline such that the 740 bp *PEX1* deletion would be identified on subsequent samples, providing reassurance to the parents that clinical prenatal testing by that lab would identify both *PEX1* variants in future pregnancies.

This case highlights the benefits of research studies to inform and improve clinical care and clinical genetic testing, and also serves as a caution that single-exon deletions are not detected by all genetic tests or genomic methodologies and, as exemplified in this case, may account for some of the missing diagnostic yield from clinical genetic testing.

Session Title: Pharmacogenomics Poster Session I

PB2126 A blood-based multi'omic analysis of response to vedolizumab treatment in IBD

Authors:

J. Rioux[1,2], G. Boucher[3], J. Thompson Legault[3], A. Forest[1], C. Des Rosiers[1,2], A. Ananthakrishnan[4], R. Xavier[4,5]; [1]Montreal Heart Inst. | Res. Ctr., Montreal, QC, Canada, [2]Université de Montréal, Montreal, QC, Canada, [3]Montreal Heart Inst., Montreal, QC, Canada, [4]Massachusetts Gen. Hosp., Boston, MA, [5]Broad Inst., Boston, MA

INTRODUCTION The inflammatory bowel diseases (IBD) are chronic relapsing inflammatory diseases of the gastrointestinal tract that affect over one million Americans. A key challenge in IBD is matching patients with the most effective therapy as this would lead to improved clinical and endoscopic outcomes, less tissue damage and a decrease in societal costs. In the current study, we chose to focus on the response to treatment with vedolizumab. Rather than blocking cytokine signaling as most biologics, vedolizumab is believed to interfere with immune cell trafficking to the intestines. Given our ultimate objective to develop a biomarker panel to facilitate therapeutic decisions in the clinic, we have chosen to prioritize blood-based biomarker discovery.
METHODS The study cohort consisted of a prospective cohort of 92 IBD patients where vedolizumab was administered intravenously at weeks 0, 2, 6 and 14, and serum samples collected at weeks 0 and 14. These serum samples were evaluated for the level of a targeted set of 49 cytokines, chemokines, and growth factors, many of which are encoded by genes within IBD loci (PMID: 34106269). In addition, we performed targeted metabolomics (amino acids, organic acids, and acyl carnitines); all metabolite classes implicated in immune cell activity and/or signaling. Moreover, we used a non-targeted lipidomics approach measuring >1500 metabolites.
RESULTS We observed that in patients that responded well to vedolizumab treatment there was an important increase in serum levels of interferon-regulated cytokines between week 0 and week 14. These cytokines are hallmarks of pro-inflammatory "M1" macrophages, and are elevated in the serum of IBD patients as compared to matched controls. In terms of the serum levels of amino acids, organic acids and acyl carnitines, we found metabolite associations in baseline samples and/or changes that occurred during the 14 weeks of treatment in responders as compared to non-responders that were consistent with a metabolic reprogramming of macrophages. Finally, we identified changes in lipid metabolites that we previously associated with host and microbial metabolic functions associated with IBD (PMID: 36662167).
CONCLUSION The results support the hypothesis that there is biological heterogeneity in patients with IBD that can have an impact on important clinical outcomes such as response to therapy. More specifically, these results suggest that in the subset of patients that respond well to vedolizumab there is a selective interference of M1 macrophage trafficking to the intestines and/or metabolic reprogramming of circulating macrophages.

Session Title: Pharmacogenomics Poster Session II

PB2127 † A Flexible Network Based Framework for Identifying Drug-Disease Relationships including Repurposing Opportunities and Adverse Effects

Authors:

R. Chen[1], Q. Wang[1], Q. Wei[2], Y. Yan[1], Y. Tan[3], A. Tiwari[1], X. Zhong[4], B. Li[1]; [1]Vanderbilt Univ., Nashville, TN, [2]Vanderbilt Univ, Nashville, TN, [3]Vanderbilt Univ. - Nashville, TN, Nashville, TN, [4]Vanderbilt Univ. Med. Ctr., Nashville, TN

Given the high cost of drug development, there has been a growing interest in drug repurposing. In parallel, predicting adverse drug reactions (ADR) for a drug, another type of drug-disease relationships, has significant value on minimizing the cost of drug development as well as mitigating the occurrence of ADRs in medical care. For effective drug repurposing and ADR prediction, it is key to integrate heterogenous data at different levels to accurately link drugs and diseases. In this study, we develop a computational framework that builds multi-layer networks of three types of nodes: genes, diseases and drugs, based on disease-disease similarity networks, gene-gene networks, disease-gene association networks, drug-gene networks, and drug-drug similarity networks. It uses the Random Walk with Restart algorithm to traverse the networks to build and score relationships of genes, diseases and drugs. Our framework is flexible and allows for easy addition of networks of any of the three types of nodes. We applied our framework on 220 diseases, with integrative networks of 1) Gene Ontology, KEGG, PPI, tissue and cell type specific co-expression networks; 2) phenotypic and semantic similarity networks for diseases; 3) structure similarity networks for drugs; 4) bipartite networks of drug-gene, disease-gene, and drug-disease connections. Overall, we observed that the top scoring drug-disease pairs exhibit a remarkably enrichment in clinical trials (permutation test, $p < 10^{-4}$) and off-label uses ($p < 10^{-4}$), suggesting novel repurposing opportunities in our prediction. Specifically, we found that 55.8% of approved drug-indication pairs (DIPs), 43.1% of off-label DIPs and 53.9% of the clinical trial DIPs are among the top 100 (of 8120) of the predictions (all $P<10^{-4}$). In parallel to drug repurposing, we found that 51% of reported Drug-Adverse Effect Pairs (DAEPs) are in the top 100 predictions ($P<10^{-4}$). To further assess whether our framework is able to predict ADR for new drugs, we collected reported DAEPs for 77 drugs that were approved after 2015, and observed that 40.4% of reported DAEPs are within the top 100 predictions, demonstrating our framework's ability to predict DAEPs for new drugs. We created a comprehensive table of all drug-disease pairs ranked by their predicted scores, encompassing 1520 drugs and 8120 diseases, which we hope are useful for the drug repurposing and ADR field.

Session Title: Pharmacogenomics Poster Session III

PB2128 A structural biology approach for PheWAS analysis for antidepressant repurposing

Authors:

L. Peng, C-Y. Chen; Biogen, Cambridge, MA

Drug repurposing is becoming an increasingly attractive and economically viable option to identify new indications for an approved or investigational drug, given the risks, costs, and slow pace of drug discovery and development. Here we present phenome-wide association studies (PheWAS) as an approach to identify protein targets from four classes of commonly-prescribed antidepressants (ADs) for neurological disorders beyond mood and behavioral disorders (depression, anxiety), guided by knowledge of the AD inhibitor-bound and *apo* (AD inhibitor-unbounded) conformational states of the target. Namely, selective serotonin reuptake inhibitors (SSRIs) target the serotonin transporter (SERT, *SLC6A4*); serotonin-norepinephrine reuptake inhibitors (SNRIs) target the norepinephrine transporter (NET, *SLC6A2*); tricyclic antidepressants (TCAs) target SERT and NET, and monoamine oxidase inhibitors (MOAIs) target monoamine oxidase A (MAOA, *MAOA*) and monoamine oxidase B (MAOB, *MAOB*) enzymes. For genes encoding these proteins we define burden sets for loss-of-function (LoF) and missense variants based on their translational consequences in the protein (residue mutations) and their location in domains known for functional regulation of neurotransmitters. PheWAS analysis on 470K UK Biobank (UKB) samples with exome sequencing data for single variants and burden sets on *SLC6A4*, *SLC6A2*, *MAOA*, and *MAOB* was conducted for 500 phenotypes across ICD codes from in-patient diagnostic records to identify rare variants and gene burdens with strong disease associations for which antidepressants can be repurposed for treatment.We identified, for example, a single variant association (P = 8.515E-6) in *SLC6A2* with intracerebral hemorrhage, suggesting a repurposing opportunity for SNRIs. Our approach demonstrates how knowledge of a protein's conformational state can be used for genetics analysis to identify genetic variants that cause disease.

Session Title: Pharmacogenomics Poster Session I

PB2129 A synergistic effects of chemical chaperone and valproic acid on GBA mutations in Gaucher disease.

Authors:

J-J. Lee[1], M. Kang[2], I. Choi[3], G-H. Kim[1,4], H. Shin[2], H. Bae[5], S. Hwang[5], B. Lee[4,5]; [1]Asan Med. Ctr., Seoul, Korea, Republic of, [2]Asan Inst. for Life Sci., Seoul, Korea, Republic of, [3]Dept. of Genetic Counseling, Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [4]Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [5]Asan Med. Ctr. Children's Hosp., Seoul, Korea, Republic of

Gaucher disease (GD) is one of the most common lysosomal disorders caused by glucocerebrosidase (GCase) deficiency. The impairment of GCase results in the accumulation of glucosylceramide (Gb1), which is deacylated form, glucosylsphingosine (Lyso-Gb1). Enzyme replacement therapy (ERT) and substrate reduction therapy (SRT) have been approved for the treatment of GD, effectively improving visceral, hematologic, and skeletal abnormalities. However, neurological manifestations remain limited in patients with GD2/3. Chemical chaperones, such as Ambroxol (ABX), enhance the GCase activity and can penetrate the blood-brain barrier, thereby improving neurological symptoms in GD. Here, we evaluated the efficacy of high-dose ABX in various GBA mutations using the COS7 cell line. we confirmed an increase in GCase activity and modulation of EMT markers in response to high-dose ABX treatment in various GBA mutations. In addition, we observed that the co-administration of ABX and valproic acid (VPA) in HepG2 cells resulted in an increase in GCase activity and modulation of epithelial-mesenchymal transition (EMT) markers. In conclusion, our finding suggests that synergistic effect of the combined treatment with high-dose ABX and VPA in promoting GCase upregulation and regulating EMT markers in GD.

Session Title: Pharmacogenomics Poster Session II

PB2130 Allele frequency analysis of genetic variants related to the pharmacogenomics of Parkinson's disease in Latinos: A second-look between population groups, towards a feasible clinical reproducibility of results.

Authors:

H. Chaparro-Solano[1,2], T. Peixoto Leal[2], I. Fernandez Mata[1,2], Latin American Research Consortium on the Geneticsof Parkinson's Disease (LARGE-PD); [1]Dept. of Molecular Med., Cleveland Clinic Lerner Coll. of Med., Case Western Reserve Univ., Cleveland, OH, [2]Genomic Med. Inst., Lerner Res. Inst., Cleveland Clinic, Cleveland, OH

Background
Despite Parkinson's disease (PD) being the second most prevalent neurodegenerative pathology worldwide, available treatments result in wide variability in patient response in terms of dosage and side effects. Although several single nucleotide polymorphisms (SNPs) have been suggested as clinically useful pharmacogenetic markers to address this challenge, none of them have been reproducible. The aim of this study was to gain insights into the genetic variants related to PD treatment response by comparing allele frequencies (AF) of SNPs associated with treatment variability in PD among Latinos and other population groups.
Methods
We used data from the Latin American Research Consortium on the Genetics of PD (LARGE-PD). Genotypes of 452 healthy participants from seven different countries (Argentina, Brazil, Colombia, Chile, Mexico, Peru, and Uruguay) were included. SNPs of interest were selected through a systematic review. Control population-level allele frequencies of these SNPs were obtained from gnomAD v2.1.1 using the "total of genotypes" (TG) and the "Latino/Admixed American" (LAA) population. AFs for our sample were calculated. Fisher's exact test was employed to assess whether there were statistically significant differences in the AFs of the selected SNPs when comparing the three groups with each other. Statistical significance was set at $P<0.05$.
Results
A total of 52 SNPs were obtained from 76 studies. Most of these studies were conducted in European populations (41%), with only 17% including Latino individuals. LARGE-PD AFs compared to TG showed statistically significant differences. A similar result was observed when comparing TG with the LAA sample, except for four of them. When comparing the LARGE-PD sample with the LAA sample, a third of the analyzed SNPs also exhibited statistical differences, including the majority of those located in the *COMT* gene, with the exception of rs4633.
Discussion
Our results suggest that differences in AF between population groups could explain the lack of reproducibility of previously published results. While the AF differences between the gnomAD TG and our sample were expected, the differences observed between the two Latino groups were not. This may be attributed to the limited inclusion of participants from all Latin-American countries, a factor that was considered and managed in our recruitment process. The consistency in rs4633 among the Latino groups is remarkable given that it is one of the most extensively studied SNPs. Since population admixture could influence AF, ensuring greater genetic diversity in future pharmacogenomic studies is essential.

Session Title: Pharmacogenomics Poster Session III

PB2131 An association of rs7442295 in SLC2A9 with urate levels at baseline and in interaction with iloperidone

Authors:

C. Tyner, S. Smieszek; Vanda Pharmaceuticals Inc., Washington, DC

Serum urate concentrations represent a complex genetic trait influenced by genetic variation as well as environmental factors. Serum uric acid levels correlate with blood pressure, metabolic syndrome, diabetes, gout, and cardiovascular disease. Hyperuricemia, can lead to monosodium urate crystal deposition and thereby cause gout, the most common type of inflammatory arthritis among adults. Recent GWAS have found common genetic variants of *SLC2A9* to be associated with increased serum urate level and gout. The *SLC2A9* gene encodes a high-capacity urate transporter in humans which is mainly expressed in kidneys, liver and intestine. Loss of function variants were previously identified in hypouricemia. Bipolar I disorder is characterized by episodes of manic and hypomanic activity, and it has one of the highest rates of serious impairment among mood disorders. Iloperidone is a second-generation antipsychotic approved by the FDA that has anti-manic effects. Here we report genetic association of rs7442295 with urate levels at baseline and in interaction with iloperidone In a placebo-controlled trial of patients with bipolar mania, treatment with iloperidone 24mg/day resulted in a small but statistically significant increase of serum urate levels of approximately 27.2 μmol/L (0.457 mg/dL) compared to 0.1 μmol/L (0.002 mg/dL) in placebo group. This observation led to an investigation to see if genetic information could be used to predict which patients may be most susceptible to increases in serum urate following iloperidone treatment. WGS was conducted using whole blood samples obtained from the study subjects. A pronounced increase of 40.1 μmol/L (0.674 mg/dL) was seen in iloperidone-treated patients homozygous for the for the rs7442295 (G) allele at the SLC2A9 gene, compared to a decrease of -16.86 μmol/L in the corresponding GG placebo group. Similar results were observed for iloperidone in a second study in schizophrenia patients supporting generalization of the results across patient populations. The results show iloperidone-associated increases in serum urate are greatest in patients who were homozygous (GG) for the rs7442295 (G) allele at the SLC2A9 gene. Among male patients with the GG genotype, serum urate concentrations frequently shifted to above the upper limit of normal for iloperidone-treated patients in comparison to placebo group. Overall, the mechanism of this iloperidone-induced increase in serum urate levels is likely due to decrease in clearance of urate through interaction with the SLC2A9 urate transporter protein.

Session Title: Pharmacogenomics Poster Session I

PB2132 Association between Genetic Polymorphisms and New-Onset Diabetes in Korean Patients Treated with Statins

Authors:

Y-A. Park[1], D. Lee[1], J. Kim[1], T-J. Song[2], H. Gwak[1]; [1]Coll. of Pharmacy and Graduate Sch. of Pharmaceutical Sci., Ewha Womans Univ., Seoul, Korea, Republic of, [2]Dept. of Neurology, Seoul Hosp., Ewha Womans Univ. Coll. of Med., Seoul, Korea, Republic of

Introduction: Statins are lipid-lowering drugs used to prevent atherosclerotic cardiovascular disease and treat dyslipidemia. However, recent studies revealed that statin therapy could develop the risk of new-onset diabetes mellitus. The mechanisms of statin-induced diabetes, including effect of gene polymorphism, are still not precise. Therefore, we analyzed the relationship between genetic polymorphisms and new-onset diabetes mellitus in patients on statin therapy. **Methods:** Four single nucleotide polymorphisms (SNPs) of *FTO* (rs8050136, rs1121980, rs7206629, and rs9941349), three SNPS of *CDKAL1* (rs10946398, rs7756992, and rs2206734), *IGF2BP2* rs4402960, *SLC30A8* rs13266634, *HHEX* rs5015480, and *CDKN2A/2B* rs10811661 were analyzed by a TaqMan genotyping assay. Univariate and multivariable logistic regression analyses were performed to investigate the associations between genetic polymorphisms and statin-induced diabetes mellitus. **Results:** A total of 597 Korean patients on statins were included in the analysis, among whom 59 developed new-onset diabetes. Demographic factors of body mass index (≥30), smoking, and co-medications of diuretics increased the risk of new-onset diabetes mellitus in the multivariable analysis. Patients with *CDKAL1* rs10946398 variant allele (C) carriers and *FTO* rs8050136 variant allele (A) carriers developed 4.0-fold (95% CI: 1.63-9.67) and 2.2-fold (95% CI: 1.22-4.00) higher risk of diabetes than those with wild-type allele carriers, respectively, after adjusting for confounders. The Hosmer-Lemeshow test for statin-induced diabetes showed a good fit for the model ($\chi^2 = 2.902$, 5 degrees of freedom, and $p = 0.715$). The AUROC value of multivariable analysis model was 0.741 (95% CI: 0.68-0.81, $p < 0.001$).**Conclusion:** The study showed that *CDKAL1* and *FTO* polymorphisms could be associated with the risk of new-onset diabetes mellitus in patients on statin therapy.

Intégré Univ.ire de Santé et de Services Sociaux du Saguenay–Lac-Saint-Jean (Univ. Hosp.), Saguenay, QC, Canada

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease (IBD) characterized by continuous colonic inflammation. Worldwide, the disease's incidence is increasing in industrial countries. In Canada, ~120,000 people suffer from UC. For patients with severe forms of UC and for whom conventional therapies cannot induce or maintain remission, the last option before surgery is biologic therapies, including tumor necrosis factor inhibitors (anti-TNF; infliximab, adalimumab, golimumab). One of the main issues with these therapies is the high variability in treatment response. Indeed, ~20-50% anti-TNF users don't improve following drug initiation and 50-90% suffer from adverse events (AE). Multiple factors influence treatment response, such as age, sex, tobacco use and genetics. Indeed, genetic variants have already been associated with phenotypes of response to anti-TNF in Crohn's disease (another form of IBD) in genes part of the pharmacodynamic of anti-TNFs. The hypothesis was made that these variants may also affect response to anti-TNF in UC. Therefore, the goal of this study is to verify the association of these candidate variants with phenotype of response to anti-TNF in UC treatment. Method: This association study included 76 participants suffering from UC and who had taken or were taking at least one anti-TNF. Each recruited participant came to the research centre for a sole visit. Medical charts were reviewed to establish phenotype of treatment response using endoscopic scores. Blood or saliva samples were collected to extract DNA and to genotype 8 selected candidate variants in genes *TNF*, *TNFAIP3*, *TNFRSF1A* and *TNFRSF1B*. Statistical analyses were done using R software. Results: In the combined cohort of anti-TNF users, 30% of individuals were non-responders, 70% suffered from AE and no variant was found to be associated with the response's phenotype. However, a sub-group analysis in infliximab users (n=44) showed that *TNFRSF1B* rs1061622 variant was associated with nonresponse to infliximab (p-value=0.028). Other co-variables were tested, and total number of biologics taken throughout UC treatment was associated with nonresponse to infliximab (p-value=<0.0001).Conclusion: This study identified the first association between *TNFRSF1B* rs1061622 and non-response to infliximab in a cohort of UC patients. Next steps are to replicate this association in independent cohorts and to perform functional studies to elucidate by which mechanisms this associated variant may influence infliximab response, which will increase evidence level of this variant so it can eventually become a clinical marker of treatment response in UC.

PB2134 Balancing cost and effectiveness in development of a sequencing panel for Pharmacogenomics variant identification

Authors:

M. Carter[1], Y. Fan[2], W. Wang[1], C. Goswami[1], J. Otto[2], L. Turner[1], C. Mozdzierz[2], J. Rosenfeld[3], H. Latif[2], G. Zhou[2]; [1]Azenta Life Sci., South Plainfield, NJ, [2]Azenta Life Sci., South Plainfield, NJ, [3]Tonix Pharma, Chatham, NJ

Pharmacogenomics (PGx) has become a staple in therapeutic development programs providing insights into the molecular underpinnings of drug responsiveness and clinical safety and efficacy. Advancements in genomics over the past 25 years have greatly given us a wide variety of tools for analyzing the genome of patients. Currently, costs are getting to a low enough level that we are able to sequence every individual in a clinical trial. These genomic findings are integrated with the trial results to identify PgX markers for that drug. Even with the current cost of a whole genome of less than $1,000 this is a significant expense for a large trial of thousands of patients. Here we apply recent advancements in NGS on clinical trial samples from Tonix Pharmaceuticals as well as standard human control samples to assess which methods, platforms, analysis approaches and combinations thereof offer the best outcomes from a performance, cost, and scalability perspective. Standard whole genome sequencing was performed using the latest generation of short read sequencing platforms (Illumina NovaSeq X+) and long read sequencing platforms (PacBio Revio). In addition, target capture-based approaches using PGx-specific enrichment panels from Twist were also performed on short and long read sequencing platforms. These methods were analyzed using a variety of bioinformatics tools independently and in combination to assess performance against truth data across ADMET genes including SNPs and complex genes such as CYP2D6 and HLA genes. The data generated here provide an outlook on how NGS adds value and holds promise in the next evolution of PGx technologies

Session Title: Pharmacogenomics Poster Session I

PB2135 † Breast cancer drugs that inhibit TOP2, including anthracyclines, induce cardiotoxicity through shared mechanisms in iPSC-derived cardiomyocytes

Authors:

E. Matthews[1], O. D. Johnson[2], K. J. Horn[3], J. Gutierrez[1], S. Powell[4], M. Ward[1]; [1]Univ. of Texas Med. Branch-Galveston, Dept. of Biochemistry and Molecular Biology, Galveston, TX, [2]Univ. of Texas Med. Branch, Biochemistry, Cellular and Molecular Biology Graduate Program, Galveston, TX, [3]Univ. of Texas Med. Branch, John Sealy Sch. of Med., Galveston, TX, [4]Univ. of Texas Med. Branch-Galveston, NeuroSci. Graduate Program, Galveston, TX

TOP2 inhibitors (TOP2i) used in the treatment of breast cancers, including the anthracyclines (AC) Doxorubicin (DOX), Daunorubicin (DNR), Epirubicin (EPI), and the anthraquinone Mitoxantrone (MTX) can lead to cardiotoxicity in some women. It is unclear whether women would experience the same adverse effects from all drugs in this class. To gain insight into whether specific drugs would be preferable for certain individuals based on their cardiotoxicity risk profile, we studied the effects of treatment of DNR, DOX, EPI, MTX, and an unrelated monoclonal antibody Trastuzumab (TRZ) on iPSC-derived cardiomyocytes (iPSC-CMs) from six females. While TRZ does not affect cell viability, all TOP2i induce cell death at concentrations observed in cancer patient serum. To elucidate primary responses due to the drug treatment, we chose a sub-lethal dose to measure effects over 24 hours. All TOP2i affect calcium handling, a function critical for cardiomyocyte contraction. Global gene expression data show that drug treatment and time accounts for most variation between samples, followed by the individual from which samples were derived. Thousands of genes respond after treatment with each of the TOP2i. We did not observe a gene expression response to TRZ. Response genes are associated with the p53 signaling pathway, DNA replication, and the cell cycle. Bayesian analysis across all drugs reveals four gene expression signatures, which we denote as TOP2i early, late, time-independent, and non-response genes. TOP2i early response genes are enriched in chromatin regulators, which have been implicated in mediating AC sensitivity in breast cancer patients. To investigate genetic effects on drug response, we first identified a reported set of eQTLs that are uncovered specifically following DOX treatment in iPSC-CMs. DOX response eQTLs are enriched in genes that respond to all TOP2i compared to baseline eQTLs. Of the 180 DOX response QTLs that respond to DOX in our cells, 93% also respond to DNR, 85% to EPI, and 20% to MTX. We next identified eight genes in loci associated with AC toxicity by GWAS or TWAS. Five of these genes respond to all ACs, including *RARG* and *HDDC2*. Finally, we investigated whether genes near SNPs associated with cardiovascular disease respond to TOP2i. DNR, EPI, and MTX response genes are enriched for atrial fibrillation genes, while no drug response genes are enriched for heart failure genes. Our data thus demonstrate that TOP2i induce thousands of shared gene expression changes in cardiomyocytes, including genes near SNPs associated with inter-individual variation in response to DOX treatment, AC-induced cardiotoxicity, and atrial fibrillation.

Session Title: Pharmacogenomics Poster Session II

PB2136 Cannabinoid 1 receptor (CNR1) 1359G>A polymorphism associated with psychotic adverse events in cannabis users with chronic pain

Authors:

K. Tremblay[1], W. Beauchesne[1], J. Turcotte[2], A-L. Gagnon[2], P. Mercier[2], M. Durand[3], D. Bergeron[3], G. Léonard[4], L. Gendron[1]; [1]Pharmacology-physiology Dept., Université de Sherbrooke, Sherbrooke, QC, Canada, [2]Res. Ctr. of Ctr. intégré universitaire de santé et de services sociaux du Saguenay–Lac-Saint-Jean (CIUSSS-SLSJ, Univ. Hosp.), Saguenay, QC, Canada, [3]RNomics platform, Université de Sherbrooke, Sherbrooke, QC, Canada, [4]Readaption Sch., Université de Sherbrooke, Sherbrooke, QC, Canada

Chronic pain is one of the leading causes of disability worldwide. Despite its high prevalence and the diverse pharmacologic therapies available, patients with chronic pain often remain with significant disability and inadequate pain control. Cannabis and cannabinoids are sometimes used in the treatment of chronic pain as they have been shown to be useful in some patients. However, they are associated with significant adverse effects. Notably, the occurrence of cannabis use disorder (CUD) and cannabis-induced psychosis, which have been associated with many genetic variants in the literature. However, the paucity of data on some reported variants and contradictory results limit our ability to use them as genetic markers to personalize cannabis treatment for patients tailored to their genetic background.

The aim of this genetic association study was to characterize the phenotypes of patients with chronic pain who were using or had used cannabis or cannabinoids in the past and to investigate the effects of previously reported genetic variants.

Phone interviews were conducted to document participants' characteristics, cannabis use and its effects, concurrent pharmacotherapy and comorbid conditions. CUD was screened for using the Cannabis Use Disorders Identification Test - Revised questionnaire. Blood or saliva samples were collected for genotyping and 19 variants on 12 candidate genes (*BDNF*, *CHRM3*, *CNR1*, *CNR2*, *COMT*, *CYP2C9*, *FAAH*, *GABRA2*, *HES7*, *NRG1*, *OPMR1*, *KAT2B*) were tested.

This study recruited 100 participants and DNA were obtained in 77 participants. We report one significant single nucleotide variation (rs1049353) in CNR1 (cannabinoid receptor 1) gene associated with psychotic adverse events. Homozygous patients for *CNR1* c.1359G>A presented higher rates of psychotic adverse events ($p = 0.008$). No variants were associated with CUD or pain relief. These results provide novel evidence of association between *CNR1* rs1049353 and psychotic adverse events but did not replicate many previously documented genetic associations for CUD. Our results also underscore the need for replication studies using adequate sample size and functional studies to elucidate by which mechanisms this associated variant may influence cannabis response.

Session Title: Pharmacogenomics Poster Session III

PB2137 Cardiometabolic drug response pharmacogenetics using EHRs from the UK Biobank

Authors:

M. Sadler[1], E. R. Pearson[2], R. Altman[3], Z. Kutalik[1]; [1]Univ. of Lausanne, Lausanne, Switzerland, [2]Div. of Population Hlth.and Genomics, Sch. of Med., Univ. of Dundee, Dundee, United Kingdom, [3]Stanford Univ., Menlo Park, CA

Despite the massive progress of genome-wide association studies (GWAS), pharmacogenetics (PGx) is advancing at a slower pace. Here, we extracted clinical and medication prescription data from electronic health records (EHRs) of 200,000 individuals of European ancestry in the UK Biobank and conducted PGx GWAS on the change in biomarkers following cardiometabolic drug therapy. GWAS of LDL cholesterol (LDL-C) response to statins (N = 15,356) identified genome-wide significant hits at *PCSK9* (P = 9.1e-12), *SORT1*/*CELSR2*/*PSRC1* (P = 7.5e-11), *LPA* (P = 2.8e-18) and *APOE* (P = 1.5e-81) which have been previously reported. GWAS of total cholesterol response to statins (N = 24,810) identified an additional locus at *CETP* which coincided with the HDL-C response locus (N = 21,908). No genome-wide significant signals were identified for HbA1c response to metformin (N = 2,890) and SBP response to major first-line antihypertensives, combined and individually (ACE inhibitors, calcium channel blockers, thiazide diuretics, N = 1,281-5,835). Since the lipid response hits (h^2_{SNP} = 8.2%) overlapped with variants impacting baseline lipid levels (h^2_{SNP} = 8.0%; genetic correlation of 0.29), we adjusted the LDL-C response GWAS for LDL-C baseline level and the polygenic risk score (PRS) of LDL-C, leaving only the *LPA* and *APOE* loci significant. It also revealed that despite higher baseline being associated with more reduction, 1SD increase in PRS leads to 0.11 mmol/L less LDL-C reduction (P = 1.2e-72). Similarly, SBP-response to antihypertensives was also attenuated for those with higher genetic predisposition (0.70 mmHg less reduction / SD increase in SBP PRS, P = 3.5e-4), but the trend was not present in the HbA1c response to metformin. Control experiments (using statin-naïve samples) showed a similar trend: Individuals with higher baseline PRS had less longitudinal decrease in LDL-C levels - indicating that part of the drug response signal is due to regression-to-the-mean. An LDL-C change GWAS in the same control cohort (N = 27,159) also identified *APOE* as the top hit, however, with a significantly lower effect size (b = 0.15) than in the statin response GWAS (b = 0.38), further evidencing the presence of both drug-specific and regression-to-the-mean effects. In summary, we present a comprehensive catalog of cardiometabolic PGx GWAS and showed that drug response genetics comprises both a drug-and disease-specific component. Our study demonstrates that EHRs enable new opportunities to study drug response to reveal the complex contribution of the genetic and environmental components of the baseline level of the targeted cardiometabolic biomarker.

Session Title: Pharmacogenomics Poster Session I

PB2138 Characterisation of pharmacogenetic variation relevant to anti-tuberculosis drug metabolism across African populations.

Authors:

T. Malinga[1,2], H. Othman[2], D. Twesigomwe[2,1]; [1]Div. of Human Genetics, Natl. Hlth.Lab. Service, and Sch. of Pathology, Faculty of Hlth.Sci., Univ. of the Witwatersrand, Johannesburg, South Africa, [2]Sydney Brenner Inst. for Molecular BioSci., Faculty of Hlth.Sci., Univ. of the Witwatersrand, Johannesburg, South Africa

Background and aims: Tuberculosis (TB) is a major health burden in Africa. Although TB is treatable, current medications (e.g. isoniazid) are associated with adverse drug reactions such as hepatotoxicity. These ADRs can partly be attributed to pharmacogenetic variation. The distribution of star alleles (haplotypes) that influence anti-TB drug metabolism, is unknown in many African ethnolinguistic groups. This presents challenges and limitations in implementing genotype-guided therapy in African clinical settings for purposes of anti-TB drug dosage optimisation with a view toward promoting safe and efficacious TB treatment. Therefore, this study aimed to characterise the distribution of star alleles in genes that are involved in anti-TB drug metabolism, namely *CYP2E1*, *NAT1*, *NAT2*, *GSTM1* and *GSTT1*, across diverse African populations. **Methods:** This study used 802 high-depth whole genome sequence datasets representative of eight Sub-Saharan African (SSA) population groups. Data sources included the 1000 Genomes Project and H3Africa AWI-Gen. *CYP2E1*, *NAT1*, *NAT2*, *GSTM1* and *GSTT1* star alleles were called from the WGS data using StellarPGx. Novel star allele-defining variants were annotated using the Ensembl Variant Effect Predictor. **Results:** We present both common and rare star alleles influencing anti-TB drug metabolism across various SSA populations, in comparison to other global populations. Among the SSA population, relatively common key star alleles were identified such as *NAT1*4*, *NAT1*10*, *GSTM1*0 (*deletion), and *GSTT1*0* (deletion) which had frequencies above 50%, while *NAT2*5B* had a frequency of 22%. Seventeen novel haplotypes were identified for these genes across SSA. Among these, three novel alleles were present at frequencies >1% (e.g. *GSTT1*A*+rs2266637(T)+rs8140585(T) was observed at a frequency of 10%), while others were relatively rare. Regarding anti-TB drug metaboliser phenotype predictions, NAT2 intermediate and slow acetylation phenotypes were the most frequent in the SSA populations in this study. **Conclusion:** This study provides insight into the distribution of star alleles relevant to anti-TB drug metabolism across various African populations, and in comparison, to global populations. Furthermore, it provides a foundation of implementing pharmacogenetic testing in Africa, to reduce risk of ADRs related to TB treatment. Future work entails characterizing the functional impact of novel alleles identified in this study and submitting them to the Pharmacogene Variation Consortium database for designation.

Session Title: Pharmacogenomics Poster Session III

PB2140 Clinically actionable pharmacogenomic landscape of psychotropic medications in a Middle Eastern population.

Authors:

P. Jithesh[1], D. Velayutham[1], K. Bastaki[2], S. Ghuloum[3], M. Azeem[4], Qatar Genome Program Research Consortium; [1]Hamad Bin Khalifa Univ., Doha, Qatar, [2]Qatar Univ., Doha, Qatar, [3]Hamad Med. Corp., Doha, Qatar, [4]Sidra Med., Doha, Qatar

Background: Psychotropic medications are prescribed widely worldwide. However, their clinical response is highly varied due to several factors including the individual's genetic variants. Understanding the distribution of clinically actionable genotypes and their predicted response phenotypes is essential in facilitating clinical implementation of pharmacogenomics in psychiatry. However, such reports are missing from several populations, including the Middle East. **Methods:** We used whole genome sequencing data from a cohort of 14,392 adult Qataris from the Qatar Genome Program (QGP) to study the frequency distribution of actionable diplotypes (a combination of variants in the gene on both the homologous chromosomes) and their predicted phenotypes. A total of 490 alleles in four genes coding for metabolizing enzymes that significantly affect response to antidepressants and antipsychotics, and have guidelines for clinical interpretation, namely *CYP2C19, CYP2D6, CYP2B6* and *CYP3A4*, were analyzed. Clinically actionable pharmacogenomic variance was defined based on guidelines from the Clinical Pharmacogenetic Implementation Consortium (CPIC) and the Dutch Pharmacogenetics Working Group (DPWG) suggesting a course of action, such as change in dosage or prescription of an alternate drug. **Results:** Following the DPWG guidelines, the clinical actionability of antipsychotics was in the range of 0.1 - 32%, based on *CYP3A4* and *CYP2D6* diplotypes . However, we found that more than 52% of the individuals may have actionable metabolizer phenotype associated diplotypes based on CPIC guideline in *CYP2C19, CYP2B6* and *CYP2D6* affecting response to tricyclic antidepressants, while for serotonin reuptake inhibitors, the frequency varied from ~2 - 51%. For example, CYP2C19 ultrarapid, rapid, poor and intermediate metabolizers need alteration in dosage or alternate prescription, and constituted 51% of the population. **Conclusion:** Our previous research has identified heavy prescription of antidepressants, especially escitalopram in Qatar. Therefore, our results from this study highlight the importance of implementation of pharmacogenomic testing prior to prescribing these medications to prevent unnecessary hospitalizations and inefficient treatment regimens, reducing the associated economic burden, and improving the quality of life of the patients. We will present the detailed results for several drugs and discuss their implications.

Session Title: Pharmacogenomics Poster Session I

PB2141 ClinPGx: An Integrated Single Resource for Pharmacogenomics (PGx)

Authors:

T. Klein[1], K. Caudle[2], A. Gaedigk[3], M. D. Ritchie[4], S. A. Scott[5], L. Gong[6], K. Sangkuhl[5], C. F. Thorn[1], C. Klein[1], I. M. Keseler[1], R. Whaley[5], M. Woon[5], I. Reinert[1], M. W. Wright[7], M. Whirl-Carrillo[5]; [1]Stanford Univ, Stanford, CA, [2]St. Jude Children s Res. Hosp., Memphis, TN, [3]Children s Mercy Kansas City, Washington, MO, [4]Univ. OF PENNSYLVANIA, Philadelphia, PA, [5]Stanford Univ., Stanford, CA, [6]Stanford Univ, Palo Alto, CA, [7]Stanford Univ. Sch. of Med., Palo Alto, CA

Pharmacogenomics (PGx) is the study of how a person's genetic makeup affects their response to drugs, with the goal of helping clinicians personalize medication management and improve patient outcomes. However, the current landscape of PGx resources is fragmented, resulting in reporting inconsistencies, duplication of efforts, and unintended barriers to implementation. To address these challenges, we propose a new long-term and conceptual framework for broadly integrating the available PGx resources into a single resource, ClinPGx. ClinPGx would complement ClinGen and ClinVar by providing essential PGx information to clinical providers and the research community.

Standardization is a critical need in the field of PGx, as inconsistencies between resources and laboratories pose significant challenges to implementation. Furthermore, barriers such as electronic health record (EHR) integration, provider education and awareness of PGx, insurance coverage, and communication gaps between laboratories and healthcare providers hinder the widespread adoption of PGx. ClinPGx will address these challenges by leveraging existing tools and resources (e.g., PharmGKB, CPIC, PharmCAT and PharmVar) to streamline efforts and ensure compatibility and reporting consistencies, facilitating integration of PGx into EHR systems, and increasing stakeholder buy-in and confidence in the scientific foundation of PGx testing and interpretation. This unified resource may also catalyze expansion of implementation and insurance coverage, increasing access to PGx testing and potentially reducing health disparities. One key aspect of this integration involves expanding the ClinGen Community Curation efforts to include PGx data, enabling the collective expertise of the community to enhance the resource's comprehensiveness and accuracy.

In conclusion, the development of a unified PGx resource represents a transformative step towards realizing the full potential of PGx, which would span from discoveries to clinical implementation. By engaging the community, leveraging existing tools, and addressing the challenges of standardization and implementation, ClinPGx will enable clinicians to make informed decisions based on individual genetic profiles, and improve patient outcomes. We will actively solicit feedback from the genomics community on the interest and development of ClinPGx to facilitate the incorporation of PGx into standard of care.

We would like to acknowledge support from the following funding agencies: NIH, NHGRI, NICHD and NIDA (PharmGKB (U24 HG010615); CPIC (U24HG010135); PharmCAT (U24HG010862), ClinGen (Baylor/Stanford U24HG009649)).

Session Title: Pharmacogenomics Poster Session III

PB2143 DDINER: Drug-Drug Interactions classification Neural network model using Random walk with restart algorithm.

Authors:

J. Seo, Y. Ko; Hankuk Univ. of Foreign Studies, Seoul, Korea, Republic of

Drug-Drug interactions (DDIs) occurs due to the unexpected pharmacological effects when multiple drugs are prescribed simultaneously. While short-term administration of multiple drugs can enhance efficacy, it can lead to severe adverse reactions. The prescription of multiple drugs relies on the clinician's experience or knowledge, lacking a standardized database for safe co-prescription. It is crucial to identify potential DDIs in advance for patient safety and treatment strategies. However, it is not feasible to experimentally identify all existing drug interactions. Instead, drug-drug interaction can be identified with computational methods by utilizing various drug features such as chemical structure, target genes, or associated pathological pathways. However, DDIs usually result from unexpected associations of target proteins or shared mechanisms and such indirectly hidden associations should be considered to predict DDIs.In this study, we proposed DDINER a novel deep learning model to predict 80 types of DDIs by utilizing various drug features such as chemical structures and drug-binding proteins. The model's training and testing were conducted using interaction data of FDA-approved drugs obtained from Drugbank, resulting in 163,574 DDIs involving 1,436 drugs. We used chemical structure and binding protein of drugs as an representation of drug. We applied the random walk with restart (RWR) algorithm to propagate drug-binding proteins across a PPI network. Our experimental results demonstrated the effectiveness of DDINER for the prediction of clinically proven epilepsy drug combinations as well as the unknown drug pairs. DDINER would be very useful for the identification of DDIs and the pharmacological mechanisms associated with DDIs. Our method could apply to all possible drug pairs and the predicted potential DDI can be used clinically with experimental validations, leading to the way to drug repurposing.

Session Title: Pharmacogenomics Poster Session I

PB2144 Determining the role of TOP2B and p53 in mediating Doxorubicin-induced cardiotoxicity in iPSC derived-cardiomyocytes

Authors:

S. Paul, J. Gutierrez, M. Ward; Univ. of Texas Med. Branch Galveston, Galveston, TX

The Anthracycline Doxorubicin (Dox), which is prescribed in 32% of breast cancer patients, can cause irreversible left ventricular dysfunction and heart failure. Dox intercalates into DNA forming a ternary complex with TOP2B. This complex induces DNA double-strand breaks, mitochondrial dysfunction and apoptosis by activating the p53 transcription factor. TOP2B is essential for the cardiotoxicity observed in mice. Under physiological conditions, TOP2B regulates DNA topology and interacts with CTCF and cohesin at topologically associated domain boundaries. However, it is unknown how these functions are affected by Dox in human hearts. To gain insight into the mechanisms behind Dox-induced cardiotoxicity, we have developed a human iPSC-derived cardiomyocyte (iPSC-CM) model to study the binding of these transcriptional regulators in response to Dox treatment. We first performed chromatin immunoprecipitation followed by sequencing (ChIP-seq) for p53, TOP2B, CTCF, and RAD21 (a cohesin subunit) in iPSC-CMs. We find thousands of genomic regions that are bound by each of these factors. 32% of TOP2B-enriched regions are co-bound by CTCF and RAD21 suggesting roles for TOP2B in gene regulation and chromatin organization in cardiomyocytes as has been observed in other cell types. To determine transcriptional regulator binding in response to Dox, we exposed iPSC-CMs to a non-lethal dose of Dox that induces thousands of gene expression changes in 24 hours compared to the vehicle control. ChIP-qPCR reveals that p53 binding is increased at the CDKN1A and MDM2 promoters in Dox-treated iPSC-CMs compared to vehicle, which suggests that Dox treatment leads to the activation of the p53 stress response pathway in these cells. Using this model, we are currently performing ChIP-seq experiments for all factors in Dox-treated iPSC-CMs to determine the gene regulatory networks activated in response to Dox that may explain the cardiotoxic effects of drug treatment.

Session Title: Pharmacogenomics Poster Session II

PB2145 Differential gene expression and regulation at single nucleus resolution in muscle of statin users

Authors:

B. Wolford[1], S. C. Hanks[2], L. Taylor[3], A. U. Jackson[2], A. Varshney[2], N. Manickam[2], A. Ramirez[3], A. T. Beck[2], H. M. Stringham[2], P. Orchard[2], N. Narisu[3], L. Bonnycastle[3], M. Erdos[3], M. Sweeney[2], J. Tuomilehto[4], M. Melbye[5], T. Lakka[6], M. Laakso[6], H. Koistinen[4], F. Collins[3], M. Boehnke[2], S. C. J. Parker[2], L. J. Scott[2]; [1]Norwegian Univ. of Sci. and Technology, Trondheim, Norway, [2]Univ. of Michigan, Ann Arbor, MI, [3]NHGRI/NIH, Bethesda, MD, [4]Finnish Inst. for Hlth.and Welfare, Helsinki, Finland, [5]Danish Cancer Inst., Copenhagen, Denmark, [6]Univ. of Eastern Finland, Kuopio, Finland

Statins are prescription drugs which reduce plasma LDL cholesterol and are important for preventing and treating cardiovascular disease and preventing premature mortality. Based on 2013 American Heart Association and American College of Cardiology guidelines, 48.6% of US adults are eligible for statins. Adverse effects such as muscle pain and weakness and even rhabdomyolysis can occur in statin users, often leading to poor adherence. The mechanism for these adverse effects is poorly understood. We hypothesize that identification of genes differentially expressed or regulated in skeletal muscle of statin users may help explain these effects.

We performed transcriptome and epigenome data analyses of muscle biopsies from 281 participants of the FUSION Tissue Biopsy Study to characterize the effects of statin use on skeletal muscle. Using bulk RNA-seq combined with single nucleus RNA-seq and ATAC-seq, we tested for differences in gene expression and open chromatin status between 48 statin (3-hydroxy-3-methyglutaryl-coenzyme A reductase inhibitors) users and 233 non-users, controlling for oral glucose tolerance test status, age, sex, and technical covariates.

Using snRNA-seq, we tested for associations between gene expression and statin use for each of 12 observed muscle cell types and subcellular components with DESeq. At 5% FDR, we observed higher expression of TRIT1 in statin users in mesenchymal stem cells and lower expression of PGGT1B in statin users in smooth muscle. Notably, PGGT1B has been associated with quantitative traits related to muscle performance in elite athletes. Gene Ontology term enrichment analysis of differentially expressed genes across cell types showed that Type 1 muscle fibers have upregulated pathways in statin users (e.g., proteasome, endopeptidase, and peptidase complexes). We observed significant differential expression in bulk RNA-seq in ABCA1 and ASPA.

Composition of muscle cell types was also significantly associated with statin use. Combining snRNA-seq and snATAC-seq reads, the number of nuclei was higher in statin users in both the neuromuscular junction (fold change 1.5 [95% CI 1.2-1.9], p-value 1E-4) and smooth muscle (fold change 1.2 [95% CI 1.1-1.4], p-value 1E-3). At 5% FDR, smooth muscle and mesenchymal stem cells had regions of differentially accessible chromatin. In mesenchymal stem cells, a differentially open region was 50 kilobases downstream of ACTR3, a gene previously associated with myopathy.

Ultimately, characterization of the impact of statins on skeletal muscle may lead to preventive measures for adverse effects, increased pharmaceutical adherence, and reduced cardiovascular events.

Unit, Dept. of Pediatrics, Faculty of Hlth.Sci., Univ. of the Witwatersrand, Johannesburg, South Africa

Clinical outcomes of tamoxifen treatment show wide inter-individual variability. Co-medications and genetic polymorphisms of enzymes involved in tamoxifen metabolism contribute to this variability. Drug-drug and drug-gene interactions have seldom been studied in African black populations. We evaluated the effects of commonly co-administered medicines on tamoxifen pharmacokinetics in a cohort of 229 South African black female hormone-receptor positive breast cancer patients. We also investigated the pharmacokinetic effects of genetic polymorphism in enzymes involved in tamoxifen metabolism including the variants *CYP2D6*17* and **29* which have been mainly reported in people of African ancestry. Tamoxifen (TAM) and its major metabolites, N-desmethyltamoxifen (NDM), 4-OH-tamoxifen (4-OHTAM), and endoxifen (ENDO), were quantified in plasma using the liquid chromatography-mass spectrometry (LC/MS/MS). The GenoPharm® open array was used to genotype *CYP2D6*, *CYP3A5*, *CYP3A4*, *CYP2B6*, *CYP2C9*, and *CYP2C19*. Results showed that *CYP2D6* diplotype and *CYP2D6* phenotype significantly affected endoxifen concentration ($p<0.001$ and $p<0.001$). *CYP2D6*17* and *CYP2D6*29* significantly reduced the metabolism of NDM to ENDO. Antiretroviral therapy (ART) had a significant effect on NDM levels and the TAM/NDM and NDM/ENDO Metabolic Ratios (MRs) but did not result in significant effects on ENDO levels. In conclusion, *CYP2D6* polymorphisms affected endoxifen concentration and the variants *CYP2D6*17* and *CYP2D6*29* significantly contributed to low exposure levels of endoxifen. This study also suggests a low risk of drug-drug interaction in breast cancer patients on tamoxifen.

Session Title: Pharmacogenomics Poster Session I

PB2147 Enhancing Asthma Pharmacogenetics through Endotype-Specific Associations

Authors:

S. Piparia[1], K. Tantisira[2]; [1]Univ. of California at San Diego, San Diego, CA, [2]Univ. of California, San Diego, La jolla, CA

Background:Asthma is a complex disease with various subtypes, known as endotypes, characterized by distinct underlying pathophysiological mechanisms. Inhaled corticosteroids (ICS) are a primary treatment for asthma, but individual response to this medication varies significantly. Although genetic variations in T-genes have been associated with differences in ICS response, they are not sufficient as predictive biomarkers. This study aims to investigate whether endotype-based pharmacogenetics can enhance the potential of precision medicine for asthma.Methods:We conducted candidate gene analysis to examine whether the pharmacogenetic association is stronger when stratifying the Childhood Asthma Management Program (CAMP) cohort by eosinophil counts (threshold of 300 cells/uL), a commonly used delineation for type 2 asthma. We dichotomized the cohort based on ICS usage into high eosinophils (n=82) and low eosinophils (n=50) and performed genetic association analysis for rs3127412, a T-gene variant previously associated with ICS response, with change in lung function on ICS. Additionally, we computed the Area Under the Curve (AUC) for the upper and lower quartiles within both EOS groups and the entire cohort.Results:Using an additive model, we observed a 5.7% increase in percent predicted FEV1 (forced expiratory volume at one second) for the entire cohort (p = 0.003), while the FEV1 change (p-values) were 7.1% (p = 0.008) for high and -0.2% (p = 0.912) for low eosinophils groups respectively, with a significant interaction (p = 0.038). The AUC of the high Eos group demonstrated good predictive value (AUC 0.71) while there was no ability of this variant to predict outcomes in the low Eos group (AUC of 0.48). Replication analysis is currently ongoing. Our findings indicate that endotypes enhance the prognostic ability of medication response. These results suggest that these genetic variants may play a role in the response to changes in lung function in pediatric patients treated with ICS.

Session Title: Pharmacogenomics Poster Session II

PB2148 Evaluating cardiometabolic risk factors and treatment efficacy in diverse British ancestries: Insights from a novel application of drug target Mendelian randomisation

Authors:

A. Carter[1], C. Maroteau[1], J. Yu[1], J. Bowden[1,2], J. Howson[1], Y. Jamshidi[1]; [1]Novo Nordisk Res. Ctr. Oxford, Oxford, United Kingdom, [2]Univ. of Exeter, Exeter, United Kingdom

Coronary artery disease (CAD) poses a significant health burden on individuals across ancestries. Individuals of South Asian ancestry living in England have over a 70% increased risk of CAD compared with the White British population and the onset of disease tends to occur at earlier ages. Given these disparities, tailored early intervention and treatment strategies for diverse ancestries need to be identified.

Using a novel Mendelian randomization (MR) approach in different ancestries, we compared the effects of three CAD risk factors, triglycerides (TG), low density lipoprotein cholesterol (LDL-C), high density lipoprotein cholesterol (HDL-C) and two gene regions reflecting drug targets (*HMGCoA* [statins], *PCSK9*) on CAD in two British cohorts: UK Biobank (UKB) and Genes and Health (G&H).

Genome wide significant polygenic scores per standard deviation increase in exposure were derived from Global Lipids Genetics Consortium ancestry specific GWAS summary statistics. Genetic variants in the *HMGCoA* and *PCSK9* gene regions were weighted by their effects on LDL-C.

UKB analyses were conducted in multi-ancestry participants (N=420,3112; CAD=42,751) and stratified by European (N=396,198; CAD=40,004) and South Asian ancestry (N=8772; CAD=1428). All G&H participants were of British Bangladeshi and British Pakistani ancestry and analysed together (N=44,396; CAD=4037).

Two-stage least squares regression, adjusted for genetic principal components, was used to estimate MR causal effects. Estimates for South Asian individuals in UKB and G&H were meta-analysed.

Analyses suggested an increased odds ratio (OR) of TG and LDL-C on CAD in Europeans (TG = 1.55; 1.45-1.66; LDL-C = 1.79; 1.64-1.96) but not South Asians (TG = 1.11; 0.86-1.36; LDL-C = 1.03; 0.77-1.29). HDL-C trended towards a greater protective effect in Europeans (0.70; 0.66-0.75) than South Asians (0.87; 0.60-1.14).

The OR for the effect of *HMGCoA* on CAD (European = 1.29; 0.99-1.68; South Asian = 0.65; 0.12-1.19) was smaller than *PCSK9* (European = 1.94; 1.66-2.27; South Asian = 1.59; 0.13-3.07).

As ancestrally diverse GWAS become available, novel applications of MR to test causal effects across ancestries can be conducted. This analysis suggests the increased burden of CAD in individuals of South Asian ancestry in England is unlikely to be due to lipids. The wide confidence intervals in South Asian analyses indicate low power for drug-target MR and the need for ever larger ancestrally diverse samples. By using genetics approaches to identify differences in cardiometabolic risk profiles and treatment effectiveness, treatment strategies can be personalised, improving cardiovascular health worldwide.

Session Title: Pharmacogenomics Poster Session III

PB2149 Exploring pharmacogenetic relationships in Malaria and Tuberculosis: A Text-Mining analysis of biomedical literature and gene diversity assessment in African Populations

Authors:

H. Othman; Sydney Brenner Inst. for Molecular BioSci., Univ. of the Witwatersrand, Johannesburg, South Africa

Malaria and Tuberculosis continue to persist as significant health challenges in Africa, claiming over 500,000 lives annually for each of these diseases. The abundant genetic diversity present in Africa necessitates the acquisition of extensive knowledge about genes associated with drug-processing mechanisms. This, in turn, requires harnessing information from various data sources, including both public and non-public repositories such as biomedical literature and chemical structures of ligands/drugs. The detection of the drug-gene relationship is a crucial piece of information that can provide insights into potential pharmacogenetic associations. In order to explore this area, we conducted a text-mining analysis of the biomedical literature focused on Malaria and TB. Initially, we constructed a predictive model to identify articles containing information about pharmacogenetic relationships. To train the model, we utilized over 20,000 abstracts from PharmGKB and more than 40,000 randomly sampled abstracts from PubMed. Additionally, we created a comprehensive list of 36 anti-TB and anti-malaria drugs, along with candidate drugs. Using Biotransformer 3.0, we predicted the phase I metabolizers for these drugs. Our preliminary analysis of the biomedical literature yielded 5,194 sentences associated with drug-gene relationships for TB, and 5,714 sentences for malaria. These sentences include information on 1,370 unique drugs/ligands and 1,794 unique genes for malaria, as well as 1,459 unique drugs/ligands and 1,868 unique genes for TB. Within the identified unique genes, we pinpointed 85 genes for malaria and 96 genes for TB, out of a total of 340 pharmacogenes. Moreover, we successfully identified 9 candidate genes involved in the metabolization of 31 out of the 36 anti-malaria and anti-TB drugs/ligands. These candidate genes include CYP2C19, CYP3A4, CYP2D6, CYP2C9, CYP1A2, CYP2B6, CYP2A6, CYP2E1, and CYP2C8. Presently, we are conducting a gene diversity assessment using whole genome sequencing and DNA genotyping array datasets of 900 and 22,000 African subjects respectively.

Session Title: Pharmacogenomics Poster Session I

PB2150 Exploring the association between polygenic score of adverse drug reaction genes and disease risk

Authors:

J. Kim[1,2], S. Lee[1], J. Sung[1], S-S. Byun[3]; [1]Seoul Natl. Univ., Seoul, Korea, Republic of, [2]Procagen, Seongnam, Korea, Republic of, [3]Seoul Natl. Univ. Bundang Hosp., Seongnam, Korea, Republic of

Background: Identification of genetic variants associated with adverse drug reaction (ADR) is important for optimizing treatment efficacy and reducing the side effects. While many studies have focused on pharmacokinetics and pharmacodynamics genes for their effects on adverse reactions it is not clear whether those genes play a role in the risk of developing common diseases as well. Our study aimed to explore the diseases that may increase the risk in individuals with general genetic tendency to adverse drug reactions (ADR).Methods: We calculate a polygenic score for ADR (PGS-ADR) based on the group 1&2 pharmacogenes in the Pharmacogenomics Knowledge Base (PharmGKB). The effect size reported in the PharmGKB (about 80% of genes), or the functional deterioration score (CADD) was used as the weighting. A phenome-wide search was conducted for the PGS-ADR.Results: We identified an association between PGS-ADR and the drug toxicity phenotype in the European ancestry population. (odds ratio (OR)=1.21; 95% confidence interval (CI)=1.08-1.39) From the phenome-wide association search, we observed a suggestive associations between PGS-ADR and schizophrenia (p=0.0007), chronic obstructive pulmonary disease (COPD, p=0.0009). Furthermore, sex-specific analyses demonstrated some diseases with discordant association between sex; men showed associations with endocrine, urological, and respiratory diseases, whereas women with mental disorders and cardiovascular diseases.Conclusion: Our findings suggest that so-called pharmacogenes may be linked with some disease susceptibilities, and require a further research whether the apparent associations imply any clues in the pathogenesis of the diseases. Moreover, the effects of pharmacogenes may exert differential effects by sex. It suggests the need for further investigation to develop precise treatment approaches based on an individual's genetic predispositions.

Session Title: Pharmacogenomics Poster Session II

PB2151 Exploring the role of local ancestry in the distribution of pharmacogenomics variants in an admixed population

Authors:

T. De Oliveira[1], R. Secolin[2], M. Naslavsky[3], T. Hünemeier[4], I. Lopes-Cendes[5]; [1]Univ. of Campinas, São Paulo, Brazil, [2]Univ. of Campinas - UNICAMP, Campinas, Brazil, [3]Univ. of Sao Paulo, Sao Paulo, Brazil, [4]Univ. of Sao Paulo, São Paulo, Brazil, [5]Univ. of Campinas, Campinas, Brazil

Introduction: Pharmacogenomics (PGx) studies in populations with multi-ethnic ancestry indicate that ancestry-informative markers were enriched in pharmacogenetic *loci*, suggesting that trans-ancestry differentiation must be carefully considered in population PGx studies. We aim to explore this issue further by investigating haplotype blocks (HB) of different ancestries in the distribution of pharmacogenomics variants in an admixed population. **Materials and Methods**: Data were collected from 1,349 admixed individuals from two Brazilian population cohorts (BRA): The Brazilian Initiative on Precision Medicine (www.bipmed.org) and the Health, Well-Being, and Aging Project (abraom.ib.usp.br). We compared these with 95 Brazilian Native-American individuals and 1,525 samples from the 1KGP database representing different ancestral origins. Data analysis included: (i) local ancestry inference using RFMix2; (ii) identification of PGx variants based on the PharmaGKB database; and (iii) exploration of the relationship between PGx variants and local ancestry in the BRA samples. **Results**: Global ancestry shows that BRA was predominantly of European ancestry, with 75% of samples having HBs with >=70% European ancestry, followed by African ancestry at 3%. None of the samples had HBs with >=40% Native American ancestry. A total of 458 PharmaGKB SNPs with an allele frequency (AF) >5% were identified in BRA. Among these, 10 SNPs were exclusively associated with European HBs, mainly related to drug efficacy. More than 81% of the PharmaGKB SNPs were found in both European and African haplotype blocks, with many of them associated with drug efficacy in phenotypes such as schizophrenia and hepatitis C and toxicity related to weight gain. Interestingly, we found PharmaGKB SNPs with AF<=5% exclusively present in the African HBs, although we observed only 3% of global African ancestry in BRA samples. In addition, we observed that while less than 9.8% of the SNPs were found in individuals with both European and Native American haplotype blocks in the same *locus* (EUR-NAT_HB), 23% of these SNPs were associated with drug efficacy in hypertension-related medications. **Conclusion**: Our findings indicate that local ancestry in admixed individuals may be linked to different patterns of PharmaGKB SNPs, raising important questions regarding the application of pharmacogenomics in individuals displaying different proportions of ancestral HBs.

Session Title: Pharmacogenomics Poster Session III

PB2152 Feasibility and utility of multi-gene, pharmacogenetic testing among patients in primary care, community-based hospital setting.

Authors:

S. Patel[1], J. Allen[2], J. Grund[2], G. Miller[2], C. Brueckner[2], A. Crider[2], J. Wallace[2], B. Phillips[2], T. Koepp[3], J. England[3], A. Desai-Naik[4], J. Chiang[4], B. Wendt[2], N. El Rouby[1]; [1]Univ. of Cincinnati, Cincinnati, OH, [2]St. Elizabeth, Edgewood, KY, [3]OneOme, Minneapolis, MN, [4]Humana, Louisville, KY

Pharmacogenetic-guided prescribing is a key component of precision medicine. Multi-gene panel testing is especially beneficial for patients who are on medications that are likely impacted by multiple Pharmacogenes. However, the data on the feasibility and utility of pharmacogenetic testing across community-based Healthcare systems are fewer compared to data from large academic hospitals.

We sought to determine the value of a multi-gene panel, pharmacogenetic testing by identifying the prevalence of drugs with pharmacogenetic evidence, and genotype-drug interaction among patients from primary care at St Elizabeth Healthcare system. We focused on primary care for two reasons: 1) this is a common setting for prescribing chronic medications with pharmacogenetics evidence; 2) patients often have co-morbidities, requiring polypharmacy.

We identified 6000 patients as candidates for pharmacogenetic testing based on recent pharmacogenetic prescription(s) from insurance claims data. Patients were contacted using letters from their payer system and Epic generated messages from St. Elizabeth. A total of 1043 patients were tested using a 27-gene, pharmacogenetic panel that captures *CYP2C19*, *CYP2D6*, *CYP2C9*, *CYP3A5*, *SLCO1B1*, *VKORC1*, *DPYD*, *UGT1A1*, *TPMT*, *NUDT15*, among others. Genotypes were collected and current pharmacogenetic medications were recorded from the electronic health records. We calculated the number and percentage of patients with 1) one or more pharmacogenetic medications at the time of testing; 2) one or more genotype-drug interactions.

Among patients with returned results, 86% have one or more pharmacogenetic medications, at the time of testing. The most commonly prescribed drugs or drug classes were statins, proton pump inhibitors (PPIs), metoprolol, Selective Serotonin Reuptake Inhibitors (SSRIs), and Non-Steroidal Anti-inflammatory Drugs (NSAIDs), representing 58%, 40%, 22%, 15%, and 13% of patients with these pharmacogenetic medications, respectively, whose responses would be influenced by variants in *SLCO1B1* (statins), *CYP2D6* (metoprolol), *CYP2C19* (SSRIs, PPIs), and *CYP2C9* (NSAIDs). Among patients with genotype-drug interactions, 31.3% had one gene-drug interactions, 19.5% had two gene-drug interactions, and 9.5% had three or more gene-drug interactions, with 60.1% of the patients having one or more gene-drug interactions.

In conclusion, the data demonstrate a high prevalence of genotype-drug interactions among primary care patients, justifying a multi-gene, panel-based, pharmacogenetic testing approach. Further research is needed to demonstrate the economic value of panel-based testing.

Session Title: Pharmacogenomics Poster Session I

PB2153 † Further Personalizing Medicine: Is There a Role for Comprehensive Genomic Evaluations for Hematopoietic Cell Transplantation Recipients?

Authors:

M. Similuk[1], J. Yan[1], T. Sissung[2], E. Damskey[1], B. Beers[1], H. Orellana[1], S. Byers[1], M. Kamen[1], C. Jodarski[1], R. Gore[1], N. Reynolds-Lallement[1], K. Lewis[1], R. Ghosh[1], B. Seifert[1], D. Dimitrova[3], J. Kanakry[3], D. Hickstein[4], T. Hughes[5], G. Uzel[1], C. Zerbe[1], H. C. Su[1], A. Freeman[1], S. De Ravin[1], H. Malech[1], L. Notarangelo[1], S. M. Holland[1], M. Walkiewicz[1]; [1]Div. of Intramural Res., Natl. Inst. of Allergy and Infectious Diseases, NIH, Bethesda, MD, [2]Genitourinary Malignancies Branch, Ctr. for Cancer Res., Natl. Cancer Inst., NIH, Bethesda, MD, [3]Ctr. for Immuno-Oncology, Natl. Cancer Inst., NIH, Bethesda, MD, [4]Immune Deficiency Cellular Therapy Program, Natl. Cancer Inst., NIH, Bethesda, MD, [5]Clinical Ctr. Pharmacy Dept., NIH, Bethesda, MD

Background: Allogeneic hematopoietic cell transplantation (HCT) provides patients with severe immune disorders the potential for effective long-term management. Improved methods are increasing the chance, duration, & quality of survival. Focused genetic testing for the underlying defect is common and informs risk assessment, conditioning, donor selection, & graft-versus-host prophylaxis. Concurrently, the accessibility of broad genetic testing is improving, as are the approaches for complex loci such as those for pharmacogenomics (PGx). More comprehensive genomic evaluations for HCT have uncertain clinical utility. We seek to address this gap through a review of HCT patients referred to our center.
Methods: We performed exome and/or genome sequencing on patients with immune disorders from 2017-2023. We analyzed the data for primary & secondary findings (SF). *Post-hoc*, we analyzed NGS-derived PGx alleles & medication history.
Results: We analyzed exome (n=144) and/or genome (n=124) data for 210 patients (202 families) who received, or had been evaluated for, HCT (85.7% & 14.3%, respectively). Participants were 41.9% female, mean age 26.8y, & 36.2% had non-European genomic ancestry. Overall, 153/210 (72.9%) patients had an identified molecular diagnosis underlying their HCT indication, most commonly with defects in *GATA2* (n=57) & *CYBB* (n=31), reflecting our center's expertise. Additionally, 10/210 (4.8%) patients had SF related to cancer (n=6: *BRCA1*, 2; *RET*, 1; *PMS2*, *MLH1*, *MSH2*, 1 each), cardiovascular disease (n=2: *TTR*, *KCNQ1*), or malignant hyperthermia (n=2: *RYR1*) conferring risks that may be exacerbated by HCT's genotoxic stress or use of succinylcholine. Among the 4 HCT recipients with cancer syndromes, no malignancies have occurred with cumulative follow up of 6.1y (2d-3.5y). Lastly, PGx analysis of *CYP2C19*, *CYP2D6*, *CYP3A5*, *NUDT15*, & *TMPT* identified ≥1 actionable allele(s) in 124/210 (59.0%) patients. Among those with at-risk genotypes, 109/124 patients (87.9%; or 109/210, 51.9% of total) were given ≥1 medication(s) that may have benefited from PGx-informed personalization including tacrolimus, azathioprine, ondansetron, opioids, SSRIs, tricyclic antidepressants, voriconazole, & proton pump inhibitors.
Conclusions: Comprehensive genomic evaluations for HCT are increasingly accessible & may be an emerging avenue for optimizing HCT approaches & outcomes. Specifically, identifying cancer or cardiovascular predisposition in a critical minority of patients may inform conditioning & post-HCT risk assessment/management. Prospective PGx may also be informative, particularly given HCT's inherent polypharmacy.

Session Title: Pharmacogenomics Poster Session II

PB2154 Genetic Diversity of variants involved in drug response among Tunisian and Italian populations: implication for personalized medcine

Authors:

H. JMEL[1,2,3], S. Sarno[4], C. Guilani[4], W. Boukhalfa,[1], S. Abdelhak[1,2], D. Luiselli[5], R. KEFI[1,2,3]; [1]Lab. of BioMed. Genomics and Oncogenetics, Inst. Pasteur de Tunis, Tunis, Tunisia, Tunis, Tunisia, [2]Univ. of Tunis El Manar, 2092 El Manar I Tunis, Tunisia, Tunis, Tunisia, [3]Genetic typing service, Inst. Pasteur de Tunis, BP 74, 13 Place Pasteur, Tunis 1002, Tunis, Tunisia, Tunis, Tunisia, [4]Lab. of Molecular Anthropology & Ctr. for Genome Biology, Dept. of Biological, Geological and Environmental Sci. (BiGeA), Univ. of Bologna, Bologna, Italy., Italy, Italy, [5]Lab. of Ancient DNA (aDNALab), Dept. of Cultural Heritage (DBC), Univ. of Bologna, Ravenna, Italy, Italy, Italy

Adverse drug reactions are a cause of significant morbidity and mortality to patients and a source of financial burden to the healthcare system. Several studies highlighted that ethnicity is one of the main factors influencing individual genetic patterns in drug response. The aim of the study is to characterize the genetic variability of some pharmacogenes invoved in drug biotransformation and ADR in Tunisian (ADR), Italian population and to compare our results to the worldwide populations. A set of 135 healthy Tunisians and 690 Italians were genotyped using array chip. Variants located in 25 Very Important Pharmacogenes involved in drug response variability and ADR were extracted from the genotyping data. Analysis of variant distribution in Tunisian and Italian populations compared to 24 worldwide populations publicly available was performed using plink and R software. Common variants between Tunisians, Italian and the 24 investigated populations were extracted from genotyping data. Results of fixation index (Fst), Principle Component Analysis and ADMIXTURE analyses showed that there is high similarity among Mediterranean populations which are genetically divergent from South African populations. Moreover, the Fst comparaive analysis highlighted 27 variants with high level of differentiation between the Tunisian, Italian and other studied populations. Among these variants, there are four SNPs rs622342, rs3846662, rs7294, rs5215 located respectively in S*LC22A1*, *HMGCR*, *VKORC1*, *KCNJ11*, involved in ADR showed genotypic frequency differences. In conclusion, our study showed that Tunisian and Italian population are genetically homogenous regarding the studied pharmacogenes. The Correlation of the genotype and allelic frequencies of risk variants with their associated adverse drug reactions would enhance the drug outcomes and have an important impact in the implementation of personalized medicine in worldwide populations. Similar studies need to be reproduced to identify populations that require attention when taking a particular drug.

Session Title: Pharmacogenomics Poster Session III

PB2155 Genetic prediction of medication side effects: a genome-wide investigation of abnormal dreams on varenicline.

Authors:

M. Chenoweth[1,2], Y. Kim[2], N. Nollen[3], C. Lerman[4], J. Knight[5], R. Tyndale[2,1]; [1]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Univ. of Kansas Sch. of Med., Kansas City, KS, [4]Univ. of Southern California, Los Angeles, CA, [5]Lancaster Univ., Bailrigg, United Kingdom

Introduction: Varenicline, the most efficacious smoking cessation aid, produces sleep disturbances including abnormal dreams. While genetic contributors to varenicline-associated nausea and cessation have been identified, the role of genetics in varenicline-associated abnormal dreams is unknown. **Methods:** We conducted a GWAS of abnormal dreams in n=188 European ancestry (EA) participants treated with varenicline for smoking cessation (NCT01314001). Additive genetic models examined the likelihood of experiencing abnormal dreams two weeks following varenicline initiation, controlling for population substructure, sex, and age. We also examined associations between the top variant and abnormal dreams in EA participants treated with nicotine patch (n=181) and placebo (n=168) and tested for replication in a second varenicline trial (NCT01836276). Finally, we tested for an association between the top variant and abnormal dreams in n=137 varenicline-treated participants of African ancestry (AA) (NCT01314001). **Results:** Thirty-eight percent of varenicline-treated EA participants experienced abnormal dreams. The top variant associated with abnormal dreams was rs901886 (Odds ratio (OR)=2.94 for T vs. C, 95% CI=1.92-4.55, P=2.03e-7; T allele frequency=52%), mapping to intron 2 of *ICAM5* on chromosome 19. The prevalence of abnormal dreams in those with rs901886 TT, TC, and CC genotypes was 62%, 36%, and 15%, respectively. Conversely, there was no association between rs901886 and abnormal dreams on nicotine patch (P=0.519) or placebo (P=0.909). In the second trial of varenicline-treated EA participants (n=184), a similar direction of effect of rs901886 on abnormal dreams was observed: the prevalence of abnormal dreams was 39.2%, 29.2%, and 27.3% for those with rs901886 TT, TC, and CC genotypes, respectively (P=0.203). In contrast to EA, rs901886 was not associated with abnormal dreams in varenicline-treated AA participants (OR=0.74 for T vs. C allele, 95% CI=0.32-1.69; P=0.407; T allele frequency=88%). However, there was some support for a region located ~74.4kb 5' of *ICAM5* in AA (top variant: rs113359011: OR=0.41 for T vs. C allele, 95% CI=0.20-0.84, P=0.00256; T allele frequency=29%). **Conclusions:** Genetic variation in *ICAM5* influences the risk for experiencing abnormal dreams on varenicline. This work improves our understanding of individual differences in smoking cessation medication response.

Session Title: Pharmacogenomics Poster Session I

PB2156 Genetic risk of immune related adverse events in melanoma patients receiving ipilimumab.

Authors:

J. Pluta[1], P. Kanetsky[2], C. Horak[3], K. Nathanson[4]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Moffitt Cancer Ctr., Tampa, FL, [3]Bristol Myers Squibb, Princeton, NJ, [4]Univ. of Pennsylvania Sch. of Med., Philadelphia, PA

Background: A side effect of ipilimumab, an immune checkpoint inhibitor targeting CTLA-4, is increased risk of serious immune related adverse events (irAE). We performed a genome-wide association study (GWAS) on patients with melanoma treated with ipilimumab monotherapy to explore inherited genetic variation associated with the development of irAE. We also examined the impact of prior treatment, i.e., surgery, chemotherapy, and/or radiotherapy, on genetic risk of irAEs. **Methods:** Genotype data and clinical information were obtained on 706 patients with metastatic melanoma enrolled on CA184-169 (NCT01515189) and treated with ipilimumab monotherapy. Trial participants were genotyped on the Affymetrix 6 array. After removing individuals failing genetic quality control and those with missing clinical data, a total of 668 patients were analyzed. SNP associations were assessed by additive logistic regression models using irAE grade 3 or greater (yes, no; n=167) as the dependent variable and SNP genotype as the independent variable; all models were adjusted for ECOG status (0, 1+), dosage (3, 10 mg/kg), number of doses (<4, 4, 4+), genetic ancestry (3 principle components), and an interaction term between SNP and any prior cancer treatment (yes, no; n= 374). The proportion of patients experiencing an irAE was similar between those with and without prior treatment ($p = 0.37$). A likelihood-ratio test was used to jointly test for an association attributable to the SNP main effect or the interaction between the SNP and prior treatment; and we used a relaxed p-value threshold of 1×10^{-5} due to the limited sample size. **Results:** The most significant marker (rs1030480; $p = 1.42 \times 10^{-7}$) is intergenic between *CDH9* and *CDH10.* Five markers mapped to genes with known or suspected roles in autoimmune disease: *NELL1* (rs7947369, $p = 4.2 \times 10^{-6}$), *MRGBP* (rs33992134, $p = 8.03 \times 10^{-6}$), *RBMS3* (rs9844665, $p = 5.34 \times 10^{-6}$), *CACNA1B*(rs7021325, $p = 3.07 \times 10^{-6}$), and ZNF479 (rs3887628, 2.54×10^{-6}). Two markers, rs1111665 ($p = 8.24 \times 10^{-6}$) and rs1857772 ($p = 4.24 \times 10^{-6}$), map to the super-enhancer regions of *FGL2* and *SEMA5A*, respectively, both of which are involved in autoimmune processes. Of the 14 associated markers, 13 statistically interacted ($p < 0.05$) with prior treatment. **Conclusions**: We found broad involvement of autoimmune markers with the development of irAE, consistent with other studies. Our results indicate prior treatment for cancer may alter genetic susceptibility to irAE. Replication of results across studies remains a challenge, likely due to limited sample sizes and heterogeneity of subjects.

Session Title: Pharmacogenomics Poster Session II

PB2157 Genetic Variants Associated with Iloperidone Response in Acute and Mixed Mania Associated with Bipolar I Disorder.

Authors:

H. Bai, S. P. Smieszek, R. Torres, C. Xiao, C. M. Polymeropoulos, G. Birznieks, M. H. Polymeropoulos; Vanda Pharmaceuticals Inc., Washington, DC

Bipolar I disorder is characterized by episodes of manic and hypomanic activity, and it has one of the highest rates of serious impairment among mood disorders. Iloperidone is a second-generation antipsychotic approved by the FDA that has anti-manic effects. Here we report genetic associations on iloperidone efficacy for treatment of bipolar manic episodes from a phase 3, randomized, placebo-controlled study. Whole genome sequencing was conducted with 30× read depth using whole blood samples obtained from the study subjects. The efficacy of iloperidone was evaluated using the Young Mania Rating Scale (YMRS) -calculated as the change in YMRS measurement from baseline to the end of study (EOS). First, we found the omega3 total levels are associated with decreased YMRS at baseline (b=-5.34±1.91, p=0.006), which is concordant with previous findings and indicates the validity of the data. In order to investigate the genetic factors that impacts the iloperidone efficacy, we then conducted GWAS in the Iloperidone group (n=167) using linear regression on YMRS change with adjustment of AGE, SEX, BMI and the first 2 PCs. Multiple variants were found to be associated with YMRS change at 1e-5 level. One of the top hits was RELN (rs55837573, b=-4.61±0.94, p=2.48e-6). RELN encodes a secretory glycoprotein critical for brain development and synaptic plasticity. Lower Reelin protein levels were reported in bipolar disorder patient brains. NAV2 (rs1118464, b=-4.15±0.89, p=6.98e-6) is a neuron navigator gene and may play a role in cell growth and migration. FAT3 (rs76876307, b=15.44±3.28, p=5.27e-6) is an atypical cadherin that is predicted to be involved in cell-cell adhesion and act upstream of dendrite development and neuron migration. SHROOM3 (rs62300864, b=12.08±2.43, p=1.64e-6) may play a role in regulating cell shapes. These variants are not associated with YMRS at baseline, which suggests potential drug mechanisms. We then defined the drug responders as subjects that having EOS YMRS decreased >=50% compared to baseline. GWAS with logistic regression were conducted, and the association of RELN (rs55837573) was robustly detected in this analysis. Over representation analysis in disease gene sets showed bipolar I disorder was the strongest result (p=1.12e-5, FDR=0.044). This was driven by the contribution of variants within BCL2, EGR4, and GADL1. In summary, we report genetic factors associated with the efficacy of iloperidone in treating bipolar manic episodes. This result suggests that the treatment with iloperidone potentially leads to improvement as captured by YMRS through acting on the identified gene pathways, setting a foundation for further investigation.

Session Title: Pharmacogenomics Poster Session III

PB2158 Genetic Variants in *GC* and *CYP24A1* are associated with Bleeding complications for Atrial Fibrillation Patients treated with Direct Oral Anticoagulants.

Authors:

D. Lee[1], Y-A. Park[1], J. Kim[1], J. Park[2], H. Gwak[1]; [1]Ewha Womans Univ., Seoul, Korea, Republic of, [2]Dept. of Cardiology, Mokdong Hosp., Ewha Womans Univ. Coll. of Med., Seoul, Korea, Republic of

The aim of this study was to investigate vitamin D-related genetic factors that are associated with bleeding complications in atrial fibrillation patients taking direct oral anticoagulants (DOACs). This study was a retrospective analysis of prospectively collected samples from June 2018 to May 2022. In order to examine the associations between vitamin D-related genetic factors and bleedings, we selected 12 single nucleotide polymorphisms (SNPs) from five specific genes: *CYP24A1* (rs1570669, rs2296241, rs6068016), *CYP27B1* (rs4646537), *CYP2R1* (rs1993116), *VDR* (rs11568820, rs2228570, rs731236, rs7975232), and *GC* (rs4588, rs7041). Multivariable logistic regression analysis was utilized to identify independent risk factors for bleeding complications. A total of 516 patients were included in the analysis, and 109 experienced bleeding complications. Both severe renal impairment (CrCl < 30 mL/min) and concurrent use of proton pump inhibitors increased the risk of bleedings (adjusted odds ratio (AOR): 2.54; 95% confidence interval (CI): 1.05-6.13, AOR: 1.82; 95% CI: 1.01-3.27, respectively). Among the vitamin D-related genetic variations, patients carrying the TT genotype of rs4588 and the CC genotype of rs6068816 exhibited 2.32- (95% CI: 1.06-5.05) and 1.59-fold (95% CI: 1.01-2.50) higher risk of bleedings. This is the first study to suggest vitamin D-related genetic markers, including both clinical and genetic factors, for bleeding complications in patients with atrial fibrillation receiving DOAC treatment. These findings would be useful for personalized DOAC therapy.

Session Title: Pharmacogenomics Poster Session I

PB2159 Genome-wide association studies categorized by class of anti-hypertensive drugs reveal complex pathogenesis of hypertension with drug resistance.

Authors:

K. Yamazaki[1,2,3], C. Terao[4], A. Takahashi[5], Y. Kamatani[6,3], K. Matsuda[7], S. Asai[2], Y. Takahashi[2]; [1]Chiba Univ., Chiba, Japan, [2]Nihon Univ. Sch. of Med., Tokyo, Japan, [3]RIKEN Ctr. for Integrative Med. Sci., Yokohama, Japan, [4]RIKEN IMS, Yokohama, Japan, [5]RIKEN, Yokohama, Japan, [6]The Univ. of Tokyo, Minato-ku, Japan, [7]The Univ. of Tokyo, Tokyo, Japan

Resistant hypertension is defined as uncontrolled blood pressure despite the use of three or more anti-hypertensive drugs of different classes. Though genetic factors may greatly contribute to hypertension with resistance to multiple drug classes, more than for general hypertension, its pathogenesis remains unknown. To reveal the genetic background of resistant hypertension, we categorized 32,239 patients whose data were obtained from the BioBank Japan Project, by prescription of seven classes of anti-hypertensive drugs and performed genome-wide association studies. Our genome-wide association studies identified four loci with significant association ($P < 5\times10^{-8}$): rs6445583 in *CACNA1D* ($P = 4.99\times10^{-8}$, odds ratio (OR) (95% confidence interval (CI)) = 1.13 (1.08-1.18)) and rs12308051 in the intergenic region on chromosome 12 ($P = 1.34\times10^{-8}$, OR (95% CI) = 1.15 (1.09-1.20)) for ARBs, rs35497065 in *FOXA3* ($P = 2.28\times10^{-8}$, OR (95% CI) = 0.89 (0.86-0.93)), for CCBs, and rs11066280 in *HECTD4* ($P = 2.71\times10^{-8}$, OR (95% CI) = 0.76 (0.67-0.85)) for αβ-blockers. Since these loci are known to be susceptibility loci for hypertension and/or blood pressure, our results indicate that resistant hypertension is caused by a combination of excessive blood pressure and drug resistance to each anti-hypertensive pharmacological class. Furthermore, to investigate the genetic difference between BP traits and the treatment effectiveness of anti-hypertensive drugs, we performed gene-set analysis and calculated the genetic correlation continuously with GWAS summary statistics of blood pressure from BioBank Japan. Most of the genetic factors were in common between BP traits and anti-hypertensive effectiveness, but it seems that the genetic architecture of the drug response to anti-hypertensive treatment is more complicated than BP traits. This corresponds to the well-known mosaic theory of hypertension. Our findings reveal the complex pathogenesis of hypertension with resistance to multiple classes of anti-hypertensive drugs.

Session Title: Pharmacogenomics Poster Session II

PB2160 Global pharmacogenetics: An analysis of the 1000 Genomes Project.

Authors:

C. Sherman[1], K. Claw[1], S-b. Lee[2]; [1]Univ. of Colorado, Aurora, CO, [2]Macrogen Inc, Seoul, Korea, Republic of

Pharmacogenetics (PGx) examines how individual genetic variations impact drug responses and has the potential to optimize medication dosage, selection, and efficacy. While there have been significant advances in our knowledge of PGx and drug-gene interactions, population-level PGx variation is still not well characterized, which could exacerbate health disparities. Previous studies have primarily focused on populations of European descent, and to ensure equitable implementation of PGx findings, it is crucial to enhance the inclusion of historically underrepresented groups. The goal of this study was to uniformly characterize population-level star alleles (haplotype pattern) and phenotype frequencies for 58 pharmacogenes within the 1000 Genomes Project (N=2,504; 26 global populations) using high-coverage whole-genome sequencing data and incorporating structural variant (SV) analyses. These pharmacogenes involve genes that have a role in drug absorption, distribution, metabolism, and excretion. PyPGx identifies star alleles from sequencing data by detecting single nucleotide variants (SNVs), insertion-deletion variants, and SVs. With previous sequencing methods, SVs in drug metabolizing enzymes have been difficult to detect and interpret in part due to high sequence homology, especially among functional genes and nonfunctional pseudogenes. PyPGx uses a machine learning-based approach with the WGS to detect SVs, including gene deletions, duplications, and hybrids. We found that while many of our star allele and phenotype frequencies were consistent with the literature, our approach was able to detect several population-specific frequencies that had at least a 2-fold difference. This suggests that previous works may have mischaracterized or inaccurately measured these frequencies. We validated known SVs and identified several novel SVs that are not present in public PGx databases. Using in-silico tools, we also identified 210 SNVs and insertion-deletion variants with severe functional consequences, 8 of these variants have been previously identified as pathogenic, likely pathogenic, or drug-responsive. Our findings provide a valuable reference resource that can be used to improve clinical care across diverse populations.

Session Title: Pharmacogenomics Poster Session III

PB2161 Human genetics of COVID-19 mRNA vaccination efficacy.

Authors:

A. Bolze[1], C. M. Clinton[1], A. Mackie[1], C-H. Chan[2], J. Grzymski[3], D. T. Harris[4], P. A. Pawloski[5], E. Cirulli[1]; [1]Helix, San Mateo, CA, [2]Sanford Res., Sioux Falls, SD, [3]Desert Res. Inst., Reno, NV, [4]The Univ. of Arizona, Tucson, AZ, [5]Hlth.Partners, Minneapolis, MN

Introduction: COVID-19 mRNA vaccines are safe and effective. Real-world data estimate that they have saved millions of lives. However, some fully vaccinated individuals have experienced SARS-CoV-2 infections with severe symptoms, prompting additional medical care and even resulting in hospitalizations. There are few studies on the genetics of vaccine failure, when people acquire severe infectious disease despite being vaccinated against it. As a result, the genetic and immunological basis of vaccine-induced protection against infections and severe disease is not well understood.
Objective: The goal of this work is to identify human genetic variants, which may be associated with (i) COVID-19 severity in fully vaccinated individuals, and (ii) the rate of declining immunity in fully vaccinated individuals.
Methods: Adults aged 18 to 75 years old living in the United States and who received at least two doses of COVID-19 mRNA vaccines were included. Cases had documented symptomatic infection while controls had no record of symptomatic COVID-19 since vaccination. Three types of human genetic analyses will be conducted: a GWAS, an HLA-WAS and rare variant gene-based collapsing tests. In addition to genome-wide discoveries, we will also test several hypotheses including whether the known genetic associations (n=49) with severe COVID-19 in the unvaccinated are also associated with severe COVID-19 disease despite vaccination.
Results: In the project's first six months, we established the research protocol and collaborations with four health systems. At least 2,000 cases have been identified and are being sequenced. The analysis will be completed in September 2023, and the results will be presented.
Conclusion: The results of this study may provide insights that could inform public health decisions regarding vaccine administration including potentially refining the definition of at-risk populations, and the timing of booster schedules.

Session Title: Pharmacogenomics Poster Session I

PB2162 Identification of African-specific*NOS3*variants associated with direct oral anticoagulant response.

Authors:

G. Yang[1], C. Parker[1], T. Priya[1], C. Alarcon[1], P. Friedman[1], E. Nutescu[2], M. Tuck[3], T. O'Brien[4], L. Gong[5], T. Klein[5], D. Meltzer[6], M. Perera[1]; [1]Northwestern Univ., Chicago, IL, [2]Univ. of Illinois Chicago, Chicago, IL, [3]Washington DC VA Med. Ctr. and The George Washington Univ., Washington, DC, [4]The George Washington Univ., Washington, DC, [5]Stanford Univ, Stanford, CA, [6]Univ. of Chicago, Chicago, IL

BACKGROUND: Direct oral anticoagulants (DOACs) are widely used for thromboembolism prevention and treatment by directly inhibiting factor Xa, a key clotting factor involved in the formation of thrombin. Clinical trials and adverse event reports suggest variability among individuals in response to DOACs. Unravelling the genetic factors influencing DOAC response is important for better clinical management. We aimed to identify pharmacogenomic biomarkers specifically related to DOAC response in African American patients, a population that suffers disproportionally from thromboembolism.**METHODS:** Samples were obtained from self-identified African American patients who had received treatment with DOACs for a minimum of 3 days. Anti-Xa levels, a key indicator of DOAC response, were collected for these patients. A genome-wide association study (GWAS) was performed to identify variants associated with alterations in anti-Xa levels, while adjusting for age, gender, and principal components. *In silico* analysis was conducted to identify potential functional variants. Nitric Oxide (NO) assays were performed to investigate the impact of these potential functional variants on NO production (surrogate marker of eNOS activity) in the plasma of African American subjects carrying the associated *NOS3* haplotype.**Results:** Our GWAS identified one locus on chromosome 7 associated with a decreased anti-Xa level. The top association, rs114982053, is located upstream of Nitric Oxide Synthase 3 **(***NOS3* - encoding eNOS) ($p=9.29x10^{-7}$,β=-0.68, 95% confidence interval=-0.95--0.42). *In silico* analyses showed three SNPs with high LD located at the potential enhancer/promoter region of *NOS3* gene. The plasma NO assay showed an increase in nitrite concentration in subjects carrying the effect alleles compared with the subjects with the reference haplotype (p=0.003).**Conclusion:** Our data suggests that a 3 SNP haplotype, located on chromosome 7 contributes to increasing NO production, resulting from the elevated *NOS3* expression and eNOS activity and decrease DOAC drug concetrations. Notably, this haplotype is African-specific. Given the pivotal role of *NOS3* in regulating vascular function and thrombosis, our results suggest a potential role of this enzyme in modulating response to DOACs and thrombosis risk. Further investigations into the precise mechanisms underlying this association may provide valuable insights for personalized treatment strategies in individuals at risk of thromboembolic events.

Sch. of Med., Shanghai, China, [13]Jingzhou Mental Hlth.Ctr., Jingzhou, China, [14]The Broad Inst. of MIT and Harvard, Boston, MA

Schizophrenia is a debilitating mental disorder that affects approximately 1% of the global population. Despite the availability of various antipsychotic medications, a significant number of patients experience inadequate response, leading to substantial suffering and economic burden. The emergence of personalized medicine offers a promising approach to address this issue by tailoring treatments based on individual genetic profiles. Thus, this study aimed to discover novel genetic variants that could serve as biomarkers for predicting the response to antipsychotic drugs in Han Chinese patients with schizophrenia. A two-stage genome-wide association study (GWAS) was conducted on a total of 3069 patients who received mono-antipsychotic therapy for a minimum of 8 weeks, including olanzapine, risperidone, quetiapine, aripiprazole, and/or amisulpride. The categorization of antipsychotic drug response groups was performed using the Positive and Negative Syndrome Scale (PANSS). Binary logistic regression identified significant single nucleotide polymorphisms (SNPs) distinguishing high responders (≥60% PANSS reduction) from low responders (≤40% PANSS reduction) for these five drugs. The GWAS analysis successfully revealed three novel genetic loci within brain-related genes and identified several previously associated SNPs related to antipsychotic drug response. Moreover, we used ordinal logistic regression to examine the SNPs associated with three drug response categories (high responders, medium responders, and non-responders) in the entire cohort. Medium responders were defined as individuals with PANSS reduction between 40% and 60%. This approach identified two novel loci that were significantly associated with antipsychotic drug response. Furthermore, a Gene Ontology (GO) enrichment analysis demonstrated that the identified genetic loci were significantly enriched in neuronal signaling pathways within the brain. Additionally, a novel five-drug scoring system was developed, incorporating both newly discovered and previously identified SNPs from the GWAS. This scoring system utilized a polygenic risk score (PRS) and exhibited relatively high prediction accuracy in both the discovery and replicate cohorts. It will enabled clinicians to predict drug response and make informed decisions regarding optimal treatment selection. The findings of this study, along with the developed drug scoring method, will contribute to a deeper understanding of the underlying mechanisms of antipsychotic drug response and the advancement of personalized treatment strategies for individual patients with schizophrenia.

Session Title: Pharmacogenomics Poster Session III

PB2164 Identification of sex-related pharmacogenetic predictors of warfarin-related hemorrhage.

Authors:

B. Davis, C. Dillon, N. Limdi; Univ. of Alabama at Birmingham, Birmingham, AL

Anticoagulants are used for prophylaxis and treatment of thromboembolism. Hemorrhage is a major adverse effect of therapy and is the target of a national action plan to prevent adverse drug reactions (ADRs). Although warfarin use has declined since the introduction of newer agents, it remains among the top prescribed drugs (#58). Warfarin exhibits female-biased bleeding ADRs, but sex-related genetic predictors of warfarin-related hemorrhage (WRH) have not been evaluated. Given sex-related differences in gene expression, genetic variant effects, and drug pharmacokinetics, we evaluated sex-related genetic predictors of WRH among African Americans (AA) and European Americans (EA).

Warfarin users (N=1,786; 48% female; 47% AA) were enrolled at UAB and followed for 2 years. Demographic and clinical data were collected at baseline and changes documented during follow-up. Samples were genotyped and imputed to the Trans-Omics for Precision Medicine (TOPMed) reference panel. Variants in ~1,200 drug-related genes were obtained from the imputed data. The influence of genetic variants on WRH were analyzed using logistic regression, stratified by sex and ancestry. We also evaluated only females >55 years old to identify differences related to hormonal variation. Among EA women, NEGR1 rs12130762, encoding a neuronal cell adhesion molecule, was associated with ~4-fold higher odds of WRH (p=9.31x10-7). Among AA women, PLCB1 rs6055904, encoding a phospholipase involved in endothelial barrier regulation, was associated with 3-fold higher WRH odds (p=3.51x10-7). These associations remained when limited to women >55 years. Additionally, UGT2B4 rs1051752 (African-specific), encoding an enzyme involved in estrogen glucuronidation, was associated with 5-fold higher odds of WRH in this age group (p=5.88x10-6). LAIR2 rs35821889, encoding a collagen receptor inhibiting collagen-induced platelet aggregation, was associated with 4-fold higher odds of WRH (p=8.36x10-6) among AA men. MOV10L1 rs138244, which influences expression of PANX2, a structural component of gap junctions, was associated with 2-fold higher odds of WRH among EA men (OR 2.37; p=8.98x10-6).

We identified age, ancestry, and sex-specific variants associated with WRH, demonstrating the importance of conducting stratified analyses. Additionally, a comprehensive evaluation of drug-related genes not commonly included in candidate gene studies, implicated pathways involved in cell adhesion, endothelial barrier integrity, and platelet aggregation that contribute to WRH. This offers insight into underlying biological processes/pathways that contribute to altered drug response.

Session Title: Pharmacogenomics Poster Session I

PB2165 iGenoMed-MTT: A prospective multi'omic study of response to molecularly targeted therapies in IBD.

Authors:

G. Boucher[1], J. Thompson Legault[1], V. Mercier[1], R. Battat[2,3], A. Bitton[4,5], J. Rioux[1,3]; [1]Montreal Heart Inst., Montreal, QC, Canada, [2]Ctr. Hosp.ier de l'Université de Montréal, Montreal, QC, Canada, [3]Université de Montréal, Montreal, QC, Canada, [4]McGill Univ. Hlth.Ctr., Montreal, QC, Canada, [5]McGill Univ., Montreal, QC, Canada

Inflammatory bowel diseases (IBD) result from chronic inflammation of the gastrointestinal tract. These are heterogenous, lifelong and debilitating conditions affecting over a million Americans. With several drugs now available to treat the disease, there is a need for physicians to identify which drug is more likely to be effective for a given patient, instead of the current trial and error approach. Over 200 genetic loci have been identified for IBD, implicated in many biological pathways. We hypothesize that measuring activity of these pathways in patients could provide information to link the underlying biology to response to therapy, with the objective to help physicians make informed decisions about treatment course. This prospective study focuses on the most recent class of molecularly targeted therapy (MTT), which can be highly effective, but also costly and potentially risky. By recruiting all patients before initiation of a new MTT, this real-life prospective approach has the potential to identify predictive biomarkers of response, and directly compare different therapies. We collected serum samples from 166 patients before initiation of treatment, and at 1st assessment visit (~16 weeks) for a subset (24) of these patients. Serum samples were analyzed for >100 protein biomarkers and >1500 lipid metabolites. Whole exome sequencing and GWAS data was generated for all participants.We found elevated levels of TNF at baseline in patients who reported prior use of anti-TNF, more than a month after anti-TNF cessation. Elevated levels of TNF were also found post treatment for patients under anti-TNF in the context of this study. Notably, these elevated levels didn't correlate with other cytokines. As an example, CXCL10, which was positively correlated with TNF levels in bio naive patients, was not found elevated in patients who reported prior use of anti-TNF. This suggests an accumulation of inactive (complexed) TNF during treatment. A similar pattern was observed for IL-12 and IL-12B after anti-IL12/IL23 treatment. Corticosteroids are often prescribed to control inflammation in IBD patients. We identified many cytokines to be associated with current use of corticosteroids. Further analyses of baseline proteomics identified promising proteomics biomarkers for prediction of remission after biologic treatment, some of which are treatment specific. This study provides promising insight into the biologic pathways implicated in response to therapy in IBD, worth investigating in larger cohorts. For this purpose, additional recruitment is ongoing in a multicentric effort, with a target of additional 600 patients.

Session Title: Pharmacogenomics Poster Session II

PB2166 Impact of global and local ancestry on pharmacogenetic analyses in African American multiple sclerosis patients

Authors:

W. Brugger, L. C. Silva, M. F. Davis; Brigham Young Univ., Provo, UT

Multiple sclerosis (MS) is a disease of the central nervous system and is treated with disease-modifying therapies such as interferon-β (IFN-β). Up to 60% of patients treated with IFN-β develop abnormal biochemical liver test results, and 1 in 50 experiences drug-induced liver injury (DILI). Single nucleotide polymorphism (SNP) rs2205986 has demonstrated a statistical association with DILI in patients of European ancestry (EP), though this association has not been explored in other patient populations. A differential risk for MS development, progression, comorbidity, and severity has been documented extensively among African American patients (AAP) compared to EP; poorer treatment responses have also been observed. We aim to evaluate the association of rs2205986 with IFN-β-induced liver injury in AAP in the context of both global and local genomic ancestry. We utilized de-identified electronic health records (EHRs) for 70 AAP from Vanderbilt University's BioVU database. We plan to expand our dataset with approximately 361 AAP whose genomic and EHR data are available through the All of Us Research Program. Patient genomes were genotyped on the Illumina MEGA^{EX} platform and imputed using the TOPMed imputation server. We estimated global ancestry via ADMIXTURE using CEU and YRI datasets from the 1000 Genomes Project as European and African controls, respectively. We estimated local ancestry values for all AAP via RFMix with the same reference genomes, highlighting regions that exhibit local ancestry differing substantially from the genome average. We will follow up on this preliminary work through 1) regression-based analyses to identify correlations between treatment response and ancestry peaks, and 2) fine-mapping analyses to identify novel or previously reported SNPs in these regions that may drive the associative signals to establish ancestry-driven discrepancies in MS treatment response. In the global ancestry analysis, we discovered that the majority of our samples had predominantly European ancestry. Local ancestry calculations highlighted multiple regions as possessing higher-than-average African genomic ancestry. A preliminary linear regression analysis revealed an association between rs2205986 and abnormal levels of alanine aminotransferase ($p = 0.02$). Our preliminary results support that AAP are susceptible to DILI resulting from IFN-β treatment, although differ from EP in whom rs2205986 was associated with abnormal levels of aspartate aminotransferase and alkaline phosphatase. Our results represent information that may be used to guide DMT treatment strategies for AAP and reduce unnecessary risks to improve patient outcomes.

Session Title: Pharmacogenomics Poster Session III

PB2167 Impaired lysosome by bafilomycin A1 induced TFEB pathway in colorectal cancer cells

Authors:

J-Y. Lee; Korea Univ, Seoul, Korea, Republic of

Lysosomes is an important cellular organelle which plays a key role in cellular homeostasis by controlling both cellular clearance and energy production to respond to environmental cues, which is dependent on lysosomal acidification. Inability to maintain lysosomal acidic pH is associated with lysosomal dysfunction as well as lysosome dependent cell death. Bafilomycin A1 (BaMA1), a vacuolar type H^+-ATPase (v-ATPase) inhibitor reducing lysosomal pH, applied to investigate its anticancer effect on colon cancer cells *in vitro* and *in vivo* zebrafish model in this study. The results showed colon cancer cells were sensitive to BaMA1, but not in normal colon fibroblast cell, CCD-18Co. Lysosomal dysregulation upon BaMA1 treatment in colon cancer cell was verified by the release of cathepsin B into the cytoplasm with enlarged lysosomes and massively increased acidic compartments, indicating impaired lysosomal membrane stability. To elucidate target gene(s) or pathway of BaMA1, RNA sequencing was performed, and activated TFEB pathway was identified. Activated TFBE further confirmed by nuclear translocation of TFBE after treatment of BaMA1. The TFEB, the master regulator of lysosomal biogenesis and autophagy through targeting the mTORC1 pathway. This regulation in turn increased gene expressions in the autophagy lysosome pathway and increased autophagosomal and lysosomal biogenesis. However, autophagy flux was blocked in our study, which further investigation of deeper mechanism is ongoing.

Session Title: Pharmacogenomics Poster Session I

PB2168 Improving *G6PD* variant interpretation through multiplexed functional assessment.

Authors:

R. Geck, M. Dunham; Univ. of Washington, Seattle, WA

Glucose-6-phosphate dehydrogenase (G6PD) deficiency affects over 500 million people. Individuals with G6PD deficiency are often asymptomatic but can experience hemolysis after infections or exposure to oxidants, including many drugs. However, diagnosis by activity-based assays give false negatives during hemolytic crises, and since *G6PD* is on the X chromosome, most heterozygotes have normal activity but must be identified to avoid triggers during pregnancy. Therefore, accurate interpretation of *G6PD* genetic testing is valuable for preventing adverse drug reactions.

Recent updates to *G6PD* variant classification systems and guidelines for medication use make now the optimal time to study *G6PD* variant function for maximal clinical actionability. Therefore, we sought to collect reports of *G6PD* variant function and to conduct a deep mutational scan (DMS) of *G6PD* to measure function of additional variants.

We previously published a collection of 1,341 *G6PD* variants from literature and databases, including 118 newly identified through All of Us. By applying ACMG guidelines for interpretation of sequence variants, we interpreted 186 VUS, bringing the total number of potentially actionable *G6PD* variants to 400. However, hundreds of variants remain of uncertain significance.

We are expanding these functional data by conducting a DMS of *G6PD*. We transformed *S. cerevisiae* lacking the *G6PD* homolog *ZWF1* with a library of all single missense *G6PD* variants. We are growing the yeast library under oxidative stress to select for G6PD activity, and deeply sequencing over time to calculate variant frequency. From this we can infer variant function by ability to rescue growth. We will benchmark our functional assay with variants of known clinical effect, compute evidence for levels of support, and incorporate this functional data into *G6PD* variant interpretations.

We are also introducing SNVs of common background haplotypes onto our variant library to conduct DMS on multiple genetic backgrounds. *G6PD* variants have historically been studied on a Caucasian background even though that does not represent the populations most affected by G6PD deficiency. We measured the function of select multiple missense variants in our yeast system and observed that the function is not always predicted from additive effects. Given this genetic complexity, our DMS on multiple backgrounds addresses an unmet need to systematically investigate the effects of common variants on rare G6PD variant activity. Altogether, our study will enable clinical interpretation of a larger number of *G6PD* alleles and ensure that these interpretations are applicable to the affected populations.

Session Title: Pharmacogenomics Poster Session II

PB2169 Inference and characterization of *CYP2D6* whole gene deletions from a SNP array in the Michigan Genomics Initiative Biobank.

Authors:

B. Vanderwerff[1], A. Pasternak[2,3], L. Fritsche[1], E. Bertucci-Richter[1], S. Patil[1,4], M. Boehnke[1], X. Zhou[1], S. Zollner[1,5], D. Hertz[2], M. Zawistowski[1]; [1]Dept. of Biostatistics and Ctr. for Statistical Genetics, Univ. of Michigan Sch. of Publ. Hlth., Ann Arbor, MI, [2]Dept. of Clinical Pharmacy, Univ. of Michigan Coll. of Pharmacy, Ann Arbor, MI, [3]Michigan Med., Ann Arbor, MI, [4]Dept. of Computational Med. and Bioinformatics, Ann Arbor, MI, [5]Dept. of Psychiatry, Ann Arbor, MI

Background: The Michigan Genomics Initiative (MGI) Biobank links genetic and electronic health record (EHR) data for >70K Michigan Medicine patients in a central data set for investigators with diverse research applications. The ability to assess variation in genes that interact with pharmaceuticals (pharmacogenes) to EHR-based phenotypes makes biobanks an attractive platform for large-scale pharmacogenomics (PGx) studies. PGx studies often use star allele nomenclature, which maps genetic variation in pharmacogenes to diplotypes which are annotated for overall protein function level (activity phenotypes). Many star alleles are called based on SNPs/indels, but for some pharmacogenes, this call depends on one or more structural variants (SV). *CYP2D6* is an important pharmacogene that metabolizes ~25% of current drugs. Accurate *CYP2D6* phenotyping requires calling *5 (whole gene deletion), one of the most common SV-based loss-of-function alleles. In this study we used a support vector machine (SVM) to classify *5 carriers among MGI participants genotyped on the CoreExome (CE) SNP array, which lacks designed content for *5 inference. **Methods:** We trained a SVM on CE array signal intensity (LRR) from 10 intragenic *CYP2D6* SNPs from 449 multi-ancestry samples with truth-known *5 calls. We evaluated SVM accuracy in a cross-validation (CV) of the training data and in a multi-ancestry test set of 42 samples. **Results:** PCA and tSNE visualizations of LRR show clusters that differentiate the known carriers and non-carriers. The SVM accurately classified all training samples in the CV analysis and the test set. The SVM classified 4,108 *5 carriers among 59,776 participants genotyped on the CE, we additionally called 613 *5 carriers among 9,506 participants genotyped on the Global Screening Array, which has explicit content for calling *5. The frequency of *5 was ~3.5% among all participants and ~3.4% among European ancestry participants (n=60,358), closely aligned with the 2.9% European frequency in PharmGKB (n=59,826). Incorporating *5 calls either reduced or introduced uncertainty for the activity phenotype of 6.4% of participants, including ~3,200 estimated to have received a prescription with a CPIC guideline for reduced *CYP2D6* function. **Conclusions:** We demonstrate an accurate, scalable method for *5 carrier classification using an array without explicit *5 content. While our method doesn't replace comprehensive PGx testing, it enables biobanks to capture *5-based drug-gene-interactions with existing array data and minimal training samples. Moreover, we envision this method may classify carriers of known deletion alleles of other pharmacogenes.

Session Title: Pharmacogenomics Poster Session III

PB2170 Leveraging Colorado Center for Personalized Medicine and electronic health records to perform HLA typing with an emphasis on potential pharmacogenetic alleles

Authors:

S. Chavan, H. Smith, M. Fisher, J. Shortt, N. Pozdeyev, L. Meng, K. Crooks, C. Gignoux, N. Rafaels, Colorado Center for Personalized Medicine (CCPM); Univ. of Colorado Anschutz Med. Campus, Aurora, CO

<Background: The Human Leukocyte Antigen (HLA) is a highly polymorphic region in the genome and plays a critical role in immunogenetics and disease research. Genotyping HLA alleles is essential for analysis of diseases and adverse drug reactions. Given the large and diverse sample size and access to clinical information through electronic health record (EHR), the data from Colorado Center for Personalized Medicine (CCPM) biobank is an excellent resource to study HLA and its role in health and disease.
Methods: HLA calling was performed using HLA-TAPAS (SNP2HLA) from the Michigan Imputation server on 73,346 CCPM Biobank samples comprising 49,372 samples from whole exome sequencing (WES) and 24,079 samples from Multi-Ethnic Genotyping Array (MEGA). Imputation was based on a global reference panel with two-field resolution comprising of 21,546 individuals with whole genome sequencing samples from five global populations including admixed African, European, East Asian, Latino and South Asian populations. Leveraging the imputed HLA alleles, we performed Phenome-wide association study (PheWAS) on the HLA alleles for 1563 phecodes available in the CCPM biobank using firth logistic regression as implemented in REGENIE. To study HLA and its role in drug reaction, we specifically homed in on potential pharmacogenetic HLA alleles namely, HLA_A*31:01 (carbamazepine), HLA_B*57:01 (abacavir), HLA_B*58:01 (allopurinol) and HLA_B*15:02 (carbamazepine, oxcarbazepine, phenytoin).
Results: To perform sensitivity analysis of the HLA genotype calls, we observed 16/16 patients positive for HLA_B*57:01 confirmed by EHR provided HLA. PheWAS analyses replicated association with psoriasis (P=7.6e-22) with HLA_B*57:01. Adding any use of allopurinol (N=3639) or epilepsy drugs (N=5510; carbamazepine, oxcarbazepine, phenytoin) as a covariate revealed associations with kidney diseases and epilepsy, respectively. Interestingly, HLA_B*15:02 revealed association with adverse drug events despite fewer patients taking medications and being positive for HLA_B*15:02 than expected, whereas HLA_B*58:01 showed no association with adverse drug events even though the number of patients taking epilepsy drugs was roughly similar.
Conclusions: HLA genotyping data from CCPM biobank is a robust resource for research-based HLA and disease association in multi-ancestry population and requiring additional validation also provides a promising resource for drug testing recommendation based on HLA calls.>

Session Title: Pharmacogenomics Poster Session I

PB2171 Leveraging donor variability in primary human hepatocytes to identify variation in drug metabolism in African Americans: CYP1A2 and glucoronidation

Authors:

C. Clark, T. De, G. Yang, C. Alarcon, J. Avitia, M. Perera; Northwestern Univ., Chicago, IL

Background: Genetic variation in drug metabolizing enzymes (DMEs), their regulatory regions, or within regulatory proteins can contribute to interindividual variability of drug response and adverse drug reactions. Genetic studies have underrepresented minority populations, such as African Americans (AA), resulting in poor prediction of drug response in these groups. This study aims to identify variation affecting drug metabolism using a clinically relevant phenotype in an AA cohort. **Method:** Hepatocytes were extracted from 75 AA cadaveric livers, assayed with probe substrates phenacetin (PHE) and acetaminophen (APAP), and underwent genome-wide genotyping. These drugs were used to examine variability of *CYP1A2* and glucuronidation through the measurement of metabolite formation rate (MFR). A genome-wide association study was conducted for each MFR with age, sex, and principal components as covariates. Additionally, a candidate gene study was conducted using genes from each probe's PharmGKB drug metabolism pathway. Significant results were prioritized based off publicly available functional data. **Results:** Loci reaching nominal significance were identified. rs10046278 (PHE, $p=9.27x10^{-6}$) is an eQTL for *TPMT*, a known phase II DME. rs166641 (APAP, $p= 1.83x10^{-6}$) is located within the 3'UTR of *SFXN1* and is an eQTL and sQTL for *SFXN1*. rs8191167 (APAP, $p= 1.03x10^{-6}$) is located within an enhancer region of *HSD17B2.* Both of these SNPs show large allele frequency difference between populations. Through candidate gene analysis, we identified a novel association of rs10203853 (APAP, $p= 5.7x10^{-5}$) near the *UGT1A* gene family and is a pQTL for *UGT1A6*. This SNP has been linked to differences in nicotine glucuronidation in AAs and shows associations to UGT1A-linked phenotypes (i.e., Gilbert's Disease, Bilirubin excretion) in a pheWAS of the combined FinnGen, UKBiobank and GWAS catalog datasets.**Conclusion:** We identified known and novel variants linked to drug metabolism. Variation in *TPMT* has been associated to increased risk of adverse events with thiopurine drugs used in auto-immune diseases and cancer. The UGT1A family is responsible for over half of glucuronidation reactions, a process which 12% of all drugs undergo. Other results have mechanistic links to DME regulation but have not been previously identified. For example, SFXN1 is a transporter involved in a-ketoglutarate metabolism, and HSD17B2 is a known regulator of steroid hormones, both of which have known links to DME gene regulation via their steroid hormone transcription factors. These findings represent some of the potential genetic variants contributing to known differences in drug response.

Session Title: Pharmacogenomics Poster Session II

PB2172 Leveraging the All of Us biobank to build multi-ancestry polygenic scores for NSAID-induced gastrointestinal bleeding.

Authors:

K. Keat, E. Ricciotti, K. Barekat, K. Cardone, G. A. FitzGerald, D. Kim, M. D. Ritchie; Univ. of Pennsylvania, Philadelphia, PA

Non-steroidal anti-inflammatory drugs (NSAIDs) are a class of widely used drugs for the management of pain, fever, and inflammation in a broad spectrum of diseases. NSAID use has been associated with both mild and life-threatening adverse drug reactions (ADRs), including gastrointestinal bleeding and acute coronary syndrome. Given the severity of these outcomes, broad use of NSAIDs, and the large number of patients affected, there is a significant need to predict individual risk of ADR from NSAIDs. The Clinical Pharmacogenetics Implementation Consortium (CPIC) has published guidelines for clinicians to modify NSAID treatment in the presence of *CYP2C9* loss-of-function variants; these variants result in reduced clearance of NSAIDs and increased risk of ADRs. However, *CYP2C9* alone explains a relatively small proportion of risk of ADR, which is currently better predicted using clinical covariates such as age, sex, concomitant drugs, and comorbidities. To gain a better understanding of the heritable risk of NSAID ADRs, we have performed the first large-scale genome-wide association study for gastrointestinal bleeding following NSAID use in a diverse population using the All of Us cohort; identifying several significant associations. We also validate these associations in other medical biobanks including the Penn Medicine BioBank and the UK Biobank and subsequently use them to evaluate the performance of a polygenic risk score (PRS) derived from the All of Us GWAS summary statistics. Furthermore, to augment the cross-ancestry performance of our PRS, we are integrating it with a transcriptomic risk score (TRS) based on imputed transcriptomes. Discovery of novel genomic risk factors for ADRs improves both our biological understanding and ability to predict NSAID ADRs. Subsequent work will be conducted to integrate pharmacogenetic, pharmacogenomic, and clinical factors such as concomitant drugs in order to build a more comprehensive and clinically actionable predictor for NSAID ADRs.

Session Title: Pharmacogenomics Poster Session III

PB2173 Long-read sequencing for *CYP2D6* genotyping of Korean: Preliminary result

Authors:

B. Kim; SMC, Seoul, Korea, Republic of

CYP2D6 is a drug metabolizing enzyme responsible for about 20% of drugs. The *CYP2D6* gene that determines the enzyme activity of CYP2D6 is about 4.3 kilobases (kb), located in the long arm of chromosome 22. *CYP2D6* is a polymorphic gene, with about 133 known alleles and different enzyme activities depending on the combination of alleles. Meanwhile, pseudogenes called *CYP2D7* and *CYP2D8* are located upstream of the *CYP2D6* gene, which makes the exact genotyping of *CYP2D6* harder. In this study, long-read sequencing and CRISPR/Cas9 method were applied for CYP2D6 genotyping to obtain the adjacent area, and the structural variations of CYP2D6 are revealed. With the samples of which CYP2D6 genotypes were determined previously, CRISPR/Cas9 target enrichment for CYP2D6 regions was done. In addition, long-range PCR for CYP2D6 genes and the adjacent area was amplified for long-read sequencing with Nanopore. Flongle and MinION flow cell (R9.4.1) was used for the sequencing by MinION Mk1B. After long-range PCR for the *CYP2D6* regions, long-read sequencing was done with Nanopore MinION, but the read sequence was not aligned at the target area. However, after CRISPR/Cas9 target enrichment for CYP2D6, the read sequence was aligned at the target area around the *CYP2D6* gene. CRISPR/Cas9 target enrichment for long-read sequencing was appropriate for the *CYP2D6* regions rather than long-range PCR.

Session Title: Pharmacogenomics Poster Session I

PB2174 Lymphocyte count-derived polygenic score and interindividual variability in CD4 T-cell recovery in response to antiretroviral therapy

Authors:

K. Cardone[1], S. Dudek[1], K. Keat[1], Y. Bradford[1], Z. Cindi[1], E. Daar[2], R. Gulick[3], S. Riddler[4], P. Sinxadi[5], D. Haas[6], M. Ritchie[1]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Lundquist Inst. at Harbor-UCLA Med. Ctr., Torrance, CA, [3]Weill Cornell Med. New York, New York, NY, [4]Univ. of Pittsburgh, Pittsburgh, PA, [5]Univ. of Cape Town, Cape Town, South Africa, [6]Vanderbilt Univ. Med. Ctr., Nashville, TN

Access to safe and effective antiretroviral therapy (ART) is a cornerstone in the global response to the HIV pandemic. Among people living with HIV, there is considerable interindividual variability in absolute CD4 T-cell recovery following initiation of virally-suppressive ART. The contribution of host genetics to this variability is not well understood. We explored the contribution of a polygenic score which was derived from large, publicly available summary statistics for absolute lymphocyte count from individuals in the general population (PGS_{lymph}). There are not available summary statistics to derive a CD4 T-cell PGS. We explored associations with baseline CD4 T-cell count prior to ART initiation (n=4959), and change from baseline to week 48 on ART (n=3274) among treatment-naïve participants in prospective, randomized ART studies of the AIDS Clinical Trials Group. We separately examined African and European PGS_{lymph}, and applied to all participants, and to African and European ancestral groups separately. Multivariate models that included PGS_{lymph}, baseline plasma HIV-1 RNA, age, sex, and 15 principal components (PCs) of genetic similarity explained ~26-27% of variability in baseline CD4 T-cell count, but PGS_{lymph} accounted for <1% of this variability. Models that also included baseline CD4 T-cell count explained ~7-9% of variability in CD4 T-cell count increase on ART, but PGS_{lymph} accounted for <1% of this variability. In univariate analyses, PGS_{lymph} was not significantly associated with baseline or change in CD4 T-cell count. Among individuals of African ancestry, African PGS_{lymph} was significantly associated with change in CD4 T-cell count in the multivariate model but not the univariate model. When applied to lymphocyte count in the general population (Penn Medicine BioBank), PGS_{lymph} explained ~6-10% of variability in multivariate models (including age, sex, and PCs) but only ~1% in univariate models. In summary, a lymphocyte count PGS derived from the general population was not consistently associated with CD4 T-cell recovery on ART. Adjusting for clinical covariates is important when estimating polygenic effects.

Session Title: Pharmacogenomics Poster Session II

PB2175 † Machine Learning Prediction on Ketamine Treatment Response in Posttraumatic Stress Disorder Based on Methylation Capture Sequencing Data

Authors:

X. Zhang[1], Y. Hu[2], C. Abdallah[3], J. Roache[4], L. Averill[3], R. Vandenhoudt[1], D. Williamson[5], A. Peterson[4], J. Krystal[6], K. Xu[7]; [1]Yale Univ., New Haven, CT, [2]Natl. Cancer Inst., Rockville, MD, [3]Michael E. DeBakey VA Med. Ctr., Houston, TX, [4]Univ. of Texas Hlth.Sci. Ctr. at San Antonio, San Antonio, TX, [5]Duke Hlth., Durham, NC, [6]Yale Sch. of Midicine, New Haven, CT, [7]Yale Sch. Med., New Haven, CT

Background: Post-Traumatic Stress Disorder (PTSD) is a psychological disorder that occurs after exposure to a traumatic event. Ketamine, primarily used for anesthesia and pain management, has shown potential as a treatment for PTSD. However, predicting individual response to ketamine treatment for PTSD symptoms remains challenging. In this study, we aimed to identify DNA methylation sites that could serve as biomarkers for ketamine response in veterans with PTSD using a machine learning approach. **Methods**: A total of 161 individuals diagnosed with PTSD took part in the study and were divided into two groups: Ketamine (n=106) and Placebo (n=55). The severity of PTSD symptoms was assessed using the PTSD Check List for DSM-5 (PCL-5) questionnaire. A Linear Mixed Model (LMM) was used to analyze the trajectory of PTSD symptoms over time. Based on the median LMM slope of PCL-5, responders (R) and non-responders (NR) were identified, resulting in four response patterns: Ketamine-R (KR), Placebo-R (PR), Ketamine-NR (KNR), and Placebo-NR (PNR). DNA methylation in blood was profiled using SureSelectXT Methyl-Seq for MC-seq. We first conducted a Linear Interaction Model (LMM) analysis to select candidate CpG sites in the genome for treatment response. The samples were randomly divided into a training set (N= 107) and a testing set (N=54), and the Support Vector Machine (SVM) method was employed to identify the best-performing model for ketamine treatment. **Results**: The top 5,000 CpGs identified by the LMM analysis were chosen for subsequent machine learning analysis. A model consisting of 1,553 CpGs exhibited the best performance in the testing set. Notably, these predictive CpGs were located in genes previously associated with PTSD, such as *ELFN1*, *MAD1L1*, and *WNT5A*. Hierarchical cluster analysis using DNA methylation beta values of the 1,553 CpGs successfully divided the samples into two distinct clusters. One cluster primarily included ketamine responders, while the other cluster mainly included placebo responders. The distribution of individuals with KR, KNR, PR, and PNR in these two clusters showed significant differences (p=4.9E-012). Therefore, the machine learning-derived methylation clusters effectively differentiated responders and non-responders to ketamine and placebo treatments. **Conclusions**: Our findings demonstrate the potential of DNA methylation as a biomarker for predicting response to ketamine and placebo treatments for PTSD.

Session Title: Pharmacogenomics Poster Session III

PB2176 Metabolomic Signature of Canagliflozin

Authors:

M. Montasser, Z. S. Yazdi, E. A. Streeten, H. B. Whitlatch, S. I. Taylor, A. L. Beitelshees; Univ. of Maryland Sch. of Med., Baltimore, MD

Sodium glucose cotransporter-2 inhibitors (SGLT2i) as second line of diabetes treatments provide many clinical benefits: HbA1C-lowering, weight loss, as well as cardiovascular (CV) and renal benefits. However, like all drugs, SGLT2i can cause rare but severe side effects. The most common are: genital mycotic infections, urinary tract infections and volume-depletion related side effects. Less common, but more severe side effects include fractures, decrease in bone mineral density, urosepsis, and ketoacidosis. The purpose of The Genetics of Response to Canagliflozin (GRC) study is to use multiomics approach to better understand the underlying biological mechanisms of these different effects and identify determinants of variation in response that can distinguish those who will be benefited most and harmed least by the use of SGLT2i, which will pave the road to reaching the precision medicine goals. Biomarker analysis and Metabolomic profiling was performed for the first 216 generally healthy Amish participants in the GRC at 3 time points: baseline before drug exposure (day 1) and after 2 and 5 doses of Canagliflozin (300 mg/d) (day 3 and day 6). 24-hour glucosuria was measured at day 3. Phenotypic and metabolomic signatures of response were determined using repeated measure analyses adjusting for age, age^2, sex, BMI, and familial correlation. There was about 5-fold variation (mean 33 ± 9 g_{gluc}/g_{cr}) in glucosuria between the participants. The response of bone biomarkers was consistent with a negative impact on bone health as presented by increase in PTH and C-terminal telopeptide (CTX) at day 3 and 6, initial increase of phosphate (P) and FGF23 at day 3 and then decrease at day 6, while $1,25(OH)_2D$ was decreased at day 3 and then returned to baseline at day 6. Consistent with beneficial CV effects, we observed a significant decrease in systolic and diastolic blood pressure and uric acid. There was highly significant increase in all ketone bodies on day 3 but the levels returned to baseline at day 6. Out of the 249 profiled metabolites, 189 were significantly altered at day 3 but only 85 were altered at day 6 compared to day 1. The large increase at day 3 reflects the acute response to the drug before the compensatory homeostatic mechanisms brings many metabolites back to normal. The most significantly changed metabolite was increased alanine (ALA), which is consistent with previously reported interactions between renal handling of alanine, glucose, and phosphate. Baseline higher ALA was also associated with better SBP response to canagliflozin with more dramatic decrease, which could represent a novel biomarker for BP lowering or CVD protection in response to SGLT2i.

Session Title: Pharmacogenomics Poster Session I

PB2177 † Methods to prevent hepatitis B vaccine escape elucidated through a genetic association study of antibody responses in Bangladeshi infants

Human leukocyte antigen (HLA) variants influence vaccine responses, but multiple challenges limit clinical translation. These include over-reliance on European-derived imputation panels, complex linkage disequilibrium, high pleiotropy, and difficulties interpreting biological mechanisms assigned to allelic associations. We sought to overcome these challenges to deliver a public health intervention, specifically in relation to hepatitis B virus (HBV) vaccination, currently delivered worldwide during infancy as an S, *adw* subtype. Our findings offer an opportunity to move towards universal vaccine responsiveness and halt HBV vaccine escape mutants.

We studied the genetic determinants of antibody responses against eight childhood vaccines in 1,096 children from Bangladesh, a region with well recognized HBV vaccine escape mutants. Using genome-wide associations, we found that the HLA locus was associated with responses against four vaccine antigens. We then constructed and validated the largest ever published south Asian ancestry HLA imputation reference panel (n = 9,448) to fine-map our signals. Specifically, we identified DPB1*04:01 as a determinant of higher antibody response against the HBV surface antigen, HBsAg ($p=4.5x10^{-30}$).

We then interrogated the binding affinity HBsAg peptides to HLA receptors *in silico*. We found that binding of HBsAg peptides to DPB1 dimers was proportional to antibody levels observed genetically. This was replicated in a cohort of African children, and at the *HLA-DQB1* and *HLA-DRB1* genes where independent associations were found in the more genetically heterogeneous African cohort. This has two clinically significant findings. First, individuals carrying HLA alleles with reduced HBsAg vaccine response, as defined by genetics and binding affinity, would benefit the most from vaccines containing HBsAg pre-S isoforms rather than the currently used *adw* types. This are consistent with vaccination trials showing that pre-S vaccines perform better than the contemporary S vaccines. Second, the difference in binding affinity between protective HLA alleles compared to other alleles was specifically at its highest in the a-determinant locus of HBsAg. This matches well reported orthogonal epidemiological observations of mutations at the a-determinant leading to HBV vaccine escape, particularly in Bangladesh. Hence, individuals with genetic predisposition to reduced response to HBV S isoform vaccines may provide a simple evolution opportunity for HBV to escape host immunity with a single amino acid mutation. Thus, pre-S containing HBV vaccines should be prioritized to help decrease the burden of these HBV mutants.

Session Title: Pharmacogenomics Poster Session II

PB2178 Methotrexate Drug Responses in Rheumatoid Arthritis are influenced by Methylation Mapping Genes

Authors:

K. ELAYAKOVILAKOM[1], M. Banerjee[2], S. S. Vishnu[3], S. sreenath[4]; [1]Rajiv Gandhi Ctr. for Biotechnology, Thiruvananthapuram, India, [2]Rajiv Gandhi Ctr Biotech, Trivandrum Kerala, India, [3]Government Med. Coll., Thiruvananthapuram, India, [4]PRS Hosp., Thiruvananthapuram, India

Rheumatoid arthritis (RA) is a crucial auto-immune and inflammatory joint disease characterized by loss of self-tolerance, severe cartilage loss, and subchondral bone erosions. The pathogenesis of rheumatoid arthritis remains unclear and this poses challenges in the effective management of disease-modifying anti-rheumatic drugs (DMARD) which also results in an unpredictable spectrum of side effects. Methotrexate (MTX) is a folic acid analog commonly used as DMARD for the treatment of rheumatoid arthritis. The variation in the responses in the MTX drug in each diseased individual may be due to the genetic variation that occurs in the drug transporters and metabolizing genes in one carbon metabolic pathway. With this background, our present study focuses on genetic variation liable for folate metabolic genes for methotrexate drug responses in rheumatoid arthritis patients**.** In the present study, the drug metabolizer gene *MTRR* a methylation mapping gene shows a significant association with MTX drug responses in RA individuals. The functional variants of the folate pathway gene *MTRR* rs1532268 CC/CT show greater efficacy to MTX drug in individuals with RA. None of the other folate genes show an association with drug responses. The study concludes that the genetic variants of the folate pathway genes are real predictive markers for methotrexate drug responses in RA.

Session Title: Pharmacogenomics Poster Session III

PB2179 Multi-omics and Functional Analysis Identifies Novel Genetic and Methylation Markers Contributing to Antipsychotic-Induced Metabolic Syndromes

Authors:

S. Qin[1], W. Zhou[1], J. Sun[2], C. Huai[1], H. Huang[3], L. He[1]; [1]Shanghai Jiao Tong Univ., Shanghai, China, [2]Jiangsu Univ., Zhenjiang, China, [3]MGH, Boston, MA

Antipsychotic-induced metabolic syndrome (APs-induced Mets) is the most common adverse drug reaction, affecting over 60% of psychiatric patients. Although extensive research has been conducted on the etiology of APs-induced Mets, there is a lack of integrated analysis of genetic and epigenetic factors. In this study, we performed genome-wide association study (GWAS), whole-exome sequencing (WES) and epigenome-wide association studies (EWAS) in schizophrenia (SCZ) patients with or without APs-induced Mets to elucidate the underlying mechanisms. Subsequently, we conducted *in vitro* and *in vivo* functional validations. Our case-control based genome-wide association analysis of 444 individuals with APs-induced Mets and 546 controls that identified six loci (P < 5E-7). Recode the Mets severity z-score (MetS-z) found 1 genome-wide-significant loci(P < 5E-8). Furthermore, set-based omics analysis revealed an imbalance of rare functional variants across the leptin and peroxisome proliferator-activated receptor (PPAR) gene sets in APs-induced Mets compared to Non-Mets cohort. Additionally, we discovered hypermethylation of *ABCG1* (chr21:43642166-43642366, adjusted P < 0.05) in APs-induced Mets compared to Non-Mets, and this hypermethylation was associated with elevated levels of total cholesterol (TC) and triglycerides (TG) in HepG2 cells. Candidate genes identified from the omics studies were further screened in *C. elegans*, and we validated associations of 17 genes with olanzapine (OLA)-induced fat deposition. Several of these genes exhibited differential expression in the Mets cohort and APs-induced in vitro/in vivo models compared to controls, thereby confirming the validity of the omics study. Notably, overexpression of one of the most significant genes, *PTPN11*, led to compromised glucose responses and insulin resistance. Pharmacologic inhibition of PTPN11 protected HepG2 cells and C57/BL mouse from APs-induced insulin resistance and disorder lipid deposit. These findings provide important insights into the mechanisms underlying APs-induced Mets.

PB2180 New drug repositioning method using multi-layer omics data based on transformer-based network method

Authors:

s. Lee[1], J-H. Ji[1], M-Y. Song[2], H. Shin[3], B. Kim[1]; [1]ajou Univ., Suwon-si, Korea, Republic of, [2]Kyung Hee Univ., seoul, Korea, Republic of, [3]Ajou Univ., Suwon-si, Korea, Republic of

Recently, deep-learning approaches have been applied to discover new drug efficacies for various cancer types using big multi-omics data of cancer patients. However, multi-omics data typically have high dimensions compared to relatively few patient samples, this imbalance is a recognized bottleneck to apply integrated characteristics of multi-omics in cancer research. To address this issue, Deep learning-based approaches including autoencoder among the dimensionality reduction techniques that are known to have strength in handling high dimensional data with few samples have been applied to devise drug repositioning methods based on deducting representative signatures of multi-omics data. However, this black box model makes it difficult to explain which genes are essential. In this study, we developed a transformer-based drug repositioning model to extract informative features and the potential anti-breast cancer therapeutic target genes to construct the gene network for finding new anti-breast cancer drug efficacy. Unlike previous approaches, our model allows for better interpretability of the essential genes, which can lead to more targeted drug development. It is based on a unified framework of applying the compressed representation learned through transformer from multi-omics data of breast cancer patients in The Cancer Genome Atlas (TCGA) and measuring network similarity between gene and drug networks using graph kernels to predict candidate anti-breast cancer drugs. We validated the performance of our algorithm using various perspectives of data. Our results showed not only an inverse correlation between drugs and cancer multi-omic signatures as the graph similarity score increased but also a pronounced increasing trend in the retention rate of breast cancer marker genes and pathways. These findings demonstrate the effectiveness of our algorithm in identifying potential anti-cancer drug candidates by leveraging the relationship between drug and cancer signatures. From this point of view, the proposed model will pave the way for a new direction to discover new anti-breast cancer efficacy due to representing the biological anti-cancer phenomena by multi-omics data.

PB2181 Novel gene polymorphisms for stable warfarin dose in a Korean population: Genome-wide association study

Authors:

J. Kim[1], S. Lee[2], J. Yee[1], K. Park[3], E. Jang[1], B. Chang[4], H. Gwak[1]; [1]Ewha Womans Univ., Seoul, Korea, Republic of, [2]Yonsei Univ. Coll. of Med., Seoul, Korea, Republic of, [3]Ulsan Natl. Inst. of Sci. and Technology, Ulsan, Korea, Republic of, [4]Bundang CHA Med. Ctr., Seongnam, Korea, Republic of

Background: Warfarin exhibits a narrow therapeutic window and considerable intra- and inter-individual variability in dose requirements. Given that most published studies on genotype-guided dosing originate from European populations, this study aimed to explore novel genetic variants associated with the variability of stable warfarin doses in a Korean population with cardiac valve replacement, utilizing the genome-wide association study (GWAS) approach. **Methods:** A retrospective cohort study using prospectively collected data was conducted from January 1982 to December 2020 at the Severance Cardiovascular Hospital of Yonsei University. The GWAS method was employed to identify associations between genotypes and the warfarin stable dose by comparing the allele frequency of genetic variants among individuals. Subsequently, the influence of genetic and non-genetic factors on dose variability was assessed. **Results:** A total of 229 participants were enrolled, and the strongest signal cluster was identified on chromosome 16 around *VKORC*1 from the GWAS. In addition to *VKORC1* rs9934438, which is a well-known polymorphism, three novel variants (*NKX2-6* rs310279, *FRAS1* rs4386623, and *FAM95C* rs1890109) demonstrated an association with stable warfarin dose requirements in univariate analysis. A predictive algorithm was developed using multivariable analysis, incorporating both genetic and non-genetic factors, accounting for 58.5% of the variations in stable warfarin doses. Within this variability, *VKORC1* rs9934438 and *FRAS1* rs4386623 contributed to 33.0% and 9.9%, respectively. **Conclusion:** This GWAS analysis revealed three novel variants (*NKX2*-6 rs310279, *FRAS1* rs4386623, and *FAM95C* rs1890109) associated with stable warfarin doses. Further research is required to validate these findings and develop personalized treatment strategies for the Korean population.

Session Title: Pharmacogenomics Poster Session III

PB2182 Novel Systematic Congenital Anomaly Case Collection Method and Preliminary Analyses Identifying Causes of Congenital Anomalies

Authors:

E. Brokamp; Vanderbilt Univ. Med. Ctr., Nashville, TN

Congenital anomalies (CAs) affect ~3% of live births, are the leading cause of infant death, and cost health care systems billions of dollars annually. Despite their frequency and consequences, the cause of ~80% CAs is unknown. Further, for the 20% with a potentially identified cause, variability in penetrance suggests additional drivers of risk exist. The interplay between environmental teratogens, such as medication use in pregnancy, and genetic predisposition impacts CA risk, but such interactions are poorly understood. Research to better understand the causes of CAs is hampered by the lack of a uniform CA identification method in electronic health records (EHRs) and biobank databases. We aim to **1.** Demonstrate the first large-scale effort to define and characterize CAs in the EHR and **2.** Test the hypothesis that pharmacogenomic variation impacts CA risk. Previous researcher lacked an accurate and universal method for CA case collection in the EHR. Phecodes, a widely used and easily adaptable phenotyping tool, provide a useful approach for CA identification. Earlier versions of phecodes lacked granularity and specificity in the CA chapter. Therefore, to identify CAs we used the new PhecodeX nomenclature that includes 5.8 times more codes for CAs compared with the previous v1.2 (365 vs 56). We also created a novel quantitative manor for assessing potential causal disease codes, such as known genomic variations, that should be considered in study design. Out of all genetic disease billing codes, 85 (19.7%) have a known association with CAs in the literature. Phenome-wide association studies revealed an additional 16 (3.7%) with one or more significant association with CA-related phecodes (Bonferroni corrected p< 2.75 x10-5). Determining CA-associated billing codes allows researchers to differentiate between idiopathic CAs and those that have a known cause, providing a scalable approach to increase power in studies designed to evaluate the epidemiologic and genetic drivers of CAs. Using phecodeX CA phecodes, we identified 3,278 CA cases and 24,224 controls of genetically determined European ancestry in BioVU. We performed a drug absorption, distribution, metabolism, and excretion (ADME)-wide association study including 5,398 independent SNPs from 292 genes. We adjusted the models for median age, gender, principle components of ancestry, and presence of a genetic disease billing code associated with CAs. Despite the relatively small sample size numerous significant associations at both the gene and SNP levels were identified. The most significant result was for *PPARA*, rs4253795 (OR=1.5, p= 6.33E-05). Future work to expand this cohort is underway.

Session Title: Pharmacogenomics Poster Session I

PB2183 Pharmacoepigenetics of antiepileptic drugs

Authors:

N. Mohan, M. Banerjee; Rajiv Gandhi Ctr. for Biotechnology, Thiruvananthapuram, India

Background: Antiepileptic drugs are the mainstay for the treatment of epilepsy. Studies in human have been shown that these AEDs tend to have teratogenic potential. And it is becoming evident that these pharmaceutical drugs can cause changes in gene expression that persist long after the exposure has ceased. Pharmacoepigenetic studies explain the role of epigenomics in intrapersonal and interpersonal variations in response of individuals to drugs, in the effects of drugs on gene-expression profiles, in the mechanism of action of drugs and adverse drug reactions. **Method:** The present study involves assessing the epigenetic modifications induced by antiepileptic drugs in cell culture model. The effect of AEDs on global DNA methylation and underlying gene expression was studied. The experimental cell line was treated with varying concentration of AEDs at different time intervals, following global DNA methylation assay and the gene expression of epigenetic modulators including DNA methyltransferases (*DNMTs*) and Ten-eleven translocases (*TETs*) was assessed. Along with the antiepileptic drugs, we have supplemented folic acid and assessed the expression pattern of *DNMT*s and *TET*s. **Results:** Data suggests decreased global DNA methylation for AED treated cells and the global DNA methylation changes show similar pattern with respect to *DNMT*s gene expression .As treatment duration increased from 12 to 48 hours, we observed a decrease in *DNMT*s (methylation) and increase in *TETs* (demethylation) expression. The gene expression of *DNMT*s and *TET*s got increased significantly with folic acid supplementation along with AEDs. And this can be attributed by the variability in the one -carbon metabolism genes -*MTHFR* and *MTRR*
Conclusion: The antiepileptic drug induced changes in global DNA methylation were observed in HEK293 and the modulation of global DNA methylation status in cell line can be attributed to variability in underlying *DNMT* and *TET* gene expression.

Session Title: Pharmacogenomics Poster Session II

PB2184 Pharmacogenetic study identifies IL6R as a genetic risk factor for imatinib-induced severe skin rash in gastrointestinal stromal tumor

Authors:

X. Liu, Y. Xia, S. Chen, X. Zhang; First Affiliated Hosp., Sun Yat-sen Univ., Guangzhou, China

Skin rash is one of the most common adverse drug reactions (ADRs) in gastrointestinal stromal tumor (GIST) patients treated with imatinib. Severe skin rash can reduce medication adherence, affect treatment efficacy, reduce quality of life and even lead to death. However, little is known about the mechanism of imatinib-induced skin rash. To investigate genetic polymorphisms associated with imatinib-induced skin rash in a Chinese population, a total of 475 patients (≥18 years) treated with imatinib for unresectable or metastatic GIST were recruited in the study. We conducted a pharmacogenetic investigation for imatinib-induced severe skin rash (31 ADR cases and 444 controls). Genetic loci in IL6R were strongly associated with imatinib-induced severe skin rash. The strongest finding (*P*=0.039, OR=0.533, 95% CI=0.292-0.970) identified as conferring ADR risk was with rs4129267, located in intron 8 of IL6R and is in linkage disequilibrium with the IL6R coding SNP rs2228145 that modifies the IL-6R peptide structure and shown to affect IL-6 serum levels. The findings could contribute to a better understanding of imatinib-induced severe skin rash and shed light on targets for new therapeutics.

Session Title: Pharmacogenomics Poster Session III

PB2185 Pharmacogenetic variability of tuberculosis biomarkers in native and mestizo peruvian populations.

Authors:

L. Jaramillo Valverde[1,2,3], K. Levano[4,2], D. Tarazona[2], S. Capristano[2], C. Sanchez[2], J. Poterico[3], E. Tarazona-Santos[5,6], H. Guio[2,3]; [1]Sch. of Med., Univ. Continental, Lima, Peru, [2]Laboratorio de Biotecnología y Biología Molecular, Inst. Natl. de Salud, Lima, Peru, [3]INBIOMEDIC Res. and Technological Ctr., Lima, Peru, [4]Sci. Dept., Helene Fuld Coll. of Nursing, New York, NY, [5]Departamento de Biologia Geral, Univ.e Federal de Minas Gerais, Belo Horizonte, Brazil, [6]RIBEF Ibero-American Network of Pharmacogenetics and Pharmacogenomics, Belo Horizonte, Brazil

BACKGROUND: In Peru, 29292 people were diagnosed with tuberculosis in 2022. Although TB treatments are effective, 3.4-13% are associated with significant adverse drug reactions, with drug-induced liver injury (DILI) considered the most predominant. Among the first-line antituberculosis drugs, isoniazid (INH) is the main drug responsible for the appearance of DILI. In liver, INH is metabolized by N-acetyltransferase-2 (NAT2) and cytochrome P450 2E1 (CYP2E1). Information regarding genetic risk factors associated with the presence of DILI to anti-tuberculosis drugs is limited in Latin American and even more so in native and mestizo Peruvian population. The objective of the study was to determine the prevalence of NAT2 and CYP2E1 genotypes in native and mestizo population.METHODS: An analytical cross-sectional analysis was performed using genetic data from mestizo patients with pulmonary tuberculosis in Lima and data from native participants Quechua, Ashaninka, Shimaa and Aymara of the EPIGEN - Brazil project. NAT2 acetylator genotype was determined as fast, intermediate and slow, and CYP2E1 genotypes were classified as c1/c1, c1/c2 and c2/c2, from molecular tests and bioinformatic analyses. RESULTS: Of the 472 participants, 36 haplotypes were identified in the mestizo population and 6 haplotypes in native population paired with NAT2. In mestizo population, the most frequent NAT2*5B and NAT2*7B haplotypes were associated with DILI risk; while in natives, NAT2*5G and NAT2*13A haplotypes were the most frequent and associated with decreased risk of DILI. In addition, the SNPs with the highest frequency was 282T in both populations. Differences were observed in the genotypes and allele frequencies of SNPs NAT2 282C>T, 481C>T, 590 G>A and SNP CYP2E1 1053 C>T between the two populations ($p<0.001$). In univariate analyzes for NAT2, non-wild genotypes of mestizo population reported a higher prevalence than wild genotypes in SNPs 282C>T, 341T>C, 481C>T, 590G>A ($p< 0.001$), while, non-wild genotypes of native population reported a higher prevalence than wild genotypes in SNPs, 341T>C, 481C>T, 590G>A and 830A>G ($p<0.001$). For CYP2E1, c1/c1 and c1/c2 allele are the most frequent in native and mestizo population, respectively. In both, non-wild genotypes reported a higher prevalence than wild-type genotypes in SNP 1053C>T ($p<0.001$). CONCLUSION: Despite the limitations of a secondary study, it was possible to report associations between NAT2 and CYP2E alleles with Peruvian native and mestizo population by prevalence ratios. The results of this study will help the development of new therapeutic strategies for a Tuberculosis efficient control between populations.

Session Title: Pharmacogenomics Poster Session I

PB2186 Pharmacogenetics of cardiotoxicity in the treatment of black Zimbabwean breast cancer patients on doxorubicin

Authors:

V. Nyangwara[1], M. Tinashe[1], Z. Chikwambi[1], M. Collen[1], T. Campbell[2], M. Borok[3], N. Ndlovu[3]; [1]AiBST, Harare, Zimbabwe, [2]Univ. of Colorado Anschutz Med. Campus, Aurora, Colorado, CO, [3]Univ. of Zimbabwe, Harare, Zimbabwe

Introduction: Doxorubicin induced cardiotoxicity (DIC) is a common nonmalignant treatment-related cause of death in cancer patients. Doxorubicin is well established as an efficacious drug for the treatment of a variety of cancers. It is administered as a single agent or more commonly in combination for breast cancer patients. This study was conducted to establish the frequency of DIC in Zimbabwean breast cancer patients on doxorubicin and to test the DIC predictive power of genetic biomarkers. **Methods:** All the 50 participants were women aged ≥ 18 years with breast cancer who were on doxorubicin. Non-black women and those with prior chest wall radiotherapy were excluded. To determine DIC, cardiologists performed echocardiographic examinations and echocardiographic recordings. The patients were evaluated for cardiovascular disease at entry (baseline), 3, 6 and 12 months during the study. Additional information, such as BMI, cumulative dose of doxorubicin, co-medications and physical performance of the patients were recorded using a questionnaire. To determine the DIC predictive power, patients were genotyped for UGTA1A6*4, SLC28A3 and RARG variants. To evaluate the impact of the clinical and genetic factors on left ventricular ejection fraction (LVEF) and cardiac failure, a uni- and multivariable logistic regression analysis was carried out. **Results:** Out of the 50 patients who were recruited into the study only 35 (54%) completed the study. The median age was 48 years (IQR 44.5 - 59.0). Twenty-eight (80%) had advanced stage breast cancer (stage III/IV) with Karnofsky performance status between 80-90%. The prevalence of HIV, diabetes and hypertension were 3%, 11% and 46% respectively. The median LVEF before treatment was 64.7%. The median cumulative doxorubicin dose was 238.89 mg/m2. Five, 14% of the patients experienced acute DCI associated with LVEF reduction of ≥ 10% from baseline (<60%). The three patients who developed cardiotoxicity were hypertensive. The final LVEF measurements of the five patients after the 12-month follow up ranged from 18.2% to 39%. The frequencies of SLC28A3 (rs7853758), UGT1A6*4 (rs17863783) and RARG (rs2229774) were 60.7%, 17.9% and 14.3%, respectively. No association between DIC and the three variants was observed. **Conclusions:** This is the first study on the prevalence of DIC and associated genetic biomarker predictive evaluation in Zimbabwean breast cancer patients. There is need for incorporation of both clinical and genetic determinants to refine toxicity risk assessment of DIC. A larger sample size with a longer follow-up time will be necessary in future studies.

Session Title: Pharmacogenomics Poster Session II

PB2187 Pharmacogenetics of Tenofovir Diphosphate and Lamivudine Triphosphate Concentrations and Hepatitis B Virus Suppression During Antiretroviral Therapy in Patients with HIV/HBV Coinfection

Authors:

J. Bae[1], M. Tantawy[1], Y. Gong[1], T. Langaee[1], M. Lartey[2], V. Ganu[2], K. Tachi[2], O. Ojewale[1], A. Obo-Akwa[3], I. Boamah[3], J. Kiser[4], L. Bushman[4], L. Ellison[4], H. Yang[5], P. L. Anderson[4], A. Kwara[1]; [1]Univ. of Florida, Gainesville, FL, [2]Univ. of Ghana Med. Sch., Korle-Bu Teaching Hosp., Accra, Ghana, [3]Univ. of Ghana Med. Sch., Accra, Ghana, [4]Univ. of Colorado-Anschutz Med. Campus, Aurora, CO, [5]Univ. of Rochester Sch. of Med. and Dentistry, Rochester, NY

Background: In Africa, up to 25% of persons living with human immunodeficiency virus (HIV) are coinfected with hepatitis B virus (HBV). Suboptimal suppression of HBV DNA during antiretroviral therapy (ART) in HIV/HBV-coinfected patients is common, ranging from 13.5% to 65%. We hypothesize that variations in genes that encode transporters and phosphodiesterase enzymes will be associated with nucleoside analogs intracellular pharmacokinetics (PK) and incomplete HBV treatment response. **Methods:** In this study, 138 HIV/HBV-coinfected patients on tenofovir (TDF)/lamivudine (3TC)-containing ART at the Korle-Bu Teaching Hospital in Ghana were enrolled. Selected single nucleotide polymorphisms (SNPs) in ABCB1, ABCC2, ABCC4, ABCC10, PDE1C, PDE3A, PDE4D, PDE11A, and SLC28A2 with potential effect on nucleoside PK were genotyped using TaqMan assays. Relationships between SNPs and steady-state intracellular concentrations of the active phosphate anabolites of TFV and 3TC called TFV diphosphate (TFVdp) and 3TC triphosphate (3TCtp), respectively, were analyzed by using multivariable linear regression adjusted for age, gender, BMI, and CD4 count. Concentrations of TFVdp and 3TCtp in peripheral blood mononuclear cells (PBMCs) were used as the reference tissue for in-vivo nucleoside reverse transcriptase studies, while that in red blood cells (dried blood spots (DBS)) were used as a measure for long-term adherence of TDF/3TC. **Results:** Of the 136 patients (mean age 45 years; 63% females) on TDF/3TC-containing ART for a median (IQR) of 6 (4.08 to 7.5) years, 9 (6.6%) had unsuppressed HBV DNA, 10 (7.4%) had unsuppressed HIV RNA, and 6 (4.4%) had suppressed HIV RNA but unsuppressed HBV DNA. The missense rs2273697 variant allele A in the ATP-binding cassette sub-family C member 2 (ABCC2) was associated with higher intracellular 3TCtp concentration in PBMC, with mean concentrations of 10.06, 10.98, and 19.31 pmol/10^6 cells in GG, AG, and AA, respectively (P=0.015). In unadjusted analysis, PDE1C rs30561 (P=0.038) and ABCC2 rs3740066 (P=0.003) were associated with TFVdp in DBS, while PDE4D rs6889641 (P=0.028) and ABCC2 rs17216177 (P=0.049) were associated with TFVdp and 3TCtp in PBMCs, respectively. None of the evaluated SNPs were associated with unsuppressed HBV DNA. **Conclusion:** This exploratory study identified a significant association between ABCC2 rs2273697 and intracellular 3TC concentration in HIV/HBV-affected African patients. Further studies with larger sample size are warranted to confirm our findings as well as elucidate the underlying molecular mechanism of ABCC2 rs2273697 and its contribution to the elimination of 3TC.

Session Title: Pharmacogenomics Poster Session III

PB2188 Pharmacogenomic Landscape of TNF Inhibitors in the Qatari Population

Authors:

Z. Jan, D. Velayutham, B. Mifsud, P. Jithesh; Coll. of Hlth.& Life Sci., Hamad Bin Khalifa Univ., Doha, Qatar

Autoimmune diseases are increasing globally, causing mortality and morbidity worldwide. Over the past few decades, TNF inhibitors that target tumor necrosis factor (TNF-α) have been widely used for the treatment of autoimmune diseases. However, 40% of the patients do not respond to TNF inhibitors. Several pharmacogenetic variants affecting TNF inhibitor response have been identified. However, the prevalence of these variants in the Qatari population is still not known. In this study, we identified the distribution of known and novel variants in 102 genes associated with response to TNF inhibitors in 14,392 Qataris from whole genome sequencing data and calculated the cumulative risk probability score. Out of the 119 known pharmacogenomic variants associated with response to TNF inhibitors, ~90% had different allele frequency distribution from other world populations present in the gnomAD dataset. High frequency of rs1143634 (*IL1B)*and rs1800896 (*IL10)* variants was observed, that are known to be associated with both negative and positive responses to infliximab and etanercept respectively. Moreover, we identified that the allele frequency of rs1295686 (*TH2LCRR*) associated with better response to Adalimumab is higher in the Qatari population. Furthermore, higher distribution of AA genotype on *HLA-E* (rs1264457) gene was observed which showed a better response to all TNF inhibitors. Additionally, we identified a novel missense deleterious variant in *TNF* (p. Pro88Ser) that increases the binding of *TNF* with *TNFR1*, which suggests the potential reduced response of TNF inhibitors in such patients. The findings of this study could be the basis for developing and implementing pharmacogenetic testing in autoimmune disease patients being considered for TNF inhibitor therapy in Qatar and beyond.

Session Title: Pharmacogenomics Poster Session I

PB2189 Pharmacogenomics Applied to Chronic Pain Treatment in Primary Care (PGx-ACT) trial; A Largely Virtual Randomized Trial

Authors:

D. Smith[1,2], R. Beyene[1], P. Kolm[1], T. A. Young[1], S. Zifa[1], V. Natividad[1], A. Licata[1], T. Moore[3], R. Walsh[1], D. Shikha[1], A. D. Walker[1], A. Turabi[1], M. B. Jacobs[1], B. N. Peshkin[4], S. M. Swain[1,2,4]; [1]MedStar Hlth., Columbia, MD, [2]Georgetown Univ. Med. Ctr., Washington, DC, [3]Kailos Genetics, Huntsville, AL, [4]Georgetown Univ., Washington, DC

Background *CYP2D6* variation is associated with reduced bioactivation of tramadol, codeine, and hydrocodone. The primary objective was to identify effects of providing pharmacogenomic (PGx) recommendations for patients with chronic pain treated in primary care clinics compared to standard care (SC). **Methods** An open-label, prospective, largely virtual trial randomized participants to a PGx-guided care (PC) or SC arm. Adults with chronic pain (≥ 3 months) treated with either tramadol, codeine, or hydrocodone enrolled from 20 primary care practice sites 1/2021 - 12/2022. Targeted next-generation sequencing was used for *CYP2D6*. CYP2D6 phenotype was assigned per genotype and drug interactions. PGx-trained pharmacists sent recommendations to provider in electronic health record (EHR). Alternative analgesic therapy was recommended for CYP2D6 intermediate or poor metabolizers (IM/PMs) for risk of ineffectiveness. Prescribing decisions were at provider discretion. Data were collected at baseline and 3 months. Analysis was in CYP2D6 IM/PMs. Primary outcome was change in pain intensity (PI) T-score in PC vs. SC arms. Secondary outcomes were number with PGx-aligned care, change in morphine milliequivalents (MME) prescribed, number with ≥ 30% improvement in PI. Analyses used t-test, Wilcoxon, Fisher's exact test. **Results** Eligibility was assessed for 4573 patients. 315 patients enrolled, 253 randomized, and 214 completed the trial (80% virtual). 104 (49%) were IM/PMs with 49 (PC) and 55 (SC). No difference was found in PI (-1.1 ± 5.6 vs. -1.5 ± 7.4; P = 0.74), ≥ 30% improvement (16% vs. 18%; P = 1), MME prescribed (-1.7 ± 13 vs. -1.1 ± 13; P = 0.82), or PGx-aligned care (69% vs. 65%; P = 0.68) between PC and SC arms, respectively. Post hoc analyses reassessed outcomes regardless of study arm. PI was -1.8 ± 6.4 vs. -0.24 ± 6.8 (P = 0.085) between those with (n=70) vs. without (n=34) PGx-aligned care. Patients with an analgesic change, with (n= 31) vs. without (n=34) PGx-aligned care had a reduced MME prescribed (-8.5 ± 16 vs. 2.8 ± 13; P < 0.001) and marginal change in PI (-2.7 ± 7.1 vs. -0.24 ± 6.8; P = 0.061). PC arm, 16% of provider notes mentioned PGx. Lessons learned 1) Since providers did not order test it may impact use of PGx 2) Providers saw participants weeks-months after PGx availability, which reduced awareness of PGx in EHR. **Conclusion** This PGx-guided strategy for patients with chronic pain prescribed select opioids was not associated with different prescribing decisions or clinical outcomes. Providers did not apply PGx for several potential reasons. Favorable post hoc analyses suggest future efforts should identify effective methods to implement and optimize PGx-aligned care.

Session Title: Pharmacogenomics Poster Session II

PB2190 Pharmacogenomics in the pediatric intensive care unit: an exome sequencing study

Authors:

N. Lynch[1], N. T. Elefant[2], J. Beckett[1], A. Geneslaw[1], V. Jobanputra[3], Z. Ren[1], D. S. Hughes[1], A. Revah-Politi[1], J. E. Motelow[2]; [1]Columbia Univ. Med. Ctr., New York, NY, [2]Columbia Univ., New York, NY, [3]New York Genome Ctr., New York, NY

Pharmacogenomics (PGx) refers to the effect of the patient's genetic architecture on medication response. Limited data in pediatric populations such as oncology and cardiology patients indicate that PGx drives changes in management by optimizing therapeutic drug levels and avoiding adverse drug events (ADEs). ADEs are more common in the pediatric intensive care unit (PICU) than the general pediatric ward, yet no prior studies have investigated the impact of PGx in the PICU. Genetic variants may govern medications commonly used in the PICU such as warfarin, fosphenytoin or proton pump inhibitors. While exome sequencing (ES) is not optimal to identify PGx variants, it is a common diagnostic tool in the PICU and a limited scope of PGx variants and phenotypes can still be identified. The objective of our study was to assess the overlap of clinically actionable metabolizer phenotypes with the administration of medication with PGx guidelines recommending modified dosing. We performed a retrospective analysis of ES from 45 children from a single PICU (the NewYork-Presbyterian/Columbia University Irving Medical Center). Exomes were aligned to human reference GRCh38 using DRAGEN and variants were called using Genome Analysis Toolkit (GATK). Star alleles and PGx phenotypes were generated using Pharmacogenomics Clinical Annotation Tool (PharmCAT). Medication administration data was collected from the electronic medical record. We found that 23 individuals received 8 unique medications for which we could identify a metabolizer phenotype from ES defined by 4 unique genes. Of these 23 individuals, seven were poor or intermediate metabolizers for medications administered to them in the PICU. Tacrolimus was the administered drug implicated in all three poor metabolizer phenotypes. In future directions, we will extend this study to 244 additional children in the PICU for a total cohort of 267 and determine whether geographic ancestry affects the identification of PGx phenotypes. To support future implementation of PGx testing for children who are at risk of frequent visits to the PICU, such as those with genetic and chronic conditions, we must lay the groundwork with data describing the expected yield and utility of PGx findings in this critical yet understudied population. Demonstrating the overlap between PGx variants and medications received in the PICU will establish preliminary data for clinical trials testing whether PGx-guided dosing improves efficacy while avoiding ADEs for children with critical illness.

Session Title: Pharmacogenomics Poster Session III

PB2191 Pharmacogenomics: Targeted Sequencing, HPRC Genome Annotation and Clinical Utilization

Authors:

Y-S. Liu[1], K-Y. Li[2], I-H. Chiu[3], C-Y. Chen[2], L-J. Shen[4], C-F. Huang[5], P-L. Chen[1,3]; [1]Graduate Inst. of Med. Genomics and Proteomics, Natl. Taiwan Univ., Taipei, Taiwan, [2]Dept. of Biomechatronics Engineering, Natl. Taiwan Univ., Taipei, Taiwan, [3]Dept. of Med. Genetics, Natl. Taiwan Univ. Hosp., Taipei, Taiwan, [4]Graduate Inst. of Clinical Pharmacy, Sch. of Pharmacy, Natl. Taiwan Univ., Taipei, Taiwan, [5]Dept. of Pharmacy, Natl. Taiwan Univ. Hosp., Taipei, Taiwan

Pharmacogenomics is a field that investigates the impact of genetic variations on drug response. Its significance lies in optimizing drug selection and dosage. Despite its potential, the complexity of pharmacogenes has limited its widespread application. This study aims to annotate the genotypes of 24 pharmacogenes to Human Pangenome Reference Consortium (HPRC) assemblies, which comprise 47 phased, diploid genomes from a genetically diverse cohort. The HPRC phased genome assemblies were aligned to the GRCh38 reference genome using Minimap2. To facilitate detection and recognition of single nucleotide variants and indels, the alignment file in PAF format was converted to the variant call format (VCF) using paftools.js. Additionally, we designed a target enrichment next-generation sequencing (NGS) panel comprising 60 important pharmacogenes selected from Clinical Pharmacogenetics Implementation Consortium (CPIC), Pharmacogene Variation (PharmVar) Consortium, and Pharmacogenomics Knowledge Base (PharmGKB). The HPRC DNA samples were sequenced using this panel, and the resulting sequencing data were compared with the HPRC VCF files. By comparing the sequencing results with the HPRC VCF files, we demonstrated the accuracy of our laboratory methodology for clinical use. Furthermore, approximately 300 participants from the National Taiwan University Hospital (NTUH) were enrolled in the trial, enabling the construction of a clinical decision support system (CDSS) for improved utilization of pharmacogenomics in clinical settings. Integrating genetic information into clinical decision-making could enhance patient care, optimize drug selection and dosage, and improve treatment outcomes. Through the comprehensive profiling of pharmacogenes and the development of a CDSS, this study offers a promising approach for advancing the integration of precision medicine into routine clinical practice.

PB2192 Predicting Precision Inhaled Corticosteroids Response in Asthma Patients

Authors:

N. Tahmin[1], A. Mitoubsi[1], B. Bakir Batu[2], A. Mohammed[2], L. Chinthala[2], A. Carlisle[2], T. Glauser[3], I. Krantz[4], K. Mandl[5], R. Davis[2], A. Wu[5], A. Khojandi[1], and members of the Genomic Information Commons Consortium; [1]Univ. Of Tennessee, Knoxville, Knoxville, TN, [2]Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN, [3]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH, [4]Children's Hosp. of Philadelphia, Philadelphia, PA, [5]Harvard Med. Sch., Boston, MA

Although most patients with asthma respond to inhaled corticosteroids (ICS), approximately 1/3 respond minimally or not at all. Evidence for an important role of genetics is emerging. However, current asthma risk assessment techniques are not fully capable of producing holistic and reliable risk scores that can guide precision treatment planning. Our study aims to develop machine learning models to predict patient-specific genome-based ICS response in asthma patients.

We leveraged the data collected through the Biorepository and Integrative Genomics (BIG) Initiative, University of Tennessee Health Science Center. We used whole exome sequence (WES) data from 290 patients (age: mean 16 years (IQR: 14-18), 52.4% Black, 47.6% non-Hispanic white) aged >6 years old, and a history of chronic ICS use. Cases were defined as patients with emergency department visit or hospitalization due to asthma within the 24-month follow-up window after the first ICS prescription. Out of all patients, there were 145 (50%) cases. We developed Random Forest (RF) models to examine the extent to which WES data can predict ICS response in patients. Data preprocessing included using MAF $\geq$ 5%, PLINK for linkage disequilibrium pruning (window size=50kb, step size=5, r^2=0.2), SNP variant ordinal encoding, and K-nearest neighbors (KNN) imputation (K=5). We performed two analyses: in analysis I, we used all remaining SNPs after feature selection using least absolute shrinkage and selection operator (LASSO); in analysis II, we used only SNPs from 17 previously identified genes affecting ICS response. Finally, models were evaluated using 10-fold cross-validation, and the mean and standard deviation of the area under the receiver operating characteristic curves (AUCs) were calculated.

Analyses I and II resulted in AUCs of 0.926±0.0861 and 0.904±0.0942 (paired t-test p-value 0.0887), respectively. Analysis I using all SNPs produced higher recall and precision. In addition, analysis I (using all SNPs) was more accurate for Black patients (11.7% misclassification for analysis I, using all SNPs, versus 22.4% misclassification for analysis II, using SNPs from previously identified genes, respectively).

Our results show that RF can accurately stratify ICS non-responders from responders, paving the way for producing patient-specific risk scores that can guide precision therapies. Furthermore, our results indicate that SNPs from genes not previously reported to affect ICS response could be relevant to improving predictions for Black patients. Future work includes external evaluation of the RF models and identifying the most important SNPs affecting ICS response.

Session Title: Pharmacogenomics Poster Session II

PB2193 Proteome-wide Mendelian randomization and conventional observational analyses reveal increased Alzheimer's disease risk associated with angiotensin-converting enzyme inhibitor use

Authors:

P. Huang[1], H. Tang[2], Z. Feng[2], E. Stergiakouli[1], T. Gaunt[1], J. Zheng[3,1], L. Yao[2,4]; [1]Univ. of Bristol, Bristol, United Kingdom, [2]Central South Univ., Changsha, China, [3]Shanghai Jiao Tong Univ., Shanghai, China, [4]King's Coll. London, London, United Kingdom

Introduction: Integrating evidence from real-world drug use data can enhance the translational value of findings from omics-based approaches to improve clinical practice. We aimed to identify plasma protein targets to inform drug discovery, repurposing, and vigilance for preventing Alzheimer's disease (AD). **Methods:** We first performed proteome-wide Mendelian randomization (MR) using protein quantitative trait locus (pQTL) data from Zheng et al. and genome-wide association data for AD from Bellenguez et al., followed by multi-omic validation, to explore potential druggable targets related to AD risk. For the top finding, we used multivariable MR (MVMR) to address possible pleiotropy and incorporated observational analyses of UK Biobank data with confounder-adjusted Cox proportional hazards models to further support the finding. **Results:** Of 593 proteins with single-*cis*, 124 proteins with multiple-*cis*, and 73 proteins with *cis* + *trans* pQTL instruments, MR identified 15 proteins (GRN, ACE, CD55, TREM2, TMEM106B, LILRB1, SIRPA, SIGLEC9, IDUA, LILRB2, TCN2, CTSH, GPC5, LILRA4 and IL6ST) with putative causal effects on AD after Bonferroni correction. After being validated by summary-data-based MR (SMR) with expression (eQTL), splicing (sQTL), and methylation quantitative trait locus (mQTL) data in blood and brain, angiotensin-converting enzyme (ACE) emerged as the most reliable target, exhibiting a protective effect against AD (OR: 0.91 [95% CI: 0.88-0.93]), and its eQTL, sQTL, mQTL SMR results had p-values < 0.05, passed the heterogeneity in dependent instruments (HEIDI) test ($P_{HEIDI} < 0.05$), and had plausible effect directions (gene expression had same effect directions and methylation in promoter areas had opposite effect directions with the protein). Despite its high relevance to blood pressure (BP) regulation, MVMR suggested the effect of ACE on AD was independent of BP. Observational evidence from UK Biobank supported our MR finding for ACE by showing a consistently increased incidence of AD among ACE inhibitor users, compared with: a) angiotensin II receptor blocker users (HR: 1.37 [95% CI: 1.02-1.84]), b) all other antihypertensive users (1.29 [1.08-1.54]), c) all participants without antihypertensive use (1.48 [1.28-1.72]), d) participants with hypertension but without antihypertensive use (1.26 [1.07-1.48]), and e) all participants without ACEI use (1.41 [1.22-1.63]). **Conclusions:** Our findings expand the understanding of potential targets for AD prevention and highlight the need for further investigation of AD risk associated with the use of ACE inhibitors, a commonly prescribed first-line antihypertensive in clinical practice.

Session Title: Pharmacogenomics Poster Session III

PB2194 RAB8A as a novel regulator of MED16 and its effect on 5'-deoxy-5-fluorouridine response.

Authors:

J. Campbell, C. Murtagh, A. Stark; Univ. of Notre Dame, Notre Dame, IN

Breast cancer is a leading cause of death among women in the United States and traditional treatment regimens commonly utilize trial and error methodologies. Individualized treatment regimens can optimize drug response in cancer patients. However, these plans depend upon a clear understanding of how genetics influences protein expression and drug response. Our objective was to identify functional protein candidates for optimizing capecitabine therapy. 5'-deoxy-5-fluorouridine is a metabolite of capecitabine, an oral prodrug and antimetabolite used for breast cancer treatment, and is the activated form of the drug used for in vitro studies. Three SNPS localized to the short arm of chromosome 19 in RAB8A that were associated with MED16 protein expression ($p = 0.00002$) and 5'-deoxy-5-fluorouridine response ($p < 0.0005$) in lymphoblastoid cells were initially identified. Importantly, MED16 expression was also correlated with 5'-deoxy-5-fluorouridine response in lymphoblastoid cells ($p = 0.01$). RAB8A is a member of the RAS superfamily, highly conserved, and implicated in tumorigenesis. Past studies have revealed that MED16 is a coactivator involved in the transcriptional regulation of many RNA-polymerase II dependent genes and plays a role in Vitamin D reception, which may affect calcium homeostasis, cell proliferation, and cell differentiation. Thus, expression of MED16 may significantly alter transcription levels of RNA-polymerase II dependent genes and affect functions such as cell proliferation which are abnormal in cancerous cell cycles. No current literature links MED16 and RAB8A. We proposed a pathway through which MED16 might operate utilizing the three SNPs identified due to their significant correlation with MED16 and location with RAB8A. We then knocked down RAB8A via siRNA in MCF7 breast cancer cells utilizing Lipofectamine as a transfection reagent and assessed RAB8A and MED16 expression levels. Utilizing qPCR analysis, our results displayed significant knockdown of RAB8A and MED16 and therefore support our hypothesized connection of RAB8A and MED16. Further evaluation will be done on down stream targets and the potential implication to capecitabine treatment.

Session Title: Pharmacogenomics Poster Session I

PB2195 Racial differences in *UGT1A1* allele frequencies and its potential impact in pharmacogenetic testing for cancer chemotherapy drugs.

Authors:

K. choi, G. Selkov, R. Huether, B. Rhead, F. De La Vega; Tempus Lab Inc., Chicago, IL

UGT1A1 pharmacogenetic (PGx) tests evaluate the risk of adverse events associated with the chemotherapy drugs irinotecan and belinostat by genotyping the promoter TA-repeat polymorphisms (*28, *36, and *37) and two exonic SNVs (*6 and *27). The prevalence of these variants differs significantly by race. In particular, the frequencies of *36 and *37 are 5% and 7% in African-descent populations, respectively, whereas in other populations they are less than 0.2% (cf. gnomAD database). *37 is known to reduce UGT1A1 enzyme activity to a greater extent than *28; however, it is not included in the current FDA drug labels. Given the prevalence of *UGT1A1* TA-repeat alleles, compound heterozygotes carrying a TA-repeat variant and either *6 or *27 are not uncommon. We analyzed racial differences in the prevalence of *UGT1A1* variants and the potential for misassignment of metabolizer phenotype in the absence of phasing. Normal tissues from 14,580 de-identified cancer patients were sequenced for *UGT1A1* using the Tempus xT 648-gene panel NGS test. TA repeat length was determined using a bespoke Bayesian repeat calling algorithm. Four race and ethnicity categories — Non-Hispanic (NH) Asian, Hispanic or Latino, NH Black, and NH White — were imputed from continental genetic ancestry derived from 654 ancestry informative markers, as described previously. We identified 121 unique exonic variants and four promoter TA-repeat polymorphisms ([TA]5-8) in *UGT1A1*. *In silico* analysis predicted 68 of the exonic variants as potentially deleterious. Notably, 17.6% of NH Black patients were carriers of either *36 or *37. Ninety-eight compound heterozygotes of potential clinical significance were identified. However, without phasing information, accurate assignment of *UGT1A1* metabolizer phenotype in compound heterozygotes is challenging. This is particularly relevant in the NH Asian population, where 6% of the population in the cohort are compound heterozygotes, a rate 6.4-fold higher than the overall cohort prevalence. Our research highlights racial differences in *UGT1A1* allele frequencies, particularly among NH Black and NH Asian populations, which could influence test results and their interpretation in some patients. Further investigation in diverse populations is crucial to ensure equality in pharmacogenetic testing related to cancer drug side effects.

Session Title: Pharmacogenomics Poster Session II

PB2196 Response to anti-IL17 therapy in inflammatory disease is not strongly impacted by genetic background

Authors:

L. Jostins-Dean[1], C. Zhang[2], K. Shestopaloff[1], B. Hollis[1], C. Kwok[1], C. Hon[3], N. Hartmann[4], C. Tian[2], M. Wozniak[5], L. Santos[6], D. West[1], S. Gardiner[1], A-M. Mallon[6], A. Readie[7], R. Martin[7], T. Nichols[1], M. Beste[3], J. Zierer[8], E. Ferrero[8], M. Vandemeulebroecke[4]; [1]Univ. of Oxford, Oxford, United Kingdom, [2]China Novartis Inst.s for Bio-Med. Res., Shanghai, China, [3]Novartis Inst.s for BioMed. Res., Cambridge, MA, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Ireland Limited, Dublin, Ireland, [6]The Alan Turing Inst., London, United Kingdom, [7]Novartis Pharmaceuticals Corp., East Hanover, NJ, [8]Novartis Inst.s for BioMed. Res., Basel, Switzerland

Response to the anti-IL17 monoclonal antibody secukinumab is heterogeneous, and not all patients respond to treatment. Understanding whether this heterogeneity is driven by genetic variation is a key aim of pharmacogenetics, and could influence precision medicine approaches in inflammatory diseases. Using changes in disease activity scores across 5218 genotyped individuals from 19 clinical trials across four indications (psoriatic arthritis, psoriasis, ankylosing spondylitis and rheumatoid arthritis), we tested whether genetics predicted response to secukinumab. We did not find any evidence of association between treatment response and common variants, imputed HLA alleles, polygenic risk scores of disease susceptibility, or cross-disease components of shared genetic risk. This suggests that anti-IL17 therapy is equally effective regardless of the genetic background of the patient, which has important implications for future genetic studies of biological therapy response in inflammatory diseases.

PB2197 Role of Pharmacogenomics in Oncology

Authors:

C. Lee, J. Leow, S. Chew; Natl. Cancer Ctr. Singapore, Singapore, Singapore

Introduction: The uptake of pre-emptive genotype testing in clinical practice has been relatively low in Singapore. There is increasing interest in the implementation of pharmacogenomics as a mainstream service in National Cancer Centre Singapore (NCCS). The gene-drug pair of CYP 2D6-tamoxifen is regarded as the most relevant. This study aims to determine the acceptance of patients on tamoxifen for genotype testing as well as the facilitators and barriers for acceptance, and to make recommendations for the establishment of a pharmacogenomics service.
Methods: This was a cross-sectional survey of patients collecting tamoxifen from 1st September 2022 to 28th February 2023 at NCCS. Patients were evaluated on their acceptance of pre-emptive genotype testing using a questionnaire derived from the Theory of Planned Behaviour. The patients' demographics, social history, knowledge of and prior experience with genetic testing were recorded.
Results: A total of 202 patients responded, all of whom were female. Seventy percent of patients responded that they intend to undergo pre-emptive genotype testing for CYP 2D6 if offered, 76.1% felt that pre-emptive testing for CYP 2D6 should be offered up front to all patients taking tamoxifen while 42% indicated they were willing to pay for testing. High overall scores for attitude, subjective norms and perceived behavioural control were independent predictors of acceptance. Potential facilitators for acceptance include adequate data security, strong family/ social support, convenient testing procedures, 3rd-party payer support, and adequate patient education. Lack of physician support, high cost of testing and lack of information and guidance from healthcare providers would discourage patients from testing.
Conclusion: There is a high level of acceptance among patients in this study for pre-emptive genotype testing. Further research is required to demonstrate the cost-effectiveness of testing. Training on pharmacogenomics should be provided to healthcare professionals to increase competency which would help in the establishment of pharmacogenomics services.

Session Title: Pharmacogenomics Poster Session I

PB2198 † Sex-biased gene expression and gene-regulatory networks of sex-biased adverse event drug targets and drug metabolism genes

Authors:

B. Lasseigne, J. Fisher, A. Clark, E. Jones; The Univ. of Alabama at Birmingham - SOM, Birmingham, AL

Previous pharmacovigilance studies and a retroactive review of cancer clinical trial studies identified that women were more likely to experience adverse drug events (i.e., any unintended effects of medication), and men were more likely to experience adverse events that resulted in hospitalization or death. These sex-biased adverse events (SBAEs) are due to many factors not entirely understood, including differences in body mass, hormones, pharmacokinetics, and liver drug metabolism enzymes and transporters. We first identified 416 drugs associated with SBAEs from the FDA Adverse Event Reporting System (FAERS) database. Next, we evaluated sex-specific gene expression of the known drug targets and metabolism enzymes for those SBAE-associated drugs and found 32 known drug metabolism enzymes and 84 drug targets enriched. We also constructed sex-specific tissue gene-regulatory networks to determine if these known drug targets and metabolism enzymes from the SBAE-associated drugs had sex-specific gene-regulatory network properties and predicted regulatory relationships. We identified liver-specific gene-regulatory differences for drug metabolism genes between males and females (e.g. immediate node neighbors), which could potentially explain observed sex differences in pharmacokinetics and pharmacodynamics. In addition, we found that ~85% of SBAE-associated drug targets had sex-biased gene expression or were core genes of sex- and tissue-specific network communities, significantly higher than randomly selected drug targets. Also, the number of SBAE-associated drug targets that were core genes of sex- and tissue-specific network communities were significantly higher than randomly selected drug targets. Lastly, we provide the sex-biased drug-adverse event pairs, drug targets, and drug metabolism enzymes as a resource for the research community. Overall, we provide evidence that many SBAEs are associated with drug targets and drug metabolism genes that are differentially expressed and regulated between males and females. These SBAE-associated drug metabolism enzymes and drug targets may be useful for future studies seeking to explain or predict SBAEs.

Session Title: Pharmacogenomics Poster Session II

PB2199 Targeting and comprehensive characterization of pharmacogenes using Oxford Nanopore Technologies' adaptive sampling

Authors:

S. Hickey[1], **C. Tyer**[1], L. Ly[1], J. Beaulaurier[1], S. Juul[2]; [1]Oxford Nanopore Technologies, Inc, Alameda, CA, [2]Oxford Nanopore Technologies, Inc, New York, NY

Variants in pharmacogenes influence pharmaceutical metabolism by changing the efficacy of uptake, signal transduction, and breakdown of certain molecules. Here, we demonstrate enrichment and comprehensive characterization of a pharmacogenomics (PGx) gene panel including 278 unique pharmacogenetic targets sourced from the FDA, PharmGKB, and the Clinical Pharmacogenetics Implementation Consortium (CPIC). The panel was enriched and sequenced using Oxford Nanopore Technologies adaptive sampling (AS), a software-based approach to enrich regions of interest by uploading a file of genomic coordinates. During sequencing, DNA strands are basecalled and mapped to a reference genome in real time. Strands that align outside of the target regions are ejected from the nanopore before sequencing is complete, while strands that are on-target are allowed to sequence completely.Patient-derived cell lines with known allelic variants were barcoded and sequenced on PromethION flow cells. AS enabled all PGx genes from the panel to be enriched to sufficient coverage for variant calling, with no drop-out for any target genes. Samples were analyzed using the wf-human-variation Epi2Me Labs pipeline from Oxford Nanopore Technologies, which called small variants with Clair3, structural variants with Sniffles2, and phased reads with whatshap. In particular, challenging structural variants in *CYP2D6*, including tandem *CYP2D6-CYP2D7* hybrids, were able to be haplotyped and fully resolved.Star (*) allele genotypes were called using PharmCAT. Calls were 89% concordant with Genetic Testing Reference Materials Coordination Program (GeT-RM) consensus calls; discrepancies were observed for certain genes due to changing definitions in the GeT-RM reference database. Additionally, using native nanopore sequencing CpG methylation sites were called using dorado, revealing haplotype-specific methylation at genes such as *VKORC1*. While the biological significance of the methylation status of PGx genes has received comparably less attention than genetic variants, this is an interesting area for future research.Overall, we demonstrate targeted nanopore sequencing with AS as a useful tool for the enrichment and phasing of PGx gene panels, resulting in high coverage for haplotyped variant calling including structural variations and methylation. The strategy allows for comprehensive PGx analysis that can be easily modified to encompass additional genes of interest as novel pharmacogenomic variants are discovered.

Session Title: Pharmacogenomics Poster Session III

PB2200 The combined effect of rare and common variants in *GSDMB/ORMDL3* is associated with response to inhaled corticosteroids among asthmatic children

Authors:

A. Wu[1], K. Voorhies[2], M. McGeachie[1], A. Mohammed[3], L. Chinthala[3], K. Mandl[1], B. Raby[1], R. Davis[4], S. Lutz[1]; [1]Harvard Med. Sch., Boston, MA, [2]Harvard Pilgrim Hlth.Care Inst., Boston, MA, [3]Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN, [4]Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN

Rationale: Inhaled corticosteroids (ICS) are efficacious in the prevention of asthma which affects more than 300 million people in the world. While genome-wide association studies identified genes involved in differential treatment responses to ICS in asthma, few studies have evaluated the potential effects of combined rare and common variants and the contribution of rare vs common variants. **Methods:** Among children with asthma on ICS with whole exome sequencing (WES) in the PrecisionLink Biobank for Health Discovery at Boston Children's Hospital, we examined if the combined effect of rare and common variants are associated with ICS response as defined by hospitalization or emergency department visits. We examined rare and common variants associated with ICS response for 12 regions previously associated with asthma and ICS response (*DPP10, FBXL7, NDFIP1, TBXT, GLCCI1, HDAC9, TBXAS1, STAT6, GSDMB/ ORMDL3, CRHR1, GNGT2, FCER2*). We used the sequence kernel association test (SKAT) to examine the combined effect of rare and common variants on ICS response using the combined sum test. We adjusted for age, sex, and BMI and stratified by race for 91 White and 20 Black children. We tested for replication in the Biorepository and Integrative Genomics (BIG) Initiative, University of Tennessee Health Science Center among 83 White and 134 Black children with asthma, ICS use, and WES data. **Results:** Using a Bonferroni threshold of 0.05/12=0.004, *GSDMB/ ORMDL3* was significantly associated with ICS response for the combined effect of both rare and common variants (p-value=0.003 for both rare and common variants, p-value=0.008 for only rare variants, p-value=0.03 for only common variants) among White children in the PrecisionLink biobank. This signal replicated in the BIG Initiative for the combined effect of rare and common variants (p-value=0.02 for both rare and common variants, p-value=0.30 for only rare variants, p-value=0.03 for only common variants). **Conclusions:** Using WES data, the combined effect of rare and common variants for *GSDMB/ORMDL3* was associated with ICS response among asthmatic children in the PrecisionLink biobank with replication in the BIG Initiative. Future studies examining the combined effect of both rare and common variants may help elucidate mechanisms underlying ICS response variability. This proof-of-concept study demonstrates the potential power of biobanks of pediatric real-life populations in genomic investigations.

Session Title: Pharmacogenomics Poster Session I

PB2201 The RNA-editing ADAR proteins broadly regulate gene expression in hepatic cells

Authors:

J. Collins, F. Yu, D. Wang; Univ. of Florida, Gainesville, FL

The adenosine deaminase acting on RNA (ADAR and ADARB1) proteins are RNA-editing enzymes that broadly regulate gene expression through editing-dependent or editing-independent mechanisms. Using siRNA-mediated gene knockdown (KD) in HepaRG cells, we found broad changes in the expression of drug-metabolizing enzymes and related transcription factors in the KDs. We used whole transcriptome and miRNA sequencing to further understand the regulatory networks of ADAR and ADARB1 on gene expression. We detected global changes to gene expression after KD of either ADAR or ADARB1, resulting in differentially expressed (DE) transcripts for both ADAR (7028) and ADARB1 (3121), including many genes related to drug metabolism and disposition. Gene ontology (GO) analysis found that pathways related to viral defense and inflammation were enriched in the ADAR KD, in agreement with previous reports in other tissues and cell types. In contrast, after ADARB1 KD, cellular homeostasis and metabolism pathways became enriched, indicating that ADAR and ADARB1 have non-overlapping targets. We also identified numerous alterations to transcript splicing isoforms and sequence edits in both KDs. Among these, several key pharmacogenes were altered (e.g., CYP3A4 and CYP3A5), supporting previous work that the ADARs regulate drug metabolism. In addition, we observed broad changes in the expression of long noncoding RNAs (ADAR KD - 7854 DE, ADARB1 KD- 3208 DE) and miRNAs (ADAR KD - 143 DE, ADARB1 KD - 122 DE). Our results showed the broad regulatory roles of ADAR and ADARB1 on the expression of mRNA, lncRNA, and miRNA in the liver, highlighting the different targets of the ADARs. These results will help elucidate the pathways and cellular mechanisms leading to changes in the expression of the pharmacogenes. Since dysregulation of the ADARs has been directly implicated in the progression of many cancers, including hepatocellular carcinoma, the results will further our understanding of cancer progression and regulation of drug metabolism in the liver.

Session Title: Pharmacogenomics Poster Session II

PB2202 Treatment of MeCP2e1 deficient mice with microglia ablating PLX3397 correlated with sex disparate on body weight but not Rett like disease severity

Authors:

D. Yasui[1], H. M. Sophia[1], K. E. Neier[1], E. G. Thrall[1], R. Kawai[1], T. A. Tran[1], C. G. Torres[1], A. L. Humphries[1], A. M. Madany[1], P. Ashwood[2], J. Lasalle[1]; [1]UC Davis Sch. of Med., Davis, CA, [2]UC Davis Mind Inst., Davis, CA

Rett syndrome (RTT) is a complex neurodevelopmental disorder that occurs in 1 in 10,000 births. Approximately 95% of RTT patients are females heterozygous for X chromosome linked *MECP2* mutations and are thus mosaic for wild-type and mutant *MECP2* expression at a cellular level. *MECP2* encodes MeCP2e1 which is necessary for brain development and MeCP2e2 which is necessary for placental development. Analysis of a construct relevant, MeCP2e1 deficient mouse model suggests that microglia contribute to RTT like gait defects, as well as gut microbiome and metabolic changes. Thus, we hypothesized that pharmacologic ablation of microglia would ameliorate RTT like phenotypes in MeCP2e1 deficient mice. Therefore, PLX3397 a CSF1R/c-kit inhibitor dissolved in AIN-76A chow at 290 PPM was orally administered to *Mecp2e1*$^{-/+}$, *Mecp2e1*$^{-/y}$ and *Mecp2e1*$^{+/+}$ and *Mecp2e1*$^{+/y}$ mice, either acutely (2 weeks) or chronically (from 4-23 weeks) to ablate microglia in brain, compared to vehicle control. *Mecp2e1*$^{-/+}$, *Mecp2e1*$^{-/y}$, and *Mecp2e1*$^{+/+}$ and *Mecp2e1*$^{+/y}$ littermates were weighed and scored for neurophenotypes for 23 weeks post-weaning. Gait, fecal cytokines, fecal short chain fatty acids and gut microbial composition was assessed in all mice before, during and after disease onset. Surprisingly, neither acute or chronic PLX3397 treatment significantly reduced neurophenotype score either in *Mecp2e1*$^{-/+}$ females or *Mecp2e1*$^{-/y}$ male mice. Instead, chronic PLX3397 treatment significantly elevated disease severity in *Mecp2e1*$^{-/+}$ females compared to vehicle *Mecp2e1*$^{-/+}$ controls. However, chronic PLX3397 treatment significantly reduced weight gain over time in *Mecp2e1*$^{-/y}$ and *Mecp2e1*$^{+/y}$ males compared to vehicle male controls, but not *Mecp2e1*$^{-/+}$ females compared to untreated *Mecp2e1*$^{-/+}$ controls. Interestingly, the use of purified Envigo AIN-76A chow reduced disease severity overall in *Mecp2e1*$^{-/+}$ female and *Mecp2e1*$^{-/y}$ male mice compared to a previous study where *Mecp2e1*$^{-/+}$, *Mecp2e1*$^{-/y}$ and *Mecp2e1*$^{+/+}$ and *Mecp2e1*$^{+/y}$ mice were fed PicoLab mouse diet, possibly due to differences in lipid composition. Neither gait stride length nor organ weight were significantly altered by acute or chronic PLX3397 treatment in both *Mecp2e1*$^{-/+}$ females or *Mecp2e1*$^{-/y}$ males. As a caveat, PLX3397 treatment affected c-kit signaling as shown by coat color changes and may have produced significant liver pathology in certain mice. Although targeting of microglia with PLX3397 did not reduce disease severity in *Mecp2e1*$^{-/+}$ female or *Mecp2e1*$^{-/y}$ Rett model mice, the results of this study together with our prior investigations of lipid deficiencies suggest a potential dietary intervention for Rett syndrome.

Session Title: Pharmacogenomics Poster Session III

PB2203 Using genome-wide gene-drug interactions to test for genomic sensitivity to statins in the treatment of hypercholesterolemia

Authors:

B. Verhulst; Texas A&M Univ., Bryan, TX

Hypercholesterolemia is a major risk factor for cardiovascular disease, which is the leading cause of death world-wide. While prescription medications (chiefly statins) are undeniably beneficial, the magnitude of their benefit may depend on an individual's genotype. Our premise is that genomic variants interact with medications resulting in heterogeneous LDL cholesterol levels. To clarify the etiological factors the culminate in heterogeneous cholesterol levels, we use a genomic moderation approach that is more sensitive to gene-drug interactions than existing methods. Two factors have hindered research on gene-drug interplay: 1) existing methods struggle to identify robust and replicable interactions; and 2) genome-wide studies have low statistical power. To overcome these obstacles, 1) we developed genomic methods that are more sensitive to genetic interactions, and 2) we use an extremely large genetically-informed dataset. Our general hypothesis is that statins may be more effective for individuals with specific genotypes. After conducting gene-statin interaction analyses for LDL cholesterol, we collate the results with pharmaceutical databases to identify corresponding significant interactions and drug targets. Our results: 1) highlight specific genotypes that increase the effectiveness of statins; 2) provide a novel test of whether pharmacologically predicted gene targets correspond with observed differential genetic associations; and 3) identify genomic pathways for future drug refinement or repurposing.

Session Title: Pharmacogenomics Poster Session I

PB2204 Variants reaching Genomic wide significance in their association with therapeutic response to Atenolol or Topiramate in migraine prophylaxis are identified.

Authors:

F. Cutrer, L. Wang, C. J. Klein; Mayo Clinic, Rochester, MN

At present, the prophylactic treatment of migraine is given to patients without knowledge of the relevant mechanism of action and with no biologically based rationale for drug selection. To address this, we performed Whole Genome sequencing using the blood DNA samples from 370 patients treated for three months with monotherapy of either atenolol (n=179) or topiramate (n=191) for migraine prophylaxis. We assessed the treatment response using the percentage of headache days reduced. Association with treatment response reached genome-wide significance in 374 variants for atenolol treatment and 1,031 variants for topiramate using PLINK with a general linear model. Among the atenolol-associated variants, 77% were substitutions, 23% were insertions/deletions while in the topiramate-associated variants, 75% were substitutions and 25% were insertions/deletions. 22% of atenolol and 26% of topiramate treatment-associated SNPs were novel with no rs ID. No shared variants were detected between the atenolol and topiramate groups. None of the variants associated with atenolol or topiramate response were reported by prior migraine GWAS studies. Non-synonymous coding SNPs (chr1:161365641:C/T:1) in *CFAP126* for atenolol; (chr7:100057239: T/G:1) in *ZSCAN21* and (chr12:122976756: G/A:1) in *OGFOD2* for topiramate treatment response were identified (p<5E-8). Top pathway using SNPs associated with either atenolol or topiramate monotherapy treatment (p<0.006) include: **Atenolol:** Regulation of commissural axon pathfinding by SLIT and ROBO p=0.000891 Genes involved *ROBO2, SLIT3;* Citric acid cycle p=0.004416, *SDHC, SUCLG2* **Topiramate:** Non-integrin membrane-ECM interactions p=0.000632 Genes involved *COL4A2, COL4A6, ITGAV, PRKCA, TNC*; Synthesis of PIPs at Golgi membrane p=0.001146 *PIK3C2G, PIK3R4, TPTE*; ROBO receptors bind AKAP5 p=0.0047 *PRKCA, ROBO2*; Laminin interactions p=0.005146 *COL4A2, COL4A6, ITGAV*; Regulation of commissural axon pathfinding by SLIT and ROBO p=0.00583 *ROBO2, SLIT3* It is interesting to note that pathways involving *SLIT* and *ROBO2* are implicated in response to both Atenolol and Topiramate. Pathways involved Synthesis of PIPs at the Golgi membrane have been highly associated with Topiramate and with verapamil in prior similar investigations of migraine prophylaxis (Cutrer et al. 2022). We propose that response to prophylactic treatment is an element of phenotype linked to a discoverable underlying relevant mechanism of action in migraine headache suppression.

Session Title: Pharmacogenomics Poster Session II

PB2205 Variation in the response to synthetic glucocorticoids is dominantly explained by a single measure of efficacy.

Authors:

N. Giroux, G. Johnson, A. Barrera, T. Reddy; Duke Univ., Durham, NC

Synthetic glucocorticoids (GCs) induce the activity of the glucocorticoid receptor (GR) at thousands of sites across the genome to inhibit inflammation and suppress autoimmunity. The development of selective GR modulators (SGRMs) would see the dissociation of these therapeutic GC effects from concomitant adverse metabolic effects. We measured the gene expression and regulatory element activity responses to ten SGRMs, including full and partial GR agonists as well as antagonists, using mRNA-seq and STARR-seq, a genome-wide high-throughput reporter assay. Differential expression was induced by SGRMs at 8,072 genes, and differential activity was induced at 49,711 regulatory elements. We further reported the efficacies, defined as the number of differentially expressed genes or the number of regulatory elements with differential activity, measured for each SGRM compared to a vehicle control. We identified highly correlated linear relationships between responses to each SGRM and dexamethasone, a strong GR agonist used as a positive control for this study, contrary to claims that these synthetic GCs selectively modulate GR activity. Using these relationships, we estimated the change in gene expression and regulatory element activity with respect to dexamethasone, defined as the coefficient of a linear regression model and referred to as the relative response. In summary, we observed that the relative responses induced by agonists were consistently larger than those of non-agonists for both gene expression (agonists: 0.39-0.96; non-agonists: 0-0.14) and regulatory element activity (agonists: 0.37-0.87; non-agonists: 0.08-0.20). Furthermore, the variances in the relative responses were largely explained by the efficacies of the SGRMs alone, with 87% of the variance in relative gene expression responses and 93% of the variance in relative regulatory element activity responses accounted for. Though we found that two antagonistic SGRMs - CORT108297 and RU486 - produced a higher proportion of repressive effects compared to dexamethasone, overall, we demonstrated limited evidence of differential anti-inflammatory or metabolic gene set enrichment. Thus, we concluded that this functional assessment of selective modulation of GR activity instead identified conserved molecular effects which were tuned by the efficacy of the synthetic GC.

Session Title: Pharmacogenomics Poster Session III

PB2206 Whole-genome sequencing pharmacogenomic variants in a census-based Brazilian cohort of admixed elderly individuals

Authors:

M. Naslavsky[1,2,3], M. Scliar[4], G. Debortoli[5], B. Thiruvahindrapuram[6], S. W. Scherer[6,7], Y. A. O. Duarte[8], M. Zatz[9,10], G. Suarez-Kurtz[11], E. J. Parra[12], L. B. Hussman Inst. for Human Genomics, Univ. of Miami Miller Sch. of Med., Miami, FL

Pharmacogenomics (PGx) studies aim the identification of genetic variants that modulate response to drugs. The distribution of PGx variants varies across populations, and whole-genome sequencing (WGS) is a comprehensive approach to detect both common and rare variants. We studied the frequency of PGx markers in a WGS dataset from the “Health, Well-Being, and Aging Study” (SABE), a census-based admixed cohort from Sao Paulo, Brazil, which includes variants from WGS of 1,171 unrelated, elderly individuals. Stargazer tool was used to call star alleles and structural variants (SVs) across 38 pharmacogenes. Clinically relevant variants classified by PharmGKB and CPIC were investigated, and the predicted drug response phenotype was analyzed in combination with the medication record to assess individuals potentially at high-risk of gene-drug interaction. 352 unique star alleles or haplotypes were observed, of which 255 and 199 had a frequency < 0.05 and < 0.01, respectively. For star alleles with frequency > 5% (n=97), decreased, loss-of-function and unknown function accounted for 13.4%, 8.2% and 27.8% of alleles or haplotypes, respectively. Structural variants (SVs) were identified in 35 genes for at least one individual, and occurred with frequencies >5% for *CYP2D6*, *CYP2A6*, *GSTM1*, and *UGT2B17*. More than 98% of the individuals carried at least one high risk genotype-predicted phenotype in pharmacogenes with PharmGKB level of evidence 1A for drug interaction. The Electronic Health Record (EHR) Priority Result Notation and the cohort medication registry were combined to assess high-risk gene-drug interactions. Overall, 42.0% of the cohort used at least one PharmGKB evidence level 1A drug, and 18.9% of individuals who used PharmGKB evidence level 1A drugs had a genotype-predicted phenotype of high-risk gene-drug interaction. We described the applicability of next-generation sequencing (NGS) techniques for translating PGx variants into clinically relevant phenotypes on a large scale in the Brazilian population and explores the feasibility of systematic adoption of PGx testing in Brazil.

Session Title: Epigenetics Poster Session I

PB2207 † 3D features of the genome impact escape from X inactivation.

Authors:

X. Deng[1], H. Fang[1], A. R. Tronco[1], G. Bonora[2], G. N. Filippova[1], C. Disteche[1,3]; [1]Dept. of Lab. Med. and Pathology, Univ. of Washington, Seattle, WA, [2]Dept. of Genome Sci., Univ. of Washington, Seattle, WA, [3]Dept. of Med., Univ. of Washington, Seattle, WA

The number and escape levels of genes that escape X chromosome inactivation (XCI) in female somatic cells vary among tissues and cell types, potentially contributing to specific sex differences. Here we investigate the role of CTCF, a master chromatin conformation regulator, in regulating escape from XCI. CTCF binding profiles and epigenetic features were systematically examined at constitutive and facultative escape genes using mouse allelic systems to distinguish the inactive X (Xi) and active X (Xa) chromosomes. We found that escape genes are located inside domains flanked by convergent arrays of CTCF binding sites, consistent with the formation of loops. In addition, strong and divergent CTCF binding sites often located at the boundaries between escape genes and adjacent neighbors subject to XCI would help insulate domains. Facultative escapees show clear differences in CTCF binding dependent on their XCI status in specific cell types/tissues. Concordantly, deletion but not inversion of a CTCF binding site at the boundary between the facultative escape gene *Car5b* and its silent neighbor *Siah1b* resulted in loss of *Car5b* escape. Reduced CTCF binding and enrichment of a repressive mark over *Car5b* in cells with a boundary deletion indicated loss of looping and insulation. In mutant lines in which either the Xi-specific compact structure or its H3K27me3 enrichment was disrupted, escape genes showed an increase in gene expression and associated active marks, supporting the roles of the 3D Xi structure and heterochromatic marks in constraining levels of escape. Our findings indicate that escape from XCI is modulated both by looping and insulation of chromatin via convergent arrays of CTCF binding sites and by compaction and epigenetic features of the surrounding heterochromatin.

Session Title: Epigenetics Poster Session II

PB2208 A cistrome-wide association study identifies novel risk loci for renal cell carcinoma.

Authors:

Z. Zhang[1], D. Osei-Hwedieh,[1,2], J. Anderson[2], S. Abou Alaiwi[1,3], A. Nassar[4], J-H. Seo[1], E. Adib[1], T. El Zarif[1], T. Choueiri[1], M. Freedman[1], S. Baca[1]; [1]Dana-Farber Cancer Inst., Boston, MA, [2]Harvard Med. Sch., Boston, MA, [3]Brigham and Women's Hosp., Boston, MA, [4]Yale Cancer Ctr., New Haven, CT

Renal Cell Carcinoma (RCC), the most common type of kidney cancer, has been extensively studied through genome-wide association studies (GWAS) to identify genetic risk loci. Most RCC risk variants map to gene regulatory elements, but how they confer risk of RCC remains largely unknown. To discover RCC risk variants that confer risk through effects on regulatory element activity, we performed a cistrome-wide association study (CWAS). This analysis integrated summary statistics from a large-scale RCC GWAS (10,784 RCC cases and 20,406 controls) and novel genetic models of regulatory element activity. We leveraged ChIP-seq profiles for H3K27ac - a histone modification associated with active regulatory elements - from 64 RCC samples. We identified 13,534 regulatory elements that were influenced by genetic variation, as determined by correlation of SNP genotype with H3K27ac peak intensity or by allelic imbalance of heterozygous SNPs in ChIP-seq reads. We identified 12 regulatory elements that were significantly associated with RCC risk. Seven mapped to known RCC risk loci such as 2*p*21, 3*q*22.1, 11*q*13.3, 12*p*12.1, and 14*q*24.2, and provided mechanistic hypotheses to explain how genetic variation confers risk at these sites by modifying activity of specific regulatory elements. Five additional RCC-associated peaks were identified in regions that did not harbor any genome-wide significant SNPs within 2Mb. By utilizing chromatin conformational data and eQTL profiles, a regulatory element on 7*q*31.33 capturing a significant GWAS variant with limited functional annotation was linked to *POT1*, a protein involved in the regulation of telomerase-mediated telomere extension. In summary, our study identified known risk loci and nominated novel risk regions contributing to the development of RCC. We highlight the increased power of CWAS to nominate risk loci and investigate mechanisms of risk conferred by genetic variation in regulatory DNA. Mechanistic insights gained from these studies may advance the biological understanding, risk stratification, and therapeutic targeting of RCC.

Session Title: Epigenetics Poster Session III

PB2209 A classifier for lifetime cannabis use based on DNA methylation.

Authors:

L. Zhou[1], B. C. Quach[1], K. G. Lawrence[2], J. van Dongen[3], J. A. Marks[1], Z. Xu[2], L. J. Bierut[4], M. Ollikainen[5], J. A. Taylor[2], J. T. Bell[6], J. Kaprio[5], D. I. Boomsma[7], K. Xu[8], D. P. Sandler[2], D. B. Hancock[1], E. O. Johnson[1], F. Fang[1]; [1]RTI Intl., Research Triangle Park, NC, [2]NIH/NIEHS, Research Triangle Park, NC, [3]VU Amsterdam, Amsterdam, Netherlands, [4]Washington Univ Sch Med, St Louis, MO, [5]Univ Helsinki, Helsinki, Finland, [6]King S Coll. London, London, United Kingdom, [7]VU Univ. Amsterdam, Amsterdam, Netherlands, [8]Yale Sch. Med., New Haven, CT

Cannabis use is highly prevalent, and its effects on health vary with potential adverse outcomes and therapeutic benefits depending on the context. However, studying cannabis-related health outcomes can be difficult due to the lack of reliable biomarkers to accurately assess cannabis use patterns. One promising biomarker is DNA methylation (DNAm), as cannabis use may result in long-lasting changes to the methylome. In this study, we utilized peripheral blood DNAm data to develop a classifier predicting lifetime cannabis use (ever vs. never).

Analyzing data from the prospective Sister Study, we identified 108 significant CpGs ($p<1E-4$) associated with lifetime cannabis use among 2,073 participants of European ancestry (1,009 ever users). Employing LASSO regression with 10-fold cross-validation on centered and scaled DNAm beta values, we selected 77 CpGs to build a model predicting lifetime cannabis use. Testing this model on an independent sample of 517 Sister Study participants (243 ever-users), the classifier achieved an AUC (area under curve) of 0.67 (95% CI 0.62~0.71). We validated the classifier's performance in an independent sample of 1,195 participants (665 ever users) in the Gulf Long-Term Follow-Up Study (GuLF). The classifier was predictive of lifetime cannabis use in both European (AUC=0.62, 95% CI 0.58~0.66) and African (AUC=0.62, 95% CI 0.57~0.66) ancestry groups. In an independent sample of 2,109 participants (551 ever users) from the Netherlands Twin Register (NTR), the classifier achieved an AUC of 0.65 (95% CI 0.63~0.68).

To consider confounding by cigarette smoking, we further evaluated the 77 CpG-classifier in subsets of participants who never smoked cigarettes in each dataset. In the validation subset of 217 Sister Study participants, the classifier achieved an AUC of 0.66 (95% CI 0.59~0.72). In GuLF, the classifier performed better among participants of African ancestry (n=343, AUC=0.6, 95% CI 0.54~0.67) than those of European ancestry (n=360, AUC=0.54, 95% CI 0.47~0.61). In NTR (n=1,253), the classifier showed modest predictive ability, with an AUC of 0.58 (95% CI 0.54~0.62).

Our DNAm-based classifier predicts lifetime cannabis use, achieving AUC values around 0.65 in independent datasets. These findings support the potential for developing a peripheral blood-based DNAm biomarker to identify lifetime cannabis use across various population groups, enabling further research into the diverse health effects associated with cannabis use.

Session Title: Epigenetics Poster Session I

PB2210 A comparison of Whole-Genome Bisulfite Sequencing and Oxford Nanopore Technology for epigenetic studies.

Authors:

D. Tay, H. Ng, M. Lam, N. Sadhu, M. Loh, J. Chambers; Nanyang Technological Univ., Singapore, Singapore

Epigenetic studies provide insights into gene regulation and disease mechanisms. This knowledge is much coveted for personalized disease diagnosis, prevention, and therapy. Two widely used techniques for methylation detection are whole-genome bisulfite sequencing (WGBS) and long reads sequencing by Oxford Nanopore Technology (ONT). WGBS is based on short-read sequencing and requires bisulfite conversion which could degrade the DNA samples. On the contrary, long-read sequencing by ONT allows direct methylation detection, thereby eradicating the need for bisulfite conversion. Despite their difference in sequencing principles, a comprehensive assessment of the two approaches has not been performed to date. Such comparison is critical to enable informed experimental decision to be made prior to the inception of epigenetic studies. Thus, this study aims to assess i) the concordance of methylation levels of the 2 technologies in relation to the array, ii) number of CpGs detected with different number of aggregated ONT flow cells (FCs), and iii) relationship between the number of aggregated ONT FCs and WGBS. A total of 16 and 214 samples were sequenced using ONT and WGBS technologies. The WGBS data have a mean coverage of 32.3x (SD=2.0) while different numbers of ONT FCs (1 to 4) were used to sequence the samples. Methylation levels detected by WGBS and ONT were first assessed for concordance with methylation levels by Illumina methylation arrays. Performance was comparable ($p=0.0836$), with average Pearson correlation of 0.957 (SD=0.004) and 0.958 (SD=0.010) achieved for WGBS and ONT respectively. Average root mean squared error (RMSE) was lower in WGBS at 0.133 (SD=0.006), relative to 0.154 for ONT (SD=0.016). Next, the impact of the number of ONT FCs used on the methylation profile was evaluated. With 2 FCs, the average number of CpGs detected increased by 47.0 folds relative to the use of 1 FC. When 3 and 4 FCs were used, the increase in the average number of CpGs detected was at 1.54 and 1.09 folds (in relation to n-1 aggregated FCs) respectively. This suggests that there is little incremental value in using more than 2 FCs if the desired minimum coverage is at 30x. Lastly, comparison of WGBS and ONT demonstrates that with a single ONT FC, the number of CpGs detected at different minimum coverage (1x to 100x) is comparable to WGBS ($p=0.246$). However, with increased number of FCs, the CpGs' minimum coverage outperforms those from WGBS ($p<0.05$). This suggests that with at least 2 ONT FCs, we can achieve results that outperform WGBS, and that the use of ONT sequencing could potentially offer better insights into the epigenetic profile.

Session Title: Epigenetics Poster Session II

PB2211 A comprehensive integrated post-GWAS analysis of reproductive lifespan reveals enhancer-based NBR2 dysregulation in ovary

Authors:

S. Kim[1], J. Chang[2], Y. Suh[1]; [1]Columbia Univ. Irving Med. Ctr., New York, NY, [2]Univ. of Maryland, Baltimore, Baltimore, MD

The ovary exhibits the earliest aging among human body parts. The reproductive lifespan (RL), a period between the onset of menarche and menopause, greatly varies from woman to woman, ranging from 20 to 50 years. The length of the RL is partially genetically determined, but the underlying genetic mechanism is not yet understood. Using UK Biobank data, we calculated RL values from the age at menarche (AMC) and natural menopause (ANM) and performed genome-wide association tests using mixed model linear regression on the RL, AMC, and ANM of 50,698 women. We identified 7,364 variants that were significantly associated ($P < 5x10-8$) with 76 loci across all three traits. Through colocalization analysis, we observed that the majority of RL variants overlapped with ANM variants, indicating that the ANM variants are the primary genetic determinants of RL. To identify potential causal variants, we applied an integrative post-GWAS analysis with public epigenomic data and prioritized 55 high-probability causal variants in 22 loci, including 12 ovary eQTLs in the NBR2 locus (17q21.31). We measured and observed allele-specific changes in the long non-coding RNA NBR2, a known regulator of the AMPK-mTOR pathway. Decreased expression of NBR2 may contribute to a longer RL and later ANM, potentially by altering the activity of the AMPK-mTOR pathway. These findings provide new insights into the biological mechanisms underlying female RL and suggest potential targets for interventions to improve women's reproductive health.

Session Title: Epigenetics Poster Session III

PB2212 A computational toolkit to integrate multi-omics time-series data across species in brain development

Authors:

M. Yu[1], B. Borsari[1], E. S. Wattenberg[1], K. Xu[2], M. Frank[1], S. Liu[1], M. Gerstein[1]; [1]Yale Univ., New Haven, CT, [2]Yale Sch. Med., New Haven, CT

Steady-state molecular studies provide a static description of molecular processes in cell differentiation or organismal development. Longitudinal studies can instead offer a deeper understanding of epigenetic and transcriptional events and how these processes evolve over time. Here, we integrate multi-omics data (ATAC-seq, DNase-seq, ChIP-seq, RNA-seq) from different consortia to understand brain development at equivalent post-conception dates in human and mouse (7-20 post-conception weeks -pcw-, and 10.5-16.5 post-conception days, respectively).Genes with key roles in human brain development are associated with enhancers showing many different dynamic patterns, while genes performing non-brain functions are more often associated with just one type of enhancers (either up- or down-regulated). This suggests that proper expression of key human brain genes may require tight, multi-gate epigenetic control which is not seen in mice. To further understand differences in brain development between human and mouse, we trained a random-forest classifier that predicts the species-specificity of enhancer-based time-series data. We found both activation and repression of enhancers happen earlier in mice than humans. This is in line with previous studies comparing molecular processes in these species. The 10-12 pcw window is key to distinguishing enhancer activation patterns between the two species. At this time, 26% of mouse enhancers have already undergone major activation and 45% have undergone major repression, while human enhancers are mostly activated or repressed between 12-13 pcw.To further uncover the potential emergence of distinct neuronal lineages during development, we developed a multivariate HMM-based method to estimate brain cell composition at each time-point by integrating bulk and single-cell ATAC-seq data. Among all the deconvolved cell types, we observed that the most predominant excitatory neuron subgroup initially emerges at around 13 pcw and displays a marked enrichment at 16 pcw. Therefore, this subgroup might represent a distinct neuronal type that differentiates and matures during brain development. This observation is in line with a prior study, where this specific neuronal group has been shown to match to the newly formed migrating excitatory neurons from developing cortex of pcw 17-18. Taken together, our study reveals highly dynamic changes in epigenetic patterns and cell type compositions that underlie neurodevelopmental processes. Our future goal is to develop a computational toolkit to best harmonize and analyze time-series data generated across species, consortia and technologies.

Session Title: Epigenetics Poster Session I

PB2213 A DNA methylation atlas of normal human cell types

Authors:

N. Loyfer[1], J. Magenheim[1], A. Peretz[1], R. Shemer[1], B. Glaser[2], Y. Dor[1], T. Kaplan[1]; [1]Hebrew Univ. of Jerusalem, Jerusalem, Israel, [2]Hadassah Hebrew Univ Jerusale, Jerusalem, Israel

DNA methylation is a fundamental epigenetic mark that governs gene expression and chromatin organization, thus providing a window into cellular identity and developmental processes. Current datasets typically include only a fraction of methylation sites and are often based either on cell lines that underwent massive changes in culture or on tissues containing unspecified mixtures of cells. Here we describe a human methylome atlas, based on deep whole-genome bisulfite sequencing, allowing fragment-level analysis across thousands of unique markers for 39 cell types sorted from 205 healthy tissue samples. Replicates of the same cell type are more than 99.5% identical, demonstrating the robustness of cell identity programmes to environmental perturbation. Unsupervised clustering of the atlas recapitulates key elements of tissue ontogeny and identifies methylation patterns retained since embryonic development. Loci uniquely unmethylated in an individual cell type often reside in transcriptional enhancers and contain DNA binding sites for tissue-specific transcriptional regulators. Uniquely hypermethylated loci are rare and are enriched for CpG islands, Polycomb targets and CTCF binding sites, suggesting a new role in shaping cell-type-specific chromatin looping. The atlas provides an essential resource for study of gene regulation and disease-associated genetic variants, and a wealth of potential tissue-specific biomarkers for use in liquid biopsies.

Session Title: Epigenetics Poster Session II

PB2214 A novel gene regulatory element that modulates cardiomyocyte maturation.

Authors:

T. Anglen, K. Hagy, R. Perrelli, D. Tran, M. Ramaker, A. Landstrom, Y. Diao, S. Shah, C. Gersbach; Duke Univ., Durham, NC

Heart disease is the leading cause of death in the world and can be caused by genetic mutations. Heart disease results in pathogenic remodeling of the heart. A molecular marker of remodeling is a decreased expression of MYH6 relative to MYH7, the two cardiac isoforms of the sarcomeric myosin heavy-chain protein that is important for heart contractions. The silencing of the lncRNA MHRT is central to this switch from MYH6 to MYH7 in mice. Remarkably, transgenic expression of MHRT in mice attenuates cardiac hypertrophy. Dissecting how MYH6 and MYH7 levels are regulated in humans will lead to mechanistic understanding of development and disease progression and inform the development of therapeutic interventions. To this end, we have performed epigenome and transcriptome profiling and high-throughput CRISPR-based epigenetic screening to decode gene regulatory mechanisms in human iPSC-derived cardiomyocytes (iPSC-CMs). We identified a novel regulatory element involved in controlling MYH6 expression in iPSC-CMs in an MHRT-independent manner. We show that by repressing or activating this regulatory element with the CRISPR-based epigenetic editors we can modulate MYH6 expression. We then use the HiCAR chromatin conformation assay to show that repression of the regulatory element disrupts the regional 3D genomic architecture and decreases how frequently the element and the promoter of MYH6 interact. Finally, we observe that the repression of this element during iPSC to CM differentiation results in phenotypic changes of the resulting CMs. Following repression of this regulatory element, the iPSC-CMs have an increased tau of decay of calcium transients linked to an increase in CM hypertrophy and a decrease in calcium sparks, linked to cardiomyocyte maturity. The iPSC-CMs also have decreased expression of developmental factors NPPA and NPPB. A similar decrease in levels of NPPA and NPPB is observed during cardiac maturation after birth. These results implicate this genomic region as an important regulatory element during cardiac development and maturation as we observed similar phenotypic changes in the iPSC-CMs that occur during *in vivo* cardiac maturation when we manipulate the epigenetic state of this regulatory element in iPSC-CMs. In conclusion, we find that this regulatory element is involved in controlling MYH6 expression and is important during cardiomyocyte differentiation and maturation. Ongoing work is investigating causal roles that this element may have in disease progression and whether human genetic variation within this element contributes to heart disease phenotypes.

Session Title: Epigenetics Poster Session III

PB2215 A trans-ancestral meta-analysis of genome-wide association study identifies 146 susceptibility loci for rheumatoid arthritis

Authors:

A. Kwon[1], S-Y. Bang[2,3], H-S. Lee[2,3], K. Kim[1], S-C. Bae[2,3]; [1]Dept. of Biology, Kyung Hee Univ., Seoul, Korea, Republic of, [2]Hanyang Univ. Inst. for Rheumatology Res., Seoul, Korea, Republic of, [3]Dept. of Rheumatology, Hanyang Univ. Hosp. for Rheumatic Diseases, Seoul, Korea, Republic of

Rheumatoid arthritis (RA) is a complex autoimmune disorder characterized by inflammation in multiple joints. The development of RA is influenced by multiple factors, including genetic factors, with approximately 65% of heritability. While genome-wide association studies (GWASs) have successfully identified specific genetic variants associated with RA, a significant portion of the heritability remains unexplained. This study aimed to enhance our understanding of the genome-scale genetic architecture of RA by conducting a trans-ancestral meta-analysis of GWAS. To this end, we expanded our previous GWAS datasets (PMID 33310728) to include a total of 4,638 patients with RA and 74,949 healthy controls. After a general quality control procedure before and after whole-genome imputation, the genetic association between variants and RA was assessed by logistic regression for each cohort followed by an inverse-variance-weighted fixed-effects meta-analysis with recent large-scale GWAS association summary statistics (PMID: 36333501; 35,072 non-Korean patients with RA and 239,398 healthy controls). A SNP-based heritability was ~21%, which was improved over the previously established heritability of 17.6% in East Asian populations in our recent study (PMID 33310728). A total of 24 novel susceptibility loci were newly identified, exhibiting the genome-wide significance level (*P*-value < 5 x 10-8) and highly consistent effect sizes between datasets. Additionally, known RA association signals at 122 loci including the HLA region were replicated. In summary, this study provides an updated catalog of RA susceptibility loci that will facilitate a deeper understanding of the underlying biology involved in the development of RA.

Session Title: Epigenetics Poster Session I

PB2216 African Americans with Sickle Cell Disease (SCD) demonstrate accelerated epigenetic aging compared to African Americans without SCD.

Authors:

A. Ashley-Koch[1], M. E. Garrett[1], B. Le[1], K. Bourassa[2], D. Hatch[3], Q. Yang[3], P. Tanabe[3], N. Shah[1], C. Oyedeji[1], N. Kimbrel[2], J. Beckham[2], M. J. Telen[1], M. Knisely[3], MIRECC Workgroup; [1]Duke Univ. Med. Ctr., Durham, NC, [2]Mid-Atlantic Mental Illness Res. (MIRECC), Ed. and Clinical Ctr., Veteran Admin., Durham, NC, [3]Duke Univ. Sch. of Nursing, Durham, NC

Sickle cell disease (SCD) is a chronic medical condition characterized by polymerization of deoxy-hemoglobin S (HbS), sickling of red blood cells, hemolysis, end-organ damage in multiple systems and reduced survival. Early mortality is associated with SCD-related end organ damage, especially to the heart, lung, kidneys and central nervous system, as well as with vaso-occlusive events. We hypothesized that early mortality is also associated with accelerated aging and that this could be quantified by measuring DNA methylation at multiple CpG loci across the genome. Several such epigenetic clocks have been developed. One of the most recent, DunedinPACE (Belsky et al., 2022), was developed from a longitudinal cohort and estimates the rate of an individual's biological aging compared to peers. Importantly, accelerated aging predicts mortality and poor health outcomes in many populations but has not been evaluated in SCD. We compared DunedinPACE epigenetic pace of aging scores in 134 African American individuals with SCD from the Outcome Modifying Genes in SCD (OMG-SCD, n=45; Elmariah et al., 2014) and SCD Implementation Consortium (SCDIC, n=89; DiMartino et al., 2018) cohorts to 1392 African American veterans without SCD from the MIRECC cohort (Calhoun et al., 2010). All subjects had global methylation data generated from the Infinium MethylationEPIC Beadchip (Illumina, San Diego, CA). Pace of aging was calculated with the R package "DunedinPACE" (Belsky et al., 2022). We found that the individuals with SCD displayed significantly accelerated epigenetic aging compared to the veterans without SCD, whereby individuals with SCD aged approximately 0.5 months more per year than the veterans ($p=5.31e^{-5}$). This was true, even though the individuals with SCD were significantly younger according to chronologic age than the individuals without SCD (mean age_{SCD}=34.4 yrs vs. mean age_{MIRECC}=39.4 yrs; $p<0.0001$), making the epigenetic aging discrepancy even more apparent. When we matched the SCD and MIRECC subjects on age, the effect size of this association was even larger (0.76 months more per year in SCD vs. veterans; $p=7.24e^{-3}$). These data support our hypothesis that individuals with SCD experience accelerated epigenetic aging as measured by global epigenetic variation. The assessment of epigenetic aging may prove useful to identify which SCD patients would most benefit from clinical interventions to reduce mortality.

Session Title: Epigenetics Poster Session II

PB2217 Alcohol sensitivity associated genome wide DNA methylation changes in alcohol use disorder patients and healthy controls

Authors:

S. Venkatesh[1], T. Gunawan[1], S. Bethany[1], M. Schwandt[2], P-H. Shen[3], C. Hodgkinson[3], M. De Biasi[4], D. Nancy[2], D. Goldman[3], V. Ramchandani[1]; [1]Human Psychopharmacology Lab., NIAAA/NIH, Bethesda, MD, [2]The Office of the Clinical Director, NIAAA/NIH, Bethesda, MD, [3]Lab. of Neurogenetics, NIAAA/NIH, Rockville, MD, [4]Univ. of Pennsylvania, Philadelphia, PA

Heavy alcohol consumption and alcohol use disorder (AUD) significantly alters genome-wide DNA methylation patterns. A lower level of response (LR) to alcohol predicts a greater risk for heavy drinking and alcohol-associated problems. In this study, we aim to identify AUD and alcohol sensitivity-associated DNA methylation changes in AUD patients and healthy controls. We analyzed genome-wide DNA methylation patterns in WBCs obtained from whole blood samples of individuals with current AUD (179) and non-AUD controls (95), using the Illumina MethylationEPIC BeadChip (850K). Differentially methylated positions (DMPs) were analyzed to identify the hypo- and hypermethylated regions between AUD and non-AUD groups after controlling for age, sex, race, principal components, and cell compositions. Given the impact of childhood trauma on long-term mental and physical health and associated epigenetic changes, we also controlled for Childhood Trauma Questionnaire scores. The LR to alcohol was measured with the Self-Report of the Effects of alcohol (SRE) questionnaire evaluating the number of standard drinks required to feel four different effects of alcohol. To identify the alcohol sensitivity-related DMPs we included SRE recent and total scores in the linear model. Between AUD and non-AUD groups, 4430 differentially methylated CpG sites were determined including 2719 hypermethylated and 1711 hypomethylated sites across exon, 3'UTR, 5'UTR, and gene body regions. After including alcohol SRE recent and total scores, the AUD group showed 909 differentially methylated CpG sites compared to the non-AUD group, including 631 hypermethylated and 278 hypomethylated sites across the 3'UTR, 5'UTR, and gene body regions. The dopamine transporter gene *SLC6A3*, which has been previously associated with heavy alcohol consumption and AUD, was among the significantly altered CpG-associated genes in both models. The 5'UTR CpG in the *SLC6A3* gene was significantly hypomethylated in the non-AUD group compared to the AUD group. Our study identified several novel AUD and alcohol sensitivity associated CpG sites/genes and provided evidence for the previously identified *SLC6A3* gene association with AUD and alcohol sensitivity. Future work will include examining the AUD and alcohol sensitivity related gene pathways and evaluating the alcohol sensitivity-association with epigenetic age acceleration.

Session Title: Epigenetics Poster Session III

PB2218 Allele-specific binding of EHMT2/G9a is required to maintain maternal imprintswithin Prader-Willi Syndrome candidate region

Authors:

S-E. Wang[1], M-A. Jang[2], J. Lim[1], Y. Cheng[1], Y. Kim[3], Y. Xiong[4], J. Jin[4], S. Wang[1], Y-H. Jiang[5]; [1]Yale Univ., New Haven, CT, [2]Soonhchunhyang Univ. Coll. of Med., Bucheon, Korea, Republic of, [3]St. Jude Children's Res. Hosp., Memphis, TN, [4]Icahn Sch. of Med. at Mount Sinai, New York, NY, [5]Yale Univ. Sch. of Med., New Haven, CT

Prader-Willi Syndrome (PWS) is a genomic imprinting disorder caused by the deficiency of paternally expressed genes in the human 15q11-q13 imprinting domain. The corresponding genes in the maternal 15q11-q13 region are transcriptionally repressed. The expression of paternally expressed and maternally silenced in the 6Mb imprinting domain of 15q11-q13 is coordinately regulated by a critical regulatory element designated as an imprinting center (IC), upstream of *SNRPN* gene. The PWS-IC is differentially modified by DNA methylation of 5mC and varies histone modifications in allele specific manner. Through a large scale small molecular screening using Snrpn-EGFP fusion protein, we previously reported that inhibitors of euchromatic histone lysine N-methyltransferase-2 (EHMT2/G9a) are capable of unsilencing the expression of PWS candidate genes, *SNORD116s* from the maternal allele both in PWS patient derived cells and in PWS mouse model without effects on the maternal specific DNA methylation. However, the exact molecular mechanism underlying the EHMT2-mediated imprinting maintenance has not been fully elucidated. In the present study, we report that *Ehmt2* deficiency in the embryonic (day18) and postnatal brain (p10) is capable of unsilencing the expression of *Snrpn-EGFP* gene from the maternal chromosome with reduced H3K9me2, but do not alter DNA methylation in PWS-IC. Unexpected, chromatin accessibility is not prerequisite for reactivation of maternal imprints. There is no chromatin state changes on PWS-IC, after treatment with EHMT2 or DNMT1 inhibitor. We first show allele specific 3D chromatin conformation in PWS-associated imprinted domains, contributing to imprinting maintenance. In addition, long noncoding RNA expressed from upstream region of PWS-IC interacts with EHMT2, regardless of its catalytic activity on H3K9. These results suggest that allele-specific recruitment of EHMT2 is necessary to maintain maternal imprint and offer a mechanism underlying the maternal reactivation of PWS paternally expressed genes via the inhibition of EHMT2 as an epigenetic therapy of Prader-Willi syndrome.

Session Title: Epigenetics Poster Session I

PB2219 Alternative promoter usage by NFkB tunes transcript diversity during the endothelial inflammatory response.

Authors:

A. Golebiewski, L. K. Stolze, C. E. Romanoski; Univ. of Arizona, Tucson, AZ

Endothelial dysfunction is a hallmark of complex diseases including coronary artery disease, the world's leading cause of death. Endothelial cells (ECs) line the innermost layer of blood vessels across tissues and are primarily responsible for maintaining blood-tissue barriers. When ECs are exposed to chronic inflammatory signals, they have aberrant expression of monocyte adhesion molecules and produce less nitric oxide, which contributes to leaky barrier function and invasion of immune cells into the subendothelial space. The EC inflammatory response is a key part of endothelial dysfunction; therefore, a better understanding of these mechanisms is necessary for a comprehensive understanding of complex disease risk. We and others have characterized the EC inflammatory response at the transcriptomic and epigenomic levels, but few have systematically evaluated the effects of inflammation on splicing. Alternative splicing is one way that cells quickly respond to their environment and is a previously uncharacterized mechanism by which ECs respond to inflammatory perturbations. To recapitulate inflammatory signaling in vitro, 53 primary human aortic EC cell lines were treated with 10 ng/mL interleukin 1 beta (IL1B), a pro-inflammatory cytokine, for 4 hours. We identified 1,056 genes whose RNAs are differentially spliced between IL1B and control treatments. 598 (57%) of the differentially spliced genes were also differentially expressed, out of a total of 3,437 differentially expressed genes. Of differentially spliced genes, 374 (35%) result in different protein-coding isoforms. For some genes, multiple splice variations were significant. Interestingly, 45% of all differentially spliced events involved alternative first exons. We found that binding of NFkB, a canonical inflammation-associated transcription factor, was enriched proximal to first exon start sites favored with IL1B treatment compared to first exon start sites favored with no treatment. We next used de novo motif enrichment analysis to identify motifs preferentially utilized at alternative promoters preferred under IL1B treatment. We identified that, in addition to the NFkB/RelA motif, the TCF12 motif is enriched at first exons preferred with IL1B treatment. The transcription factor TCF12 is an initiating factor in endothelial-to-mesenchymal transition, one hallmark of endothelial dysfunction. Taken together, this analysis provides novel insight into gene regulation during the EC inflammatory response and identifies a novel role for transcription factors as regulators of alternative promoter usage and protein diversity.

Session Title: Epigenetics Poster Session II

PB2220 Alzheimer's disease risk alleles are enriched in myeloid transcription factor binding sites.

Authors:

A. Chriss[1,2,3,4], D. Mattei[1,2,3,4], A. Ravi[1,2,3,4], M. Schertzer[5,6,7,8], D. Knowles[5,6,7,8], T. Raj[1,2,3,4]; [1]Dept. of Genetics and Genomic Sci., Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]Nash Family Dept. of NeuroSci. & Friedman Brain Inst., Icahn Sch. of Med. at Mount Sinai, New York, NY, [3]Ronald M. Loeb Ctr. for Alzheimer's Disease, Icahn Sch. of Med. at Mount Sinai, New York, NY, [4]Icahn Inst. for Data Sci. and Genomic Technology, Icahn Sch. of Med. at Mount Sinai, New York, NY, [5]New York Genome Ctr., New York, NY, [6]Data Sci. Inst., Columbia Univ., New York, NY, [7]Dept. of Computer Sci., Columbia Univ., New York, NY, [8]Dept. of Systems Biology, Columbia Univ., New York, NY

Background: Genome-Wide Association Studies (GWAS) have revealed over 75 genetic loci associated with Alzheimer's Disease (AD) risk. Many of these GWAS hits map to noncoding regions of the genome, where it is challenging to determine the regulatory mechanisms underlying these genetic associations. Recent studies highlight the role of myeloid cells including microglia and monocytes in AD pathology, but little is known about the functional mechanisms of AD risk variants in these cell types.
Methods: To dissect potential functional mechanisms of these genetic associations with cell-type specificity, we generated ChIP-seq for four AD-implicated transcription factors - PU.1, CTCF, MEF2C, C/EBPβ - and one active histone mark (H3K27ac) in both primary human microglia isolated from postmortem brain tissue and peripheral monocytes from disease and control donors. To enhance the detection of variants that impact binding affinity, we employed a pooling strategy and performed ChIP-seq analysis on a cohort consisting of 14 microglia and 32 monocyte donors. We performed several key analyses including peak calling, motif enrichment, assessment of peak distribution, LD score regression, as well as integration with microglia eQTL data (n=550) and fine mapped variants from AD GWAS.
Results: Our results reveal a substantial enrichment of AD heritability within our myeloid-specific ChIP-seq peaks compared to other regulatory (e.g., enhancer or promoters) annotations of brain cell types. We observed heritability enrichment of AD GWAS in the peaks for PU.1 ($p = 2.40 \times 10^{-7}$), CTCF ($p = 2.13 \times 10^{-2}$), MEF2C ($p = 3.27 \times 10^{-3}$), and C/EBPβ ($p = 6.56 \times 10^{-4}$). Several of these peaks directly coincide with fine-mapped credible sets of variants from at least 18 AD GWAS loci. This includes the lead GWAS SNP located in the *RASGEF1C* locus, which is as an eQTL (*RASGEF1C*, $p= 1.52 \times 10^{-17}$) and is found within microglia ATAC-seq and H3K27ac peaks, and strongly disrupts PU.1 binding.
Conclusion: We are currently incorporating genotypes with ChIP-seq peaks to identify binding quantitative trait loci (bQTLs), linking genetic variants to changes in the binding affinity of these transcription factors. Using statistical colocalization, we will identify bQTLs that intersect fine-mapped AD risk variants, prioritizing functional variants that disrupt transcription factor binding and increase AD risk. Overall, our findings emphasize the significance of myeloid cells in AD and highlight the potential role of differential transcription factor binding in driving a significant portion of AD risk.

Session Title: Epigenetics Poster Session III

PB2221 Analysis of 14392 whole genomes reveals 5.2% of Qataris carry medically actionable variants.

Authors:

A. Elfatih[1], C. Saad[2], B. Mifsud[1], H. Mbarek[2], The Qatar genome research consortium; [1]Hamad Bin Khalifa Univ., Doha, Qatar, [2]Qatar Genome Program, Doha, Qatar

Arabic populations are underrepresented in large genome projects, therefore the frequency of clinically actionable variants in such highly consanguineous populations is largely unknown. Here, we investigated genetic variation in 14392 whole genomes from the Qatar Genome Programme (QGP) across the updated list of 78 actionable genes (v3.1) determined by the American College of Medical Genetics and Genomics (ACMG). We examined QGP variants that overlapped with the 78 ACMG genes with a minor allele frequency (MAF) < 5%. We categorized the variants that were not annotated in ClinVar as Benign (B) or Likely Benign (LB) into one of the following groups: 1) Validated and previously reported known Pathogenic (KP), 2) Expected pathogenic (EP), and 3) Rare variants of uncertain significance predicted to be pathogenic (pVUS). We identified 248 distinct variants in 50 ACMG genes that fulfilled our criteria to be included in one of the three groups. They affected 7.2% of the QGP cohort. Across the three categories, *TTN* variants were the most frequent, followed by variants in *RYR1* and *ATP7B*. The analysis revealed 104 KP variants in 425 genotype positive participants (GPP) identified based on ClinVar and HGMD disease entries. In addition, 82 PVS1 loss of function EP variants were carried by 244 GPP. Moreover, the study cohort was deeply phenotyped, featuring cardiovascular, cancer, and hypercholesterolaemia disease evidence, which allowed us to obtain significant disease-relevant phenotype association for 13 rare (MAF < 1%) variants that were either previously unreported, were reported as VUS or had a conflicting interpretation of pathogenicity in ClinVar. These variants also had in silico prediction support for pathogenicity (REVEL score > 0.7), therefore we could classify them as EP variants, which were carried by 78 GPP. Lastly, we described 49 additional variants in the pVUS list that had the same characteristics but lacked statistically significant disease association in the QGP cohort. The prevalence of reported secondary findings was 3.8%. A further 46 heterozygous variants in six genes with an autosomal recessive mode of inheritance (*MUTYH*, *ATP7B*, *BTD*, *GAA*, *RPE65*, and *TRDN*) were detected in 200 individuals, accounting for an additional 1.4%. In total, they affect 5.2% of the population. Due to the high consanguinity rate in the QGP cohort (28% in spouses and 60% in parents), actionable variants both in genes with dominant and recessive inheritance are important for developing better treatment options and preventive strategies in Qatar and the Arabic population of the Middle East.

Session Title: Epigenetics Poster Session I

PB2222 Analysis of competitive endogenous RNA (ceRNA) networks as epigenetic regulators of cardiogenesis.

Authors:

C. Bell[1], D. Bittel[2], J. E. O'Brien, Jr.[3], N. Kibiryeva[2]; [1]Kansas City Univ. - Coll. of Med., Kansas City, MO, [2]Kansas City Univ. - Coll. of BioSci.s, Kansas City, MO, [3]Ward Family Heart Ctr., Children's Mercy Hosp., Kansas City, MO

The epigenetic regulation of human embryonic heart development is not well understood. The regulation of heart specific genetic pathways is closely controlled in temporal and spatial patterning by transcription factors and post-transcriptional modifiers. Recently, functional non-coding RNAs (ncRNAs) have been discovered to play a post-transcriptional regulatory role during organ development. Competitive endogenous RNA (ceRNA) networks are large regulatory networks formed by both coding and noncoding RNA transcripts interactions. While there are several RNA:RNA interactions that are key to ceRNA network formation, one of the most important interactions is that between long non-coding RNA (lncRNA) and complementary microRNA (miRNA) transcripts. When these interactions form, the lncRNAs function as miRNA sponges, affecting downstream messenger RNA (mRNA) expression levels. These axes of interaction are frequently denoted as lncRNA/miRNA/protein coding gene axis of regulation. Evidence is beginning to accumulate, suggesting a link between dysregulation of epigenetic processes and congenital heart defects. But yet, little is known about the function and significance of ceRNA networks during fetal heart development. We compared expression patterns of lncRNA and mRNA during different gestational time points of human cardiogenesis. We identified several ceRNA networks that appear important for proper formation of the heart. Identifying these networks will help us understand complex epigenetic regulation of morphological changes in developing heart and potentially will lead to better understanding of mechanisms involved in congenital heart defects.

Session Title: Epigenetics Poster Session II

PB2223 ASD-associated alterations in chromatin accessibility and chromosome conformation pinpoint dysregulated transcription factor network and highlight genetic variants in distal regulatory regions

Authors:

J. Yin, J. Huang, J. Ou, L. Bicks, J. Haney, D. Geschwind; Univ. of California, Los Angeles, Los Angeles, CA

Despite phenotypic and genetic heterogeneity in autism spectrum disorder (ASD), recent studies have shown that molecular changes in ASD brains converge on common pathways. However, how genetic variants act via multiple epigenetic layers and contribute to ASD remains poorly understood. Here, we profiled bulk chromatin accessibility and cell-type specific 3D genome architecture in post-mortem brains of 48 ASD-affected and neurotypical subjects. We identify over 5,000 differentially accessible regions (DARs), showing coordinated changes with differential gene expression and Hi-C interactions. We demonstrate that idiopathic and syndromic (Dup15q) ASD subjects share common dysregulation of frequently interacting regions (FIREs). We further pinpoint transcription factors (TFs) underlying the DARs, and genetic variants that increase disease risk. Taken together, these findings elucidate how genetic risk factors alter the transcriptional regulatory landscape and contribute to ASD etiology. Our work provides a framework for employing multimodal profiling to decipher the molecular mechanism of complex human diseases.

Session Title: Epigenetics Poster Session III

PB2224 Assessing cell-type specificity of enhancer-promoter interactions in neurons.

Authors:

J. Koesterich, A. Kreimer; Rutgers Univ., Piscataway, NJ

Genome wide association studies (GWAS) have found that the majority of disease associated variants are located within the non-coding genome. It is still largely unknown how mutations in these non-coding sequences cause functional disruptions, even though these sequences constitute 98.5% of the human genome. One hypothesis is that they disrupt regulatory regions consisting of enhancer or promoter regions and disrupt the proper functioning of transcription. This hypothesis is challenging to explore since different cell types have different active enhancers, as well as different interactions between enhancers and nearby genes. To decipher the functional impact of non-coding mutations, we need to gain a better understanding of the mechanism by which they disrupt such regulatory regions.To this end, we collected epigenetic and gene expression data from multiple neuronal cell types, including Neural Progenitor Cells (NPCs), Excitatory cells, Inhibitory cells, and Motor Neurons. Using this data, we generated enhancer-promoter interaction pairs using the Activity By Contact (ABC) model and grouped the interaction pairs based on the pattern of their scores within each cell type. We have identified interaction pair groupings that are cell type specific and groupings that have similar interaction scores across closely related cells. For each of these groupings, we identify enrichments for cell type relevant biological processes. Next we applied bi-clustering techniques to the grouped interaction pairs network to observe and analyze the distribution of its different sub-structures. Namely, (i) single enhancer interacting with a single target gene, (ii) single enhancer interacting with multiple genes, (iii) multiple enhancers interacting with a single gene, (iv) multiple enhancers interacting with multiple genes. This analysis highlights different modes of gene regulation programs across cell types.We then predicted transcription factor (TF) binding motifs within enhancers to identify if there were preferences in TF usage and to quantify enhancers' possible involvement with transcription. Finally, we mapped neurological disease associated variants onto the predicted regulatory regions to identify enriched regions of overlap in the individual cell types. Overall, our results indicate that the enhancer-promoter interaction network is largely cell type specific and is enriched for cell type relevant biological annotations. Additionally, the clustering of this network can be leveraged to better understand the mechanism underlying disease associated variants, as well as a selection method for function assays in the studied cell type.

Session Title: Epigenetics Poster Session I

PB2225 Assessing HiFi Long Read Sequencing versus Whole Genome Bisulfite Sequencing and Methylation EPIC BeadChip Array: A Comparative Analysis Utilizing DNA Methylation Standards.

Authors:

X. Yang, R. Yancey, A. De Silva, K. Chang, J. Bhasin, K. Booher; Zymo Res. Corp., Irvine, CA

DNA methylation, one of the most abundant and extensively studied epigenetic modifications, plays crucial roles in various biological processes such as development, cancer, aging, and complex diseases. The Illumina array has been widely employed as a classical platform for high-throughput screening in large cohort studies like The Cancer Genome Atlas (TCGA). However, this type of array covers less than 3% of CpG sites in the human genome. The latest generation of DNA sequencing technologies, exemplified by the PacBio HiFi system, offers the unique capability of generating long sequence reads spanning up to 25 kilobases. Recent advancements by Pacific Biosciences (PacBio) have focused on enhancing per-base accuracy and the ability to detect DNA modifications. In this study, we evaluated the performance of PacBio HiFi sequencing using DNA methylation standards. The DNA standards comprised of human DNA enzymatically methylated at CpG sites and unmethylated human DNA derived from the HCT116 DKO cell line. 1 ug of DNA was prepared for sequencing on the PacBio Sequel IIe system using the SMRTbell prep kit 3.0. Samples were sequenced to about 8X coverage. DNA methylation data were generated by interpreting polymerase kinetics during HiFi read sequencing with a convolutional neural network developed by PacBio, and pb-CpG-tools were used to extract methylation values from BAM files. We then compared the results obtained from PacBio HiFi sequencing to those generated by the EPIC array and Whole Genome Bisulfite Sequencing (WGBS). We found that WGBS and PacBio HiFi native DNA methylation calling exhibited a high level of concordance with each other, outperforming the EPIC array in both concordance with the methylation standard and number of CpGs reported. Using a methylated standard sample, HiFi data reports approximately 85% of CpG sites have methylation ratios greater than 90%, with an average of 93% genome wide. Similarly, WGBS data presents approximately 85% of CpG sites have methylation ratios greater than 90%, with an average of 95% genome wide. In contrast, EPIC array only reports 40% of CpG sites had methylation ratios greater than 90%, and an average of 87% across the genome. These results demonstrate HiFi long read sequencing can detect DNA methylation signal accurately for regions close to 100% methylated. Our study provides insights into the performance of PacBio HiFi sequencing in detecting DNA methylation patterns and its potential as an alternative to the EPIC array. The findings from this study illustrate how DNA methylation standards can be used as a ground truth reference to evaluate DNA methylation calling models.

Session Title: Epigenetics Poster Session II

PB2226 Assessment of changes of mRNA isoform proportion after scaRNA knockdown.

Authors:

B. Earl[1], M. Filla[1], N. Kibiryeva[1], J. O'Brien[2], D. Bittel[1]; [1]Kansas City Univ. of Med. and BioSci.s, Kansas City, MO, [2]Children's Mercy Hosp., Kansas City, MO

Congenital heart defects (CHD) are the most common type of birth defect in the United States. Mendelian and chromosomal syndromes account for a small percentage of CHD cases, but nearly 80% of CHD cases are due to idiopathic genetic mechanisms that are poorly understood. Unfortunately, even with proof that alternate splicing of mRNA plays a role in the elusive genetic mechanisms that cause CHD, little data has been found to elucidate how these alternate splicing patterns lead to such lethal and debilitating heart defects. One such example of an impairing CHD is Tetralogy of Fallot (TOF). It is the most common form of cyanotic CHD that is often treated by one or several heart surgeries. This study will explore which isoforms created by alternative splicing after scaRNA1 knockdown lead to TOF. In our previous studies, it has been found that there was a significant decrease in pseudouridylation levels in the right ventricles of patients born with TOF when compared to children born with normal hearts. The amount of pseudouridylation in spliceosomal RNA U2 is influenced by scaRNA1 expression, and thus when scaRNA1 is knocked down, U2 spliceosomal activity is changed. This leads to alternative splicing of mRNA that is important in embryonic development. We propose to quantify mRNA isoform proportions after we knockdown scaRNA1 in cell culture samples to create a model for examining scaRNA1 function. By obtaining a numerical value for the isoforms, we can use this to guide our future studies that will follow how changes in mRNA isoforms contribute to the dysregulation of regulatory networks in patients with TOF.

Session Title: Epigenetics Poster Session III

PB2227 Associations between DNA methylation and cognitive function in early-stage breast cancer patients

Authors:

S. Liu[1], D. Liu[2], C. M. Bender[3], K. I. Erickson[4,5], S. M. Sereika[3,6], Y. P. Conley[3,1], J. R. Shaffer[1,7], D. E. Weeks[1,6]; [1]Dept. of Human Genetics, Sch. of Publ. Hlth., Univ. of Pittsburgh, Pittsburgh, PA, [2]Dept. of Genetics and Genomic Sci., Icahn Sch. of Med. at Mount Sinai, Pittsburgh, PA, [3]Sch. of Nursing, Univ. of Pittsburgh, Pittsburgh, PA, [4]Dept. of Psychology, Kenneth P. Dietrich Sch. of Arts and Sci., Univ. of Pittsburgh, Pittsburgh, PA, [5]AdventHlth.Res. Inst., NeuroSci. Inst., Orlando, FL, [6]Dept. of Biostatistics, Sch. of Publ. Hlth., Univ. of Pittsburgh, Pittsburgh, PA, [7]Dept. of Oral and Craniofacial Sci., Sch. of Dental Med., Univ. of Pittsburgh, Pittsburgh, PA

Nearly 33% of breast cancer patients experience decline in cognitive function before treatment, however, the biological mechanisms for this remain unclear. We aimed to use DNA methylation (DNAm), a dynamic gene regulator, to identify genes associated with cognitive function in postmenopausal women with early-stage hormone receptor-positive breast cancer.

Both objective and subjective measures of cognitive function were assessed. Seven objective cognitive function domains (executive function, mental flexibility, processing speed, attention, working memory, verbal memory, and learning and memory) were derived from a neuropsychological test battery. Subjective cognitive function was defined as the total score from the Patient's Assessment of Own Functioning Inventory. Genome-wide DNAm data were collected via the Infinium MethylationEPIC Beadchip using whole blood samples. After quality control procedures, 110 participants and DNAm measurements at 700,779 5'-cytosine-phosphate-guanine-3' sites (CpGs) were included for analysis. Epigenome-wide association studies (EWAS) for each cognitive domain phenotype were conducted while adjusting for age and verbal IQ scores, which we refer to as the cell type heterogeneity (CTH)-unadjusted EWAS. We further controlled for chip artifacts and CTH using surrogate variable analysis. Differentially methylated regions (DMR) were detected by the dmrff R package using EWAS summary statistics.

Participants were primarily diagnosed with stage 0 or stage I (73%) breast cancer and self-reported as White (89%) with an age of 62 years and a verbal IQ score of 112, on average. cg11875060 in a neurodegeneration-associated gene *SLC33A1* met the genome-wide significance threshold of 9E-08 in the CTH-unadjusted EWAS of learning and memory (*p*-value = 7.2E-08), although the signal was not observed when adjusting for CTH. In the CTH-adjusted EWAS, cg10331779 near *CTNND2* (*p*-value = 9.7E-09), which is involved in neuronal development and functioning in the Wnt signaling pathway, and cg25906741 in *MLIP* (*p*-value = 2.0E-08), were inversely associated with processing speed and subjective cognitive function, respectively. Three significant DMRs with Bonferroni-adjusted *p*-values<0.05 were detected for processing speed in/near the genes *SLC6A11*, *PRKG1/CSTF2T*, and *FAM3B*. Two DMRs were found for mental flexibility in/near the genes *PI4KB* and *SGCE/PEG10*.

In conclusion, we identified several genes associated with cognitive function domains in women with early-stage breast cancer. These findings will enhance the understanding of the biological mechanisms behind cognitive function decline in breast cancer patients.

Session Title: Epigenetics Poster Session I

PB2228 *BCL11B*-related disorder is associated with a DNA methylation episignature.

Authors:

S. Haghshenas[1], Q. Sabbagh[2,3], M. A. Levy[1], J. Kerkhof[1], H. McConkey[1,4], N. Karp[5,6], C. Prasad[5,6], V. M. Siu[5,6], T. B. Balci[5,6], D. Genevieve[2,3], B. Sadikovic[1,4]; [1]Verspeeten Clinical Genome Ctr., London Hlth.Sci. Ctr., London, ON, Canada, [2]Montpelier Univ., Inserm U1183, Montpellier, France, [3]Reference Ctr. for Rare Disease and Malformative Syndrome, Clinical Genetic Dept., Montpellier Univ. Hosp., Montpellier, France, [4]Dept. of Pathology and Lab. Med., Western Univ., London, ON, Canada, [5]Dept. of Paediatrics, Div. of Med. Genetics and Metabolism, Western Univ., London, ON, Canada, [6]Children's Hlth.Res. Inst., London, ON, Canada

Rare genetic conditions, including neurodevelopmental disorders, often present with overlapping clinical symptoms, complicating definitive diagnosis. Additionally, genetic testing often leaves many cases unresolved due to factors such as variants of uncertain clinical significance (VUSs). Recently, DNA methylation episignatures have emerged as reliable and stable biomarkers. They are currently being used worldwide to diagnose ambiguous cases in clinical settings and to reclassify VUSs. The *BCL11B*-related disorder (*BCL11B*-RD) is a disorder caused by variants in *BCL11B*. It is characterized by symptoms such as intellectual disability, distinct facial features, and immune impairment. In this study, two separate episignatures for *BCL11B*-RD were identified, and two classification models were developed. One model prioritized sensitivity, aiming to accurately identify samples with pathogenic or likely pathogenic variants in *BCL11B*. The other model prioritized specificity, aiming to minimize false positive results. Having two episignatures with distinct emphasis on sensitivity and specificity allows researchers to select the appropriate one based on the specific diagnostic needs and goals of a given scenario. These classifiers were applied to thousands of unresolved cases within the EpiSign™ Knowledge Database and identified one sample, which lacked any known variants. Subsequent review of patient records showed that a *de novo BCL11B* likely pathogenic variant had been detected on a multigene intellectual disability panel, providing support for the utility of these classifiers for screening of undiagnosed cases.

Session Title: Epigenetics Poster Session II

PB2229 Blood DNA Methylation in Infants Hospitalized for Bronchiolitis is Prospectively Associated with Recurrent Wheezing and Asthma During Childhood.

Authors:

Y. Li[1], Z. Zhu[2], C. A. Camargo, Jr.[2], J. A. Espinola[2], A. Yaskolka Meir[1], K. Hasegawa[2], L. Liang[1,3]; [1]Dept. of Epidemiology, Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, [2]Dept. of Emergency Med., Massachusetts Gen. Hosp., Harvard Med. Sch., Boston, MA, [3]Dept. of Biostatistics, Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA

Background: Bronchiolitis is the most common lower respiratory tract infection among infants, and is associated with a substantially higher incidence of childhood asthma. DNA methylation may contribute to the elevated asthma risk among infants with bronchiolitis.
Objectives: Among infants hospitalized for bronchiolitis, we sought to identify DNA methylation differences in infant blood that are associated with subsequent outcomes of recurrent wheezing and asthma during childhood.
Methods: We analyzed data from a multi-center prospective cohort study of US infants hospitalized for bronchiolitis. Epigenome-wide DNA methylation profiling was performed using the Illumina EPIC array on blood samples collected at hospitalization from infants <12 months of age. Recurrent wheezing by age 36 months and asthma diagnosis at age 6 years were ascertained from follow-up interviews with parents. Linear regression models were used to assess the association between DNA methylation and wheezing/asthma at each CpG site, adjusting for potential confounders. The comb-p method was applied to identify differentially methylated regions (DMRs) related to wheezing and asthma based on the linear regression results. A state-of-the-art deconvolution method was employed to estimate the cell-type specific effects driving the DMRs.
Results: Among 506 infants hospitalized for bronchiolitis (median age: 3 months), 35% experienced recurrent wheezing by age 36 months, and 22% were diagnosed with asthma by age 6 years. After multiple testing corrections by the Šidák method, 21 DMRs were associated with recurrent wheezing (Šidák $p<0.05$). The top three DMRs (Šidák $p<5.0\times10^{-8}$), each containing 12 CpGs, were annotated to the promoter regions of *ANKRD3*, *GNMT*, and *ALOX12*, respectively. Notably, we identified a DMR (*chr2:54087008-54087343*, 9 CpGs, Šidák $p=7.2\times10^{-4}$) overlapping with the promoter region of *ASB3*, a gene involved in smooth muscle proliferation. This DMR was hypomethylated in recurrent wheezing cases compared to non-cases, with the hypomethylation driven by the effect in B cells. Additionally, 21 DMRs associated with asthma at age 6 years (Šidák $p<0.05$) were identified, including two (*chr17:6899085-6899758*, *ALOX12*; *chr6:42927940-42928056*, *GNMT*) overlapping with DMRs associated with recurrent wheezing by age 36 months.
Conclusion: Among infants hospitalized for bronchiolitis, blood DNA methylation at multiple novel genomic regions was associated with later outcomes of recurrent wheezing and asthma during childhood. These findings provide valuable insights into the underlying mechanism of asthma development in this high-risk clinical population.

Session Title: Epigenetics Poster Session III

PB2230 Both exercise intensity and training state influence the cell sources and magnitude of cell-free DNA accumulation in human plasma upon exercising.

Authors:

K. Rodrigues[1], Z. Weng[1], C. Tuggle[2], B. Peoples[3], G. Seay[3], C. Kelley[3], S. Yang[3], J. McAdam[2], K. Lavin[2], S. O'Bryan[3], D. Drummer[3], Z. Graham[2], M. Bamman[2], T. Broderick [2], S. Montgomery[1]; [1]Stanford Univ., Stanford, CA, [2]Florida Inst. for Human and Machine Cognition, Pensacola, FL, [3]Univ. of Alabama at Birmingham, Birmingham, AL

Exercise is critical for health and reducing risk for chronic inflammatory diseases. Exercise also drastically increases cell-free DNA (cfDNA) in blood plasma, but the origins of this DNA have not been comprehensively quantified in humans for all tissues and cell types. Neutrophils are a potential source, as they release chromatin in inflammatory contexts like exercise (NETosis). We hypothesized that enzymatic methylation sequencing (EMseq), paired with cell type proportion deconvolution, could precisely and comprehensively quantify the extent to which every cell type contributes to inducing cfDNA during exercise. To do this, we analyzed DNA methylation of cfDNA in 50 plasma samples over time from 10 healthy individuals in the Precision High-Intensity Training Through Epigenetics (PHITE) randomized dose-response trial. Participants exercised 3 d/wk for 12 weeks, followed by 4 weeks of detraining. To study the effects of exercise intensity, participants were randomized to high intensity tactical training (HITT) or traditional, moderate intensity combined endurance and resistance training (TRAD). Plasma was collected at five timepoints: before and immediately post exercise at weeks 0 and 12, then at rest during week 16. cfDNA was extracted, and EMseq was performed to measure methylation of cfDNA molecules. PCA showed post-exercise samples clustered distinctly from pre-exercise and resting samples. GREAT analysis found exercise-induced differentially methylated regions of cfDNA were enriched for immune-related gene ontology annotations. After implementing cell-type proportion deconvolution using DNA methylation atlases as reference and computing absolute abundances of cfDNA for each tissue and cell type, we observed exercise significantly increased cfDNA from neutrophils (>48-fold), dendritic cells (>5-fold), and macrophages (>2-fold). Surprisingly, muscle, bone, and fat cells did not contribute to the changes in cfDNA. Notably, we found that the amount of cfDNA released into circulation is proportional to exercise intensity (HITT > TRAD). Further, the extent of the increase in cfDNA after exercise diminished as an effect of training (wk 12 < wk 0) regardless of intensity, and specifically for dendritic cells and macrophages, but not neutrophils. These results suggest that exercise training desensitizes dendritic cells and macrophages to exercise-induced inflammatory activation. Combined, our study provides critical insight into which cell types contribute to exercise-induced accrual of circulating cfDNA and may guide understanding of how exercise could protect from or mitigate chronic inflammatory processes in humans.

Session Title: Epigenetics Poster Session I

PB2231 Cell-specific roles of 5-methylcytosine and 5-hydroxymethylcytosine in early AD onset and progression.

Authors:

Y. Li, H. Shen, B. Yao; Emory Univ., ATLANTA, GA

Alzheimer's disease (AD) is a progressive, irreversible neurodegenerative disorder representing the most common cause of dementia and affecting over 50 million people worldwide. Despite aberrant gene expression observed in multiple brain cell types during AD pathogenesis, molecular mechanisms behind these changes remain poorly understood. The most abundant DNA modification 5-methylcytosine (5mC) and its oxidized product 5-hydroxymethylcytosine (5hmC) has been extensively investigated as gene expression regulators and reported to be globally dysregulated in AD. However, accurate and comprehensive genome-wide brain cell-specific regulatory roles of 5mC and 5hmC at single-base resolution in early AD onset and progression remains elusive due to the lack of available early-stage human AD brain samples and the absence of high-resolution experimental techniques. In the present study, we employed a novel bisulfite treatment independent approach, TAPS (TET-assisted pyridine borane sequencing), to detect base-resolution DNA methylation signal by directly converting methylated cytosine to thymine and distinguished 5hmC from 5mC by additional β-glucosyltransferase labeling on 5hmC loci. Leveraging the power of TAPS combined with high-depth sequencing, we obtained accurate single-base resolution 5mC and 5hmC profiles during early onset and progression of AD using 3-month and 9-month 5xFAD, a well-established AD mouse model. Comparing with the relatively lower level of 5hmC in mouse embryonic stem cell, we detected comparable levels of 5hmC and 5mC on CpG loci in cortex of 9-month-old mouse, suggesting 5hmC accumulates in brain during development and aging. Global hyper-methylation and hypo-hydroxymethylation on CpG loci were simultaneously observed in 9-month 5xFAD mouse cortex, which is specifically preference in intragenic regions and potentially regulating expression of multiple neuronal genes such as *Grin2d* and *Bdnf*. Furthermore, integrated analysis of AD dysregulated DmR and DhmR with corresponding gene expression changes revealed specific roles of 5mC and 5hmC in gene transcriptional regulation. We then utilized immunopanning approach to successfully isolate neurons, astrocytes, microglia and oligodendrocyte progenitor cells in 3-month and 9-month 5xFAD mouse brains along with their age-matched littermate controls. We will apply TAPS to identify cell-specific DNA modification alterations during AD pathogenesis. Collectively, this study provides a comprehensive understanding of how aberrant epigenetic alteration promote early AD pathogenesis and progression in a cell type-specific manner.

Session Title: Epigenetics Poster Session II

PB2232 † Characterization of Native Allele Specific Methylation by Nanopore Adaptive Sampling Sequencing

Authors:

Y. Tian[1], L. Wang[2]; [1]Moffitt cancer center, Tampa, FL, [2]Moffitt Cancer Ctr., Tampa, FL

5-methylcytosine (5mC) is a crucial DNA modification occurring regularly across the human genome. To detect the modification at the single base resolution, bisulfite sequencing is commonly used to identify the 5mC status. However, this short read sequencing is often involved in the PCR amplification, which may cause 5mC detection bias by introducing duplicates. The short read also restricts co-methylation analysis between any two CpG sites. To address these issues and estimate the native 5mC methylation, we re-analyzed the Nanopore adaptive sampling sequencing run on human CpG islands. We applied the LD R^2 to calculate the co-methylation in nanopore data, and further identified 27875, 50481, 26542 and 51189 methylation haplotype blocks (MHB) in COLO829, COLO829BL, HCC1395 and HCC1395BL cell lines, respectively. Interestingly, while we found the majority of the co-methylation happens in a short range (≤200bp), a small portion (1~3%) occurs with long distance (≥1000bp), suggesting potential remoting regulatory mechanisms across the genome. To further characterize the epigenetic changes related to transcription factor binding, we profiled the 5mC percentage changes surrounding the JASPAR motif sites, and found that CTCF, KLF5, ZNF93 and ZBTB33 binding sites showed reduced methylation, while MEF2D, FOXE1, MAFK, and ZNF354A sites showed increased methylation in the above cell lines. To further investigate the allele specific 5mC in prostate genome, we designed a target region covering mQTL and GWAS germline variants and generated long reads with adaptive sampling run in BPH-1 and 22Rv1 cells. After phasing, we compare the methylation on both strands and identified 333 and 3031 significantly (q-value≤0.1) haplotype specific methylated regions in BPH1 and 22Rv1 cell line respectively. We also found that the haplotype specific methylation contributed largely to the MHB identified across the genome. By comparing to the ATAC-seq data in the BPH-1 and 22Rv1 cells, we found the haplotype specific methylation was highly correlated with chromatin accessibility in the human genome. Our work identified native methylome profiling with intact haplotype information and will provide innovative result to uncover the regulatory machinery of human prostate genome.

Session Title: Epigenetics Poster Session III

PB2233 Characterizing epigenetic aging in an adult sickle cell disease cohort.

Authors:

B. Lê[1], D. Hatch[1], Q. Yang[1], M. Garrett[1], N. Shah[1], P. Tanabe[1], A. E. Ashley-Koch[2], M. Knisely[1]; [1]Duke Univ., Durham, NC, [2]Duke Univ. Med. Ctr., Durham, NC

Sickle cell disease (SCD) affects approximately 100,000 predominantly African-American individuals in the United States. The pathophysiology of SCD contributes to significant cellular damage over time, increased disease complications, and ultimately premature death. While previous studies have sought to illuminate mechanisms of SCD pathophysiology through associations with genetic loci, the contribution of epigenetic factors to this pathophysiology is unexplored. DNA methylation (DNAm), a primary epigenetic mechanism for regulating gene expression in response to the environment, is an important driver of normal cellular aging. Several epigenetic clocks were developed to serve as a proxy for cellular aging, which use DNAm cytosine-phosphate-guanine (CpG) sites to calculate epigenetic age. Here, we calculated the epigenetic ages of an adult cohort of 90 people with SCD (mean age: 30.64 years; 60.64% female) across five published epigenetic clocks: Horvath, Hannum, PhenoAge, GrimAge, and DunedinPACE. We hypothesized that, in a chronic disease like SCD, patients would demonstrate epigenetic age acceleration. However, both epigenetic age acceleration and deceleration were observed in this cohort, dependent on the specific clock used. The effects of chronological age, gender, genetic ancestry, sickle cell genotype, and SCD disease severity on epigenetic age were also analyzed, to identify the presence of epigenetic acceleration/deceleration above and beyond those components. Chronologic age was significantly correlated with epigenetic age in four of the five clocks (Horvath, r=0.88; Hannum, r=0.89; PhenoAge, r=0.85; GrimAge, r=0.88). Sickle cell genotype was associated with epigenetic age in one clock (PhenoAge, p=0.02), but genetic ancestry, gender, and SCD disease severity were not associated with any clock. Finally, the CpG probes comprising the five clocks were compared to evaluate the level of overlap across the clocks, finding that each clock measures almost entirely distinct CpG sites. This likely explains the different observations of acceleration and deceleration observed within the same individual. We conclude that the specific epigenetic clock used to calculate epigenetic age influences associations with demographic and clinical phenotypes in adult SCD patients, and that further development of epigenetic clocks can improve predictive ability and utility in chronic diseases like SCD.

PB2234 Circulating cell-free methylated DNA reveals tissue-specific, cellular damage from radiation treatment.

Authors:

M. McNamara[1], N. Loyfer[2], A. J. Kiliti[1], M. O. Schmidt[1], S. Shabi-Porat[2], S. Jain[1], S. M. Roth[1], A. McDeed[1], N. Shahrour[1], E. Ballew[3], Y-T. Lin[1], H-H. Li[1], A. Deslattes Mays[4], S. Rudra[3], A. T. Riegel[1], K. Unger[3], T. Kaplan[2], A. Wellstein[1]; [1]Georgetown Univ., Washington, DC, [2]The Hebrew Univ. of Jerusalem, Jerusalem, Israel, [3]Medstar Georgetown Univ. Hosp., Washington, DC, [4]Sci. and Technology Consulting, LCC, Farmington, CT

Radiation therapy is an effective cancer treatment although damages to healthy tissues are common. Here we analyzed cell-free, methylated DNA released from dying cells into the circulation to evaluate radiation-induced cellular damages in different tissues. To map the circulating DNA fragments to human and mouse tissues, we established sequencing-based, cell-type specific reference DNA methylation atlases. We found that cell-type specific DNA blocks were mostly hypomethylated and located within signature genes of cellular identity. Cell-free DNA fragments were captured from serum samples by hybridization to CpG-rich DNA panels and mapped to the DNA methylation atlases. In a mouse model, thoracic radiation-induced tissue damages were reflected by dose-dependent increases in lung endothelial and cardiomyocyte methylated DNA in serum. The analysis of serum samples from breast cancer patients undergoing radiation treatment revealed distinct dose-dependent and tissue-specific epithelial and endothelial responses to radiation across multiple organs. Strikingly, patients treated for right-sided breast cancers also showed increased hepatocyte and liver endothelial DNA in the circulation indicating the impact on liver tissues. Thus, changes in cell-free methylated DNA can uncover cell-type specific effects of radiation and provide a readout of the biologically effective radiation dose received by healthy tissues.

PB2235 Community engagement in epigenomic and neurocognitive research on post-traumatic stress disorder in Rwandans exposed to the 1994 genocide against the Tutsi: lessons learned. 08/2022

Authors:

A. Rugamba; Univ. of Rwanda, Kigali, Rwanda

Epigenomic & neurocognitive studies have provided new perspectives on post-traumatic stress disorder & its intergenerational transmission. This article outlines the lessons learned from community engagement (CE) in such research on Rwandan genocide survivors. A strong trauma-related response was observed within the research project-targeted community (genocide survivors) during the explanation of the project. CE also revealed privacy concerns, as community members worried that any leakage of genetic/(epi)genomic data could affect not only themselves but also their close relatives. Adopting a culture of CE in the process of research implementation enables the prioritization of targeted community needs & interests. Furthermore, CE has stimulated the development of mental healthcare interventions, which married couples can apply to protect their offspring and thus truly break the cycle of inherited vulnerability. Plain language summary: Studies of how human genes are affected by the environment (epigenomic studies) have provided new perspectives on post-traumatic stress disorder & its intergenerational transmission. This article describes the lessons learned from community engagement (CE) in this type of research in a Rwandan genocide-exposed population. A strong trauma-related response was observed within the community while explaining the project. CE also revealed the participants' privacy concerns related to the leakage of genetic/(epi)genomic data that could also affect their close relatives. Adopting a culture of CE in the process of research implementation enables the prioritization of community needs and interests. CE has furthermore stimulated the development of preventive interventions for married couples to protect their offspring & thus truly break the cycle of inherited vulnerability.

PB2236 Comparative 3D genome analysis between neural retina and RPE reveals differential cis-regulatory interactions at retinal disease loci

Authors:

E. D'haene[1,2], V. López Soriano[1,2], P. M. Martínez-García[3], S. Kalayanamontri[3], A. Dueñas Rey[1,2], A. Sousa-Ortega[3], S. Naranjo[3], S. Van De Sompele[1,2], L. Vantomme[1,2], Q. Mahieu[1,2], S. Vergult[1,2], A. Bastos Neto[3], J. L. Gómez-Skarmeta[3], J. R. Martínez-Morales[3], M. Bauwens[1,2], J. J. Tena[3], E. De Baere[1,2]; [1]Ghent Univ., Ghent, Belgium, [2]Ctr. for Med. Genetics, Ghent Univ. Hosp., Ghent, Belgium, [3]Centro Andaluz de Biología del Desarrollo, Sevilla, Spain

Vision depends on the functional interplay between the photoreceptor cells of the neural retina and the supporting cells of the underlying retinal pigment epithelium (RPE). Many genes involved in inherited retinal diseases (IRD) display highly specific spatiotemporal expression within these interconnected retinal components through the local recruitment of *cis*-regulatory elements (CREs) in 3D nuclear space.
To understand the role of differential 3D genome topology in establishing tissue-specific expression patterns at IRD loci in the human neural retina and the RPE, we mapped genome-wide chromatin interactions by applying *in situ* Hi-C and H3K4me3 HiChIP to human adult post-mortem donor retinas. A comparative 3D genome analysis between neural retina and RPE/choroid using both Hi-C and HiChIP data revealed that almost 60% of known IRD genes were marked by differential 3D genome structure and/or *cis*-regulatory interactions. Next, we used UMI-4C to zoom in on regulatory chromatin interactions at the *ABCA4* locus, which is implicated in the most common autosomal recessive IRD. Upon integration with bulk and single-cell epigenomic datasets and *in vivo* enhancer assays in zebrafish, we revealed tissue-specific CREs interacting with *ABCA4*.
In summary, through extensive comparative 3D genome mapping, based on genome-wide (Hi-C), promoter-centric (HiChIP) and locus-specific (UMI-4C) assays of human neural retina and RPE, we have shown that gene regulation at key IRD loci is likely mediated by tissue-specific chromatin interactions. These findings do not only provide insight into tissue-specific regulatory landscapes at retinal disease loci, but also delineate the search space for non-coding genomic variation underlying unsolved IRD.

Session Title: Epigenetics Poster Session I

PB2237 Comprehensive methylation analysis of 309 children born SGA targeting imprinting disorders

Authors:

K. Yamazawa[1], M. Nakashima[1], T. Inoue[2,3], A. Nakamura[4,3], K. Matsubara[3], M. Kagami[3]; [1]Natl. Hosp. Organization Tokyo Med. Ctr., Tokyo, Japan, [2]Univ. of Tokyo, Tokyo, Japan, [3]Natl. Res. Inst. for Child Hlth.and Dev., Tokyo, Japan, [4]Hokkaido Univ. Graduate Sch. of Med., Sapporo, Japan

Background: Small-for-Gestational Age (SGA) is a heterogeneous condition caused by diverse factors, including maternal, placental, umbilical, and fetal elements. Various imprinting disorders (IDs) can be associated with fetal growth impairment, and thus, it is postulated that some cases of SGA may include IDs, though there is currently little evidence to substantiate this.
Objective: The aim of this study was to elucidate the role of IDs in SGA.
Method: A total of 309 SGA infants, having a birth weight below the 10th percentile for gestational age, were investigated. Cases with evident congenital anomaly syndromes were excluded. Buccal mucosa DNA was collected and subjected to bisulphite treatment. Subsequently, methylation analysis of ten differentially methylated regions (DMRs) associated with the onset of IDs was conducted using pyrosequencing.
Results: Of the 309 cases, methylation abnormalities in one or more DMRs suggestive of IDs were identified in 6 cases (1.9%):
Case 1: 2-year-old boy, hypermethylation in *PLAGL1*:alt-TSS-DMR, indicating a potential diagnosis of Silver-Russell syndrome (maternal uniparental disomy of chromosome 6).
Case 2: 13-year-old girl, hypomethylation in *MEG3*/*DLK1*:IG-DMR and *MEG3*:TSS-DMR, suggesting Temple syndrome.
Cases 3 and 4: 5-year-old boy and 10-month-old boy, respectively, both showing hypermethylation in *SNURF*:TSS-DMR, implying possible Prader-Willi syndrome.
Case 5: 1-year-old girl, with hypermethylation in *ZNF597*:3' DMR and hypomethylation in *ZNF597*:TSS-DMR, indicating a potential diagnosis of maternal uniparental disomy for chromosome 16.
Case 6: 5-year-old boy, with hypomethylation in *ZNF597*:TSS-DMR, suggesting a potential *ZNF597* methylation disorder.
In Cases 1 and 6, the above observations were confirmed with peripheral blood-derived DNA, establishing the diagnosis of IDs.
Discussion: This study reveals that a certain proportion of SGA cases, excluding those with apparent congenital anomaly syndromes, include IDs. Methylation anomalies and uniparental disomy, considered as epigenetic variants (epivariants), are usually assumed to occur *de novo*, a finding of significant importance for genetic counseling.
Conclusion: IDs are one of the causative factors in SGA, and methylation analysis is an effective tool for investigation.

Session Title: Epigenetics Poster Session II

PB2238 Context-specific single-cell transcriptomic analysis in hiPSC-derived neurons informs novel gene regulatory mechanism in schizophrenia

Authors:

J. Duan[1], H. Zhang[2], C. Li[3], S. Zhang[4], L. Liang[5], A. Kozlova[6], A. Sanders[4], Z. Pang[7], X. He[8]; [1]Northshore Univ Hlth.system/Univ of Chicago, Evanston, IL, [2]NorthShore Univ. Hlth.System, Evanston, IL, [3]Northshore Res. Inst., Evanston, IL, [4]North Shore Univ Hlth.System, Evanston, IL, [5]Univ. of Chicago, Chicago, IL, [6]The Res. Inst., NorthShore Univ. Hlth.System, Evanston, IL, [7]Child Hlth.Inst. of New Jersey, New Brunswick, NJ, [8]Univ Chicago, Chicago, IL

Despite a large number of risk genes identified by GWAS for neuropsychiatric disorders (NPD), their functional interpretation remains challenging, especially in the context of interaction between polygenic and environmental risk factors. Human induced pluripotent stem cell (hiPSC)-derived neurons have emerged as a promising cellular model for ascertaining the cell type-specific polygenic effects for neuropsychiatric disorders in a context-dependent manner, e.g., under neural activation that may mimic the physiological effects of environmental stimuli such as social experiences, stress, or drugs of abuse. To this end, we modelled neural activation by potassium chloride (KCl) stimulation in co-cultured excitatory/inhibitory neurons of ~100 hiPSC lines, followed by assaying activity-dependent single-cell multiomes (scRNA/ATAC-seq). For each main neural subtype (GABAergic inhibitory, NEFM+ or NEFM- excitatory neurons) clustered from scRNA-seq, we identified reproducible cell type-specific expression changes in thousands of genes after 1hr or 6hrs of KCl stimulation. We found that only the KCl-upregulated genes are enriched for synaptic gene ontology (GO) terms. Our MAGMA gene-set analysis further showed that mainly the KCl-upregulated genes were enriched for neuropsychiatric GWAS risk variants, with the strongest enrichment for schizophrenia (SZ). To further identify context-specific SZ-associated differentially expressed genes (DEGs), we performed single-neuron transcriptomic DEG analysis using MAST for 28 SZ cases and 50 controls (~700,000 cells). We found that 3-5%, 4-6%, and 15-23% of genes were SZ-associated DEGs in NEFM+ excitatory, NEFM- excitatory, and GABAergic neurons, respectively, and most of which were cell subtype-specific and stimulation-specific. Notably, Notably, DEGs in stimulated GABAergic neurons (up-regulated genes) and NEFM+ excitatory neurons (downregulated genes) were more enriched for synapse-related GO terms and for risk genes of SZ and other neuropsychiatric disorders than in unstimulated neurons. Interestingly, the upregulated genes in SZ cases in the stimulated (only at 6hr) NEFM+ excitatory neurons showed strong enrichment for GO terms related to cholesterol synthesis of which the top-ranking genes *ACAT2* and *HMGCR* were reported to be upregulated *in vitro* by atypical antipsychotic drug clozapine. Our study suggests that many neuropsychiatric genes may only elicit disease-relevant effects upon neuronal activation, providing novel insights into how polygenic risk factors interact with environmental stimuli for NPD.

Session Title: Epigenetics Poster Session III

PB2239 Cord blood epigenetic gestational age acceleration and childhood blood pressure trajectories from 3 to 15 years of age

Authors:

J. Hu[1], A. Yaskolka Meir[1], X. Wang[2], L. Liang[1]; [1]Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, [2]Johns Hopkins Univ. bloomberg Sch. of Publ. Hlth., Baltimore, MD

Background: Epigenetic gestational age acceleration has been considered a biomarker for physiological development and maturity of fetus. Decreased epigenetic gestational age has been associated with perinatal environmental exposures and maternal adverse pregnancy outcomes. However, the impact of epigenetic gestational age acceleration at birth on childhood blood pressure (BP) trajectory remains unclear.
Methods: This study included 940 children (500 boys; 440 girls) from the Boston Birth Cohort, with data on cord blood DNA methylation (profiled using Illumina MethylationEPIC BeadChip) and BP at 3-15 years (6,570 observations; retrieved from electronic medical records). Systolic (SBP) and Diastolic (DBP) BP percentiles were calculated based on the 2017 American Academy of Pediatrics Clinical Practice Guideline. LOWESS (locally weighted scatterplot smoothing) curves were fitted to examine BP trajectories from 3 to 15 years. We identified 4 distinct trajectories for both SBP and DBP percentiles: high-steady, high-decrease, normal-increase, and normal-steady. Epigenetic gestational age was estimated using the *EPIC clock* model. Extrinsic age acceleration (EAA) was calculated as residuals of associations between epigenetic and chronological gestational ages (in weeks). Intrinsic age acceleration (IAA) was calculated using the same method with adjustment for cord blood cell compositions.
Results: We found inverse associations between EAA and IAA with repeated measures of SBP and DBP percentiles, after adjusting for maternal age, race, pre-pregnancy body mass index, education, smoking during pregnancy, gestational age at delivery, and birth weight. Significant associations were found between EAA and SBP percentiles in boys (β = -2.02; P = 0.02) but not in girls (β = -0.49; P = 0.58). Both EAA and IAA were inversely associated with SBP percentiles in girls who were born preterm (<37 weeks of gestation; β_{EAA} = -2.95; β_{IAA} = -3.00; $P < 0.05$). Compared to normal-steady SBP trajectory, significant inverse associations were observed between IAA and high-steady, high-decrease, and normal-increase SBP trajectories in boys (β = -0.21 to -0.31; $P < 0.03$), and significant positive associations were observed for high-decrease and normal-increase SBP trajectories in girls (β = 0.23 to 0.32; $P < 0.01$). Significant sex differences were also observed ($P_{sex\text{-}interaction} < 2\times10^{-16}$).
Conclusions: Epigenetic gestational age acceleration at birth was inversely associated with child BP, and such associations significantly differ by sex, indicating that reduced biological maturity at birth may be related to long-term cardiovascular risk in a sex-specific manner.

Session Title: Epigenetics Poster Session I

PB2240 CRISPR-targeting of scaRNA1 to investigate effects of mRNA splicing and heart development

Authors:

M. Brown[1], M. Filla[1], N. Kibiryeva[1], J. E. O'Brien, Jr[2], D. C. Bittel[1]; [1]Kansas City Univ., Kansas City, MO, [2]Ward Family Heart Ctr. Children's Mercy Hosp., Kansas City, MO

Congenital heart defects (CHDs) affect ~1% of babies. A clear genetic cause for CHDs has yet to be identified, but small Cajal body-specific RNAs (scaRNAs) appear to play a role in spliceosome function and regulation of heart development. scaRNAs are small non-coding RNAs that target the RNA subunits of the spliceosome for biochemical modification. Our research team identified 12 scaRNAs that were reduced in the right ventricle of babies with tetralogy of Fallot (TOF, a CHD). We subsequently showed that mRNA splicing was deregulated and furthermore we showed scaRNA played a direct role in the regulation of mRNA alternative splicing. We hypothesize that scaRNAs influence mRNA splicing and are important for heart development. To test this theory, I used CRISPR-Cas13d and a guide RNA (gRNA) that targets the scaRNA1 transcript for knockdown (KD) in quail QM7 cells to evaluate the efficiency of the vectors. These experiments will contribute to our understanding of a novel epigenetic regulatory mechanism that appears to be critical for vertebrate heart development.

Session Title: Epigenetics Poster Session II

PB2241 Deciphering Transcriptional Regulatory Elements during Inhibitory Interneuron Differentiation using Deep Learning

Authors:

R. Birnbaum[1], R. Alatawna[1], Y. Salomon[1], Y. Orenstein[1,2]; [1]Ben Gurion Univ., Beer Sheva, Israel, [2]Bar Ilan Univ., Ramat gan, Israel

During neurogenesis, the generation and differentiation of neuronal progenitors into inhibitory gamma-aminobutyric acid-containing interneurons is dependent on the combinatorial activity of transcription factors (TFs) and their corresponding regulatory elements (REs). However, the roles of neuronal TFs and their target REs in inhibitory interneuron progenitors are not fully elucidated. In this study, we developed a deep-learning-based framework to identify enriched TF motifs in gene regulatory elements (eMotif-RE), such as active, poised, repressed enhancers and putative silencers. Using histone modifications associated with gene regulatory elements datasets, such as ATAC-seq and H3K27ac/me3 ChIP-seq, from human interneuron progenitors, we distinguished with high accuracy between active enhancer sequences (open chromatin with H3K27ac) and non-active enhancer sequences (open chromatin without H3K27ac). Using our eMotif-RE framework, we analyzed potential regulatory elements and discovered enriched motifs of TFs such as ASCL1, SOX4, and SOX11 in the active enhancer set. We showed that these ASCL1 and SOX4/11 factors cooperativity function to control active enhancers of neuronal progenitors. Interestingly, we found that ZEB1 and CTCF motifs are enriched in the non-active set. We showed that ZEB1 and CTCF control the dynamic activity of regulatory elements. Using an *in vivo* enhancer assay, we showed that most of the tested putative REs from the non-active enhancer set have no enhancer activity. However, two of the eight REs (25%) showed function as poised enhancers in the neuronal system. Moreover, mutated REs for ZEB1 and CTCF motifs increased their *in vivo* activity as enhancers indicating a repressive effect of ZEB1 and CTCF on these REs that likely function as repressed enhancers or silencers. Overall, this study integrates a novel framework based on deep learning together with a functional assay that elucidated novel functions of TFs and their corresponding REs. Our approach can be applied to better understand gene regulation not only in inhibitory interneuron differentiation but in other tissue and cell types.

PB2242 † Deconstructing the cancer-associated Pol III transcriptome.

Authors:

K. Van Bortle, S. Lizarazo, R. K C, S. Zhou, R. Cheng, A. Jayanth, L. Mouli, D. Condroski, G. He; Univ. of Illinois Urbana-Champaign, Urbana, IL

RNA polymerase III (Pol III) transcription, which produces tRNA and other small RNA that promote protein synthesis and cell growth, is commonly upregulated in cancer. Despite evidence that specific Pol III-derived ncRNAs contribute to cancer initiation and metastasis, the mechanisms and functional significance of Pol III overactivity in cancer remain poorly defined. Additionally, due to limited genomic exploration of Pol III in humans, the full extent of Pol III transcription remains unclear, precluding a comprehensive understanding of how Pol III contributes to small RNA patterns observed in cancer. To address this, we developed a novel computational framework that integrates ChIP- and ATAC-seq to identify RNA polymerase occupancy and related gene activity signatures across the non-coding transcriptome. We apply this method to genomic data across hundreds of tissues and cancers, generating an unprecedented meta-map of Pol III occupancy and activity that recovers both canonical and non-canonical transcription patterns. Our genomic meta-map identifies a core Pol III transcriptome shared by all tissues while highlighting restricted activity patterns that emerge in human cancers. Cancer-associated Pol III signatures further segregate into a subrepertoire of ncRNAs that are related to the expression of a specific Pol III subunit, RPC7α, implicating dynamic Pol III composition as a mechanistic driver of Pol III overactivity and reorganization in cancer. By combining genomic and biochemical approaches, we further complement our survey of the cancer-associated Pol III transcriptome with evidence that Pol III overactivity increases the abundance of small RNA species retaining uncapped 5’ triphosphate signatures detected by RIG-I-like pattern recognition receptors, suggesting an intersection of Pol III upregulation and innate immune responses. These findings address important gaps in our understanding of Pol III transcription and further highlight the need for future exploration of Pol III as an important player in cancer.

PB2243 Deep learning predicts brain cell type-specific regulatory variants for DNA methylation and improves fine mapping for psychiatric disorders

Authors:

S. Han[1], J. Zhou[2], D. Weinberger[2]; [1]Lieber Inst. for Brain Dev., Ellicott, MD, [2]Lieber Inst. for Brain Dev., Baltimore, MD

DNA methylation (DNAm) is essential for brain development and function, and its aberrations are implicated in psychiatric disorders. Studies of DNAm quantitative trait loci (mQTLs) have uncovered numerous genetic variations associated with DNAm levels in the human brain, which may illuminate causal genetic variations within GWAS risk loci. However, most studies have relied on bulk brain samples that may not capture cell type-specific mQTLs, and face challenges in identifying functional variations impacting DNAm levels. Here we present INTERACT, a deep learning model that integrates convolutional neural network with transformer, to predict cell type-specific regulatory variants affecting DNAm levels in the human brain. We show that cell type-specific INTERACT models reveal transcription factors that potentially shape cell type-specific DNAm profiles. Furthermore, predicted DNAm regulatory variants reflect cellular context and show enrichment for heritability of brain-related traits in relevant cell types. Importantly, we demonstrate that incorporating the predicted cell type-specific effects as priors improves the fine mapping of risk loci for schizophrenia and depression, leading to the identification of potential novel risk genes within a cellular context. Our study highlights the potential of deep learning technologies in identifying cell type-specific regulatory variants, which could enhance our understanding of the genetic underpinnings of complex traits.

Session Title: Epigenetics Poster Session II

PB2244 Defining the role of MeCP2e1 in Rett Syndrome symptom progression

Authors:

V. Haghani[1], D. Yasui[1], O. Sharifi[1], I. Korf[2], J. Lasalle[1]; [1]Univ. of California, Davis, Sch. of Med., Davis, CA, [2]Univ. of California, Davis, Davis, CA

Rett Syndrome (RTT) is a progressive, X-linked dominant neurodevelopmental disorder that affects ~1:10,000 females. RTT patients suffer from seizures, language and motor regression, cognitive impairment, and metabolic abnormalities with variable disease onset after 12-18 months. Paternally inherited de novo mutations within the X-linked *MECP2* (methyl CpG-binding protein 2) gene account for roughly 95% of RTT cases. RTT patients are *MECP2* heterozygotes and thus mosaic for wild-type and mutant MeCP2 expression. MeCP2 is expressed as two isoforms, MeCP2e1 and MeCP2e2. Loss of MeCP2e1 contributes to RTT-relevant neurological phenotypes. Currently, the best characterized functions of MeCP2e1 are as a methyl CpG DNA binding protein, transcriptional modulator, and chromatin organizer. Few established links exist between cell type specific MeCP2 pathways and RTT symptoms due to the asynchronous onset of symptoms. One key phenotype in MeCP2-deficient mice is the loss of excitatory/inhibitory neuronal balance. Therefore, we aim to identify how loss of MeCP2e1 binding in Camk2a and Vip neurons correlates with gene expression and epigenetic patterns before (postnatal day 30, PND30), during (PND60), and after (PNP120 for males, PND150 for females) symptom progression in an MeCP2e1-deficient mouse model of RTT.

For this project, male mice homozygous for Camk2a-Cre and Sun1-GFP or Vip-Cre and Sun1-GFP transgenes were bred with Mecp2e1 heterozygous females to produce *Mecp2e1*$^{-/+}$, *Mecp2e1*$^{+/+}$ females and *Mecp2e1*$^{-/y}$ and *Mecp2e1*$^{+/y}$ males with Camk2a/Sun1GFP or Vip/Sun1GFP expression. Cortical nuclei were recovered using isolation of nuclei tagged in specific cell types (INTACT) at each time point. MeCP2 binding was assayed by CUT&RUN, analysis of gene expression by RNA-seq, and DNA methylation by WGBS in isolated nuclei. For RNA-seq validation, results were compared with single nuclei RNA-seq analysis of Camk2a and Vip neurons in a parallel study.

Initial findings suggest that MeCP2 acts as a distal transcriptional modulator with long-range regulatory activity, as most binding sites are approximately 50-500 kb from transcriptional start sites and associate with 1-2 genes. MeCP2 expression in cortex increases over time, thus significantly more MeCP2 bound regions are observed at later time points compared to the pre-disease stage. Gene ontology analysis revealed that genes with oxidoreductase functions emerge earliest, becoming significant at PND60 in male excitatory neurons. These findings are important for clinical translation as they identify specific gene targets in specific cell types and stage-specific changes in MeCP2e1 binding activity.

Session Title: Epigenetics Poster Session III

PB2245 Determining mechanisms of somatic and germ cell gene expression by KDM5C histone H3K4 demethylase.

Authors:

I. Venkatachalam, K. M. Bonefas, S. Iwase; Univ. of Michigan, Ann Arbor, MI

Several neurodevelopmental disorders (NDDs) are caused by mutations in chromatin regulators, and their mechanisms of altered development are unknown. Intellectual developmental disorder, X-linked syndromic, Claes-Jensen type (MRXSCJ) is one such NDD caused by mutations in KDM5C, a demethylase that removes the active transcription-associated histone 3 lysine 4 di- and tri-methylation marks (H3K4me2/3). In our *Kdm5c*-KO mouse model, we unexpectedly found that germline genes are derepressed in somatic cells including neurons. In addition to the germline genes, somatic cell genes such as neuronal genes were also dysregulated in *Kdm5c*-KO mice brains. Both germline genes and somatic-cell genes can be important contributing factors to behavioral and synaptic deficits found in *Kdm5c*-KO mice.

However, we do not know how KDM5C controls germline and somatic-cell genes. MRXSCJ patient mutations span several domains of KDM5C, including conserved domains with unknown function. Patients exhibit phenotypic variability in the severity of intellectual disability, epileptic seizures, short stature, and aggressive behavior. The molecular mechanisms that cause this range of phenotypes are unexplained. We hypothesize that KDM5C protein domains specify the regulation of different sets of genes that underlie the phenotypic variability among patients. Here, we determine which KDM5C protein segments specifically regulate germline and somatic-cell genes. To this end, we will perform a systematic deletion screen of KDM5C domains and deliver these proteins into *KDM5C*-KO human embryonic stem cells (hESCs) via lentiviral transduction and differentiate the hESCs into neuroprogenitor cells. KDM5C's gene silencing activity will be measured via qPCR of representative germline and somatic-cell genes and ChIP-seq of re-introduced KDM5C mutants and H3K4me2/3. Our research will provide insights into the functional roles of KDM5C domains, which could begin to explain the underlying biology and potential pathological mechanisms that arise from different mutations in patients with MRXSCJ. Characterizing the functional impacts of chromatin modifier domains can provide insight into the altered development course of different mutations and illuminate targeted therapeutic opportunities.

Session Title: Epigenetics Poster Session I

PB2246 Determining the molecular features of BAF-regulated chromatin loci.

Authors:

A. Gulka, D. Gorkin; Emory Univ., Atlanta, GA

Chromatin remodeling is essential for eukaryotic transcriptional regulation, and mutations in genes encoding components of the chromatin remodeling machinery are prevalent causes of cancer and neurodevelopmental disorders. In mammals, chromatin is remodeled at many cis-regulatory sequence elements (cREs) in an ATP-dependent manner by BRG-1/BRM-Associated Factors (BAF) complexes, generating an “accessible” chromatin state that permits binding by transcription factors (TFs) and other regulatory proteins. BAF complexes are deposited at tens of thousands of cREs, with little overlap between BAF-bound loci in different cell types. However, the mechanisms by which BAF complexes are localized to cREs remain unclear, as no subunits of this complex are known to recognize specific DNA sequences. Notably, inappropriate targeting of BAF complexes has been observed in several cancer contexts. Thus, in addition to furthering our understanding of fundamental aspects of transcriptional regulation, defining the mechanisms driving BAF localization may yield insight into how BAF mutations result in disease phenotypes. To identify factors that may play a role in BAF localization, we characterized patterns of TF binding and histone modification at genomic loci that depend on BAF complex activity for maintenance of their accessible state. Specifically, we measured genome-wide changes in chromatin accessibility in the immortalized human lymphoblastoid cell line GM12878 following treatment with small molecules that either inhibited or induced proteasome-dependent degradation of the BAF ATPase subunits. Importantly, the genomic distributions of over 200 TFs and histone modifications have been profiled by the ENCODE Consortium in this cell line. In agreement with previous reports, BAF perturbation resulted in broadly altered patterns of chromatin accessibility, with the most striking trend being loss of accessibility at transcription start site-distal elements. We found that these TSS-distal sites of lost accessibility were specifically enriched for binding by multiple “pioneer” TFs - including members of the Activator Protein 1 (AP-1) TF family, PU.1, and C/EBPB, all of which are known to interact in vitro with BAF complex subunits - as well as H3K4 monomethylation (H3K4me1). These findings provide a more nuanced understanding of the characteristics that distinguish BAF-dependent and -independent accessible chromatin, and implicate pioneer TFs and H3K4me1 in the localization and function of these complexes.

Session Title: Epigenetics Poster Session II

PB2247 Diet dependent epigenomic and molecular adaptations in the aging retina.

Authors:

A. Mondal[1], D. C. Brock[1], J. Gumerson[1], Z. Yang[2], K. V. Rajulpote[2], J. Kun[2], J. Tang[2], K. Jiang[1], J. Nellissery[1], A. Remaley[2], E. Chew[1], A. Swaroop[1]; [1]Natl. Eye Inst., NIH, Bethesda, MD, [2]Natl. Heart, Lung, and Blood Inst., NIH, Bethesda, MD

Purpose: Age-related macular degeneration (AMD) is a leading cause of blindness among adults and is often described as a "vascular-metabolic-inflammatory" disease with complex etiological origins. Genetics, aging and lifestyle factors such as diet and smoking are among significant contributors to AMD risk. Epigenome is an interface of cellular response to extrinsic factors like diet. Clinical trials have indicated lower risk of progression to late stages of AMD among patients adhering to Mediterranean diet (MED), while high-fat diet (HFD) can exacerbate AMD progression. AMD pathology is marked by large drusen that include apolipoproteins and cholesterol rich lipoproteins of potential dietary origin. Despite pathological links, retinal response to diet remains poorly. We designed this study to characterize aging-related retinal molecular adaptations to diets and examined both transcriptome and DNA methylation profiles.
Methods: Twelve-month-old male and female C57/BL6J mice were fed isocaloric MED or HFD for a period of six-months. In the end, retinal samples were harvested to generate transcriptomic and genome-wide methylation. Lipid and fatty acid abundances were quantified to identify diet-related retinal changes.
Results: PCA showed diet-related retinal DNA methylome clustering. Differential methylation between MED and HFD was observed around genes of MTOR signaling, complement cascade, and arachidonic acid metabolism. Transcriptomic analyses revealed significant alterations in metabolism and inflammation related pathways in the two diet groups. We found the pentose phosphate pathway to be enriched with MED related over-expressing genes such as *Taldo1*, *Pgd* and *Tkt*, some of which are targets of MTOR signaling. On the other hand, genes for multiple amino-acyl tRNA synthetases were found over-expressing in HFD retinas. In addition, fatty acid metabolism and PPAR signaling genes were found to be altering in the two diet groups. Interestingly, we also observed disparity in abundance of specific fatty acids, with the MED group showing enrichment of omega-3 and omega-6 fatty acids. All together our experiments show evidence of distinct diet-dependent molecular adaptations in the retina.
Conclusions: Our study shows notable diet-associated retinal alterations in metabolic and inflammation related genes and processes. Using an integrative approach, we have characterized diet-related molecular adaptations in the aging retina. Epigenomic shifts are known to be drivers of retinal aging and response to environment. Our results indicate a possibility of epigenome-metabolism crosstalk in the retina.

Session Title: Epigenetics Poster Session III

PB2248 Differential chromatin accessibility analysis defines regulators of human coronary artery disease.

Authors:

J. T. Stubbs[1,2], A. W. Turner[2], J. V. Mosquera[1,2], A. Gaëlle[2], C. J. Hodonsky[2], G. Cummings[2], J. Smith[1,2], C. Miller[1,2,3,4], N. C. Sheffield[1,2,3,4,5]; [1]Dept. of Biochemistry and Molecular Genetics, Univ. of Virginia, Charlottesville, VA, [2]Ctr. for Publ. Hlth.Genomics, Univ. of Virginia, Charlottesville, VA, [3]Dept. of BioMed. Engineering, Univ. of Virginia, Charlottesville, VA, [4]Dept. of Publ. Hlth.Sci., Univ. of Virginia, Charlottesville, VA, [5]Sch. of Data Sci., Univ. of Virginia, Charlottesville, VA

BACKGROUND: Genome-wide association studies (GWAS) have identified hundreds of loci associated with coronary artery disease (CAD); however, the regulatory mechanisms for candidate variants remain mostly unknown. Given that most disease-associated variants reside in non-coding, cis-regulatory elements, we evaluated the epigenomic landscape in coronary artery segments using the Assay for Transposase Accessible Chromatin followed by sequencing (ATAC-seq). METHODS: We analyzed bulk ATAC-seq of human coronary artery (HCA) tissue from 119 patients (heart transplant recipients or donors) and identified ~170,000 accessible regions. We stratified the data into three categories based on the heart and coronary segment classification: non-ischemic/non-lesion (Control; n=41), ischemic/non-lesion (I-N, n=51), and ischemic/lesion (I-L, n=27). Across these categories, we computed differentially accessible (DA) chromatin regions using DESeq2. We linked DA regions to the nearest coding genes, tested for pathway enrichment, compared categories to define the chromatin state of CAD, and prioritized GWAS candidates for follow-up. RESULTS: We found 12,226 control-specific and 1,023 I-L-specific regions in HCAs. Ischemic-lesioned CA tissue samples were enriched for immune-related GO terms, such as "immune system process" and "T cell activation." We found a novel association between ~300 CAD-associated SNPs and DA regions. We found endothelial/smooth-muscle-associated genes (e.g., *EDNRA*, *ADAMTS7*, and *COL4A2*) proximal to control-specific DA regions and CAD-associated genes (e.g., *FHL5*, *LTA*, and *C4B*) proximal to I-L-specific DA regions. Notably, we also identified two macrophage-associated genes (*C4B* and *FCHO1*) that were concordantly differentially expressed in bulk RNA-seq of lesion-containing coronary segments. SUMMARY: Consistent with global gene-set enrichment analyses, I-L HCAs are associated with inflammation, lipid, and immune epigenetic markers. We believe the role of gene regulatory networks in CAD will be better understood through continued illustration of chromatin accessibility in CAD disease specimens.

Session Title: Epigenetics Poster Session I

PB2249 Differential gene regulation associated with alcohol use disorder in human nucleus accumbens and dorsolateral prefrontal cortex.

Authors:

J. White[1], C. Willis[1], B. C. Quach[1], S. Han[2], R. Tao[2], J. Shin[2], A. Deep-Soboslay[2], B. T. Webb[1], R. D. Mayfield[3], E. O. Johnson[1], J. E. Kleinman[2], L. J. Bierut[4], D. B. Hancock[1]; [1]RTI Intl., Research Triangle Park, NC, [2]Lieber Inst. for Brain Dev., Baltimore, MD, [3]Univ. of Texas at Austin, Austin, TX, [4]Washington Univ. Sch. of Med., St. Louis, MO

Alcohol use disorder (AUD), characterized by compulsive alcohol seeking despite adverse social, occupational, or health consequences, is a leading cause of preventable death worldwide. Many genetic loci have been associated with AUD in increasingly large genome-wide association studies, and previous studies have identified differential gene expression and DNA methylation (DNAm) associated with alcohol consumption and AUD in peripheral blood as well as postmortem brain tissue. However, our understanding of the regulation of genes associated with AUD and their tissue specificity is limited. Here we integrated findings from genome-wide analyses of differential DNAm and differential gene expression by AUD status in the dorsolateral prefrontal cortex (DLPFC) and nucleus accumbens (NAc) from 120 decedents of European ancestry (59 cases with 2+ DSM-5 AUD symptoms, 61 controls with no AUD symptoms). Illumina HumanMethylation EPIC array data were analyzed using robust multivariable linear regression. Results were adjusted using *bacon* to minimize inflation. At false discovery rate (FDR) < 0.05, we identified 31 differentially methylated CpGs (DMCs) in DLPFC associated with AUD status. 52 DMCs were identified in NAc and none overlapped across the two regions. Bulk RNAseq data from the same samples yielded 20,666 genes in DLPFC and 20,324 genes in NAc for analysis. Differential expression was tested using covariate-adjusted negative binomial regression models. At FDR < 0.05, we identified 98 differentially expressed genes (DEGs) in DLPFC and 90 DEGs in NAc (12 genes significant in both). Within our significant DMCs and DEGs for each brain region, we identified three intersections, where a DMC occurred within 250kb and on the same strand as a DEG: *HMGB2* (cg19310307) in DLPFC and *HMGN1* (cg25077654) in NAc, both members of the *HMG* chromatin remodeling family, and *OGA* (cg10725316) in NAc, implicated in synaptic plasticity. We additionally tested for an interaction between DNAm and AUD status using multivariable linear regression, with expression as the outcome, for all CpGs located in gene promoter regions and found that the relationship between DNAm at cg01840401 and expression of the *TOMM7* gene differed by AUD status. *TOMM7* encodes a subunit of the translocase of the outer mitochondrial membrane and helps to stabilize the translocase complex on the outer membrane of depolarized mitochondria, which has been shown to occur more frequently in liver cells of mice exposed to alcohol. Overall, these results suggest complex gene regulatory mechanisms associated with AUD and implicate several avenues for better understanding this disorder.

Session Title: Epigenetics Poster Session II

PB2250 Dissecting the molecular mechanisms of BRPF1 in rare disease.

Authors:

M. Thaker, I. Angres, M. Singh, B. Russell, V. Arboleda; Univ. of California, Los Angeles (UCLA), Los Angeles, CA

Background: Pathogenic mutations in *BRPF1* cause a rare disease known as Intellectual Developmental Disorder with Dysmorphic Facies and Ptosis (IDDDFP). BRPF1 is an epigenetic reader that facilitates histone H3 acetylation in complex with the lysine acetyltransferases KAT6A/B. While BRPF1 is a critical epigenetic regulator, the molecular mechanisms by which BRPF1 functions in normal physiology and human disease are unknown. Our approach utilizes IDDDFP patient blood samples to study BRPF1 gene regulation (RNA-seq) as well as novel cell models to study BRPF1 protein functionality (immunoprecipitation, immunofluorescence). These cell models contain an endogenous reporter at the 5'-end of *BRPF1*, HiBiT, and have been subsequently edited to recapitulate the *BRPF1* mutations in our patient cohort. Together, these approaches will enable us to profile downstream gene expression, direct binding partners, and subcellular localization. **Methods:** To study the effects of disease-causing *BRPF1* mutations on the transcriptome, we performed RNA-seq on patient blood samples (n=6) and matched controls (n=10). Differential expression analysis between BRPF1-mutated samples and controls was performed using DESeq2. Genes with a p-adjusted<0.05 were considered significantly differentially expressed. To generate HiBiT-BRPF1 reporter lines, we performed HDR mediated CRISPR/Cas9 editing to knock-in the HiBiT tag at the 5'-end of the gene in an immortalized neural cell line. Homozygous knock-in HiBiT-BRPF1 clones were selected for a second round of editing to generate patient-specific *BRPF1* mutations. The HiBiT antibody was used for western blotting, immunoprecipitation, and immunofluorescence studies (Promega, #N7200). **Results:** Transcriptomic analysis showed that BRPF1 mutations significantly alter the transcription of 24 downstream genes in patient samples, and one gene that is highly expressed is NRG1 (log2FC=2.14, adj. p-val=3.99E-4). NRG1 has a key role in neurodevelopment through the inhibition of neural circuit mechanisms involved in synaptic plasticity. To facilitate functional studies, we knocked-in the reporter, HiBiT, at the 5'-end of *BRPF1* in a neural cell line. Western blotting, immunoprecipitation, and immunofluorescence assays confirmed localization of the protein. To study the effects of pathogenic mutations on BRPF1 functionality, we generated clonal, patient-specific *BRPF1* mutations in the HiBiT-BRPF1 lines to perform the studies above. **Conclusions:** In this project we are utilizing orthogonal approaches to investigate the normal and dysregulated functions of BRPF1 in rare disease using patient blood samples and novel cell models.

Session Title: Epigenetics Poster Session III

PB2251 Distinct methylation patterns in carriers and non-carriers of *APOL1* risk alleles in African American and Hispanic/Latino populations: results from the Population Architecture using Genomics and Epidemiology (PAGE) consortium.

Authors:

A. W. Scadden[1], X. Zhang[2], Y. Zheng[3], V. Buchanan[2], M. Graff[2], K. Ferrier[1], A. E. Justice[4], Y. Qu[3], L. Hou[3], C. Gignoux[1], S. Buyske[5], S. Rich[6], T. Matise[5], C. Kooperberg[7], C. Haiman[8], R. Loos[9], K. E. North[2], A. Mottl[2], M. A. Stanislawski[1], H. M. Highland[2]; [1]Univ. of Colorado Anschutz Med. Campus, Aurora, CO, [2]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Northwestern Univ., Chicago, IL, [4]Geisinger Hlth., Danville, PA, [5]Rutgers Univ., Piscataway, NJ, [6]Univ. of Virginia, Scottsville, VA, [7]Fred Hutchinson Cancer Ctr., Seattle, WA, [8]Univ. of Southern California, Los Angeles, CA, [9]Icahn Sch. of Med. at Mount Sinai, New York City, NY

Chronic kidney disease (CKD) is disproportionately higher in individuals with African ancestry compared to individuals with primarily European ancestry, partly due to the higher prevalence of risk haplotypes (termed G1 and G2) of the apolipoprotein L1 (*APOL1*) gene on chromosome 22. While much is known about APOL1's role in immunity, the mechanisms surrounding *APOL1* risk alleles and their involvement in CKD are not fully understood. Here we compared DNA methylation patterns in African American and Hispanic/Latino carriers of two *APOL1* high-risk alleles versus non-carriers in six cohorts from the Population Architecture using Genomics and Epidemiology (PAGE) consortium (N = 3,926; 770 [19.6%] carriers, 3,156 [80.4%] non-carriers). Methylation of CpG sites in individuals with *APOL1* high-risk genotypes (G1/G1, G2/G2, and G1/G2) were compared to non-carriers (G0/G0) methylome-wide; heterozygotes (G1/G0 or G2/G0) were excluded. DNA methylation levels were measured using Illumina 450K or 850K BeadChip arrays and transformed to M-values for modeling. We estimated associations between the *APOL1* haplotypes and 790,422 CpG sites using linear regression models, stratified by study and controlling for age, age-squared, sex, smoking status, 10 genetic principal components (PCs), estimated blood cell proportions, and cohort-specific covariates. We then performed fixed-effects sample size-weighted meta-analysis and adjusted the p-values using the Benjamini-Hochberg method (FDR ≤ 0.05).
APOL1 risk haplotypes were significantly associated with methylation levels at 56 CpG sites. Of these 56 CpG sites, 48 were located on chromosome 22, many of which (N = 19) were located in the gene regions of *APOL1-4* and *MYH9*, which have also been previously reported to be associated with CKD. Among our findings on other chromosomes, some of the genes with *APOL1*-associated CpG sites are involved in cellular proliferation (e.g *ATAD2B* on chr2 and *DEPDC1B* on chr5) or cellular transport mechanisms (e.g. *SLC12A7* on chr5 and *SLC16A3* on chr17). Our results reveal differential methylation as a possible mechanistic link between *APOL1* risk haplotypes and CKD, which may help to open new avenues for CKD targeted interventions, such as early detection and personalized treatment approaches.

Session Title: Epigenetics Poster Session I

PB2252 DNA Methylation Association with Energy Homeostasis in a Hispanic Childhood Obesity Cohort

Authors:

C. Serrano[1], M. Kos[2], N. Butte[3], A. Comuzzie[4], S. Cole[5], M. Carless[5]; [1]Univ. of Texas at San Antonio, San Antonio, TX, [2]The Univ. of Texas Rio Grande Valley Sch. of Med., San Antonio, TX, [3]Baylor Coll. of Med., Houston, TX, [4]The Obesity Society, Rockville, MD, [5]Texas BioMed. Res. Inst, San Antonio, TX

Obesity is an ongoing issue characterized by an imbalance of energy intake, storage, and expenditure, which disproportionately affects Hispanics and African Americans. Neither genetics nor environment have been determined as solely causal, and therefore epigenetics is a potentially relevant mechanism contributing to obesity. We are examining the role of DNA methylation in obesity and energy metabolism in Hispanic children (age 4-19 years) that participated in the Viva la Familia study (VIVA). The VIVA study was designed to genetically map childhood obesity in a familial Hispanic population and included 24-hour room calorimetry, providing extensive phenotypic data on energy utilization and metabolism for our analyses. Using the Roche KAPA HyperPrep Targeted MethylSeq system and incorporating a custom probe pool that utilizes a hybrid candidate gene/genome-wide approach, we have profiled blood-based DNA methylation signatures for 2.6 million CpG sites in 916 Hispanic children using the NovaSeq 6000 system. Using SOLAR, we performed preliminary association analysis for BMI in 350 children from the VIVA cohort using the inverse-normalization of BMI and adjusting for covariates (sex, age, age^2, age x sex interaction, and age^2 x sex interaction). After adjusting for multiple comparisons using Benjamini and Hochberg's FDR method, we did not observe statistically significant associations. Among the most significantly associated genes was *KLB* ($p=2.3x10^{-7}$), which has been implicated in human obesity studies and was found to be underexpressed in children with low physical activity. Using DAVID, we performed functional annotation and enrichment testing of the 5,000 most significant CpG loci associated with BMI. The most significantly enriched pathways included those related to thermogenesis, insulin secretion, insulin resistance and adipocytokine signaling. We are currently analyzing the full data set of 916 samples, which we expect will allow us to identify DNA methylation loci indicative of obesity risk in a relevant, at-risk population.

Session Title: Epigenetics Poster Session II

PB2253 DNA methylation changes associate with kidney structural injury in an American Indian cohort with type 2 diabetes.

Authors:

S. E. Day[1], R. L. Hanson[2], H. C. Looker[2], C. Koroglu[2], K. Susztak[3], R. G. Nelson[2], C. Bogardus[2], L. J. Baier[2]; [1]Midwestern Univ., Glendale, AZ, [2]NIDDK, Phoenix, AZ, [3]Univ Pennsylvania, Philadelphia, PA

Diabetes is a leading cause of chronic kidney disease with characteristic structural lesions, but the molecular mechanisms underlying these lesions are not well understood. DNA methylation is an epigenetic mechanism that can regulate gene expression. The goal of this project was to identify DNA methylation patterns associated with kidney structural injury in American Indians with type 2 diabetes. Morphometric evaluation of kidney tissue by light and electron microscopy was performed to analyze 9 structural parameters in kidney biopsies from 76 participants (mean age=46 ± 10 years; 75% female). For all participants, DNA methylation was measured using the Infinium HumanMethylation450 array in whole blood collected from an exam within 2 years of the kidney biopsy (73% are within one year). The methylation data were analyzed for association with each of the 9 kidney parameters by analysis of variance (ANOVA) using Partek Genomics Suite. Among 196,642 DNA methylation probes that mapped to known enhancer/promoter regulatory regions, 86,110 had some evidence for association ($P < 0.05$) with at least one kidney structural parameter. Some probes associated with more than one parameter, and 5 probes associated with 7 of the 9 parameters. One probe (cg02213103) with 7 associated parameters is near *SOX2OT*, which alleviates glucose-induced kidney damage. These methylation patterns suggest associations encompassing many interconnected structural elements affected by diabetic kidney disease (DKD). However, since specific kidney structural lesions may also occur at different stages of disease progression, some valid associations may only occur with one measure. Probes of interest with only one association include cg10954392 near *BUB1* associated with glomerular basement membrane width ($r = -0.52$; $P = 3x10^{-6}$); *BUB1* is involved with acute kidney failure. Probe cg17285536 near *OGG1* associated with global glomerular sclerosis ($r = 0.50$; $P = 5x10^{-6}$); *OGG1* has a key role in kidney disease progression through a range of physiological processes. Probe cg13976219 near *INSR* associated with percent fenestrated endothelium ($r = 0.52$; $P = 2x10^{-6}$); *INSR* is critical for insulin signaling and is expressed in glomerular podocytes. Probe cg13614753 near *SEMA3B* associated with glomerular filtration surface density ($r = 0.59$; $P = 3x10^{-8}$); *SEMA3B* is an antigen in the glomerular basement membrane in membranous nephropathy. In summary, many epigenetic targets were identified that may potentially lead to better understanding of mechanisms responsible for morphometric changes involved in DKD. Our plans for this ongoing project include functional assessment of these DNA methylation sites.

Session Title: Epigenetics Poster Session III

PB2254 † DNA methylation correlates of chronological age in diverse human tissue types

Authors:

N. Jain[1], L. Tong[1], J. Li[1], K. Demanelis[2], M. Kibriya[1], F. Jasmine[1], L. Chen[1], B. Pierce[1]; [1]The Univ. of Chicago, Chicago, IL, [2]Univ. of Pittsburgh, Pittsburgh, PA

While the association of chronological age with DNA methylation in whole blood has been extensively studied, the tissue-specificity of age-related DNA methylation changes remains an active area of research. Studies investigating the association of age with DNA methylation in tissues such as brain, skin, immune, fat, and liver have identified tissue-specific CpGs, thus, motivating future studies to examine other human tissues. Here, we performed an epigenome-wide association study (EWAS), leveraging DNA methylation data (Illumina EPIC array, >800,000 CpG sites) from 9 tissues from The Genotype-Tissue Expression (GTEx) project: breast (n=38), testis (n=50), kidney (n=50), prostate (n=119), ovary (n=157), colon (n=223), lung (n=223), skeletal muscle (n=47), and whole blood (n=54). To examine how DNA methylation across the genome is associated with chronological age, we used a linear regression adjusting for sex, BMI, race/ethnicity, ischemic time, batch variables, and surrogate variables representing cell type composition. We identified age-associated differentially methylated CpGs (false discovery rate < 0.05) in 8 tissues (all except skeletal muscle). This included 132,841 unique hypermethylated and 68,559 hypomethylated CpGs, with 111,933 hypermethylated CpGs and 59,480 hypomethylated CpGs detected in a single tissue. Age-related CpGs in two or more tissues (e.g., *ELOVL2* (n=8) and *ZNF549* (n=7)) were found near gene regions known to be associated with aging. While we observed that a majority of age-related differentially methylated CpGs are tissue-specific, the patterns of enrichment among genomic features, such as chromatin state and CpG island status are similar across most tissues, suggesting common mechanisms underlying chronological aging. Consistent with previous findings, we observed that age-related hypermethylated CpGs are enriched in regions with polycomb repression marks and CpG islands, while hypomethylated CpGs preferentially occur in non-CpG islands and regions with active histone marks (e.g., enhancers). Additionally, we extended our analysis to assess the correlation between age-related gene expression and DNA methylation changes to identify age-associated expression quantitative trait methylation (eQTMs). Identifying age-related eQTMs provides insights into the functional effects of these DNA methylation changes, thus, improving our interpretation of the EWAS results. Overall, our findings will aid future work on identifying biomarkers of chronological aging and understanding the mechanisms of aging in different human tissues.

PB2255 DNA methylation in *ABCG1* mediates an effect of lipoproteins on atherosclerotic markers

Authors:

M. Nasr[1], A. Teumer[2]; [1]Univ. of Med. Greifswald, Greifswald, Germany, [2]Univ. Med. Greifswald, Greifswald, Germany

The association between atherosclerosis and cardiovascular disorders including myocardial infarction and stroke is widely established. Although it is widely accepted that atherosclerosis is associated with chronic low grade inflammatory processes in the vessel wall, the atherosclerotic process itself is not fully understood. Blood metabolome and DNA methylation changes may play a role in the development or downregulation of the underlying immune response related to atherosclerosis. The aim of this study is to identify markers of the plasma metabolome, i.e. lipoproteins associated with subclinical atherosclerosis and its risk factors, and to analyse if these associations are mediated by DNA methylation. Serum values of 112 different lipoprotein measurements assessed in up to n=4010 individuals of the population-based German SHIP-Trend cohort were grouped according to their densities and regressed with atherosclerotic and low grade inflammatory markers related to carotid intima media thickness (IMT), periodontitis, retinal microcirculation, and cytokines adjusting for potential confounders and technical factors. Next, an epigenome-wide association study (EWAS) on lipoprotein levels was conducted in a subset of 490 individuals typed from blood using the EPIC array. Significant CpG associations were selected by Bonferroni correction for the number of sites and lipoproteins. The regression results revealed that lipoproteins were significantly (false discovery rate < 0.05) associated with multiple analyzed traits. Among these results, IMT (n = 4010) and meta-analyzed low grade inflammatory markers (n = 209) were robustly associated with low density lipoproteins potentially mediated by DNA methylation. In detail, our EWAS detected one CpG site on chromosome 11 (cg05325763) and another CpG site on chromosome 21 (cg06500161) in *ABCG1* that were significantly associated with low density lipoproteins ($p < 4.73E-10$), DNA methylation beta of cg06500161 was associated with an increase in serum soluble tumor necrosis factor receptors 2 (STNF2) ($p = 0.024$), while (cg05325763) methylation beta was associated with a decrease in IL10 levels ($p = 0.044$). Our results provide a step towards understanding the inflammatory process of atherosclerosis. Next, we will focus on its impact on cardiovascular outcomes and on causal pathways of these associations.

Session Title: Epigenetics Poster Session II

PB2256 DNA methylome analysis of trauma exposure in the human postmortem cortex

Authors:

D. Nunez-RIos[1], T. Meyer[2], S. T. Nagamatsu[1], J. Martínez-Magaña[1], G. Fries[3], L. Stertz[2], C. Walss-Bass[2], J. Montalvo-Ortiz[1]; [1]Div. of Human Genetics, Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT, [2]Dept. of Psychiatry and Behavioral Sci., Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX, [3]Dept. of Psychiatry and Behavioral Sci., Univ. of Texas Hlth.Sci. Ctr. at Houston, New Haven, CT

Background: Growing literature from our group and others have shown that epigenetic marks, which mediate the interplay between genetic and environmental factors, are associated with trauma and trauma-related disorders. However, these studies have been limited to peripheral tissue. Given the tissue and cell-type specificity of epigenetic marks, research evaluating human brain tissue is warranted. **Methods:** We assessed brain DNA methylation (5mC) patterns of trauma exposure in the prefrontal cortex (PFC) of 92 postmortem brain samples: 54 samples from the UTHealth Brain Collection (UTHBC) and 38 samples from the National Center of PTSD Brain Bank (NCPBB). Trauma exposure was defined as being exposed to at least one of the following: physical or sexual abuse, illness or accident, threat and loss of close relative, combat. In the UTHBC, 5mC was assessed using the Illumina EPIC BeadChip array and analyzed using meffil, minfi, and Enmix R packages for the epigenome-wide association analysis (EWAS). In the NCPBB, 5mC was assessed using reduced representation oxidative bisulfite sequencing and the EWAS was conducted using the methylKit R package. Genome-wide significance (GWS) was defined using Bonferroni correction. We also evaluated replication across the cohorts. **Results:** No GWS CpG sites were found in the UTHBC cohort. In the NCPBB, we identified 1141 GWS CpG sites associated with trauma exposure. Among these, cg05711542 was replicated in the UTHBC cohort (p value 0.02605). This CpG site maps to the exon 1 of *ZNF326*, a gene involved in alternative splicing. When evaluating CpG sites within 10 base pairs upstream and downstream of the identified GWS CpG site. Five additional CpG sites were replicated in the UTHBC cohort, including cg02009280 and cg18446159**NGFR*, cg13790603**THRB*, cg13031623 and cg06392442**STOX2*, and cg05250953**CDK6*. **Conclusion:** Our EWAS analysis in individuals with trauma exposure revealed genes with differential DNA methylation in the human postmortem cortical tissue replicated in an independent cohort. Our findings shed light on the epigenetic dysregulation in the brain associated with trauma exposure.

Session Title: Epigenetics Poster Session III

PB2257 Dynamic Alu CpG Methylation Changes of Dermal Fibroblasts in Normal Aging and Diastolic Hypertension

Authors:

S. Jiraboonsri, J. Meevassana; Chulalongkorn Univ., Bangkok, Thailand

Epigenetic alteration is an important element of the aging process. Changes in DNA methylation have been observed in association with chronological aging and age-related disease such as hypertension. Nonetheless, methylation of Alu element, the most abundant interspersed repetitive elements are largely still unexplored. Therefore, in this study, we aimed to determine the dynamic Alu methylation change during chronological aging and progression of hypertension, a recognized age-related disease using primary fibroblast as a model. Biopsies of dermal fibroblasts were performed on 39 patients with various ages and blood pressure statuses. The patients were grouped into three categories based on their systolic blood pressure (SBP) and diastolic blood pressure (DBP): Normal (SBP = 130 mmHg; DBP = 85 mmHg), High Normal (SBP = 130-139 mmHg; DBP = 85-89 mmHg) and Hypertensive (SBP ≥ 140 mmHg; DBP ≥ 90 mmHg) and three groups according to their age into three age groups: young (< 45 years old), middle (45-60 years old) and old (> 60 years old). The DNA was then extracted and subjected to Combined Bisulfide Restriction Analysis and Alu PCR to determine the level and pattern of Alu methylation. We found a highly significance difference of Alu methylation level between young, middle and old age groups using Two-way ANOVA with DBP status as covariate (31.2 ± 2.14%, 30.7 ± 1.79%, and 29.4 ± 2.03 respectively; $p < 0.01$). A statistically significant difference of Alu methylation level was also found between DBP groups with high normal the highest followed by the hypertensive and normal group (29.6 ± 1.85%, 31.1 ± 1.78%, and 30.2 ± 2.48% for normal, high normal and hypertensive respectively; $p < 0.05$). Regarding the pattern, the increase in proportion of $^{u}C^{u}C$ methylation pattern was observed with higher chronological age while the dynamic change of $^{m}C^{u}C$ and $^{u}C^{u}C$ proportion was found in the progression of diastolic hypertension. No methylation change was found in relation with SBP. Interaction between DBP and chronological aging was also observed. In conclusion, there is a dynamic Alu methylation change with possible methyl group transfer between Alu loci in the process of diastolic hypertension. Furthermore, Alu hypomethylation is associated with chronological aging which is in line with global hypomethylation found in aging.

Session Title: Epigenetics Poster Session I

PB2258 Effect of artificial light modern lifestyle and their association with circadian gene expression

Authors:

N. Fatima; King George's Med. Univ., Lucknow, India

The large no. of world population daily exposed to the blue light, from few minutes to several hours. Blue light/ screen light provide negative effect on circadian rhythm which causes sleep deprivation and develops many diseases. Total 12 Wistar rats were enrolled and divided into two groups. Control group and Blue Light (BL) treated group which consist of six rats in each group. BL model was developed by placing the rats in 12hr blue light and 12 hr in dark till three months. Half of the rats were sacrifices and remaining rats were shifted to Normal Light (NL) for three months to see the legacy effect. These rats were sacrificed and blood samples were collected. Body weight was measured monthly, with blood glucose, Insulin, melatonin, lipid profile were estimated and mRNA were expressed by RTPCR. The percentage gain of body weight of BL treated group was **27.9%** as compared of control group (**20.2%)**. Blood glucose levels were increased and circulatory level of insulin, melatonin, total cholesterol, TG, HDL and LDL were decreased in blue light treated rats. BL treated group were shifted on NL they showed increase in **2.3%** body weight, melatonin and total cholesterol and HDL were significantly increased (**p= 0.0258)** and **(p= 0.037)** respectively. Level of glucose were significantly decreased (**p>0.05**). Per1 and Bmal1 gene were up regulated in BL group and the expression of these gene shows the significantly down regulated in NL group **p= 0.0394 and p= 0.0403** respectively. We found that the exposure of artificial light increases the prevalence of obesity and metabolic disorders.

Session Title: Epigenetics Poster Session II

PB2259 Effects of Assisted Reproductive Technology on genome-wide DNA methylation, imprinting and gene expression in human placenta.

Authors:

P. Auvinen[1], J. Vehviläinen[1], I. Laukkanen[1], K. Rämö[1], H. Marjonen[1], E. Wallén[1], V. Söderström-Anttila[2,3], H. Kahila[3], C. Hyden-Granskog[3], T. Tuuri[3], A. Tiitinen[3], N. Kaminen-Ahola[1]; [1]Dept. of Med. and Clinical Genetics, Medicum, Univ. of Helsinki, Helsinki, Finland, [2]The Family Federation of Finland, Fertility Clinic, Helsinki, Finland, [3]Dept. of Obstetrics and Gynecology, Helsinki Univ. Hosp., Univ. of Helsinki, Helsinki, Finland

Background: Approximately one in six couples experience infertility worldwide and the usage of Assisted Reproductive Technology (ART) for its treatment has increased over the last decades. ART has been associated with increased risk for adverse perinatal and life-long outcomes but the mechanisms by which ART affects these risks are still largely unknown. ART has been suggested to affect fetal development through epigenetic modifications as the procedures take place during extensive epigenetic remodeling occurring in the periconception period and early development. Although ART-associated DNA methylation (DNAm) alterations have been found, especially in developmentally important and epigenetically regulated imprinted genes, it remains unclear which procedures contributes to these effects and what is the functional relevance in terms of gene expression. Moreover, it is still debated whether the adverse outcomes are a result of ART methods, underlying parental subfertility, or both.
Methods: To explore the effects of ART, we collected full-term placental samples from a total of 80 ART and 100 naturally conceived newborns. To discern the effects of different ART methods, we divided the ART samples into subgroups of newborns derived through *in vitro* fertilization (n = 50) and intracytoplasmic sperm injection (ICSI) (n = 30) and to study the effects of embryo freezing, into subgroups of newborns derived from fresh (FRESH) (n = 42) and frozen-thawed (FET) (n = 38) embryos. Newborns' anthropometrics was analyzed by using standard deviations (SDs) based on Finnish growth charts. We performed genome-wide DNA methylation (DNAm) and gene expression analyses of placentas by using microarrays (EPIC, Illumina) and mRNA sequencing, respectively.
Results: The birth measures (SDs) or placental weights (g) did not differ between ART and control newborns. However, FET placentas were significantly heavier compared to FRESH placentas and the head circumference of ICSI female newborns (n = 18) was smaller compared to control females (n = 48) (P = 0.022 and P = 0.015, respectively). Our preliminary results showed no alterations in placental genome-wide average DNAm or in repetitive elements' DNAm but there were 164 ART-associated differentially methylated CpGs with DNAm difference greater than 5% and 787 differentially methylated regions (DMRs). DMRs were associated with several imprinted genes as well as with genes that were enriched in pathways involved in hormonal regulation, nervous system development, and immune defense. Moreover, 71 differentially expressed genes associated with ART and were enriched in pathways involved in vascularization.

PB2260 Enhanced Single Cell DNA Methylation Analysis Using Combinatorial Sequencing.

Authors:

S. Khare[1], H. Sin[2], A. Woodfin[1], E. Pu[2], L. Lin[2], P. Dang[2], D. Skinner[1], A. Beck[1], M. Nakamoto[1], B. Walczak[2]; [1]Scale BioSci.s, San Diego, CA, [2]Scale BioSci.s, San Carlos, CA

The epigenetic landscape of the human brain undergoes a plethora of changes during natural development and in malignant transformation. In recent years, DNA methylation based epigenetic modifications have been widely studied using traditional techniques like bisulfite sequencing and enzymatic methyl sequencing (EM-seq). However, these methods analyze bulk cell populations and lack the granularity of single-cell analysis. Although advances in single-cell analysis have revolutionized our understanding of cellular heterogeneity and functional diversity within complex biological systems, they are still costly, low throughput, and laborious. To address these challenges, ScaleBio has pioneered combinatorial indexing technology, enabling a significant increase in cell throughput. This novel method utilizes the cell itself as a compartment to perform 2-3 rounds of sequential barcoding in a plate-based workflow, eliminating the need for complex and expensive instrumentation. This technology has been successfully adapted to assess DNA methylation at the single-cell level offering a robust, affordable, high-throughput protocol that enhances yield, diversity, and coverage. In this study we used ScaleBio's single-cell methylation kit to investigate DNA methylation patterns during development and oncogenesis using fetal and adult brain cells along with cancer cells with widespread DNA methylation changes, such as isocitrate dehydrogenase (IDH) mutant glioma cells at the single-cell level. The IDH gene family, comprising of *IDH1-3*, encodes enzymes involved in the tricarboxylic acid (TCA) cycle. Mutations in *IDH1/2* genes are frequently found in tumors and exhibit a distinct hypermethylation pattern. We achieved high cell recovery and robust cytosine coverage throughout our analysis of single cell methylomes isolated from brain tissue. Using this data we generated a ranked list of the top hypo- and hypermethylated genomic regions and identified cell type specific clusters seen in different developmental or pathological states by looking at Differentially Methylated Regions (DMR), and compared them to known bulk methylation profiles, uncovering unique single-cell methylation profiles that may be obscured by bulk or pseudo-bulk analysis. Taken together these data show that the ScaleBio single-cell methylation workflow offers increased sensitivity, specificity, and accuracy in identifying DNA methylation sites when compared to previously available techniques while offering a comprehensive view of methylomes and providing unprecedented insights into cellular heterogeneity and trajectories.

Session Title: Epigenetics Poster Session I

PB2261 Epigenetic characterization of pseudogenes across human tissues

Authors:

Y. Jiang, B. Borsari, M. B. Gerstein; Yale Univ., New Haven, CT

Pseudogenes have long been considered non-functional remnants of genome evolution. With the advent of long-read RNA sequencing, we now have a better understanding of their genome-wide annotation as well as their transcriptional activity across tissues and organs. Nonetheless, little is known about epigenetic features that distinguish pseudogenes from protein-coding genes. Here, we extensively characterize promoters of pseudogenes from an epigenetic perspective by integrating multi-omics data across 26 human tissues generated by the ENCODE EN-TEx project. We analyzed RAMPAGE data to identify Transcription Start Sites (TSSs) at base-pair resolution. We found that pseudogenes are systematically less supported by RAMPAGE peaks compared to protein-coding genes, independently of their degree of tissue-specificity, the accuracy of their annotation, or their level of gene expression. Thus, we propose that a subset of pseudogenes may undergo TSS choices different from what was previously annotated, with potential epigenetic mechanisms playing a role in these choices. Moreover, whenever present, RAMPAGE peaks at pseudogenes are usually upstream of the annotated TSSs, contrary to protein-coding genes, which have more often downstream peaks. When focusing on pseudogenes with RAMPAGE-validated TSSs, we found that they show persistently lower histone marking, especially H3K4me3, and H3K27ac, across tissues compared to protein-coding genes and long non-coding RNAs. These differences in epigenetic marking appear unrelated to differences in the level of expression of the different classes of genes. This suggests that patterns of histone modifications may instruct the genome to distinguish different biological types of genes, in particular pseudogenes from protein-coding and lincRNAs. In conclusion, our research lays the foundation for a more profound epigenetic comprehension of pseudogenes.

Session Title: Epigenetics Poster Session II

PB2262 Epigenetic research contribution to public health: experience of an academic health center in Brazil during the COVID-19 pandemic

Authors:

L. Kulikowski, Ana Ritto, Lucas Vieira, Gleyson Carvalho, BeatrizWolff, Marina Silva, Ester Sabino, Geraldo B Filh; Univ.e de Sao Paulo, São Paulo, Brazil

The COVID-19 pandemic, caused by the SARS-CoV-2 virus, has triggered an urgent global research effort to mitigate its impact. The Hospital das Clínicas and Faculdade de Medicina of the University of São Paulo (HC-FMUSP), the largest academic health system in Latin America, has installed an emergency institutional task force to support interdisciplinary research initiatives on COVID-19 and a Steering Committee was established to map, monitor and support research groups to utilize these institutional resources. Samples and correlated data from the hospitalization of more than 5,500 adults with a confirmed diagnosis of COVID-19 between October 2020 and April 2021, and from 800 adults reassessed between 6 and 11 months after hospitalization for COVID-19 were stored and compiled. There are more than 45,000 blood samples supporting different research initiatives that investigate pathophysiological aspects of COVID-19, disease sequelae to a wide range of biomarkers of inflammation, neurodegeneration, intestinal permeability, peptidomics and metabolomics, among others. In this context, the Cytogenomics Laboratory (HC-FMUSP) is studying Brazilian epigenomic data related to COVID-19. We analyzed 72 DNA samples using the Infinium ImmunoArray-24v2 BeadChip and identified patients who developed multiple sclerosis and asthma post-covid-19 and who have allelic compatibility for six specific SNPs associated with the respective diseases. Another study constructed the differential methylation profile of 30 hospitalized patients with severe and mild symptoms without comorbidities using the Infinium MethylationEPIC BeadChip 850K and the results revealed a clear difference in the methylation status between the groups of patients allowing recognition of two main signaling pathways affected by DMRs (the MAPK kinase and TNF) that contributed to the increase in symptoms. So far, we found epigenomic variants associated with the onset of post-Covid immune diseases with a significant impact on the Brazilian population, as well as an distinct epigenomic profile showing a significant difference in the global methylation status between groups with severe and less affected patients infected by SARS-CoV-2 that may influence the expression of genes that contribute to the progression of COVID-19. Innovative epigenomic research strategies, different from traditional clinical research methods, are essential to achieve breakthroughs that help improve public health.

Session Title: Epigenetics Poster Session III

Colorado and Univ. of Colorado Denver, Anschutz Med. Campus, Aurora, CO, [15]Icahn Sch. of Med. at Mount Sinai, New York, NY

Asthma is a heterogeneous, complex disease, with variable mechanisms and clinical manifestations. Understanding endotypes of asthma that result in phenotypic heterogeneity has been shown to be important, and here we use atopy-defined subgroups. Epigenetic signatures of disease may elucidate genetic and environmental mechanisms that impact gene regulation and asthma outcomes. We use nasal epithelial cell DNA methylation (DNAm) collected from self-identified African-ancestry subjects across four sites (Baltimore, Chicago, Denver, and Washington DC) in the Consortium on Asthma among African-ancestry Populations in the Americas (CAAPA). We aim to understand the etiology of asthma by identifying differentially methylated CpGs (DMCs) associated with active and atopic asthma. DNAm was measured using the Illumina EPIC array and a new asthma and allergy (A&A) array that targets allergy-related regions. Sample/probe QC was performed with the minfi R package. Associations were adjusted for age, sex, plate, site, 2 genetic principal components estimated from MEGA chip genotypes, and latent factors estimated by the CorrConf R package to correct for unwanted variation. DMCs had q-value < 0.05. Cases were limited to those with active asthma (N=149, defined by severity index > 0) and compared to never-asthma controls (N=182). We then performed a subgroup DMC analysis, where atopic, active asthma cases (N=128) were compared to non-atopic, never-asthma controls (N=75). Atopy was defined by phadiatop-measured, allergen-specific IgE >0.35 PAU/L or total IgE >100IU. CpGs were mapped to genes based on proximity, an external promoter-capture Hi-C dataset, and the results from an eQTM analysis associating DNAm to nasal epithelium gene expression from RNA-seq in these samples. On the EPIC array, 193 DMCs were associated with active asthma agnostic to atopy; there were 428 DMCs in the atopy subset. The A&A array detected 0 DMCs agnostic to atopy and 26 DMCs considering atopy. The 11 most significant active asthma DMCs (q<0.001) mapped to genes associated with T cell development, chemokine binding, and responsiveness to glucocorticoid receptors, including *CDHR3* and *FKBP5*. *CDHR3* is an epithelial cell receptor for RV-C and was associated with asthma exacerbations/hospitalizations in the first 5 years of life. Our eQTM analysis revealed that DNAm at *FKBP5*, which is also associated with increased inhaled corticosteroid use, may mediate the association between *FKBP5* nasal epithelium gene expression and asthma. Our analysis highlights the importance of considering specific phenotypic subtypes when working with heterogeneous phenotypes in epigenetic association studies.

Session Title: Epigenetics Poster Session I

PB2264 Epigenome-wide association study of exposure to arsenic provides evidence that exposure to arsenic causally impacts DNA methylation.

Authors:

J. Li[1], N. Jain[1], L. I. Tamayo[1], L. Tong[1], K. Demanelis[2], F. Jasmine[1], M. Kibriya[1], L. S. Chen[1], H. Ahsan[1], B. L. Pierce[1]; [1]Univ. of Chicago, Chicago, IL, [2]Univ. of Pittsburgh, Pittsburgh, PA

Introduction: Inorganic arsenic (As) is a carcinogen, and >200 million people worldwide are exposed to As through drinking water. Long-term exposure to As increases the risk of chronic diseases including cancer and cardiovascular disease. One proposed As toxicity mechanism is dysregulation of the epigenome.
Methods: We performed an epigenome-wide association study (EWAS) of exposure to As using data on 1,186 adults from the Health Effects of Arsenic Longitudinal Study in Bangladesh. DNA methylation (DNAm) was measured at ~850,000 CpGs in leukocytes using the Illumina EPIC array. We evaluated the association between As measured in urine (and in drinking water) with DNAm using linear regression models adjusting for covariates and surrogate variables representing cell type composition. After identifying As-associated CpGs, we performed Mendelian Randomization (MR) to assess the causal effect of As on these CpGs, using genetic variants associated with arsenic metabolism/elimination efficiency as instruments. Next, we build an epigenetic biomarker of exposure to As using an elastic net regression consisting of all As-associated CpGs (FDR<0.05). We then assessed the relationship between this epigenetic biomarker of exposure to As and arsenical skin lesion status, the common sign of arsenic toxicity (93 cases, 186 controls).
Results: In total, we identified 135 CpGs associated with log2-transformed creatinine-adjusted urinary As using a Bonferroni significance threshold. Urinary As-associated CpGs were enriched in non-CpG islands and shores and depleted in islands. Of the 135 CpGs, 116 were also associated with log2-transformed As concentrations measured in drinking water at an FDR of 0.05. Using these 116 CpGs in the MR analysis, we discovered that the vast majority of these CpGs (80%) were directionally consistent (one-sided binomial p=1.8E-11). We built an epigenetic biomarker of exposure to As using all CpGs that were associated with urinary As at an FDR<0.05 (1,177 CpGs) and covariates, and observed moderate correlation between epigenetically predicted and measured As levels (R^2=0.49). In an independent validation set, we observed a strong association between our epigenetic biomarker of exposure to As and skin lesion status (OR=1.7, p=1.5E-3, AUC=0.56).
Conclusion: Our study provides evidence that exposure to As causally impacts DNAm at many CpGs in the epigenome. We introduce an epigenetic biomarker of arsenic exposure that can potentially be used in contexts where it is difficult to directly assess exposure to As. Furthermore, our study suggests that impacts of arsenic exposure on the epigenome correlate with human health.

Session Title: Epigenetics Poster Session II

PB2265 Epigenome-wide association study of incident type 2 diabetes in Black and White participants from the Atherosclerosis Risk in Communities (ARIC) Study.

Authors:

S. Venkataraghavan[1], J. Pankow[2], J. Coresh[1], E. Boerwinkle[3], M. Fornage[4], E. Selvin[1], D. Ray[1]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Univ Minnesota, Minneapolis, MN, [3]Univ. of Texas Hlth.Sci. Ctr. at Houston, Houston, TX, [4]Univ. of Texas Hlth.Sci. Ctr. at Houst, Houston, TX

DNA methylation (DNAm) in several genes are associated with type 2 diabetes (T2D) in populations outside the US. However, the link between DNAm and incident T2D has not been previously examined in US populations. We conducted a prospective cohort study of 2,091 Black and 1,029 White participants with mean age of 58 years in the Atherosclerosis Risk in Communities (ARIC) using Cox regression model to examine the association between ~480K CpG sites, measured using the Illumina450Karray, and incident T2D. Participants were aligned at baseline using the visit of DNAm measurement (Visit 2: 1990-92 or Visit 3: 1993-95) with mean follow-up of 17 years. At a Bonferroni-corrected epigenome-wide significance threshold of 10^{-7}, we identified 7 novel T2D-associated CpG sites: *GPX6* (cg02793507: HR= 0.85, p=2.7 x 10^{-8}) and (cg00647063: HR= 1.20, p=2.5 x 10^{-8}), *C1orf151* (cg05380846: HR= 0.89, p=8.4 x 10^{-12}), *ZNF2* (cg01585592: HR= 0.88, p=1.6 x 10^{-9}), *JPH3* (cg16696007: HR= 0.87, p=7.8 x 10^{-9}), chr11p15 (cg13738793; HR= 1.11, p=7.7 x 10^{-8}) and chr17q25 (cg16865890: HR= 0.8, p=6.9 x 10^{-9}). The CpG sites at *GPX6*, *C1orf151*, *ZNF2*, and *JPH3* were identified in Black adults, chr17q25 was identified in White adults alone, and chr11p15 was identified in the meta-analysis of the 2 groups. After adjustment of BMI as a continuous covariate in the Cox regression model, there was minimal change in effect size of CpG sites at *JPH3* (HR=0.87) and *GPX6* (HR=0.85) which remained significant after adjustment. The CpG site at *JPH3* (HR=0.87) was also significant after adjustment for fasting glucose levels with minimal effect size change. In vivo studies have identified correlations between *JPH3* expression and GPx protein levels with insulin. Our analysis replicated known CpG site associations at significance level of 10^{-7} in one or more groups including cg19693031 at *TXNIP*, cg00574958 at *CPT1A*, cg16567056 at *PLBC2*, cg11024682 at *SREBF1*, cg08857797 at *VPS25*, and cg06500161 at *ABCG1*. We used differentially methylated region analysis to examine if groups of proximal CpG sites within gene-regions of promoter, gene-body, and 3' UTR were associated with incident T2D. We found promoter regions of *TP63* to be differentially methylated across all groups. A previous study showed TAp63, an isoform of *TP63*, knockout mice developed insulin resistance and glucose tolerance. Differences in DNAm levels identified across groups could reflect differences in statistical power, differences in environmental exposures and/or allele frequencies at variants controlling DNAm levels. Our study demonstrated that including participants from diverse populations can help discover yet-unidentified DNAm-T2D associations.

PB2266 Epigenome-wide association study of perceived discrimination in the Multi-Ethnic Study of Atherosclerosis (MESA)

Authors:

W. Zhao[1,2], L. Lin[2], K. Kelly[3], L. Opsasnick[2], B. Needham[2], Y. Liu[4], A. Diez Roux[5], S. Sen[6], J. A. Smith[2,1]; [1]Inst. for Social Res., Univ. of Michigan, Ann Arbor, MI, [2]Sch. of Publ. Hlth., Univ. of Michigan, Ann Arbor, MI, [3]Inst. for Behavioral Genetics, Univ. of Colorado, Boulder, CO, [4]Duke Univ. Med. Ctr., Durham, NC, [5]Drexel Dornsife Sch. of Publ. Hlth., Philadelphia, PA, [6]Michigan NeuroSci. Inst., Univ. of Michigan, Ann Arbor, MI

Background: Perceived discrimination, recognized as a chronic psychosocial stressor, has various negative consequences on health. DNA methylation (DNAm) may be a potential mechanism by which stressors get embedded into the human body at the molecular level and subsequently affect health outcomes. However, relatively little is known about the effect of perceived discrimination on DNAm. This study aimed to identify the DNAm sites across the genome that are associated with discrimination in a multi-ethnic study. **Methods:** We conducted epigenome-wide association analyses (EWAS) of three discrimination measures (everyday discrimination, race-related major discrimination, and non race-related major discrimination) in 1,151participants (565 self-reported non-Hispanic European American, 365 self-reported Non-Hispanic African American, and 221 self-reported Hispanic) from the Multi-Ethnic Study of Atherosclerosis (MESA). DNAm in purified monocytes was measured using Illumina HumanMethylation450 BeadChip. The primary analyses were adjusted for age, gender, smoking, study site, cell contamination, genetic principal components, and batch effects (random effect). Comb-p was subsequently applied to EWAS results to identify differentially methylated regions (DMR). We conducted both race/ethnicity-stratified analyses as well as trans-ethnic meta-analyses. For the identified CpGs/DMRs, we further evaluated their cis-effects on RNA transcripts or potential mediation effects on health outcomes related to hypertension and diabetes. **Result:** At false discovery rate of 10%, three CpGs, three DMRs (*ASPG*, *DUSP5*, *IL17C*), and one CpG were associated with everyday discrimination in African Americans, Hispanics, and meta-analysis respectively. One CpG was associated with race-related major discrimination in African Americans. For non race-related major discrimination, one CpG was associated in Hispanics whereas one CpG and one DMR (*GLI3*) were associated in meta-analysis. All associations remained substantially similar after adjusting for potential confounding/mediating factors (body mass index, alcohol consumption, educational attainment, and depression). Some of the identified CpGs have been previously reported to be associated with aging, inflammatory diseases, or tumor cells. One CpG, cg14656411, was associated with overexpression of *NDUFS5* and *AK1RIN1*. No mediation effects on health outcomes were identified. **Conclusion:** Our study demonstrated the potential influence of discrimination on DNA methylation and subsequent gene expression. However, the potential impact on health outcomes remains to be determined.

Session Title: Epigenetics Poster Session I

PB2267 Epigenomic profiling of the infrapatellar fat pad in osteoarthritis

Authors:

P. Kreitmaier[1,2,3], Y-C. Park[1], D. Swift[4], A. Gilly[1], J. Wilkinson[4], E. Zeggini[1,2]; [1]Helmholtz Zentrum Muenchen, Neuherberg, Germany, [2]Technical Univ. of Munich (TUM) and Klinikum Rechts der Isar, Munich, Germany, [3]Graduate Sch. of Experimental Med., TUM Sch. of Med., Technical Univ. of Munich, Munich, Germany, [4]Dept. of Oncology and Metabolism, The Univ. of Sheffield, Sheffield, United Kingdom

Osteoarthritis is a complex joint disease that affects more than 300 million people worldwide. Due to increasingly aging populations, the impact of osteoarthritis on public health systems is estimated to increase further. Current treatment methods are limited to pain management and joint replacement, underlining the need to develop novel, personalised treatment strategies. Thus, it is important to extend our knowledge about the genetic and genomic basis of osteoarthritis. Here, we investigate matched genotype and methylation profiles from infrapatellar fat pad as well as blood samples from 70 knee osteoarthritis patients undergoing joint replacement surgery. We perform an epigenome-wide association study to examine epigenetic differences between fat pad and blood methylation. We generate a genome-wide cis-methylation QTL (mQTL) map in fat pad. Furthermore, we combine this mQTL map with results from genome-wide association studies for osteoarthritis using colocalisation and two-sample Mendelian randomization to identify epigenetic mechanisms mediating the effects of genotype on osteoarthritis risk in fat pad. Comparing the DNA methylation profiles between fat pad and blood reveal 84,973 differentially methylated sites ($p < 6.4x10^{-08}$). We produce the first genome-wide methylation quantitative trait locus (mQTL) map of fat pad and identify 35,948 mQTL targeted methylation sites. Using colocalisation and Mendelian randomization analyses, we resolve eleven osteoarthritis GWAS signals and provide insights into the molecular mechanisms underpinning osteoarthritis aetiopathology. Together, we report widespread differences between fat pad and blood methylation, generate the first mQTL map in fat pad and reveal methylation sites with a putative causal role in osteoarthritis. Our findings provide the first view of the epigenetic landscape of infrapatellar fat pad primary tissue in osteoarthritis.

Session Title: Epigenetics Poster Session II

PB2268 Epigenomic signature of major congenital heart defects in newborns with Down syndrome.

Authors:

J. Mouat[1], S. Li[2], S. Myint[2], B. I. Laufer[1], P. J. Lupo[3], J. M. Schraw[3], J. P. Woodhouse[3], A. J. de Smith[2], J. M. Lasalle[1]; [1]Univ. of California Davis, Davis, CA, [2]Univ. of Southern California, Los Angeles, CA, [3]Baylor Coll. of Med., Houston, TX

Background: Congenital heart defects **(CHDs)** affect approximately half of individuals with Down syndrome **(DS)** but the molecular reasons for incomplete penetrance are unknown. Previous studies have largely focused on identifying genetic risk factors associated with CHDs in individuals with DS, but comprehensive studies of the contribution of epigenetic marks are lacking. We aimed to identify and characterize DNA methylation differences from newborn dried blood spots **(NDBS)** of DS individuals with major CHDs compared to DS individuals without CHDs.
Methods: We used the Illumina EPIC array and whole-genome bisulfite sequencing **(WGBS)** to quantitate DNA methylation for 86 NDBS samples from the California Biobank Program: 1) 45 DS-CHD (27 female, 18 male) and 2) 41 DS non-CHD (27 female, 14 male). We analyzed global CpG methylation and identified differentially methylated regions **(DMRs)** in DS-CHD vs DS non-CHD comparisons (both sex-combined and sex-stratified) corrected for sex, age of blood collection, and cell type proportions. CHD DMRs were analyzed for enrichment in CpG and genic contexts, chromatin states, and histone modifications by genomic coordinates and for gene ontology enrichment by gene mapping. DMRs were also tested in a replication dataset and compared to methylation levels in DS vs typical development **(TD)** WGBS NDBS samples.
Results: We found global CpG hypomethylation in DS-CHD males compared to DS non-CHD males, which was attributable to elevated levels of nucleated red blood cells and not seen in females. At a regional level, we identified 58, 341, and 3,938 CHD-associated DMRs in the Sex Combined, Females Only, and Males Only groups, respectively, and used machine learning algorithms to select 19 Males Only loci that could distinguish CHD from non-CHD. DMRs in all comparisons were enriched for gene exons, CpG islands, and bivalent chromatin and mapped to genes enriched for terms related to cardiac and immune functions. Lastly, a greater percentage of CHD-associated DMRs than background regions were differentially methylated in DS vs TD samples.
Conclusions: A sex-specific signature of DNA methylation was detected in NDBS of DS-CHD compared to DS non-CHD individuals. This supports the hypothesis that epigenetics can reflect the variability of phenotypes in DS, particularly CHDs.

Session Title: Epigenetics Poster Session III

PB2269 Evaluating Hi-C data using deep neural networks.

Authors:

M. Benton, A. Rodriguez Perez; Baylor Univ., Waco, TX

Background: The three-dimensional (3D) chromatin architecture of the human genome is vital for maintaining appropriate levels of gene expression. Disruptions to this structure can change the existing enhancer-promoter interactions and have been associated with a wide range of disease phenotypes, including cancers and severe developmental and neurological disorders. Thus, we must be able to evaluate the quality of existing Hi-C datasets, which map 3D chromatin organization and its interactions, and create accurate methods for comparing Hi-C matrices genome-wide. Current correlation-based metrics for comparing Hi-C interactions do not fully capture known structure in these data, while annotation-informed approaches rely on additional external datasets. Here, we present a novel data-driven approach to evaluate the reproducibility of Hi-C data using neural networks to predict whether two portions of Hi-C contact matrices correspond to biological replicates.
Methods: Neural networks are a strong function approximation model that have proven useful in a wide range of problems, including chromatin conformation prediction. Here, we employ Siamese networks, which have been used extensively for similarity problems. We consider several evaluation scenarios that test the ability of the models to identify biological replicates, evaluate how well the task generalizes across different cell types, and assess the differences in the quality of the results across the genome.
Results: Through our experiments, we show that models can learn to predict the desired output when trained and tested in multiple cell types simultaneously. Across 7 different cell types, we achieve accuracy ranging from 91.7-95.9% and find that the effectiveness of the models is largely stable across chromosomes. However, training the models with data from multiple cell types and testing on a novel one produces models with lower and more variable accuracy (46.0%-73.8%). This suggests that the model does not learn broader patterns when trained on cross-tissue data, and that patterns are not transferable across cell types.
Conclusions: Our preliminary results pave the way for new avenues of research in understanding spatial genome organization and dynamics using data-driven approaches. Using the power of neural networks and the vast amount of Hi-C data available, we can develop more robust reproducibility measurements and gain deeper insights into the complex mechanisms underlying chromatin organization.

Session Title: Epigenetics Poster Session I

PB2270 Evaluation of X chromosome inactivation escape heritability across human tissues and cell type.

Authors:

H. Markus[1,2], B. Jiang[3], L. Carrel[4], D. Liu[3,2]; [1]Penn State Coll. of Med., Hershey, PA, [2]Pennsylvania State Univ., University Park, PA, [3]Pennsylvania State Univ. Coll. of Med., Hershey, PA, [4]Penn State Univ Col Med, Hershey, PA

X-chromosome inactivation (XCI) silences one X in females to balance gene dosage with males. Yet up to 10% of genes consistently escape XCI and 15-30% of genes variably escape XCI in a subset of tissues or individuals. A few studies suggest possible genetic influences on variable XCI escape, yet its extent remains to be quantified. Creating a comprehensive landscape of XCI states across tissue/cell types requires improved methods to infer XCI escape from population scale RNASeq data. Two types of methods exist to identify escape genes. As XCI escape leads to increased expression level in females, male and female differential expression (DGE) allows identifying genes that escape XCI among many individuals but cannot determine whether the gene escapes XCI in a given sample. On the other hand, as XCI escape yields more balanced allelic expression, methods that compare allelic imbalance (AI) between escape and sample skewing (i.e., AI calculated from inactivated genes) through allele specific expression (ASE) can identify gene escape in a given individual. ASE-based methods are underpowered for samples with balanced skewing and needs heterozygous SNPs within transcribed regions. To improve existing approaches, we propose a novel statistical method that combines the strength of male-female DGE and AI to infer XCI states across all individuals irrespective of XCI skewing or heterozygous SNP in bulk RNA-seq data. In simulations and empirical estimations in the GEUVADIS dataset, our method has well controlled type 1 error and increased power to infer XCI states in moderate to balanced XCI skew samples (i.e., skewing ≤75:25) when compared to XCIR, an ASE-based method. We then assessed XCI states in female samples from the Genotype Tissue Expression (GTEx) Project for an average of 202 genes per tissue (range 19-356) across 42 tissues. Genes inferred as escape using our method were concordant with previous consensus XCI states. Together we infer XCI states of 22 genes not previously described and identify 187 previously silenced genes that escape or variably escape in at least one tissue. Lastly, we analyze XCI escape status as a trait and quantify its heritability of each variably escape gene. In total, we identified and replicated 108 genes with significant XCI escape heritability in at least one tissue (average heritability 0.19, range 0.015-1.13). Overall, our method enabled us to provide a comprehensive atlas of XCI escape genes across human tissues and quantify QTLs that influence XCI escape status. These results will increase our understanding of the mechanisms of XCI escape genes and sex-biased diseases.

Session Title: Epigenetics Poster Session II

PB2271 EWAS of Gulf War Illness in the Gulf War Era Cohort and Biorepository (GWECB)

Authors:

X. Qin[1,2], Y. Shi[3], S. Boyle[1], A. Stone[4], W. Carter[4], L. Griffin[4], S. Pyarajan[3], B. Despard[3], K. Markianos[3], J. Vahey[2,1], M. Johnson[1], A. Press[1], J. Upchurch[1], S. Petry[1], A. Thompson[1], T. Redding IV[1], E. Gifford[2,1], K. Sims[1], C. Williams[1], E. Hauser[2,1]; [1]Durham VA Hlth.Care System, Durham, NC, [2]Duke Univ., Durham, NC, [3]VA Boston Hlth.care System, Jamaica Plain, MA, [4]Central Arkansas Veterans Hlth.Care System, Little Rock, AR

Many Veterans who were deployed to the Persian Gulf during the Gulf War report a constellation of pervasive chronic symptoms such as alterations in mood and cognition, fatigue, and musculoskeletal problems that have become to be known as Gulf War Illness (GWI).The etiology of GWI is unknown, although there is evidence that some military exposures are risk factors for GWI. There are no biomarkers for GWI and treatments are very limited. A previous GWAS performed in this dataset suggested significant heritability of the CDC Severe GWI (CSGWI) case definition and genetic variants of modest effect were associated with CSGWI. The goal of this research is to explore the epigenetic landscape for CSGWI. The GWECB consists of DNA and survey data from 1275 individuals who served in the US Armed Forces in 1990-1991. Self-reported symptoms captured by the GWECB survey determined CSGWI case status. Methylation data were generated from the Illumina EPIC array with Illumina quality control (QC) performed at the Pharmacogenomics Analysis Laboratory. The analysis pipeline developed for the Million Veteran Program, incorporating Sesame, minfi, meffill, limma, SVA and implemented in GenISIS was used for additional sample, probe and batch QC, normalization and Housman cell type estimates. EWAS was conducted using linear regression of the log2 methylated/unmethylated ratio with CSGWI as the independent variable adjusted for covariates of age, sex, blood cell type estimates and 6 genetic PCs to adjust for ancestry. CpG sites were annotated and ranked by p-value from the CSGWI coefficient. The EWAS Atlas (https://ngdc.cncb.ac.cn/ewas/atlas) was searched for published associations of CpG sites and genes. After final QC, EWAS was completed for 685,395 probes in 1018 samples. Of these, 223 (21.9%) met criteria for CSGWI with 77% male and 35% self-reported non-European ancestry. Population stratification was reasonably well-controlled with QQ plot lambda of 1.07. Eight CpG probes had p-values in the suggestive ($p< 1 \times 10^{-5}$) range. The top annotated CpG results were in genes TMEM37 ($p=1.44 \times 10^{-6}$), SNX3 ($p=1.77 \times 10^{-6}$), SYT2($p=4.17 \times 10^{-6}$), LIPT1 ($p=4.28 \times 10^{-6}$), TLE3 ($p=5.49 \times 10^{-6}$), and MYL12A ($p=7.28 \times 10^{-6}$). In the EWAS Atlas, published EWAS associations with these genes included Gulf War Illness (SNX3, SYT2) and ME/CFS (TMEM37, SYT2, TLE3). We have completed the largest genome-wide epigenetic analysis of CSGWI to date which provides evidence for differential methylation between CSGWI cases and controls. The EWAS results indicate that larger sample sizes are needed for adequate statistical power but also that epigenetic analyses may be useful in identifying biological associations in GWI.

Session Title: Epigenetics Poster Session III

PB2272 Exploring the Relationship Between Epigenetic Age Acceleration and Carotid Plaque Presence in a Multi-Generational Family Study of Dominicans.

Authors:

S. Parmar[1], N. Dueker[2], H. Gardener[1], D. Cabral[3], L. Wang[3], T. Rundek[4], S. Blanton[3]; [1]Univ. of Miami Miller Sch. of Med. - - Miami, FL, MIAMI, FL, [2]Univ. of Miami Miller Sch. of Med., Miami, FL, [3]Univ. of Miami, Miami, FL, [4]Univ Miami, Miami, FL

Chronological age (CA) is a major risk factor for common diseases including hypertension, cancer, dementia, and stroke. Epigenetic clocks based on methylation patterns have been developed to estimate an individual's biological age, providing insight into lifestyles and exposures which may modulate these disease risks; this biological age provides a holistic assessment of an individual's health status. These clocks include the first-generation Horvath and Hannum, as well as second-generation GrimAge and PhenoAge. When biological age is regressed onto CA, an age acceleration (AA) measure is obtained; a positive value (pAA) indicates a person's biological age exceeds their CA with a negative value (nAA) indicating a biological age younger than their CA. Previous studies have found AA measures to be heritable, with estimates ranging from 21% to 64%. Furthermore, pAA has been associated with increased risk for cardiovascular disease (CVD) and carotid traits including carotid intima-media thickness and carotid plaque. However, these studies involved primarily European or African ancestry samples, and the generalizability of these clocks is unknown. Therefore, the present study aimed to estimate the heritability of various AA measures and to determine if AA is associated with carotid plaque presence in a sample of extended families from the Dominican Republic (DR). To accomplish this, DNA methylation in blood was assayed using the Illumina Infinium Human MethylationEPIC BeadChip in 61 extended DR families (n=792) for whom carotid plaque presence data was available. Heritability estimates for HannumAA, PhenoAA, GrimAA and IEAA (Horvath) were obtained using SOLAR, and t-tests were performed to determine if AA measures were associated with carotid plaque presence (y/n). In our sample, the mean CA was 46 y (range 18-94 y) and mean AA ranged from 0.03 ± 3.55y for HannumAA to 1.26 ± 5.94y for PhenoAA. All AA measures were heritable: PhenoAA (h^2=0.51, P=5.0x10^{-13}), GrimAA (h^2=0.51, P=5.8x10^{-16}), HannumAA (h^2=0.47, P=5.0x10^{-14}), and IEAA (h^2=0.47, P=1.8x10^{-16}). Additionally, we observed an increase in the mean PhenoAA in those with carotid plaque presence vs. those without (P=1.9x10^{-06}). No other AA measures were associated with carotid plaque presence. Mixed model analyses with covariate adjustments are underway to formally quantify the association between PhenoAA and carotid plaque presence. In conclusion, our study provides suggestive evidence for an association between PhenoAA and carotid plaque presence, highlighting the importance of PhenoAA in our Dominican sample and demonstrates the generalizability of these clocks across race/ethnic groups.

Session Title: Epigenetics Poster Session I

PB2273 † Extensive profiling of transcription factors in postmortem brains defines genomic occupancy in disease relevant cell types and links TF activities to neuropsychiatric disorders

Authors:

J. Loupe[1], A. G. anderson[1], L. Rizzardi[1], I. R. Nunez[1], B. Moyers[1], K. Trausch-Lowther[1], W. E. Bunney[2], P. Cartegena[2], A. Sequeira[2], S. J. Watson[3], H. Akil[3], G. M. Cooper[1], R. M. Myers[1]; [1]HudsonAlpha Inst. for Biotechnology, Huntsville, AL, [2]Univ. of California, Irvine, CA, [3]Univ. of Michigan, Ann Arbor, MI

Transcription factors (TFs) orchestrate gene expression programs crucial for cell physiology by binding to specific genomic loci and regulating nearby target genes. However, our knowledge of their function is limited, as the vast majority of the thousands of genomic occupancy maps available for human TFs are derived from a small set of immortalized cell lines that are biologically distinct from the cells and tissues relevant for many diseases. Particularly in the context of neurological diseases, few TFs have been studied in human brain tissues and cell-types, like neurons. To address this gap, we have generated a multi-omic resource highlighted by ChIP-seq for more than 100 TFs, (1,072 total experiments) using bulk tissues and NeuN/Olig2-sorted nuclei from multiple human post-mortem brain regions. Nearly a third of the TF-bound regions we have identified lack any annotation in the Registry of candidate cis-Regulatory Elements (cCREs) from the ENCODE Consortium and are enriched for neuronal pathways, highlighting the shortage of brain tissue in existing datasets. By uniformly profiling a large number of TFs, we are able to demonstrate unique occupancy profiles for each TF and how they change across brain regions and cell types. We identified regions of high TF occupancy and demonstrate improved measurements of TF activity upon their removal, including motif recognition and gene expression modeling. Further, we find that computational methods to predict TF binding demonstrate a bias for high occupancy sites, and miss many distal enhancer elements bound by subsets of TFs that are enriched for neuronal pathways. Neuronal TFs SATB2 and TBR1, for example, bind unique elements that regulate neuron-specific gene expression. Further, we find several TFs with far greater enrichment for GWAS loci associated with brain disorders compared to commonly assessed epigenetic measurements such as histone marks and ATAC-seq. The highest enrichment for neuropsychiatric disease variants was found in ChIP-seq performed on neuron-enriched NeuN+ sorted nuclei, including TBR1 and PKNOX1, while enrichment for neurodegenerative variants was found in TF binding sites identified in microglia-enriched $NeuN^-/Olig2^-$ nuclei. This dataset is one of the largest collections of TF binding maps in human tissues to date, and the only such resource for human brain. It will be a unique and powerful resource for future studies seeking to understand the role of TFs in epigenetic regulation in neurological disease.

Session Title: Epigenetics Poster Session II

PB2274 Functional characterization and network analysis of regulatory regions using genome-wide functional screens and chromatin interactions

Authors:

K-Y. Ko[1], K. Siklenka[2], A. Barrera[3], G. Yardimci[4], E. Aiden[5], T. Reddy[2]; [1]Duke, Durham, NC, [2]Duke Univ., Durham, NC, [3]Duke Univ., Durhan, NC, [4]Knight Cancer Inst., Portland, OR, [5]Baylor Coll. Med., Houston, TX

Objective

Establishing non-coding mechanisms for disease remains a major goal in human genetics. Identifying the genomic mechanisms that contribute to gene regulation is critical to achieving that goal. Two promising technologies for identifying those mechanisms are high-throughput reporter assays and CRISPR screens. The goal of this study is to test a hypothesis that high-throughput reporter assays detect regulatory element activity independent of chromatin context, while CRISPR screens identify regulatory elements that are active in the studied cell model.

Method

Phase 4 of the ENCODE project included a coordinated effort across eight labs to functionally characterize human gene regulatory elements using high-throughput reporter assay screens and high-throughput CRISPR perturbational screens. Together, ENCODE completed hundreds of such screens. Here, we compared the ability of the different functional characterization technologies used in ENCODE to identify genomic sites with transcription factor binding, histone modifications associated with active gene regulation, and chromatin interactions in the same cell models.

Results

Overall, we found substantial concordance across functional characterization assays, but also considerable assay-specific preferences in the characteristics of regulatory elements detected. While we identified enhancers such as GATA1 and MYC in multiple assays, we observed a mix of concordant and discordant signals in regions such as FADS and HBE1 loci. Our results suggested that variations in regulatory activities among the assays may be due to the differences of genomic features across the regions.

While functional annotations such as promoter/enhancer-like signatures were enriched in regulatory regions, some genomic features could partially explain the variations among the assays. TFs such as EP300 and AP1 were more enriched in ATAC-STARR-seq and TFs such as ELK1 and SP1 were more enriched in whole genome STARR-seq and MPRA. CTCF binding had lower enrichment scores than other TFs in STARR-seq and MPRA. However, several regions such as FADS loci were found not only had discordant signals across CRISPRi and reporter assays, but also contained CTCF and cohesin binding sites. Therefore, we hypothesized that chromatin organization may contribute to the differences among the assays.

To test the hypothesis, we constructed chromatin interaction networks and found CRISPR-based regulatory regions were more enriched at loop anchors than regions in other assays. Taken together, we proposed that CRISPR screens are more sensitive to chromatin spatial organization compared to reporter assays such as STARR-seq and MPRA.

Session Title: Epigenetics Poster Session III

PB2275 † Functional characterization of the mammalian genome.

Authors:

K. Siklenka[1], J. Zhang[2], D. Shigaki[3], K-Y. Ko[4], J. Oh[3], R. Venukuttan[1], A. Barrera[1], ENCODE Functional Characterization Center, M. Beer[5], E. Aiden[6], H. Yu[7], T. Reddy[1], G. Yardimci[8]; [1]Duke Univ., Durham, NC, [2]Cornell Univ., Ithica, NY, [3]Johns Hopkins, Baltimore, MD, [4]Duke, Durham, NC, [5]Johns Hopkins Univ, Baltimore, MD, [6]Baylor Coll. Med., Houston, TX, [7]Cornell Univ, Ithaca, NY, [8]Oregon Hlth.and Sci. Univ., Portland, OR

The ENCODE consortium has mapped millions of elements associated with regulatory potential across the human and mouse genomes. To assess the functionality of those elements in different genomic contexts, we systematically measured activity and essentiality of human and mouse regulatory elements across hundreds of complementary functional characterization experiments. The assays included genome-wide studies and coordinated high-resolution studies focused on select loci. Together, the studies comprise tens of billions of DNA fragments assayed in high-throughput reporter assays, millions of CRISPR-based perturbations, and thousands of in vivo whole-mouse transgenic reporter assays.

We first developed analysis methods to uniformly report similarities and differences between the regulatory element activity detected from these assays. Overall, 30% of tested open chromatin regions have detectable activity in high-throughput reporter assays, and 5% have a functional readout with CRISPR interference.

We observe that while a subset of high confidence regulatory regions are detectable across all assay types, there are considerable differences in the types of elements each assay observes. We reveal sequence specific differences between high-throughput reporter assay classes, with activity from MPRA explained by promoter-like motifs, while activity from STARR preferring distal. Moreover, we report similar patterns of enrichments of transcription factors and histone modifications at assay-specific active regions as measured by ChIP-seq.

Meanwhile, we observe 3D chromatin organization accounts for major differences in detection between reporter assays and CRISPR screens. CRISPR-based active-regions are enriched with chromosomal contacts, and constrained to the topological domain of the gene target, an observation not observed in reporter assays

Taken together, these results suggest a hierarchy of regulatory function in the human genome and provide a framework for integrative analysis and interpretation of those assays moving forward. In that model, DNA sequence features define a subset of open chromatin sites that have cell- and condition-specific regulatory activity in reporter assays; and the chromatin context further restricts regulatory function as detected with CRISPR-based perturbations.

Session Title: Epigenetics Poster Session I

PB2276 Further refinement of the differentially methylated distant lung-specific *FOXF1* enhancer in a neonate with alveolar capillary dysplasia

Authors:

P. Szafranski[1], R. Garimella[2], H. Mani[3], R. Hartman[4], G. deutsch[5], A. Silk[6], A. Benheim[7], P. Stankiewicz[1]; [1]Baylor Coll. Med., Houston, TX, [2]Dept. of Pediatrics, Inova LJ Murphy Children's Hosp., Falls Church, VA, [3]Dept. of Pathology, Inova Fairfax Hosp., Falls Church, VA, [4]Inova Dept. of Genetics, Inova Fairfax Med. Campus, Falls Church, VA, [5]Univ. of Washington Sch. of Med., Seattle, WA, [6]Neonatology, Fairfax Neonatology Associates, Inova Fair Oaks Hosp., Inova LJ Murphy, Children's Hosp., Fairfax, VA, [7]Div. of Pediatric Cardiology, Inova LJ Murphy Children's Hosp., Falls Church, VA

Heterozygous loss-of-function of the mesenchymal transcription factor *FOXF1* gene has been found in 80-90% of neonates with histologically-verified alveolar capillary dysplasia with misalignment of pulmonary veins (ACDMPV, MIM 265380), a lethal lung developmental disorder. Analyses of 34 ACDMPV-causative overlapping CNV deletions leaving *FOXF1* intact enabled us to define the distant ~ 60 kb lung-specific enhancer region (chr16:86,212,040-86,271,919, hg19) mapping ~ 286 kb upstream to *FOXF1* and harboring a LINE & *Alu* genomic instability hotspot. We previously reported that transcription of not only *FOXF1* but also of the neighboring and inversely oriented lncRNA gene *FENDRR* is strongly regulated by this enhancer. Intriguingly, *Fendrr*$^{-/-}$ mice developed lethal heart defects and hypoplastic lungs, similar to those found in *Foxf1*$^{+/-}$ mice. Recently, we proposed a bimodal structure and parental functional dimorphism of this *FOXF1* & *FENDRR* enhancer, with Unit 1 having a higher activity on the paternal chr16 and non-overlapping Unit 2 on the maternal chr16 (PMID: 36157490). Unit 1 harbors an evolutionarily ultra-conserved ~ 660 bp segment and encodes two antisense long non-coding RNAs, whereas Unit 2 features lung-specific histone H3 modifications characteristic for an active enhancer. Interestingly, two regions of differential methylation and allelic differences of the H3K27Ac profile were also identified in Unit 2. Here, we describe a novel unusual sized pathogenic CNV deletion involving a centromeric portion of the *FOXF1* enhancer on maternal chr16 that narrows Unit 2 to an essential ~ 9-kb segment. This region harbors the enhancer-promoter interaction site and the binding sites for TFs involved in chromatin modification and/or regulation of cell cycle and motility. Using a restrictase-based assay, we found that this segment is weakly methylated at ApT adenine, with twice the frequency of methylation on the maternal versus paternal chr16. This difference might contribute to the proposed higher activity of the enhancer Unit 2 on maternal compared to the paternal chr16. Our data provide further insight into structure and function of the lung-specific *FOXF1* & *FENDRR* enhancer.

Session Title: Epigenetics Poster Session II

PB2277 Genetics and Epigenetics of Alcohol-Associated Liver Disease: Analysis of Single Nucleotide Variants and DNA Methylation change.

Authors:

B. Shankarappa[1,2], J. Mahadevan[2], P. Murthy[2], M. Purushottam[2], B. Viswanath[2], H. Devarbhavi[1], A. Mysore[1]; [1]St Johns Med. Coll. Hosp., Bangalore, India, [2]Natl. Inst. of Mental Hlth.and NeuroSci.s, Bangalore, India

Introduction:To understand whether there is an underlying genetic signature for predisposition to Alcohol Use Disorder with cirrhosis (AUDC+ve) we studied single nucleotide polymorphism (SNPs) & DNA methylation change in genes involved in alcohol metabolism (ADH2, ADH3 and ALDH2), lipid metabolism (PNPLA3 and TM6SF2) and one carbon metabolism pathway (MTHFR and MTR). Alcohol has a toxic effect on all organs, and this may underlie disease syndromes such as cirrhosis, neuropathy, and neuropsychiatric manifestations. This study will help us to understand how genetic factors may intersect with methylation and increase risk of disease syndromes.

Methods:Study included men with AUDC+ve, N=136 and AUD without liver cirrhosis, N=107 based on ICD10 criteria, drawn from the clinical services of St.John's Medical College Hospital (Gastroenterology and Psychiatry) & NIMHANS. Fibroscan and/or sonographic findings were used to rule out fibrosis (Liver Stiffness Measurement, LSM <7kPa).PCR-RFLP was performed to study the SNPs. The SNP-based genetic risk score was calculated for all the SNPs studied. For DNA methylation, DNA was bisulfite converted followed by PCR for the LINE-1, ALDH2, MTHFR, PNPLA3 and TM6SF2 loci and Pyrosequencing (PyroMark Q24).Results:AUDC+ve group had consumed lesser quantities of alcohol for a shorter duration and had a later age of onset of drinking compared to AUDC-ve group. The AUDC+ve had higher levels of conjugated and direct bilirubin, AST/ALT ratio, ALP and GGT, also lower levels of total protein, albumin, Haemoglobin levels and MCV. We observed a global DNA hypomethylation (P<0.01) and ALDH2 hypomethylation (P 0.03) in AUDC+ve compared to AUDC-ve subjects. ALDH2 hypomethylation showed significant association with MELD score (cirrhosis severity). TM6SF2 loci showed lower methylation in AUD-C+ve group compared to AUD-C-ve group (P=0.02). Genetic Risk Score was significantly higher in AUDC+ve group compared to AUDC-ve group and control data (SAS population) (P = 0.03).

Conclusion and Discussion:Present study, we found DNA hypomethylation at LINE1 loci in AUDC+ve. Thus, a dip in global DNA methylation, following chronic, heavy alcohol use, may occur in patients who eventually progress towards HCC. ALDH2 hypomethylation might lead to mitochondrial damage, hepatic inflammation, and fibrosis due to the increased accumulation of acetaldehyde. TM6SF2 hypomethylation may affect it's transcription activity and leads to increased triglyceride accumulation in the liver.Altered methylation in blood DNA at candidate loci may serve as a biomarker for severe liver disease in the context of prolonged severe alcohol abuse.

Session Title: Epigenetics Poster Session III

PB2278 Genome-wide association analysis identified a novel locus for epigenetic age acceleration

Authors:

Cardinal Stefan Wyszynski Univ., Warsaw, Poland, [8]Dept. of Forensic Genetics, Pomeranian Med. Univ., Szczecin, Poland, [9]Dept. of Anthropology, Univ., Łódź, Poland, [10]Ctr. for Forensic Sci. Univ., Warsaw, Poland, [11]Inst. of Zoology and BioMed. Res. of the Jagiellonian Univ., Krakow, Poland

The DNAm-based age estimators, also known as DNAm clocks can consider various aspects of the aging process such as health span, mortality risk, and the pace of aging. In addition, the epigenetic age acceleration (EAA) measure which is the discrepancy between DNAm age and chronological age, has emerged as a potential clinical biomarker in association with various diseases. Besides, previous GWAS analysis has emphasized the importance of genetic factors in epigenetic age acceleration and implies that genetic variations may contribute to inter-individual differences in epigenetic aging. Here we performed GWAS analysis on blood samples obtained from the Polish population to further investigate genetic variants associated with different EAA measures. The DNA methylation and genomic profile of samples were obtained using the Methylation EPIC array and the Global Screening Array (GSA). (Illumina, San Diego, CA, USA). DNAm ages were calculated for different DNAm clocks including Horvath2013, Hannum, Skin&Blood, PhenoAge, GrimAge, and FitAge. Respective epigenetic age acceleration (EAA) measures were calculated, as the residual of the DNAm age regressed on chronological age. Also, DNAm-based pace of aging (DunedinePACE) and Mortality Risk Score (MRS) were measured. GWAS analysis was done using PLINK 1.9. We found a novel genome-wide significant SNP for GrimAge Acceleration, which is an estimation of all-cause mortality risk, calculated based on the DNAm surrogate measures for plasma proteins, smoking pack years plus sex, and age. The detected SNP located on chromosome 18 is mapped to the *SOCS2* gene which encodes a member of the suppressor of cytokine signaling (SOCS) family and has been reported to act in aging and longevity, potentially through its negative regulatory impact on mitochondrial fatty acid oxidation, and plasma IGF1 levels. Decreased levels of plasma IGF1 have been linked to extended lifespan in mice and the absence of SOCS2 expression leads to reduced lifespan in mice with high-growth characteristics. Our study suggests that genetic variations can influence the DNAm-based mortality risk signal captured by the GrimAge clock and endorse the *SOCS2* gene as a target for further anti-aging investigation.

Session Title: Epigenetics Poster Session I

PB2279 Genome-wide Association and Mendelian Randomization Analysis among 120,671 Chinese Pregnancies Identifies Novel Genetic and Molecular Risk Factors of Gestational Diabetes and Glycemic Traits.

Authors:

Y. Gu, H. Zheng, Y. Liu, S. Bian, S. Liu; Sch. of Publ. Hlth.(Shenzhen), Sun Yat-sen Univ., Shenzhen, China

Gestational diabetes mellitus (GDM) and hyperglycemia are the most common disorders in pregnancy. However, the causes of GDM remain obscure. To investigate the genetic and molecular risk factors underlying the phenotypic spectrum of GDM and glycemic traits, we collected non-invasive prenatal sequencing (NIPT) data, five glycemic and 52 biochemical measurements, and electronic medical records of 120,761 pregnancies, including 12,024 patients diagnosed with GDM, during a four-year period at two hospitals in Shenzhen, China. We conducted genome-wide association studies (GWAS) between genotypes derived from the NIPT sequencing and the GDM diagnostic, as well as the five glycemic traits that reflect GDM severity. Mendelian randomization (MR) was performed to explore the potential causal effects of the 52 biochemical measurements on GDM and glycemic levels. Through meta-analysis, we identified nineteen genetic loci significantly associated with GDM susceptibility ($P < 5\times10^{-8}$). Notably, several genetic variants demonstrated a strong association with GDM but only a suggestive or insignificant association with type 2 Diabetes (T2D), which present in the *MTNR1B* and *FOXA2* et al gene loci, indicating different etiological factors between GDM and T2D. One hundred and five genetic loci including 66 novel ones, were also significantly associated with the five glycemic traits. We observed substantial genetic differences among the baseline glycemic level (FPG and OGTT0H), glycemic level after the oral glucose challenges (OGTT1H and OGTT2H), and glycated hemoglobin level (HbA1c). Genetically higher body mass index, lymphocyte percentage, and genetically lower hemoglobin F and absolute neutrophils were causally associated with increased fasting glucose concentration and an increased risk of GDM risk. As the most powerful genetic study on GDM nowadays, our study suggests that public health strategy may take into account a patient's genetic predisposition for a better understanding, prevention, and treatment of GDM. Future clinical trials may be warranted to investigate the modulation of BMI or the incidence of the inflammatory response through nutrition therapy or medicine.

Session Title: Epigenetics Poster Session III

PB2281 Genome-wide association study of an epigenetic signature of monozygotic twinning

Authors:

J. van Dongen[1], Twinning Genetics Consortium, Genetics of DNA methylation Consortium, E. A. Ehli[2], F. A. Hagenbeek[1], J. J. Hottenga[1], D. I. Boomsma[1]; [1]VU Amsterdam, Amsterdam, Netherlands, [2]Avera Inst. for Human Genetics, Sioux Falls, SD

Monozygotic (MZ) twins and higher-order multiples arise when a zygote or embryo splits during pre-implantation stages of development. The underlying mechanisms of this event have remained a mystery. We recently identified a DNA methylation signature of MZ twinning in blood samples from adult twins, which showed strong replication across cohorts and in buccal samples from children (van Dongen et al 2021 PMID: 34584077). Here, we report a genome-wide association study (GWAS) on the DNA methylation score for MZ twinning in two datasets from the Netherlands Twin Register (NTR): Illumina 450k array data from blood (N=2841, EU ancestry, mean age=37, 66% females, 56% MZ twins) and Illumina EPIC array data from buccal (N=1150, EU ancestry, mean age=10, 47% females, 84% MZ twins). Genotyping was done on the Affymetrix 6, Affymetrix Axiom or Illumina GSA array. Genotype data were imputed against the Human Reference Genome plus Genome of the Netherlands (GoNL) reference panel. GWAS analysis was performed in gcta using --fastGWA-mlm correcting for 10 genetic ancestry PCs and genotype platform. GWAS analysis of the blood 450k array data identified three genome-wide significant loci. The top SNP (rs76157694, MAF=0.25) maps to *TBX4*; an embryonic transcription factor primarily known for its role in hindlimb development. This finding is consistent with our previous results of MZ-differentially methylated positions being enriched within *TBX4* binding motifs (van Dongen et al 2021 PMID: 34584077). GWAS analysis of the buccal EPIC array data identified no genome-wide significant loci. Next steps will be to perform a GWAS meta-analysis with the Genetics of DNA methylation consortium (GoDMC).

PB2282 † Genome-wide chromatin conformation analysis in individuals of African versus European ancestry reveals ancestry-specific chromatin interactions. individuals of African versus European ancestry reveals ancestry-specific chromatin interactions.

Authors:

L. Wang[1], W. Xu[2], X. Liu[2], F. Rajabli[1], K. Celis[1], L. Lu[3], M. Gearing[4], D. Bennett[5], M. Flanagan[6], S. Weintraub[7], C. Geula[8], T. Schuck[9], D. Davis[1], W. Scott[1], D. Dykxhoorn[1], A. Griswold[1], M. Pericak-Vance[1], J. Young[1], F. Jin[3], J. Vance[1]; [1]Univ. of Miami, Miami, FL, [2]Case Western Reserve Univ, Cleveland, OH, [3]Case Western Reserve Univ., Cleveland, OH, [4]Emory Universit, Atlanta, GA, [5]Rush Univeristy Med. Ctr., Chicago, IL, [6]Northwestern Univ., Chicago, IL, [7]Northwestern Univeristy, Chicago, IL, [8]Northwestern Univ, Chicago, IL, [9]Univ of Pennsylvania, Phildelphia, PA

Introduction: Genetic risk for Alzheimer Disease (AD) varies across populations with different ancestry. Identifying the mechanisms underlying these differences can lead to therapeutic interventions. Three-dimensional (3D) genome architecture regulates gene transcription, which could confer differential disease risk. At the top layer of 3D genome structure, the genome can be partitioned into Compartment A and B representing transcriptionally active and silenced chromatin, respectively. At the fine-scale level, chromatin loops are formed, often representing promoter-enhancer interactions. Genome-wide Hi-C analyses have revealed dynamic 3D genome structure during development and disease progression. The variation of 3D genome structure on different ancestry backgrounds, however, has not been studied.
Methods: Hi-C libraries from brain dorsal lateral frontal cortex were constructed with a 4-cutter enzyme. On average, 700 million of paired-end reads per library were obtained in 8 *APOE*e4 homozygotes (4 AF and 4 EU) who are age and sex-matched. Local ancestry (LA) blocks were calculated using RFMix and a reference panel from 1000 Genomes for EU, AF, and Amerindian ancestry. The AF samples have 68~88% AF genome while each EU sample has >95% EU genome. DeepLoop was used to call chromatin loop at a 5-kb resolution. Ancestry-specific loops were identified using pairwise T-test ($P<0.05$, Fold Change>2)
Results: 6206 compartment bins were compared at a 500kb-resolution. Most of the A and B compartments were consistent among individuals with 2~3% of them switched between ancestry groups. Of the switched compartment bins, more (2x) transcriptionally active chromatin was observed over EU LA than AF LA blocks. Of the 1,095,151 chromatin loops called, 12,082 loops are EU-specific, and 2885 loops are AF-specific. Compared to the EU-specific loops (median size=496 kb), the AF-specific loops are smaller (median size=158 kb) and more likely represent promoter-enhancer interactions as they are enriched for co-localization with H3K4me3 and H3K27ac marks while the EU-specific loops are enriched for CTCF occupancy. DNA sequence variations within the CTCF binding motif contribute to some ancestry-specific loops (N=30).
Conclusion: Hi-C analysis demonstrates ancestry-specific chromatin interaction differences in brain frontal cortex. The compartment variation reflects large-scale genome activity, and the fine-scale loop level variation is likely governed by complex mechanism such as DNA sequence variations. Our data suggest novel epigenomic mechanisms for ancestry-specific genetic risk which could reflect GWAS differences between ancestries.

Session Title: Epigenetics Poster Session II

PB2283 Genomic dissection of enhancer context sensitivity and synergy

Authors:

M. Maurano, R. Ordoñez, G. Ellis, H. J. Ashe; NYU Sch. of Med., New York, NY

Noncoding disease and trait-associated genetic variation is frequently interpreted in the context of genomic regulatory elements such as DNase I hypersensitive sites (DHSs). Most genomic DHSs lie within a few kilobases of another DHS, but individual DHSs are typically analyzed independently without accounting for their surrounding context. Using our recently developed Big-IN approach for rewriting genomic loci, we have previously identified distance-dependent synergy among the DHSs at the *Sox2* Locus Control Region (LCR) in mouse embryonic stem cells. Here, we extend our synthetic regulatory genomics approach to identify widespread genomic examples of context-dependent enhancers which have no activity on their own but can double the activity of a nearby DHS. We show that this synergy between nearby DHSs decays as a characteristic function of distance and its influence extends up to several kilobases. Finally, we fine map this context dependency to the contribution of individual TF recognition sequences. Our approach implicates specific sequence and architectural features underpinning the influence of genomic context, and suggests that interpretation of noncoding variation must be done at a haplotype level rather than implicitly assuming the surrounding sequence matches the genomic reference.

Session Title: Epigenetics Poster Session III

PB2284 High-throughput DNA methylation BeadChip assay for population-scale EWAS studies.

Authors:

D. Goldberg[1,2], N. Renke[3], S. Gruber[3], W. Zhou[1,2]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Children's Hosp. of Philadelphia, Philadelphia, PA, [3]Illumina, Inc., San Diego, CA

DNA methylation is a stable covalent chemical modification to DNA that shapes cell identity and impacts diverse processes from genome stability to gene expression. Infinium Methylation BeadChips contain probes for preselected CpG sites and can be used for highly accurate quantification of CpG methylation at selected loci. Such microarrays are a cost effective and computationally tractable alternative and have been successfully utilized for population scale EWAS studies. Despite the successes of previous BeadChip versions, some traits associate with only subtle differences in DNA methylation, necessitating ever larger sample sizes. Therefore, a highly consolidated BeadChip strategically designed for EWAS studies would be beneficial for the population epigenetics community. To that end, we designed a compact Infinium Methylation BeadChip containing ~300K probes, approximately 30% of the size of the newly released EPICv2 array. We incorporated known EWAS hits of high statistical significance while also adding new CpGs to facilitate discovery and scientific rigor in EWAS. Approximately 50% of probes were derived from mining EWAS databases and literature. The methylation of these CpGs are linked to 8511 biological features from broad categories including cardiovascular, metabolic, neurodegenerative/psychiatric, autoimmune, genetic, environmental exposure and infection-related traits and diseases that were studied using existing Infinium array platforms. The remaining 50% are novel probe designs obtained from integrative analysis of >300 public bulk and single-cell WGBS datasets. These probes target DNA methylation associated with cell type, gene expression, chromatin accessibility and mono-allelic expression. Additional cytosines were selected from recent regulatory region annotations throughout the human genome to further enhance discovery power. While the vast majority of EWAS studies have focused exclusively on 5mC, our identification and incorporation of tissue specific and variable regions of 5-hydroxymethylcytosine will enable deeper insights into the epigenetic landscape. Altogether, our newly developed EWAS array contains both previously identified markers and candidate CpG sites and will be a valuable, more scalable tool for population level EWAS studies.

Session Title: Epigenetics Poster Session I

PB2285 How the phenotypes and genotypes affect irritable bowel syndrome (IBS)

Authors:

S-Y. Tsai[1,2,3,4,5], S-C. Hsieh[6], C-F. Kuo[7], N-W. Hsu[3], S. Hsieh[3]; [1]Dept. of Hlth.Policy and Management, Johns Hopkins Bloomberg Sch. of Publ. Hlth., Johns Hopkins Univ., Baltimore, MD, [2]Dept. of Lab. Med., Mackay Mem. Hosp., Taipei City, Taiwan, [3]Dept. of Med., Mackay Med. Coll., New Taipei City, Taiwan, [4]Inst. of BioMed. Sci., Mackay Med. Coll., Taipei City, Taiwan, [5]Inst. of Long-Term Care, Mackay Med. Coll., Taipei City, Taiwan, [6]Dept. of Res., Mackay Mem. Hosp., Taipei City, Taiwan, [7]Div. of Infectious Diseases, Dept. of Internal Med., Mackay Mem. Hosp., Taipei City, Taiwan

Introduction: Patients with IBS demonstrate symptoms such as recurrent and persistent abdominal pain combined with change of stool passage over a period 3 months. We aimed to conduct the first study to investigate the impact of the phenotypes and genotypes on IBS to propose clinical implications. **Methods:** Genotyping Data and Quality Controls SNP genotyping was conducted by using custom Taiwan BioBank (TWB) chips. We implemented quality control procedures for subsequent analysis for SNP exclusion: failure to achieve Hardy-Weinberg equilibrium (with a p value$< 1 \times 10^{-5}$), MAF< 5%, and a genotyping call rate <95%. There were a total of 291,928 SNPs remaining. Patient selection and statistics methods We investigated the data, including questionnaires with the phenotypes, such as health status, environment factors, etc**.** and whole genome genotyping. After excluding the participants without genetic data, we used propensity score to match age and sex ratio. Sequentially, we analyzed 1316 participants filtering and merging using PLINK 1.9. Univariate and multiple logistic analysis were performed to identify risk factors for IBS using R (version 4.2.2) to analyze the relevant data including phenotypes and genotypes between IBS and relevant cormobidities. **Results:** The prevalence of IBS recorded in TWB was 2.56%, with 58.22 % in the male group and 41.78% in the female group. Univariate analysis revealed that all the included factors increasing the risk of IBS and then multivariate regression analysis through two models to develop a nomogram for estimating the risk of IBS through the following formula: The risk of IBS = -(0.69 x sleep quality=poor) -(0.48 x sleep quality= moderate)+(0.444 x Peptic ulcer disease)+ (1.059 x gastroesophageal reflux disease)+ (0.869 x depression)+(0.751 x migraine) +(0.364 x Back and waist pain) -(0.772 x rs12116694=C pair to C) +(0.538 x rs9287949=C pair to C) +(0.756 x rs544951885=pair without A) +(0.45 x rs544951885= pair with one A) **Conclusions:** Depression is our significant comorbidity and correlated with a SNP, rs193922209, in the *FBN1* gene. Our findings have uncovered novel genetic contributions to IBS, given its multifactorial nature and the likely interactions of multi-omics, represent a promising approach to integrating phenotypes and genome-wide analysis and highlight the importance of genetic predisposition to IBS. To explore disease mechanisms, and the associations between genetic variation and syndromes, and intermediate phenotypes for identifying potential therapeutic targets is a warrant. Healthcare providers should be aware of those comorbidities and variants with their clinical implications.

Session Title: Epigenetics Poster Session II

PB2286 † HTRAnet predicts regulatory activity for sequences in diverse reporter assays and enables systematic comparative analysis of high throughput reporter assays

Authors:

Z. Chen[1], K. Siklenka[2], R. Castro[3], R. Tewhey[3], T. Reddy[2], A. Kundaje[1]; [1]Stanford Univ., Palo Alto, CA, [2]Duke Univ., Durham, NC, [3]Jackson Lab., Bar Harbor, ME

High-throughput reporter assays (HTRAs) such as episomal and lenti-virus massively parallel reporter assays (MPRAs) and self-transcribing active regulatory region sequencing (STARR-seq) can directly measure regulatory potential of libraries of candidate regulatory elements. Despite apparent similarities, different HTRAs often exhibit poor concordance of measured activity for matched sequences. Systematic comparison of these assays is challenging due to distinct input libraries and different biases. Further, the causal sequence syntax driving similarities and differences between these assays is not well understood. Deep learning models have been effective at modeling diverse regulatory profiling experiments such as DNase-seq and ATAC-seq. The models can also be interrogated to decipher predictive sequence motifs and syntax rules. Although previous studies have proposed deep learning models for reporter assays, they are often optimized for each specific assay and do not attempt to generalize across them. Further, reporter assays have not been compared through the lens of cis-regulatory syntax learned by predictive models.

In this study, we introduce HTRAnet (High Throughout Reporter Assay Network), a convolution neural network architecture to learn accurate sequence models of regulatory activity from diverse reporter assays. We trained HTRAnet on MPRA, lenti-MPRA, whole-genome-STARR-seq and ATAC STARR-seq experiments in the K562 cell-line. For all pairs of assays, HTRAnet predicted activity was substantially more concordant across matched sequences relative to measured activity, suggesting effective denoising of the signal. We interrogated the models with sequence attribution and motif discovery methods to extract and compare predictive sequence features. The ATAC-STARR-seq model revealed a strong sequence composition bias, which motivated the development of an automated bias correction approach. We further identified systematic differences of predictive sequence motifs and syntax between assays. e.g. SP1 motifs in promoters were preferentially identified in MPRA, whereas GFI1B and SNAI2 repressors were preferentially detected by STARR-seq. We further identified substantial similarity between sequence syntax from HTRAnet models and syntax derived from analogous BPNet models trained on ATAC-seq and DNase-seq data. HTRANet is a unified deep learning network that predicts regulatory activity from sequences accurately and facilitates a more comprehensive understanding of different reporter assays.

Session Title: Epigenetics Poster Session III

PB2287 Identification of exposure- and genetically driven epigenetic associations with lifetime cannabis use.

Authors:

S. Giamberardino[1], L. Zhou[1], J. Marks[1], K. A. Lawrence[2], Z. Xu[2], J. Taylor[2], D. P. Sandler[2], D. B. Hancock[1], E. O. Johnson[1,3], F. Fang[1]; [1]GenOmics and Translational Res. Ctr., RTI Intl., Research Triangle Park, NC, [2]Epidemiology Branch, Natl. Inst. of Environmental Hlth.Sci., NIH, Research Triangle Park, NC, [3]Fellow Program, RTI Intl., Research Triangle Park, NC

Cannabis use is prevalent among the U.S. population, yet reliable, long-term biomarkers for quantifying its use over an individual's lifespan are limited. This knowledge gap hinders our ability to accurately assess cannabis exposure and its potential effects on health outcomes. DNA methylation (DNAm) may serve as a viable and sensitive biomarker of cannabis use. We previously identified DNAm associations with lifetime cannabis use, which may reflect exposure-based (i.e., DNAm change resulting from exposure to cannabis) or predisposing risk (i.e., DNAm influenced by nearby genetic variation). Differentiating between these two interpretations will help inform their utility as biomarkers. We conducted a *cis*-methylation quantitative trait loci (meQTL) meta-analysis of two cohorts, GuLF (Gulf Long-term Follow-up Study; n=843) and ALSPAC (Avon Longitudinal Study of Parents and Children; n=904). We tested cannabis-implicated CpGs (p < 0.001 from our previous study) for association with 1000 Genomes-imputed genetic variants. *Cis*-meQTLs were identified using Matrix eQTL (adjusting for age, sex, surrogate variables, cell type proportions, cigarette smoking status, and study-specific covariates) and defined as occurring within a 1Mbp window around each CpG. Results were combined via inverse variance-weighted meta-analysis (using the software METAL). A significant *cis*-meQTL was defined based on meta-analysis p-value < 1×10^{-8}. Location-based enrichment for CpG and genic regions was tested using the LOLA R package. Of the 1,297 cannabis-implicated CpGs, 331 (~25%) had at least one significant *cis*-meQTL. CpGs with *cis*-meQTLs were enriched for intergenic and CpG shore regions and depleted in CpG islands and 5'UTRs, as compared to the total set of cannabis-implicated CpGs. Incorporating publicly available *cis*-meQTL results from the Genetics of DNA Methylation Consortium (GoDMC) study comprised of 32,851 individuals from 36 cohorts independent from ours, we found that 166 of our CpGs with *cis*-meQTLs were also present in GoDMC, and 165 of them have significant *cis*-meQTLs reported in GoDMC. In our *cis*-meQTL analyses, we identified a subset of cannabis-DNAm associations that are potentially driven by nearby genetic variation, suggesting the remaining CpGs may be primarily influenced by cannabis exposure. Future work will include incorporating additional cohorts of different ancestral backgrounds into the meta-analysis to increase the generalizability of our findings. Furthermore, identified *cis*-meQTL variants will be incorporated into epigenome-wide association studies of cannabis use to minimize genetic confounding.

Session Title: Epigenetics Poster Session I

PB2288 Identification of multi-sample consensus open chromatin regions using ROCCO

Authors:

N. Hamilton[1], T. Furey[2]; [1]UNC Chapel Hill, Chapel Hill, NC, [2]Univ North Carolina, Chapel Hill, Chapel Hill, NC

Analysis of open chromatin regions across multiple samples from two or more distinct conditions can determine altered gene regulatory patterns associated with biological phenotypes and complex traits. The ATAC-seq assay allows for tractable genome-wide open chromatin profiling of large numbers of samples. However, stable, broadly applicable genomic annotations of open chromatin regions are not available. Thus, most studies first identify open regions as peaks using methods designed for individual samples. These results are then combined heuristically to obtain a consensus peak set. But reconciling these sample-specific results post hoc from a large cohort with many samples is challenging, and informative spatial features specific to open chromatin signals are not leveraged effectively.

To address these issues with popular existing methodology, we propose a novel method, *ROCCO*: **R**obust Detection of **O**pen **C**hromatin Regions via **C**onvex **O**ptimization. The proposed method determines consensus open chromatin regions across multiple samples simultaneously by employing robust summary statistics to formulate a constrained optimization problem accounting for both enrichment and spatial features of open chromatin data. We show this formulation admits attractive theoretical and conceptual properties as well as superior empirical performance compared to benchmarks using publicly available data from 56 lymphoblastoid ATAC-seq samples.

Session Title: Epigenetics Poster Session II

PB2289 Identification of pathological circRNA landscape signatures and pathways at a critical window for severe progression of Alzheimer's disease

Authors:

F. Wang[1], Y. Li[1], H. Shen[1], P. Martinez-Feduchi[1], J. Kuehner[1], Y. Feng[2], B. Yao[1]; [1]Dept. of Human Genetics, Emory Univ. Sch. of Med., Atlanta, GA, [2]Dept. of Pharmacology and Chemical Biology, Emory Univ. Sch. of Med., Atlanta, GA

Circular RNAs (circRNAs) are covalently closed, single-stranded transcript, conserved and enriched in the brain, which are changed in age and longevity of a wide spectrum of eukaryote from nematodes to mammals. With the in-depth studies of circRNA functions in age-related neurodegenerative disorders, such as it has been showed a novel window into mechanisms of Alzheimer's disease (AD). circRNAs could contribute to AD by sponging microRNA (miRNA) and RNA-binding proteins (RBPs) to regulate the messenger RNA (mRNA) targets. Our recent study established a robust platform to identify circRNA landscape in human neurons and oligodendrocytes. Using this platform, we discovered alterations of cortical circRNA landscapes in the 5xFAD mouse model of AD between 5- and 7-month of age, a critical window for the transition of starting pathology to full manifestation. We revealed that circGigyf2, which was reported that it locates in neuron body and the whole dendritic arbor and is high expressed in brain, is the most significantly dysregulated circRNA in the 5xAD mouse cortex associated with pathologic advancement, which is highly conserved and progressively downregulated along with increased severity of dementia in human AD brains. Moreover, the alteration in circGigyf2 is probable positively associated with the age of onset of AD in the 5xFAD mouse model. Mechanistically, we identified AD-affected splicing factors that regulate the biogenesis of circGigyf2, which can sponge specific miRNAs that were hyperactivated along with the disease-stage-specific deficiency of circGigyf2. Additionally, we found that circGigyf2 interferes with key polyadenylation factors to modulate global and loci-specific mRNA polyadenylation and subsequent protein level. Together, our results unveiled pathological circRNA landscape changes during a critical window for severe AD progression and identified novel molecular mechanisms underlying dysregulation of conserved circRNA pathways that contribute to AD pathogenesis.

Ctr., Bedford, MA, [7]Dept. of Ophthalmology, Boston Univ. Sch. of Med., Boston, MA, [8]Dept.s of Biostatistics, Boston Univ. Sch. of Publ. Hlth., Boston, MA

Introduction: The Alzheimer's disease (AD) hallmark pathological abnormalities of neuritic amyloid-β plaques and neurofibrillary tangles are often present in postmortem brains from persons who were cognitively normal prior to death, i.e. asymptomatic AD (AsymAD). We hypothesized that DNA methylation (DNAm) patterns in postmortem brain tissue differ between AsymAD and symptomatic AD (SymAD).
Methods: We obtained RNA sequencing and DNAm data derived from brain tissue in participants of the Religious Orders Study and Rush Memory and Aging Project (ROSMAP). Genome-wide differential methylation between 185 AsymAD and 254 SymAD individuals was analyzed using a linear regression model with covariates for age at death, sex, and batch effect. Next, we evaluated differential expression of genes within 50 kb of significantly differentially methylated CpG sites using a regression model with covariates for age at death, sex, RNA integrity number, postmortem interval, and batch. For significantly differentially expressed genes, we tested for association tests of DNAm at their corresponding CpG site and expression level using linear models adjusted by the same covariates in the differential expression analysis. To identify shared methylated CpG sites accounting for both protection on AsymAD and changes in gene expression, we investigated colocalization of DNAm with AsymAD and gene expression. The posterior probability (PP) threshold that both traits were linked to a common site was set at 0.9.
Results: We identified 18 differentially methylated CpG sites within 50 kb of 53 genes between AsymAD and SymAD with false discovery rate adjusted P<0.05. Top-ranked findings include CpG site cg19832721(logFC=-0.020, $P=5.4x10^{-8}$) in the *MAPT-KANSL1* region and cg20510285 (logFC=0.012, $P=8.7x10^{-7}$) in *NEDD9*. *MAPT*, *MAPT-AS1*, *KANSL1*, *KANAL-AS1*, and *NEDD9* were differentially expressed between AsymAD and SymAD (top-ranked finding with *KANSL1*: log2FC=0.086, $P=4.6x10^{-5}$). Methylation of cg19832721 site was associated with *MAPT* (β=1.76, P=0.007), *MAPT-AS1* (β=2.02, P=0.005),and *KANSL1-AS1* (β=-4.81, P=0.008, Colocalization analysis revealed that methylation of cg20510285 was a common epigenetic variation (PP=0.92) for clinical symptoms of AD or expression of its nearby gene *NEDD9* (β=4.95, $P=9.6x10^{-4}$).
Conclusion: DNAm profiles in the *MAPT-KANSL1* region may explain resilience to clinical manifestations of AD by modulating expression of genes in this region. Our study provides insights about mechanisms that could be targeted to prevent onset of AD clinical symptoms and the preservation of cognitive health even in presence of AD-related neuropathological changes.

Session Title: Epigenetics Poster Session I

PB2291 Identification of RNA biomarkers and potential regulatory mechanisms and therapeutic targets for type 1 diabetic using a competing endogenous RNA regulatory network analysis

Authors:

M. Malik[1], M. Dashti[1], A. Channanath[1], S. John[2], R. Iqbal[1], M. Alhusayan[1], F. Al Mulla[1], T. Thanaraj[1]; [1]Dasman Diabetes Inst., Kuwait, Kuwait, [2]Dasman Diabetes Inst., 15462, Dasman, Kuwait

Type 1 diabetes mellitus (T1D) is a growing autoimmune disease characterized by a genetic predisposition. There is a rising interest in understanding the involvement of microRNAs (miRNAs), circular RNA (circRNA), and long non-coding RNA (lncRNA) in the pathogenesis of this disease. However, the specific roles of these molecules in T1D remain unclear. Hence, the objective of this study was to identify distinct miRNA, circRNA, and lncRNA signatures and explore their contributions to T1D through the analysis of competing endogenous RNA (ceRNA) networks. Accumulating evidence suggests that mRNA, miRNAs, circRNA, and lncRNA play crucial roles in the processes associated with the pathogenesis of T1D. To identify differentially expressed lncRNAs, mRNAs, and miRNAs, expression profiles from GSE133217, GSE133225, and GSE55100 were obtained from the Gene Expression Omnibus. These profiles were derived from peripheral blood mononuclear cells of both T1D patients and healthy controls. Subsequently, a ceRNA regulatory network was constructed, followed by functional and pathway enrichment analysis. Additionally, a T1DM-related ceRNA regulatory network was established using the Human microRNA Disease Database for further pathway enrichment analysis. Simultaneously, T1D-related pathways were extracted from the Comparative Toxicogenomics Database (CTD). In this study, potential blood biomarkers related to T1D are identified using large-scale gene expression data. This is achieved through the computational construction of miRNA, circRNA, and lncRNA-target gene interactomes, as well as transcription factor networks. To enhance our understanding of T1D diagnosis, prognosis, and therapeutic interventions, further validation of these computational results is warranted through in vitro and in vivo studies in the future.

Session Title: Epigenetics Poster Session II

PB2292 Identification of small volatile inhibitors targeting methylation mediated dysregulated ribonucleoproteins in lung adenocarcinoma

Authors:

A. Mukherjee, M. Kuppusamy Selvam; Manipal Inst. of Technology, Manipal, India

Lung carcinoma is one of the most prevalent and life-threatening cancers globally, with tobacco smoking being the most significant cause of lung cancer deaths. Alterations in DNA methylation at CpG sites are associated with smoking-induced lung cancer. Enhancers play a vital role in gene expression, and aberrantly methylated enhancers can lead to malignant traits. The study involved linking enhancer status with the expression of target genes. The network-based approach aided in determining the dysregulated ribonucleoproteins TWISTNB, TRUB1, and RSL1D1, playing an important role as central regulators of dysregulated Ribosome biogenesis and RNA processing. Small molecules targeting epigenetic regulations have emerged as attractive therapeutics to overcome resistance to anticancer drugs. The study focused on volatile compounds with low molecular weight, high vapour pressure, and lipophilic. The Principle Component Analysis (PCA) was employed, and 1042 compounds were clustered based on structural similarity using the k-means algorithm to discover novel hits from large chemical libraries with similar pharmacokinetic and structural properties. The study investigated a technique for predicting the altered methylation in enhancer regions in modulating target genes by combining epigenomic and transcriptomic data. The PCA demonstrated the vigour of the novel method in screening potential leads by reducing high dimensional volatile chemical space, and the pharmacokinetics and toxicity profiling eliminated unfavourable leads, averting the side effects. Three potential leads were identified, #309 and #949, from the chemical class of benzenoids, and #347, from organic acids and derivatives, possessing higher binding affinity with the dysregulated ribonucleoprotein targets. The MD simulation of the complexes revealed their stability and rigidity and intermolecular Hydrogen bonds contributing to higher binding energies of the complexes.

Session Title: Epigenetics Poster Session III

PB2293 † *In vitro* model of gastrulation: Effects of alcohol on methylome, transcriptome and metabolome.

Authors:

E. Wallén[1], K. Rämö[1], J. Vehviläinen[1], J. Sokka[2], H. Marjonen-Lindblad[1], H. Skottman[3], T. Otonkoski[2,4], R. Trokovic[2], P. Auvinen[1], O. Kärkkäinen[5], N. Kaminen-Ahola[1]; [1]Dept. of Med. and Clinical Genetics, Medicum, Univ. of Helsinki, Helsinki, Finland, [2]Res. Programs Unit, Stem cells and Metabolism and Biomedicum Stem Cell Ctr., Faculty of Med., Univ. of Helsinki, Helsinki, Finland, [3]Faculty of Med. and Hlth.Technology, Tampere Univ., Tampere, Finland, [4]Children's Hosp., Helsinki Univ. Central Hosp., Univ. of Helsinki, Helsinki, Finland, [5]Sch. of Pharmacy, Faculty of Hlth.Sci., Univ. of Eastern Finland, Kuopio, Finland

Prenatal alcohol exposure (PAE) can have detrimental effects on early embryonic development, including alterations of gene regulation and DNA methylation (DNAm) as well as a wide range of physiological and neurological defects associated with Fetal Alcohol Spectrum Disorders (FASD). The underlying molecular mechanisms are poorly understood, but epigenetic changes can play a major role as early pregnancy is a sensitive period for environment-induced epigenetic changes. Gastrulation is one of the most critical events in embryonic development, involving the formation of the three germ layers. As human gastrulation is difficult to study due to technical and ethical limitations, we investigated the effects of alcohol exposure in human embryonic stem cells (hESCs) and in differentiated endodermal, mesodermal, and ectodermal cells as a model of gastrulation. hESCs (H1) were differentiated into the embryonic germ layers by using the STEMdiff™ Trilineage Differentiation Kit. For the alcohol-exposed wells, the media were supplemented with alcohol at final concentrations of 20 mM (moderate exposure) or 70 mM (severe exposure). Genome-wide DNAm was measured using the Illumina Infinium MethylationEPIC Array, gene expression was analysed with 3'mRNA-sequencing and metabolite profiles were characterized using a liquid chromatography-mass spectrometry-based (LC-MS) non-targeted metabolomics method. Our results show that especially severe alcohol exposure alters DNA methylation and gene expression of genes important for early development in hESCs and all germ layers. Metabolomic data indicate extensive perturbations in hESCs and all germ layers, highlighting the broad cellular impact of alcohol exposure. We observed the most prominent alterations in the ectodermal cells, including DNAm and gene expression alterations in the developmentally important genes *MAP2*, *NEUROD4*, *RAX* and *SIX3* and disruptions in the energy metabolism, such as changes in the levels of citrulline, citric acid and succinic acid. Our final aim is to combine these data sets with multi-omics methods to create a versatile picture of the possible mechanisms underlying the alcohol exposure. This study demonstrates that each of the germ layers exhibit a unique response to alcohol and provides new insights into the effects of alcohol in the beginning of embryonic development.

PB2294 Insights into pathogenetic basis of KMT2D related hearing loss from mice and humans

Authors:

A. Kalinousky[1], T. Luperchio[2], K. Schrode[1], L. Zhang[1], J. Harris[3], A. Lauer[1], H. Bjornsson[4]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Johns Hopkins Sch. of Med., Ellicott City, MD, [3]Kennedy Krieger Inst., Baltimore, MD, [4]Univ. of Iceland, Reykjavik, Iceland

Background: Kabuki syndrome (KS) is a Mendelian disorder of the epigenetic machinery caused, most commonly, by loss of function variants in *KMT2D*, resulting in KS type 1. Clinical criteria for diagnosis of KS includes intellectual disability, characteristic facial features, postnatal growth deficiency, and skeletal anomalies. In addition to these phenotypes, another penetrant phenotype is progressive hearing loss. Current clinical dogma states that hearing loss in KS is the result of either repetitive ear infections in early life in context of immune dysfunction or related to the abnormal craniofacial structure. There are currently no clinical recommendations to prevent or mitigate the progressive hearing loss and the mechanistic basis is currently unknown. **Methods:** Hearing loss in a mouse model of KS1 was determined using auditory brainstem response testing (ABR). ABR stimuli consisted of brief clicks that excite auditory neurons to assess overall integrity of auditory function. Immunofluorescent staining was performed to quantify inner and outer hair cells (OHC) along the cochlea. Lastly, we gathered information about hearing loss from 21 children and adults with a molecularly confirmed diagnosis of KS1. **Results:** 15 participants reported hearing loss, with the average age of hearing loss occurring at 7 years. Three participants have hearing loss from birth, and 5 individuals reported having either middle and/or inner ear abnormalities. 53% of those with hearing loss experienced a severe number of infections (16-50). Interestingly, 40% of those without hearing loss experienced either a severe or a moderate number of ear infections (6-15). When performing ABRs using KS mice, unexpectedly, we observe significant abnormalities of hearing from the onset of hearing in KS mice at all frequencies in comparison to their wildtype (WT) littermates. Examination of the sensory epithelium by immunofluorescence staining in a small cohort showed a subtle increase in percent missing OHCs in adolescent KS mice compared to WT littermates at higher frequencies. **Conclusions:** Our findings suggest that KMT2D-dysfunction leads to early and progressive hearing loss, with outside factors, such as infection, aiding to this hearing loss. 40% of participants with hearing loss reported having sensorineural hearing loss, which results from damage to the hair cells within the inner ear, the vestibulocochlear nerve, or the brain's central processing centers. Staining of hair cell markers showed subtle damage in KS mice, but further quantification would need to be done to make any strong conclusions on etiology of the hearing loss in KS mice.

PB2295 Integrating 3D genome maps with vertebrate synteny blocks to identify genomic regulatory blocks for conserved traits

Authors:

A. Zimmerman[1,2], J. Palermo[3], A. Chesi[1], F. Doldur-Balli[1], S. Sonti[2], M. Pahl[2], E. Brown[3], J. Pippin[2], A. Wells[2,1], D. Mazzotti[4], P. Gehrman[1], A. Keene[3], A. Pack[1], S. Grant[2,1]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Children's Hosp. of Philadelphia, Philadelphia, PA, [3]Texas A&M, College Station, TX, [4]Univ. of Kansas Med. Ctr., Kansas City, KS

The last decade has seen advances in genome sequencing along with large-scale genome-wide association studies (GWAS) for complex traits; however, functional interpretation of these data is complicated by modest effect sizes, causal gene prediction, and model organism interrogation. A major limitation in GWAS efforts is identification of a causal effector gene connected to variants residing predominantly in non-coding regions. Epigenomic information such as chromatin conformation and gene expression can help link GWAS variants to a putative effector gene(s). Ultimately, functional characterization in cultured cells or model organisms is necessary to determine the role of a variant and/or gene on a phenotype, yet this step is rarely performed. Functional interpretation of GWAS results using model organisms can be obscured by poor genetic conservation between human and the model or misidentification of the true effector gene. We propose a pipeline for the identification of true effector genes by integrating high-resolution epigenomic data with model organism synteny maps to implicate not only effector genes, but causal regulatory interactions that have been conserved across evolution for a highly conserved trait: sleep. Sleep is one of the most conserved behaviors in the animal kingdom, and many genes that regulate sleep are highly conserved. For this reason, we took human GWAS sentinel variants for sleep traits, such as insomnia and sleep duration, and performed our validated variant-to-gene mapping approach integrating these variants with ATAC-seq and high-resolution promoter-focused capture C across a panel of cell-types. This approach identified putative causal effector genes, whose promoters harbor an accessible chromatin contact by ATAC-seq/ promoter capture C and are highly expressed within a trait-relevant cell type, such as neural progenitor cells. We then performed a screen of candidate causal genes using neuron-specific (nSyb) RNA interference in *Drosophila* to narrow our list to high-confidence effector genes producing robust sleep phenotypes. Finally, we leveraged genomic synteny maps in a diurnal vertebrate, zebrafish, to identify genes which are conserved within a syntenic block harboring the GWAS-implicated gene (nearest to the GWAS variant) and the effector gene implicated through our variant-to-gene approach. Interestingly, the chromatin contacts from human data overlap with syntenic blocks in zebrafish, whereby genes conserved at both the gene and synteny level produced the most consistent phenotypes across species. These data suggest GWAS findings represent critical genomic regulatory blocks conserved across species.

Session Title: Epigenetics Poster Session III

PB2296 Investigating the potential of single-cell DNA methylation data to detect allele-specific methylation and imprinting

Authors:

N. Johnson, D. Cutler, K. Conneely; Emory Univ., Atlanta, GA

Allele-specific methylation (ASM) is an epigenetic modification whereby one parental allele becomes methylated and the other unmethylated at a specific locus. ASM is most often driven by the presence of nearby heterozygous variants that influence methylation, but also occurs somatically in the context of genomic imprinting. In this study, we investigate ASM using publicly available single-cell reduced representation bisulfite sequencing (scRRBS) data on 608 B cells sampled from six healthy individuals. We developed a likelihood-based criterion to test whether a CpG exhibited ASM, based on the distributions of methylated and unmethylated reads both within and across cells. Applying our likelihood ratio test, 65,998 CpG sites exhibited ASM according to a Bonferroni criterion ($p<8.4\times10^{-9}$). We also called ASM at the sample level: across the 6 samples, 93,290 CpG sites exhibited ASM in at least 1 sample, while 4,613 showed ASM in ≥2 samples, and 298 CpG sites showed ASM in ≥3 samples. To evaluate the accuracy of our method, we called heterozygous variants from the scRRBS data, which enabled variant-based calls of ASM within each cell for CpGs within 50bp of a heterozygous variant. Comparing sample-level ASM calls to the variant-based measures of ASM, we observed a positive predictive value of 68-100% across samples. We observed high concordance of ASM across samples and an overrepresentation of ASM in previously reported imprinted genes (OR: 3.7, 95% CI [2.4, 5.8]; $p=8.9\times10^{-11}$) and genes with imprinting binding motifs (OR: 5.3, 95% CI [5.0, 5.5]; $p<10^{-15}$). Our study demonstrates that single-cell bisulfite sequencing is a potentially powerful tool to investigate ASM, especially as studies expand to increase the number of samples and cells sequenced.

Session Title: Epigenetics Poster Session I

PB2297 Large-scale cross-ancestry genome-wide meta-analysis of serum uric acid

Authors:

C. Cho[1], B. Kim[1], D. Kim[1], M. Hwang[2], I. Shim[3], M. Song[1], Y. Lee[1], R. Do[4], W-Y. Park[5], W. Myung[6], B-J. Kim[7], Y. Kim[7], H-H. Won[1]; [1]Sungkyunkwan Univ., Seoul, Korea, Republic of, [2]NIH, Cheongju-si, Korea, Republic of, [3]Sungkyunkwan Univ., Seongnam-si, Gyeonggi-do, Korea, Republic of, [4]Icahn Sch. of Med. at Mount Sinai, New York, NY, [5]Samsung Med Ctr, Seoul, Korea, Republic of, [6]Seoul Natl. Univ. Bundang Hosp., Seongnam, Korea, Republic of, [7]Korea NIH, Cheongju-si, Korea, Republic of

Background Serum uric acid (SUA) is a biological waste produced by breaking down purine. A high SUA level (hyperuricemia) is associated with increased risk for gout and several diseases. We aimed to identify novel variants, genes, and pathways associated with SUA through a large-scale cross-ancestry genome-wide association study (GWAS) meta-analysis.
Methods We performed a large-scale cross-ancestry meta-analysis of 1,029,323 individuals of multiple ancestries (Europeans = 677,373, East Asians = 219,768, others = 132,182) to identify novel loci and ancestry-specific meta-analysis (European and East Asian) to examine the shared and distinct genetic architecture of each ancestry. We performed a transcriptome-wide association study (TWAS), colocalization analysis, and functional enrichment analysis to identify SUA-associated genes and pathways.
Results The cross-ancestry meta-analysis additionally identified 21 loci that were previously unreported. The genetic correlation of SUA between two ancestries (European and East Asian) was estimated to be high (ρge = 0.942, s.e. = 0.079). In total, 173 genes in glomerular (GLOM) and tubulointerstitial (TUBE) tissues from the Nephrotic Syndrome Rare Disease Clinical Research Network III (NEPTUNE) were colocalized with our GWAS results (posterior probability of colocalization > 0.8). As a result of TWAS, while 178 genes were commonly significant in the three meta-analyses, 183 of 945, 83 of 780, and 75 of 334 significant genes were significant only in the cross-ancestry, European, and East Asian, respectively. The tissue enrichment analysis identified various significantly enriched tissues in the urogenital, digestive, and endocrine systems. Moreover, we identified additional results of the KEGG pathway, such as "systemic lupus erythematosus" related to the high-level functions of biological systems through gene-set enrichment analysis.
Conclusion In summary, we investigated variants, genes, tissues, and pathways associated with SUA through the large cross-ancestry and ancestry-specific meta-analysis for SUA and various subsequent analyses. Our study adds insights into the genetic architecture by aggregating abundant genomic data.

Session Title: Epigenetics Poster Session II

PB2298 Leveraging multi-omics data to interpret a genome-wide meta-analysis of DNA methylation and PTSD in 23 military and civilian cohorts.

Authors:

M. Logue[1], S. Katrinli[2], A. Wani[3], A. Maihofer[4], A. Zannas[5], N. Nugent[6], X. Zhao[7], C. Nievergelt[8], M. Uddin[9], A. Smith[10], PGC PTSD Epigenetics Workgroup; [1]Natl. Ctr. for PTSD at VA Boston, Boston, MA, [2]Emory Hlth.care, Atlanta, GA, [3]Coll. of Publ. Hlth., Univ. of South Florida, Tampa, FL, [4]UCSD, La Jolla, CA, [5]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [6]Brown Univ., Providence, RI, [7]Boston Univ. Sch. of Publ. Hlth., Boston, MA, [8]Univ California San Diego, La Jolla, CA, [9]Univ. of South Florida, Tampa, FL, [10]Emory Univ, Atlanta, GA

Background: Epigenetic factors, including DNA methylation (DNAm), are impacted by traumatic stress, and may help to distinguish between individuals with and without posttraumatic stress disorder (PTSD). Here, we present the results of the largest epigenome-wide association study (EWAS) of PTSD to date. **Methods:** This study includes 5,077 participants (2,156 PTSD cases and 2,921 trauma-exposed controls) from 23 cohorts participating in the Psychiatric Genomics Consortium (PGC) PTSD Epigenetics Workgroup. DNAm was assayed from blood with the Illumina HumanMethylation450 BeadChip, which measures DNAm at approximately 450K methylation sites across the genome, or the Illumina MethylationEPIC BeadChip (850K sites). For each cohort, a common consortium-developed quality control pipeline was applied, and DNAm of each CpG site was regressed on PTSD, sex (if applicable), age, blood-cell proportions, and principal components for ancestry. Meta-analyses were performed using an inverse variance-weighted approach. TOAST was used to test for cell-type-specific associations in the subset of 11 cohorts with EPIC BeadChip data. An epigenome-wide significance threshold of $p<9e^{-8}$ was applied across all analyses. **Results:** We identified 11 CpG sites associated with PTSD in the overall model, as well as 14 associated with analyses of specific strata (sex, ancestry, and military vs civilian cohorts), including sites implicated in our previously published analyses. Many of these CpGs exhibit blood-brain correlation in methylation levels, cross-tissue associations with PTSD in multiple brain regions of postmortem samples, and associations with genetic and gene-expression variation. For example, methylation of cg04987734 (*CDC42BPB*) was higher in PTSD cases than controls in blood (Z=5.53; $p= 3.26e^{-8}$) and the dorsolateral prefrontal cortex (T=2.99; $p= 3.90e^{-3}$); blood-based eCpGs (R=0.2, p=0.023) and gene-based tests (Z=3.20; p=6.94E-04) also showed significant associations for this locus. None of the CpGs from the bulk-tissue analysis could be attributed to individual immune cell types. However, additional associated CpGs were identified in the cell-type specific analyses: 88 in B cells, 1 in CD4+ T cells, 2 in CD8+ T cells, and 5 in NK cells. **Conclusions:** This study identifies novel PTSD-associated CpGs from bulk tissues and individual lymphocyte subtypes. Leveraging data from postmortem brain samples, in vivo models, GWAS, and genome-wide expression data can elucidate the biological processes associated with PTSD by identifying methylation in particular pathways and cell types involved in PTSD pathophysiology.

Session Title: Epigenetics Poster Session III

PB2299 Locus-specific neuroepigenome editing for X-linked intellectual disability

Authors:

J. Halmai, J. Waldo, C. Gonzalez, K. Braczyk, D. Cameron, M. Singh, K. Fink; UC Davis, Sacramento, CA

A disproportionate number of genes causative for intellectual disability are found on the X chromosome (XLID). A potential therapeutic approach for XLIDs that affect females is to reactivate the silenced wild-type allele in cells that express the mutant allele. We have previously demonstrated that targeted X chromosome reactivation (XCR) using CRISPR/dCas9 is possible in human and mouse cells. We demonstrated that DNA CpG de-methylation editing of an X-linked gene promoter results in reactivation of the target gene. To further characterize the rule sets underlying targeted XCR, we aim to establish genomic and epigenomic features that will predict targeting of X-linked genes using epigenomic perturbations on a X chromosome-wide scale. This screen was first applied to human ENCODE tier 1 cell lines, and future studies will address this approach *in vivo* in the mouse genome. In addition, these experiments will interrogate the temporal order required for epigenome editors to change chromatin marks and removal of promoter DNA hypermethylation in favor of targeted XCR. In order to do so, chemical induced proximity ligation of CRISPR/dCas9 editors was used following a washout period to allow sequential epi-editing of chromatin loci. Finally, to investigate the usage of a hypercompact Cas variant, we have established a toolbox of epi editor fusion proteins tested in a MeCP2 reporter cell line and *in vivo*. If successful, locus-specific neuroepigenome editing holds great promise for those suffering from XLID and other neurological disorders with an X-linked etiology.

Session Title: Epigenetics Poster Session I

PB2300 Longitudinal DNA methylation highlights genes for COPD progression.

Authors:

O. Rafique[1], Y. Huang[1], K. H. Shutta[1,2], R. Min Hyung[1], K. Kim[1], P. Kachroo[1], C. Lopes-Ramos[1], K. A. Pratte[3], R. Bowler[4], E. K. Silverman[1,5], V. J. Carey[1], D. L. DeMeo[1,5]; [1]Channing Div. of Network Med., Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, [2]Harvard T.H. Chan Sch. of Publ. Hlth., Dept. of Biostatistics, Boston, MA, [3]Div. of Biostatistics and Bioinformatics, Dept. of Med., Natl. Jewish Hlth., Denver, CO, [4]Div. of Pulmonary and Critical Care Med., Dept. of Med., Natl. Jewish Hlth., Denver, CO, [5]Div. of Pulmonary and Critical Care Med., Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA

To investigate the impact of time varying nature of DNA methylation (DNAm) on the progression of chronic obstructive pulmonary disease (COPD), we conducted a longitudinal epigenome-wide association study (EWAS). The EWAS findings were integrated with proteomic data to reveal the interplay between methylation and proteomics in COPD. Methods: Infinium MethylationEPIC BeadChip data was obtained from peripheral blood leukocyte DNA from 4,493 current and former smokers from the Genetic Epidemiology of COPD (COPDGene) study consisting of two time points of DNAm and FEV1 data (baseline and 5-year follow-up visits) of non-Hispanic white and African American subjects with a history of smoking, a median age of 62.2 years at enrollment and 51 percent male subjects. SomaScan blood proteomic data was available from the 5-year follow-up visit. Linear mixed-effects regression (LMER) was used to find the associations between longitudinal DNAm and longitudinal forced expiratory volume in 1 second (FEV1); adjusted for sex, age, race, cell counts, pack-years of smoking, current smoking status, height and time since baseline visit. Causal mediation analysis to identify proteins potentially mediating the relationship between DNAm and FEV1 was conducted using a nonparametric bootstrap procedure from the R package Mediation. Functional overlap analysis on the genome-wide significant CpGs was performed using the eFORGE tool. Results: From the longitudinal FEV1 and longitudinal DNAm data, LMER identified 66 CpGs having genome-wide significant associations with FEV1 ($p \leq 5 \times 10\text{-}8$). Intraclass correlation (ICC) of the 66 CpGs calculated using DNAm M-values from both time points revealed that the majority (40) have ICC between 0.5 and 0.8 and 22 CpGs have ICC greater than 0.8, suggesting that FEV1-associated CpGs are stable over 5 years. Chromosome 17 demonstrated three significant associations over a 440 base pair region annotated to the SOCS3 gene (cg13343932 with $p = 2.12 \times 10\text{-}18$, cg11047325 with $p = 8.77 \times 10\text{-}16$ and cg18181703 with $p = 1.07 \times 10\text{-}13$). An X chromosome CpG near the zinc-finger repressor, BCOR, was also associated with longitudinal FEV1 (cg18422972 with $p = 2.14 \times 10\text{-}8$). Functional Overlap analysis of the 66 CpGs revealed significant enrichment in histone methylation (H3K4me1 and H3K4me3) in blood and lung tissue. Mediation analysis identified ITPRIPL1, NOTCH1 and IGFBP5 as three candidate proteins partially mediating the signal between DNAm and FEV1. Conclusions: EWAS of longitudinal DNAm data revealed that the CpG sites that are stable over time are associated with longitudinal lung function (FEV1) and are linked with epigenetic and inflammatory signals.

Session Title: Epigenetics Poster Session II

PB2301 Long-read Khoe-San genomes reveal structurally divergent loci overlapping genic regions

Authors:

D. Soto[1], W. Palmer[2], J. Prado-Martinez[3], P. Norman[4], M. Dennis[5], B. Henn[6]; [1]Univ. of California Davis, Davis, CA, [2]Gencove, Long Island City, NY, [3]Inst. Pasteur, Paris, France, [4]Univ. of Colorado, Aurora, CO, [5]Univ. of California, Davis, Davis, CA, [6]UC Davis, Davis, CA

Long-read sequencing of hundreds of individuals is increasing our understanding of the genomic variation landscape of modern humans, including complex structural variation. While West African populations have been included in long-read sequencing efforts, most regions of Africa remain underrepresented. Considering that genetic diversity within African populations can be even greater than between continental groups, the lack of long-read sequencing representation suggests that ample genetic diversity is missing in these datasets. In particular, the Khoe-San indigenous peoples of southern Africa contain many of the most divergent haplotypes in extant human lineages. We performed 10X Genomics long-range sequencing and de novo assembly of three individuals of Khoe-San ancestry, including one ǂKhomani San and two Nama individuals, obtaining diploid pseudo haplotypes (N50: 54, 88,and 155 kbp, respectively). Collectively, the Khoe-San genomes harbor 146 kbp of short non-reference unique insertions (NUI), or non-repeat sequences (<10% repeats), not represented in the human reference assemblies GRCh38, which is of mostly West African ancestry, and T2T-CHM13, of European ancestry. NUIs range in size from a lower bound of 50 bp to 1.5 kbp, and overlap 18 genes, three of which are predicted to disrupt coding sequence. Compared to previously published assemblies from other ancestries (n=8), we found that 63 kbp (43%) of NUIs are Khoe-San-specific. We also identified 13,161 contigs not mapping to either reference, mostly lacking repetitive sequences, potentially representing the most divergent loci and totalling ~12 Mbp. Further, focusing on structural variants (>50 bp), we identified 34,164 deletions, 1,925 mobile element insertions, and 341 inversions, out of which 19,396 (57%), 790 (41%), and 230 (67%) were only found in the Khoe-San assemblies, respectively. Notably, of the Khoe-San specific variants, 28 deletions and 19 inversions ablated or affected splicing of protein-coding genes. To establish their population frequencies, we genotyped these events in a short-read sequencing cohort of Khoe-San ancestry (n=92). From this cohort, we also identified genes with divergent copy-number in Khoe-San populations, some of which have not been annotated as segmental duplications in the T2T-CHM13 reference of European ancestry. Finally, we leveraged long haplotypes to investigate divergence of structurally complex loci, including the highly divergent HLA locus, and assess the improvement of mappability on reference bias in individuals of Khoe-San ancestry.

Session Title: Epigenetics Poster Session III

PB2302 † Massive-scale meta-analysis of genetic regulation of RNA editing in the human brain identifies new risk genes and mechanisms for neurological disease

Authors:

J. Humphrey, W. H. Cuddleston, B. Z. Muller, K. BP, T. Raj; Dept.s of NeuroSci., and Genetics and Genomic Sci., Ronald M. Loeb Ctr. for Alzheimer's Disease, Icahn Sch. of Med. at Mount Sinai, New York, NY

Genome-wide association studies (GWAS) have identified genetic loci associated with neurodegenerative and neuropsychiatric diseases, but it remains challenging to describe the precise causal variants and link them to genes and underlying molecular mechanisms. Quantitative trait locus (QTL) mapping associates genotypes with molecular phenotypes, and determining whether GWAS risk loci and QTLs share a genetic basis can elucidate molecular pathways which potentiate disease risk. Efforts to identify genetic variants which regulate gene expression (eQTLs) and splicing (sQTLs) outpace that of all other gene regulatory phenotypes, but there is a critical need to consider other molecular traits.

Adenosine to inosine (A-to-I) RNA editing is among the most abundant of post-transcriptional modifications, whose role in brain homeostasis and disease has been extensively reported. Although a large body of work has focused on regulation of A-to-I editing by trans-acting factors, regulation of A-to-I editing by cis-acting genetic variants (edQTL) is largely unresolved in the brain, as nearly all studies which report edQTLs make use of the relatively small GTEx resource (<300 unique donors).

To test the hypothesis that edQTLs explain neurological disease heritability, we are mapping edQTLs in the largest collection to date of paired transcriptomic and genetic data from human brain tissues, the BigBrain project, which unites 15 cohorts of 13,061 samples sourced from 7 unique brain regions, representing a 30-fold enhancement of sample size from previous edQTL studies.

We have mapped edQTLs in 11 cohorts (2,707 samples, 1,574 unique European donors), using random effects meta-analysis to identify 26,564 significant cis-edQTLs in 3,261 genes, comprising ~16.3% of all tested A-to-I editing sites (FDR < 0.05). Using GWAS summary statistics from several neurological and psychiatric diseases we performed genetic colocalization. By including eQTL and sQTL summary statistics mapped in the same BigBrain cohorts, we have identified several examples of shared associations between editing, expression and splicing, such as *ICA1L* in Alzheimer’s disease and *CTSB* in Parkinson’s disease. However, several GWAS loci colocalized solely with RNA editing, such as the Alzheimer’s disease locus *APH1B*.

Comprehensively defining genetic regulation of RNA editing in the brain is informing novel relevance for non-coding A-to-I events, and will support our understanding of how RNA editing drives complex brain disease phenotypes. We will discuss our further plans for testing for mediation between editing, splicing and expression QTLs, and searching for trans-genetic effects.

Session Title: Epigenetics Poster Session I

PB2303 MethPhaser: Methylation-based haplotype phasing of human genomes

Authors:

Y. Fu[1], S. Aganezov[2], M. Mahmoud[3], J. Beaulaurier[2], S. Juul[2], T. Treangen[1], F. Sedlazeck[3]; [1]Rice Univ., Houston, TX, [2] Oxford Nanopore Technologies Inc, New York, NY, [3]Baylor Coll. of Med., Houston, TX

The assignment of variants across haplotypes, a process called phasing, is crucial for predicting the consequences, interaction, and inheritance of mutations and is a critical step in improving our understanding of phenotype and disease. This is exemplified in the case of the genes HLA or TPMT, where the functional inactivation of the gene depends on whether certain variants are in cis- or trans-relationships to each other. While there are three main phasing methods, only one (read-based phasing) can comprehensively provide information also about de novo single nucleotide variants (SNVs) and their origin. But this is often limited by the read size and length of homozygous regions in the genome.

To address this, we developed MethPhaser, the first method that uses haplotype-specific methylation signals from Oxford Nanopore Technologies (ONT) to extend SNV-based phasing. MethPhaser operates on a set of already-phased SNVs to extend or merge individual phased regions together, often by extending the phase blocks into homozygous regions that contain haplotype-specific methylation signatures.

Benchmarking using trio-based phasing data showed that MethPhaser is able to extend the genome-wide phasing by 1.6 to 2.5 fold, depending on the overall read length and ONT chemistry used, while only marginally increasing the phasing error rate from 0.03% to 0.05%. We observed that MethPhaser can successfully improve phasing across TPMT and HLA regions that are medically relevant. Here it is further able to even include SV in phasing, which is often challenging. To demonstrate the versatility of MethPhaser, we evaluated its performance on various human populations (HG01109, HG02080, and HG03098), as well as across blood samples from a cohort of patients with cardiovascular disease. In each case, MethPhaser is able to improve phaseblock N50 with methylation information. MethPhaser represents a novel approach that uses easily accessible nanopore methylation data to improve phasing and thus the interpretation of variant interactions across many medically important genes. In the future, we plan to investigate the utility of MethPhaser across cancer samples to obtain insights into oncogene regions. MethPhaser is open-source and available at https://github.com/treangenlab/methphaser.

Session Title: Epigenetics Poster Session II

PB2304 Methylome analysis of whole blood in ancestrally diverse Alzheimer's disease cohorts as a biomarker of disease

Authors:

T. Gu[1], L. Gomez[1], M. Mews[2], P. L. Whitehead[1], K. L. Hamilton-Nelson[1], M. Contreras[1], J. Sanchez[1], S. Tejada[1], L. D. Adams[1], P. R. Mena[1], T. Starks[3], C. Silva[4], M. R. Cornejo-Olivas[5], M. Illanes-Manrique[5], M. L. Cuccaro[1], J. M. Vance[1], W. S. Bush[2], G. S. Byrd[3], B. E. Feliciano-Astacio[4], J. L. Haines[2], G. W. Beecham[1], M. A. Pericak-Vance[1], A. J. Griswold[1]; [1]Univ. of Miami, Miami, FL, [2]Case Western Reserve Univ., Cleveland, OH, [3]Wake Forest Univ., Winston-Salem, NC, [4]Univ. Central Del Caribe, Bayamón, PR, [5]Inst. Natl. de Ciencias Neurologicas, Lima, Peru

Background: Alzheimer's disease (AD) is a neurodegenerative condition that is the most common form of dementia in the elderly. The disease process starts before the onset of symptoms and before the diagnosis can be made, making development of preventative therapies challenging. More than 30 genetic loci have been associated with AD; however, these loci can vary drastically between individuals of different genetic ancestral backgrounds. Thus, investigation into differences in risk markers enabling early intervention across diverse populations is critical. One such marker could be epigenetic features such as DNA methylation. **Methods**: As part of an ongoing study of the genetics and epigenetics of AD in diverse populations, we performed a methylome analysis in a cohort of 698 individuals. DNA from peripheral whole blood was analyzed using the Illumina MethylationEPIC 2.0 targeting more than 935,000 CpG sites. After filtering for quality and principal component outliers, 626 samples were included in the analysis. These consisted of both AD and cognitively intact (CI) individuals of European (68 AD, 67 CI), African (98 AD, 106 CI), or Hispanic (Puerto Rican - 85 AD, 76 CI; Peruvian - 41 AD, 41 CI; or Cuban - 22 AD, 22 CI) backgrounds. For quality control of methylation probes and downstream analysis, we utilized the SeSAMe R package. Probes with detection P-value > 0.05 in more than 5% of the samples were removed, as well as probes with low mapping quality or having a common SNP with MAF > 5%. We performed differential methylation analysis between AD and CI in the overall dataset and within each ancestral population. We used a linear model with covariate variables sex, age of exam, batch effect, global ancestry and estimated immune cell type proportions. **Results**: After quality control filtering, a total of 878,853 CpG sites were tested for differences between AD status. Overall, we identified 563 CpG sites with nominally significant differences (p-values <= 0.001) between AD and CI. Within each ancestral group, the number of differentially methylated sites differed: European - 442 sites, African - 217 sites, Hispanic - 475. Notably, however, these markers within the ancestral group did not overlap. **Conclusion**: Identifying the genes and biological pathways involved in AD is critical in the effort to develop effective therapies. Our analysis suggests the possibility of ancestry specific whole blood DNA methylation patterns as signatures of AD pathogenesis. Convergence of these methylation sites with existing genomic and transcriptomic data may reveal distinct genes but similar underlying pathological processes contributing to AD across individuals of diverse ancestries.

Session Title: Epigenetics Poster Session III

PB2305 Multigenerational impacts on DNA methylation signatures in autism spectrum disorder.

Authors:

G. E. Kuodza[1], Y. J. Ludena[1], J. S. Mouat[1], S. M. Hakam[2], R. Kawai[1], T. N. Sullivan[1], C. R. Torvick[1], D. H. Bennett[1], I. Hertz-Picciotto[1], J. M. Lasalle[1]; [1]Univ. of California Davis, Davis, CA, [2]Univ. of California, Berkeley, Berkeley, CA

The prevalence of Autism Spectrum Disorder (ASD) has been on the rise in recent years, and the underlying causes are not fully understood. The etiology of ASD is complex, as several hundred genes have been implicated as well as multiple environmental exposures. Epigenetic mechanisms, including DNA methylation, have emerged as a novel way to capture the complex gene by environmental interface of multivariate ASD etiologies. Past epidemiological investigations have suggested that grandparental factors, such as increased age or smoking, may increase the risk for ASD in the grandchild, but replication and molecular explanations for grandparental risk factors are currently lacking. One potential mechanism is multigenerational epigenetic inheritance (MEI), whereby DNA methylation marks on some loci are transferred across generations. Animal models have shown MEI in association with behavioral changes in the third and fourth generations, but this has not been studied in human cohorts. In order to investigate the potential impact of grandparental factors and MEI on the development of ASD, our study recruited participants from the CHARGE (Child Autism Risks from Genetics and the Environment) study, including grandparents, parents, and children (probands with ASD or typical development). We hypothesized that DNA methylation patterns associated with ASD in the probands may be detectable across generations and associated with grandparental environmental exposures. A questionnaire was used to gather information about the participants' exposure to environmental factors, including lifestyle exposures (smoking, drug use), medications, occupations, and other demographics. Biospecimens, including saliva samples collected from family members and newborn dried blood spots obtained from probands and parents from the California Newborn Registry, were collected. DNA was extracted from 349 saliva samples from 85 families and subjected to whole genome bisulfite sequencing (WGBS) to analyze DNA methylation. Sequence alignments and bioinformatic analyses are ongoing, utilizing DMRichR to identify individual genomic loci associated with ASD in each of the three generations and Comethyl to compare correlation patterns between methylation marks and selected variables, including grandparental exposures. Newborn blood spot collections of parents and probands are ongoing and will be used to identify potential ASD epigenomic signatures that are tissue and life-stage independent. This research will provide new insights into the increased prevalence and underlying etiology of ASD that should pave the way for future research in the field.

Session Title: Epigenetics Poster Session I

PB2306 Neuronal DNA double-strand breaks lead to chromosomal structural variations and 3D genome disruption in neurodegeneration

Authors:

V. Dileep[1], C. Boix[1], H. Mathys[1], A. Marco[1], G. Welch[1], H. Meharena[1], A. Loon[1], R. Jeloka[1], Z. Peng[1], D. Bennett[2], M. Kellis[1], L-H. Tsai[1]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]Rush Alzheimer's Disease Ctr., Chicago, IL

Persistent DNA double-strand breaks (DSBs) in neurons are an early pathological hallmark of neurodegenerative diseases including Alzheimer's Disease (AD), with the potential to disrupt genome integrity. We used single-nucleus RNA-seq in human post-mortem prefrontal cortex samples and found that excitatory neurons in AD were enriched for mosaic gene fusions. Gene fusions were particularly enriched in excitatory neurons with senescence and DNA repair gene signatures. In addition, chromosomal structural variations and gene fusions were enriched in neurons burdened with DSBs in the CK-p25 mouse model of neurodegeneration. Neurons enriched for DSBs also had elevated levels of cohesin along with progressive multiscale disruption of the 3D genome organization aligned with transcriptional changes in synaptic, neuronal development, and histone genes. Overall, this study demonstrates the disruption of genome stability and the 3D genome organization by DSBs in neurons as pathological steps in the progression of neurodegenerative diseases.

Session Title: Epigenetics Poster Session II

PB2307 Novel Mitochondrial DNA Variations reveal insights from the Taiwanese Population

Authors:

T. Chou[1,2], P-M. Chien[2], P-X. Chen[2], T-H. Tseng[2], J. Hsu[3], P-L. Chen[1]; [1]Nation Taiwan Univ., Taipei city, Taiwan, [2]Graduate Inst. of Med. Genomics and Proteomics, Natl. Taiwan Univ., Taipei, Taiwan, [3]Natl. Taiwan Univ., Taipei City, Taiwan

Analyzing population mtDNA variation profiles can provide insights into the clinical significance, which plays a crucial role in energy homeostasis. Despite the availability of certain databases, there is a notable scarcity of data specifically for mitochondrial variants in East Asian populations. Furthermore, it is worth noting that the Taiwan Biobank does not encompass mtDNA variant information. To address this gap, our study utilized whole genome sequence data from 1,484 individuals in the Taiwan Biobank. We utilized the GATK Best Practices for SNP/Indel Variant Calling in Mitochondria (V.4.1.8.0) to identify mtDNA variants and their corresponding allele frequencies. We also classified subjects based on high-digit mtDNA sub-haplogroups. Among the Taiwanese population, we observed a total of 2,361 variants, with the most predominant haplogroup being M, followed by D and F. Comparing variant allele frequencies with gnomAD East Asian population revealed significant similarity between Taiwanese and East Asian populations. Notably, our analysis uncovered 77 novel variants in the Taiwanese population compared to the gnomAD v3.1 database. Furthermore, a comparison with MitoMap unveiled 63 novel single nucleotide variants (SNVs). We also made intriguing observations related to pathogenic variants. One individual out of 184 carried a confirmed pathogenic variant with a heteroplasmy level exceeding 10%. The m.1555A>G variant, known for its association with antibiotics-induced hearing loss, exhibited a relatively higher frequency in the Taiwan Biobank (0.204%) compared to gnomAD (0.112%) and MitoMap (0.141%). Furthermore, we identified a unique variant, m.4300A>G, associated with Maternally Inherited Cardiomyopathy (MICM), in a single individual from the Taiwan Biobank, which was not detected in either gnomAD or MitoMap. Our study provides valuable mtDNA variant data with allele frequencies among the Taiwanese population that supports the integration of mtDNA analysis alongside nuclear variants and facilitates diagnostic interpretation and research studies.

Session Title: Epigenetics Poster Session III

PB2308 PHF20 regulates starvation-induced autophagy by epigenetic control

Authors:

J. Kim[1], S. Park[2], S. Oh[2], S. Baek[2], D. Park[1]; [1]Ajou Univ., Suwon 16499, Korea, Republic of, [2]Seoul Natl. Univ., Seoul 08826, Korea, Republic of

Autophagy is a vital cellular process that eliminates unnecessary proteins and damaged organelles to maintain cellular balance. Defective autophagy can contribute to the development of serious human diseases, including type 2 diabetes, neurodegenerative disorders and cancer. To ensure optimal autophagic flux under cellular stress conditions, it is crucial to epigenetically regulate the transcription of autophagy components. In this study, we utilized genome-wide approaches and unveiled the role of PHF20, a member of the PHF family, in autophagy during glucose starvation. Initially, we observed a reduction of autophagy in Phf20−/− mouse embryonic fibroblasts (MEFs) compared to WT MEFs under both glucose and amino acid starvation conditions. To elucidate the role of PHF20 in autophagy at transcriptional level, we performed RNA-seq to compare the expression of autophagy genes between wild-type (WT) and *Phf20* KO MEFs under glucose starvation. By *k*-means clustering followed by functional analysis and gene set enrichment analysis, we revealed the genes related to the autophagic process were expressed in a PHF20-dependent manner. To investigate how PHF20 regulated autophagy at the epigenetic levels, we conducted ATAC-seq and explored the alteration of chromatin states in the absence of PHF20 during autophagy. We globally defined chromatin states by chromHMM and found that the non-promoter regions showed relatively strong dependency on PHF20 for starvation-induced chromatin opening. Moreover, we confirmed that H3K4me1 and H3K4me2, which were an active *cis*-regulatory element, increased at PHF20-dependent open chromatin in WT MEFs, but not in *Phf20*$^{-/-}$ MEFs upon glucose starvation.Furthermore, we also found that PHF20-dependent chromatin opening at enhancer regions was co-occupied by H3K36me2 and H3K4me1/2 in chromHMM. To further confirm the role of PHF20 as an epigenetic reader of H3K36me2, we tested the binding of GST-PHF20 Tudor 1 and 2 domains to various histone modifications including H3 and H4 methylation and acetylation. The peptide binding array and in vitro peptide binding assay revealed specific binding of PHF20 Tudor 1&2 to H3K36me2 as well as other di-methylated lysine peptides. Our findings suggest a novel insight into the role of PHF20 in regulating autophagy genes under glucose starvation. As an epigenetic reader and activator of autophagy genes, the recognition of H3K36me2 by PHF20 was essential to control the expression of autophagy genes. Moreover, these findings will be applicable in drug development research to target autophagy-related diseases.

Session Title: Epigenetics Poster Session I

PB2309 † Placental DNA methylation changes as predicting markers for gastroschisis

Authors:

M. Narechania[1], D. Jhala[2], U. Ratnamala[3], S. Nath[4], U. Radhakrishna[5,6]; [1]Gujarat Univ., Ahmedabad, India, [2]Sch. of Sci., Gujarat Univ., Ahmedabad, India, [3]Univ. school of Sci., Gujarat Univ., Ahmedabad, India, [4]Oklahoma Med. Res. Fndn., Oklahoma City, OK, [5]Green Cross Pathology & Molecular Lab., Ahmedabad, India, [6]Univ. of Pittsbourgh, Pittsbourgh, PA

Background: Gastroschisis, is the most common congenital abdominal wall defect in which babies are born with their abdominal organs outside of their bodies. It is primarily considered a complex multifactorial condition. Although the exact cause of gastroschisis is unknown, research suggests that genetic factors may contribute to the disease, though no study has examined epigenetic factors. This exploratory study aimed to identify mechanisms involved in gastroschisis pathogenesis that are epigenetically dysregulated. **Method:** We conducted a genome-wide methylation study (GWMS) of placental tissues using the Illumina Human Methylation EPIC BeadChip array on 24 placental tissues with gastroschisis and 24 age, ethnicity, and sex-matched controls. Statistical, bioinformatics, computational biology, and analysis were performed to distinguish gastroschisis from controls. Genes containing top differentially methylated CpGs (FDR $P<0.05$) were analyzed for pathway and network. **Results:** Significant alterations in cytosine nucleotide ('CpG') methylation were found at 7581 CpG loci in gastroschisis cases (FDR $p\leq0.05$) (AUC$\geq$0.75) including 6398 hypomethylated 1184 hypermethylated. Among these, 83 markers had high diagnostic accuracy (AUC$\geq$0.90) for gastroschisis detection, representing 83 discrete genes. Pathway analysis revealed the involvement of several dysregulated signaling pathways including Wnt/β-catenin signaling, Hippo signaling pathway, VEGF signaling pathway, and Ras signaling pathway, which are thought to play a role in gastroschisis pathophysiology.**Conclusions:** This is the first study that employed a robust assessment of placental global DNA methylation in several placental samples. The study provides substantial evidence that DNA methylation variation in placental DNA may contribute to gastroschisis, which opens the door to more accurate and early detection of the disorder.

Session Title: Epigenetics Poster Session III

PB2311 Regional principal components enhance cell type-specific detection of Alzheimer's disease-associated DNA methylation changes.

Authors:

T. Eulalio, D. Nachun, S. B. Montgomery; Stanford Univ., Stanford, CA

DNA methylation, a key regulator of gene expression, influences downstream physiological changes and is intricately associated with genetic variation and complex phenotypes. Despite abnormal methylation patterns being observed across various complex diseases, their mechanistic implications often remain elusive. We addressed this challenge using *in silico* cell type deconvolution to identify cell type-specific differentially methylated genes associated with genetic variants and Alzheimer's Disease (AD). Further, we introduce regional principal components (rPCs), a novel feature-level summary derived through principal components analysis (PCA), to improve gene-level methylation measurement. The rPCs enhanced the detection of AD-associated methylation changes, outperforming traditional CpG-level methylation and average-based methods, as evidenced by an over three-fold increase in significant differentially methylated features. We next explored the biological relevance of the observed methylation changes through cell type-specific methylation quantitative trait loci (meQTL) mapping and colocalization analysis with AD genome-wide association study (GWAS) data. This analysis identified 31 genes with significant evidence of shared causal variants regulating AD risk and feature-level methylation changes, implying a shared genetic basis for AD susceptibility and DNA methylation. There was strong evidence of colocalization between AD risk and methylation of the *AP2A2* gene in oligodendrocytes, supporting its link to AD pathogenesis. Notably, this colocalization was found using rPCs but not with averages. We conducted a transcriptome-wide association study (TWAS) to identify causal links between cell type-specific feature-level methylation and AD risk and integrated these results with colocalization using INTACT. We identified 27 loci, including genes like *RELB* in neurons and *DEF6* in oligodendrocytes, showing strong evidence of causal links between methylation and AD risk in specific cell types. In comparison to averages, rPCs identified a marginally higher number of putative causal genes and displayed increased cell type-specificity. In summary, our study demonstrates the effectiveness of rPCs for gene-level DNA methylation summarization, improving the detection of cell type-specific AD-associated methylation changes. By integrating genetic information through cell type-specific meQTL mapping, colocalization analysis, and probing potential causal pathways, we identified relationships between DNA methylation, genetic variation, and AD risk.

Session Title: Epigenetics Poster Session I

PB2312 Relationships between asthma biomarkers and immune cell DNA methylation profiles in a deeply phenotyped twin-family cohort

Authors:

A. Van Asselt[1], J. Beck[1], B. Johnson[1], C. Finnicum[2], N. Kallsen[1], L. Ligthart[3], J- . Hottenga[3], A-H. Maitland-van der Zee[4], S. Vijverberg[4], E. De Geus[5], D. Boomsma[3], E. Ehli[1], J. van Dongen[3]; [1]Avera McKennan Hosp. and Univ. Hlth.Ctr., Sioux Falls, SD, [2]Avera McKennan Hosp. & Univ. Hlth.Ctr., Sioux Falls, SD, [3]Dept. of Biological Psychology, Vrije Univ.it, Amsterdam, Netherlands, [4]Dept. of Pulmonary Med., Univ. of Amsterdam, Amsterdam, Netherlands, [5]Vrije Univ.it, Department of Biological Psychology, Vrije Univers, Netherlands

Asthma is a complex respiratory disease characterized by chronic airway inflammation and variable airflow obstruction. The etiology and pathogenesis of asthma involve intricate interactions between genetic and environmental factors, leading to extreme amounts of disease heterogeneity from both a phenotypic and molecular perspective. Due to this variability, investigating biomarkers associated with asthma may provide better clarity to its origins and drivers. Recently, DNA methylation has emerged as a crucial player in gene expression regulation and disease development. Understanding the relationship between DNA methylation and asthma biomarkers can provide insights into the mechanisms underlying the disease. The objective of this study was to investigate the relationships of DNA methylation patterns from whole blood samples (measured via the Illumina Infinium EPIC methylation array) in 341 individuals of twin families from the Netherlands Twin Register (MZ Twins = 76, DZ Twins = 95, Parents = 157, Siblings = 13). Participants were adult parents with their young adult twin offspring where at least 1 family member suffered from severe asthma. We studied baseline lung function, bronchial hyper-responsiveness, positive skin prick tests (SPT) to 11 allergens, IgE, positive specific IgE tests to four allergens, and eosinophil counts. In an exploratory analysis, we assessed the association of the measured endo-phenotypes to the top 10 principal components derived from the DNA methylation data, which showed correlations between principal component 2 and several measures of lung functionality including forced expiratory volume and total lung volume. The number of independent dimensions in the asthma endo-phenotype data was estimated by MatSpd. We then performed epigenome-wide association studies (EWAS) for four lung function measurements over 759,263 CpG's correcting for familial structure and adjusting for multiple covariates (sample cellular proportions, technical batch effects). After Bonferroni correction, these analyses identified 22 and 78 CpG's associated with peak flow and forced expiratory volume, respectively. Next steps for this study include performing additional EWAS's for each of the measured biomarkers and further investigation of these identified CpG's.

Session Title: Epigenetics Poster Session II

PB2313 Relative Telomere Length shortening and association with DNA promoter differential methylation in Thyroid Cancer.

Authors:

F. Jasmine[1], B. Aschebrook-Kilfoy[1], B. Pierce[1], M. Kamal[2], H. Ahsan[1], M. Kibriya[1]; [1]Univ. of Chicago, Chicago, IL, [2]The Lab., Dhaka, Bangladesh

Background: Telomere and telomerase regulation may contribute in cancer. Thyroid cancer (TC) is the most common malignancy of the endocrine system. In some study, telomerase reverse transcriptase (*TERT*) expression was detected in TC and some suggest *TERT* promoter mutation correlate with *BRAF V600E* mutation in TC. We have recently shown the association of *BRAF* mutation status and differential methylation in TC. In this study, we investigate (a) the change in Relative Telomere Length (RTL), a surrogate marker of telomere maintenance, in TC tissue compared to corresponding normal thyroid tissue and (b) if there is any association of RTL shortening and promoter methylation. **Material & Methods:** We included 40 differentiated TC patients (male=12, female=28). Twenty-nine of them had papillary thyroid carcinoma (PTC), 7 had follicular variant of papillary thyroid carcinoma (FVPTC) and 4 had follicular thyroid carcinoma (FTC). In paired TC tissue and surrounding healthy thyroid tissues from same patient, we measured the RTL using a Luminex-based assay. We also looked for the *BRAF V600E* mutation and genome-wide DNA methylation. **Results:** The RTL was measured as a ratio of intensity from telomeric region and that from a reference gene region. The RTL was found to be significantly shorter in the TC tissue compared to normal tissue (0.73 ±SD0.28 vs. 1.11 ±SD0.31, p= 2.01x10-10). This magnitude of RTL shortening (by ~0.38) in tumor tissue is equivalent to RTL shortening seen in human leukocytes over more than 20 years of aging measured by the same assay and is ~3 fold more marked than it is seen in colorectal carcinoma. The RTL shortening in TC tissue was seen irrespective of gender, age group, histological type, presence/absence of capsular invasion, lymph node involvement and BRAF mutation status. We divided the patients by the magnitude of RTL shortening (above and below median). The frequency of greater TEL shortening was higher among the *BRAF* wild type compared to *BRAF V600E* mutants (68% vs 28%, p=0.026). We compared the list of significantly differentially methylated loci (FDR 0.05) for both the groups. The genes differentially methylated only in patients with greater TEL shortening showed significant enrichment ($p<0.05$) in *MAPK* signaling, *ErbB* signaling, *Ras* signaling, thyroid cancer and thyroid hormone signaling pathways. However, none of the 109 promoter loci in telomere maintenance genes showed significant differential methylation. **Conclusion**: In TC tissue, there is significant RTL shortening compared to normal tissue from same patient. This shortening is associated with differential methylation changes in different pathways involved in cancer.

Session Title: Epigenetics Poster Session III

PB2314 † Reproducible human methylation variation fine-mapped to epigenetic haplotypes by 5-base HiFi sequencing

Authors:

E. Grundberg[1], B. Ge[2], W. Cheung[1], M. Lathrop[2], T. Pastinen[1]; [1]Children's Mercy Res. Inst., Kansas City, MO, [2]McGill Univ., Montreal, QC, Canada

Large-scale population profiling of DNA methylation (DNAme) by microarrays has identified genetic influences on epigenetic variation with evidence of overlap with genetic control of common diseases. However, the sparse coverage of CpGs on arrays prevents insight into coordinated patterns of DNAme variation as well as for the identification of genetically or environmentally controlled epigenetic landscapes. We present a comprehensive, high-resolution atlas of DNAme variation from ~3500 unrelated blood samples assayed across different platforms covering ~3.5 million CpGs: methylC-capture sequencing (MCC-Seq, N~2000), whole-genome bisulfite sequencing (WGBS, N~1000) and long-read 5-base HiFi genome sequencing (5-base HiFi-GS, N~500), respectively. We identify strong correlation of effects sizes from genetic association of single CpGs (mQTL, P<10-8) across short-read data sets (MCC-Seq vs WGBS: r=0.96) with less concordance when contrasting correlation of effects from significant mQTLs (P<10-8) detected by consortia (GoDMC) utilizing microarray (GoDMC vs MCC-Seq: r=0.75). We define a stringent orthogonally validated set of mQTLs requiring both effect size concordance and peak genetic signal (colocalization) concordance. Using these criteria, we identify ~350,000 CpGs in MCC-Seq that show same genetic signal in WGBS or 5-base HiFi-GS. Of note, only 7.5% of these curated genetically controlled CpGs overlap array-based mQTLs and concordance of genetic association among these is only 55% between sequencing and microarray mapping. In the MCC-Seq dataset we generate genome-wide DNAme correlation blocks (n~42,000, average CpGs/block=15) to clusters (~500bp) and demonstrating high reproducibly (>60%) using similar correlation matrix in independent WGBS. Around half of coordinated DNAme in the blocks is explained by local *cis*-regulatory genetic effect, whereas remainder is due to *trans*-acting and/or environmentally impact on coordinated DNAme. Finally, using the genetically controlled subset of DNAme coordination we utilize the 5-base HiFi GS data to develop high-resolution "haplotypes" of DNAme variation in long, continues reads (>12kb) to reveal interaction of DNA variation to local epigenetic and regulatory control where individual, constrained *cis*-regulatory sequences are strongly enriched. In summary, our layered approach to develop a validated map pf genetic and environmental impacts on population methylome reveals hundreds of thousands of previously uncharacterized links between methylome and DNA variation and uncovers their organization to biologically interpretable epigenetic features.

PB2315 Sex-specific DNA methylation marks in Rab-regulatory genes underly sex-biased risk of recurrence in unprovoked venous thromboembolism

Authors:

O. Bezerra[1], M. Rodger[2], M. J. Kovacs[3], G. Le Gal[4], P-E. Morange[5], G. Munsch[6], D-A. Trégouët[6], C. M. T. Greenwood[7], F. Gagnon[1]; [1]Univ. of Toronto, Toronto, ON, Canada, [2]McGill Univ., Montreal, QC, Canada, [3]Univ. of Western Ontario, London, ON, Canada, [4]Univ. of Ottawa, Ottawa, ON, Canada, [5]Aix-Marseille Univ., Marseille, France, [6]INSERM, Bordeaux, France, [7]Jewish Gen. Hosp., Montreal, QC, Canada

Deciding whether to stop oral anticoagulants beyond initial treatment (3-6 months) after an unprovoked venous thromboembolism (VTE) is challenging and controversial, partially due to an intriguingly higher risk of recurrence in men after therapy discontinuation compared to women. In preliminary work, we observed sex-specific blood DNA methylation (DNAm) marks in genes of the vitamin K cycle and its regulation (*VKORC1* and *UBIAD1*), relevant to the coagulation cascade and vascular integrity; vitamin K cycle plays a pivotal role in VTE biology. We hypothesized that sex-specific DNAm are associated with the observed sex-biased VTE recurrence (rVTE). Here, using the Illumina EPIC array, we performed a sex-stratified epigenome-wide association study (EWAS) with rVTE using peripheral blood samples of 417 European ancestry unprovoked VTE patients (REVERSE I study). Cox hazard regression was adjusted by age, principal components, and cell type heterogeneity. A follow-up methylation quantitative trait locus (meQTLs) analysis was performed within 250Kb (+/-) around the DNAm associated sites in the REVERSE I cohort. We identified two male (*TBC1D22B*-cg01060850 and *ZHX2*-cg07808424) and one female (*DENND3*-cg03401656) hypomethylated CpG sites associated with rVTE (P value < $7\times10-8$). Sensitivity analysis applying adaptations of the Cox model and repeating the EWAS while adjusting for other covariates revealed similar estimates of association. In a replication attempt, the female association displayed the same direction of effect in 139 French VTE women, although not significant (MARTHA study). *TBC1D22B* and *DENND3* are regulators of the Rab family proteins involved in vesicle trafficking, corroborating previous findings on the participation of Rab proteins - acting on exocytosis of Weibel-palade bodies - in VTE recurrence. Moreover, we identified common *cis*-meQTL variants known to modulate DENND3 methylation, also reported as eQTL (expression QTL) in whole blood by GTEx. Allele A carriers of the synonymous variant rs1045303 (G>A) significantly decreased DNAm of probe cg03401656 in VTE recurrent patients (Kruskal-Wallis, P value=0.004). Our results showing several independent DNAm sites associated with sex-specific rVTE may optimize decision-making on prophylaxis after a first VTE event. Further replication and functional analyses can expand insights into the molecular mechanisms driving sex-biased rVTE.

PB2316 Single-cell integrated RNA-sequencing and ATAC-sequencing in human motor cortex identifies cell-specific genetic drivers of ALS

Authors:

J. Cooper-Knock[1], S. Zhang[2], A. Weimer[3], E. Marie Monte[4], L. Jiang[4], X. Yang[4], T. Moll[5], K. Kenna[6], R. Highley[1], M. Snyder[7]; [1]Univ. Of Sheffield, Sheffield, United Kingdom, [2]Univ. Of Florida, Gainesville, FL, [3]Broad Inst., Boston, MA, [4]Stanford Univ., Stanford, CA, [5]Univ. of Sheffield, Sheffield, United Kingdom, [6]UMC Utrecht, Utrecht, Netherlands, [7]Stanford Dept. of Genetics, Palo Alto, CA

Amyotrophic lateral sclerosis (ALS) is an archetypal complex disease with a polygenic architecture. Despite high heritability, the latest ALS genome-wide association study (GWAS) identified a genetic risk factor in <10% of patients. Moreover, where the field has identified genomic regions containing disease-associated genetic variants, we often lack a biological understanding of the effect of the genetic variation, which is a necessary requirement to allow development of therapeutic interventions. We previously applied ATAC-seq to profile chromatin accessibility within normal motor neurons (MNs). By focusing on regulatory regions which are open and active within MNs, our machine learning method reduced the search space by >90% and uncovered 690 ALS risk genes, corresponding to 35% of SNP-based heritability. Here we have applied single-cell integrated RNA-sequencing and ATAC-sequencing to nuclei extracted from human motor cortex from ALS patients and controls. We have discovered cell-specific risk genes across neuronal subtypes and glia thereby increasing further the proportion of explained SNP-based heritability. Trajectory analysis of gene expression within microglia and astrocytes provides a data-driven method for discovering physiological glial phenotypes in vivo. Using this analysis we have identified ALS-associated glial expression of known ALS risk genes and provided previously missing functional annotations for known ALS GWAS loci.

Session Title: Epigenetics Poster Session III

PB2317 Single-nucleus chromatin accessibility variations implicate microglia and deep-layer excitatory neurons for major depressive disorder.

Authors:

A. Chawla[1], D. Cakmakci[1], W. Zhang[1], M. Maitra[2], M. Suderman[3], X. Zhang[1], Y. Li[1], C. Nagy[4], G. Turecki[5]; [1]McGill Univ., Montreal, QC, Canada, [2]Douglas Hosp., Montreal, QC, Canada, [3]Univ. of Bristol, Bristol, United Kingdom, [4]Douglas Mental Hlth.Univ. Inst., Verdun, QC, Canada, [5]Mc Gill Univ, Montreal, QC, Canada

Motivation: Major Depressive Disorder (MDD) is a debilitating psychiatric disorder and a major risk factor for suicide. However, its biological underpinnings are scarcely understood. While many brain cell-types have been associated with MDD, investigation of genetic and epigenetic factors holds promise to uncover a more coherent picture. To this end, MDD genome-wide association studies (GWAS) identified hundreds of genetic variants residing primarily in regions of non-coding genome whose functions remain to be determined. Single-nucleus ATAC sequencing (snATAC-seq) [1] provides an unprecedented opportunity for interrogation of such variants through the lens of accessible chromatin. **Objectives:** We aimed to identify cell-type specific accessibility differences in MDD and determine transcription factors (TFs) disrupted by accessibility variations influenced by MDD-related epigenetic and genetic factors. **Methodology:** Using snATAC-seq, we sequenced accessible regions of the genome in more than 200,000 nuclei extracted from dorsolateral prefrontal cortex of 84 MDD individuals or age- and sex-matched healthy controls. Next, we integrated snATAC-seq with snRNA-seq from matching subjects to identify gene-expression changes associated with MDD linked accessibility variations. Finally, we trained gapped-kmer SVM (gkmSVM) [3] and fine-tuned an attention-based deep learning model called DNABERT [4] to predict cell-type specific accessibility from genomic sequences, and pinpointed MDD SNPs causing significant allelic variations via in-silico mutation. **Results:** Majority of accessibility differences in MDD were found in grey matter microglia (58%) showing decreased binding of immune-regulatory TFs and demonstrating suppressed immune-functions. Additionally, NR4A2+ deep-layer excitatory neurons showed prominent accessibility variations (21%) and specifically enriched for MDD GWAS SNP-based heritability using LD score regression. Moreover, in-silico mutagenesis via sequence-based cell-type-specific classifiers revealed potential disruption of several neurodevelopmentally-important TFs in NR4A2+ excitatory neurons and a lineage-specifying TF in microglia. Finally, we identified significant differences in ligand-receptor interactions between these subtypes, implicating phagocytosis-related signaling pathways in MDD. **Conclusions:** Overall, we elucidate specific subtypes of neurons and microglia showing significant accessibility variations in association with MDD SNPs. 1. Buenrostro, J., *Nature* **523,** 486-490 (2015). 2. Lee, D. *Bioinformatics* **32**, 2196-2198 (2016). 3. Ji, Y. *Bioinformatics* **37**, 2112-2120 (2021)

Session Title: Epigenetics Poster Session I

PB2318 SMYD5 is a novel epigenetic gatekeeper of the mild hypothermia response

Authors:

S. Rafnsdottir[1], K. Jang[1], S. T. Halldorsdottir[1], A. Tomasdottir[1], M. Vinod[1], K. Möller[1], T. Reynisdottir[1], L. H. Atladottir[1], K. E. Allison[1], J. He[2], L. Zhang[3], F. J. Northington[3], R. Chavez-Valdez[3], K. J. Anderson[1], H. Bjornsson[1]; [1]Univ. of Iceland, Reykjavik, Iceland, [2]Michigan State Univ., East Lansing, MI, [3]Johns Hopkins Univ., Baltimore, MD

Physicians widely employ a strategy called targeted temperature management, which involves cooling patients to ~32°C to decrease the risk of neurological damage following asphyxia. Three genes (*SP1*, *CIRBP* and *RBM3*) are specifically upregulated at this exact temperature as part of the mild hypothermia response (MHR). Recent work suggests these genes mediate the neuroprotective effect of hypothermia. We have recently created mild hypothermia indicators (MHI) which translate transcriptional activity of the three key genes into fluorescent signals. Using these MHIs, we have shown that: 1) the MHR is specific as all show maximal activity at 32°C, with much less activity at other temperatures; 2) the MHIs mirror response at endogenous loci; 3) this is a generalized phenomenon even in cells of diverse origins; 4) the response is particularly strong in cells with neuronal characteristics including HEK293; and 5) the maximal response occurs after 6 hours for SP1-MHI, followed by RBM3- and CIRBP-MHIs, respectively. We have used the MHIs for two strategies: 1) screening an FDA-approved drug library on cells carrying SP1-MHI, which yielded a compound (Entacapone) that is able to activate the SP1-MHR at 37°C; and 2) a CRISPR-Cas9 genome-wide library screen which yielded multiple potential regulators of the SP1-MHR. The screen caused a dramatic shift in fluorescence of mutagenized cells, supporting the idea that there must be a number of factors upstream of SP1. One such candidate repressor from our screen was SMYD5, a histone lysine methyltransferase that places H3K36me3, H3K9me3 and H4K20me3 marks. In mouse embryonic stem cells (mESC) there is SMYD5 binding at *SP1* and *CIRBP* promoters (CUT&TAG) and upon knockout (KO) of SMYD5 in mESC there is an increase in *SP1* mRNA. Upon SMYD5 KO in HEK293 cells we see a significant increase of SP1 protein at 37°C and SMYD5 knockdown shows increased fluorescence of the SP1-MHR, supporting that SMYD5 acts as a repressor at euthermia. We also observe that SMYD5 levels show temperature dependence with less SMYD5 binding (CUT&RUN) and SMYD5 amounts *in vitro* and *in vivo* after 6 hours at 32°C. This repression is mirrored by temperature-dependent levels of H3K36me3 at the *SP1*-locus and globally indicating that the mammalian MHR is regulated at the level of histone modifications. We identified 45 additional SMYD5-bound temperature dependent genes suggesting a broader MHR-related role for SMYD5. Our study provides an example of how the epigenetic machinery integrates environmental cues into the genetic circuitry of mammalian cells and suggests novel therapeutic avenues for neuroprotection after catastrophic events such as neonatal asphyxia.

PB2319 Systematic genome-wide association scans across binary variables in the Canadian Longitudinal Study on Aging (CLSA).

Authors:

M. Kazemi, D. Taliun; McGill Univ., Montreal, QC, Canada

Systematic genome-wide association scans across binary variables in the Canadian Longitudinal Study on Aging (CLSA). The Canadian Longitudinal Study on Aging (CLSA) is a large 20-year follow-up cohort study on 50,000 residents of Canada aged 45-85 and recruited between 2010-2015. The participants underwent genome-wide genotyping from blood samples, and a large amount of phenotypic information was collected, including questionnaire data and physical measurements. In this project, we aim to perform systematic genome-wide association studies (GWASs) across all available phenotypes in this study and share generated summary-level association results with the broad research community for replication, validation, and other downstream analyses including the construction of polygenic risk scores and Mendelian randomization. Here we present the results from the first step in our project, where we focused on binary phenotypes. From the 765 baseline binary variables in the CLSA, we identified 35 corresponding to diverse health conditions, including neurological (e.g., multiple sclerosis, 178/25,029 cases/controls), mental health (e.g., depression, 4,170/20,976), cardiovascular (e.g., high blood pressure, 9,291/15,830), digestive (e.g., bowel disorder 2,453/22,708), endocrine (e.g., type 2 diabetes, 2,214/20,855), respiratory (e.g., asthma, 3,342/21,811), genitourinary (e.g., kidney disease, 706/24,461), sensory disorders (e.g., macular degeneration, 1,062/24,047), immune system conditions (e.g., allergies 9,606/15,432), and various types of cancers. For these phenotypes, we performed GWASs on 43,232,256 genetic variants imputed with the state-of-the-art TOPMed reference panel (imputation quality >0.3, minor allele count >20). We used the Regenie generalized mixed model association test to account for relatedness with sex, age and the first 20 principal components as covariates. At the moment of writing, the genotype data were available for 26,622 CLSA participants, and 25,254 of them were of European genetic ancestry based on our PCA analysis. Thus, we limited our GWASs to Europeans to maximize statistical power. We identified 1,502 statistically significant associations (P-value < 5×10-8) distributed across 23 independent loci. Our next steps include expanding GWASs to more binary phenotypes and setting up the public interactive browser for easy results lookups, comparisons and visualizations.

PB2320 Systems biology approach reveals intricate DNA methylation dynamics in skeletal muscle with age.

Authors:

A. Khamis[1,2], M. Boissel[1], L. Ning[1], L. Maurin[1], V. Raverdy[3], M. Derhourhi[1], F. Pattou[3], A. Bonnefond[1,2], P. Froguel[1,2]; [1]Inserm U1283, CNRS UMR 8199, EGID, Inst. Pasteur de Lille, Univ. of Lille, Lille, F-59000, France, Lille, France, [2]Dept. of Metabolism, Digestion and Reproduction, Imperial Coll. London, London, United Kingdom, [3]Univ. of Lille, Inst. Pasteur de Lille, Inserm U1190, EGID, CHU Lille, Lille, France

Maintaining human glucose homeostasis requires intricate complementary mechanisms, and skeletal muscle is the main regulator of glucose expenditure. We assessed whether this metabolic process is impacted by genetics and acquired factors, such as aging. Here, we assessed the effects of age on gene expression and DNA methylation in skeletal muscle biopsies from 84 individuals that underwent bariatric surgery. Using transcriptomics data, we performed a transcriptome wide association study (TWAS) we did not identify any gene expression changes associated with age (when adjusting for sex, body mass index [BMI] and ancestry). We then performed an epigenome wide association study (EWAS), adjusting for sex, BMI, ancestry and cellular composition, and identified 303 CpGs associated with age (bacon-corrected FDR < 0.05), of which ~ 60% have been previously identified in skeletal muscle. Consistent with other studies, none of the present CpGs were associated with nearby gene expression within ± 1 Mb window. We then hypothesised that genetic variants, known to influence DNA methylation, might be potential confounders of methylation-expression (ME) associations. Therefore, using genotyping data in the same individuals, we developed and applied a systems biology approach: ME were adjusted for genotype, which allowed the identification of robust functional CpGs associated with age and gene expression independently of individual's genotype. We removed SNPs associated with nearby gene expression (eQTLs) and/or nearby CpGs (mQTLs). Using this model, we found that 46, out of the 303 CpGs, were associated with a change in nearby gene expression, whereby the vast majority (87%) did not implicate the nearest gene. Pathway analysis of differentially expressed genes linked to the CpGs and aging revealed that one of the top pathways was the "glucose metabolic process", including key genes in glucose uptake: the down-regulation of INSR encoding the insulin receptor and TBC1D1; and the up-regulation of glucose and lipid metabolic enzymes TPI1, FADS3, and DCXR. In contract, a TWAS and EWAS with glucose and insulin measures (HbA1C, fasting glucose, fasting insulin and HOMA2-IR) revealed that none of these traits were associated with DNA methylation or gene expression changes. Therefore, our comprehensive, multi-omic pipeline revealed the importance of studying DNA methylation dynamics in their cis-regulatory context and highlights that the effects on glucose homeostasis in skeletal muscle is not directly influenced by glucose measures, but occurs indirectly through age.

Session Title: Epigenetics Poster Session I

PB2321 TDP-43 chronic deficiency leads to genome-wide dysregulation of the transcriptome and transposable elements by affecting R-loop and 5hmC crosstalk.

Authors:

Y. Hou[1], Y. Li[1], J-F. Xiang[1], K. Tilahun[1], J. Jiang[1], V. G. Corces[1], B. Yao[2]; [1]Emory Univeristy, Atlanta, GA, [2]Emory Univ., Atlanta, GA

TAR DNA-binding protein 43 (TDP-43) is an RNA/DNA-binding protein involved in numerous aspects of RNA metabolism, but its molecular roles in regulating gene and transposable elements (TEs) at the genomic level is not extensively explored. TDP-43 loss-of-function due to progressive cytoplasmic aggregations serves as a pathological hallmark and potential causality for several neurodegenerative diseases. Recent evidence suggest acute knockdown of TDP-43 affects the formation of R-loops, nuclear DNA:RNA hybrid structures implicated in transcription regulation. However, how stable and chronic functional perturbation of TDP-43, which more closely resembles age-related neurodegeneration, impact global transcriptome via R-loop dysregulation remains unclear. Here we demonstrate that stable and prolonged TDP-43 knockdown impairs cell proliferation and cell response to DNA damage. At the molecular level, TDP-43 chronic deficiency impacts gene expression either locally or distally by concomitantly altering the crosstalk between R-loops and 5-hydroxymethylcytosine (5hmC) in gene bodies and long-range enhancer-promoter interactions. Furthermore, TDP-43 knockdown induces substantial disease-relevant TE activation by influencing their R-loop and 5hmC homeostasis in a locus-specific manner. Taken together, our findings highlight the previously understudied genomic roles of TDP-43 in modulating R-loop/5hmC coordination in coding genes, distal regulatory elements, and TEs, and present a general molecular mechanism underlying the contribution of proteinopathies to the etiology of neurodegenerative disorders.

Session Title: Epigenetics Poster Session II

PB2322 Temporally specific single-cell epigenomic and chromosomal architecture reconfiguration in the developing human hippocampus and prefrontal cortex

Authors:

M. Heffel; UCLA, Los Angeles, CA

The human hippocampus (HPC) and prefrontal cortex (PFC) play critical roles in learning and cognition, yet the dynamic molecular characteristics of their development remain enigmatic. Here we investigated the epigenomic and 3D genome reorganization during the development of the HPC and PFC using more than 53,000 joint single-nucleus profiles of chromatin conformation and DNA methylation (sn-m3C-seq). The remodeling of DNA methylation predominantly occurs during late-gestational to early-infant development and is temporally separated from chromatin conformation dynamics. Neurons have a unique Domain-Dominant chromatin conformation that is different from the Compartment-Dominant conformation of glial cells and non-brain tissues. We reconstructed cell-type regulatory programs across developmental and differentiation trajectories, identifying temporal and lineage specific molecular markers idiosyncratic to each data modality. Integrating our data with previous GWAS studies, we find putatively causal common variants for schizophrenia strongly overlapping with chromatin loop-connected, cell-type-specific regulatory regions. Our data demonstrate that single-cell 3D-epigenomics is a powerful approach for dissecting neuropsychiatric risk loci.

Session Title: Epigenetics Poster Session III

PB2323 The atypical parent-of-origin effects dependent methylome is associated with the rate of aging in humans

Authors:

Y. Zeng[1], C. Gao[1], P. Navarro[2], A. McIntosh[2], C. Haley[2], R. Walker[3], C. Amador[2], A. Campbell[2], R. Madden[2], M. Adams[2], X. Bai[1], Y. Liu[1], M. Li[1], C. Hayward[2], D. Porteous[2], X. Shen[2], K. Evans[2]; [1]Sun Yat-Sen Univ., Guangzhou, China, [2]The Univ. of Edinburgh, Edinburgh, United Kingdom, [3]Univ. of Exeter, Exeter, United Kingdom

Aging at adulthood may be related to early events acting through the genomic regions that are both sensitive to early environments and related to health phenotypes in adulthood. The parent-of-origin-effect (POE)-regulated methylome includes regions targeted by genetically-controlled imprinting effects (the typical type of POE) and regions targeted by parental environmental effects (the atypical POE). The “early event/environment sensitive nature” of this part of the methylome making it a potential hub connecting early exposures, the epigenome and aging. In this study, a phenome-wide association analysis is performed for the POE-influenced methylome using GS:SFHS ($N_{discovery}$=5,087, $N_{replication}$=4,450). A total of 92 significant POE- CpG - phenotype associations are statistically identified and replicated. The POE-CpGs belonging to the atypical class contribute most of the associations and the most enriched and strongly associated phenotypes are aging (DNAmTL acceleration), intelligence and parental (maternal) smoking exposure phenotypes. The atypical- POE-CpGs could also form co-methylation networks (modules) which are associated with these phenotypes, one of the modules associated with aging shows an elevated level of methylation connectivity as age increases. We also reported additional aging-related features of the atypical POE-CpGs: high levels of methylation entropy, fast entropy loss with age and a high correlation with constituent CpGs of epigenetic clocks. These findings uncover the association between the part of methylome influenced by atypical-POE and the aging process, offering new evidence supporting the "early development of origin" theory for aging in humans.

Session Title: Epigenetics Poster Session I

PB2324 The methylome and transcriptome of maturing iPSC-derived retinal 3D organoids over a 2-year period of culturing

Authors:

C. Kiel[1], T. Strunz[1], P. Berber[1], B. H. F. Weber[1,2]; [1]Univ. of Regensburg, Regensburg, Germany, [2]Univ. Hosp. Regensburg, Regensburg, Germany

Purpose: 3D *in vitro* organoids have become popular in recent years as they provide complex and highly specialized model systems structurally most often related to the native tissue. Whether such models indeed also reflect a comparable functional context during developmental maturation processes remains unclear at present. Specifically, the context of DNA methylation and global RNA expression is of interest to better understand the possible use and the optimal time point to investigate normal and diseased states of an organoid. Here, we focused on retinal organoids (ROs) as a model system to clarify methylation pattern and RNA expression profiles over an extended period of culturing time.
Methods: ROs from three unrelated donors were analyzed at different time points and compared with profiles of naïve human retinae. For methylation analysis (Human MethylationEPIC BeadChip) ROs were harvested after 0.5 years (n = 19, 3 donors), 1 year (n = 11, 3 donors), 1.5 years (n = 5, 1 donor) and 2 years (n = 5, 1 donor) of cultivation and compared with 12 human retinae (mean age 55 years). Furthermore, transcriptomes (RNA-Seq) were generated and compared for 9 human retinae (mean age 57 years), as well as ROs with a cultivation time of 0.5 years (n = 6, 2 donors), 1 year (n = 21, 3 donors), 1.5 years (n = 11, 2 donors) and 2 years (n=6, 1 donor).
Results: PCA analysis of methylation data including human primary tissues such as PBMCs or fibroblasts, iPSCs and iPSC-derived cell lines (RPE and endothelial cells) highlighted clustering of ROs and human retinae. Interestingly, ROs can be distinguished on the basis of their methylation and gene expression pattern by cultivation time. While the three later time points (1 year, 1.5 and 2 years) differ only marginally and overall showed most similarity with adult retinae, ROs at the age of 0.5 years are significantly distinct. Overall, with an increasing cultivation time methylation increases, while gene expression decreases accordingly. Enrichment analysis of differentially expressed genes as well as methylated regions displayed most significant differences for pathways participating in anatomical structure development and visual perception.
Conclusion: During a 2-year maturation process the methylome and transcriptome of ROs converge to human adult retinae. Notably, our data suggest that the maturation process of ROs is almost completed after about 1 to 1.5 years while further changes in methylation and transcription, specifically of many visual perception genes are slowly but constantly occurring over time.

Session Title: Epigenetics Poster Session II

PB2325 The reninness score: integrative analysis of multi-omic data to define renin cell identity.

Authors:

B. Xue[1], S. Medrano[1], J. Smith[1], A. Martini[2], N. Sheffield[1], M. Sequeira Lopez[1], R. Gomez[1]; [1]Univ. of Virginia, Charlottesville, VA, [2]Univ. of Brasília, Brasilia, Brazil

BACKGROUND: Renin cells are crucial for survival. They are well-known for their function in blood pressure regulation, fluid-electrolyte homeostasis, kidney development, and tissue morphogenesis. In the fetal kidney, renin cells are progenitors for multiple cell types that retain epigenetic memory of the renin phenotype in adults. Renin cell descendants regain the endocrine renin phenotype to overcome homeostatic threats, a process known as recruitment. The determinants that control the identity, fate, and recruitment of renin cells are not well understood. **We aim to 1) define the chromatin pattern that determines renin cell identity; and 2) develop a computational tool to score samples by similarity to that pattern.**

RESULTS: We compared open chromatin regions (ATAC-seq) between non-renin-expressing and renin-expressing samples from three different sources and stimulation states: 1) primary renin cells in basal state (WT); 2) primary renin cells chronically stimulated to produce renin (recruited); and 3) constitutively renin-expressing tumoral cells. Differential analyses between the three types of renin cells and the non-renin cells revealed 1,525 unique open chromatin regions shared in at least two renin groups, including regions associated with renin cell-specific genes: *Ren1* and *Akr1b7*. Motif enrichment analyses showed that the bZip family was the most enriched motifs in the tumoral cells, and MEF2 family was the most enriched in primary cells, which aligns with our previous research. Co-enriched motifs found in *Ren1* and *Akr1b7* regions suggest a group of TFs govern their co-expression. In addition, we identified unique open chromatin regions and enriched motifs in recruited renin cells, suggesting associated TFs involved in recruitment.

Next, we used a machine-learning approach to calculate a "reninness" score by training a genomic region model with renin and non-renin ATAC-seq data. We identified a cluster of regions (n = 112,992) around the trained renin label, which included 89% of the increased-accessibility regions from the differential analyses. We calculated the reninness score based on the distance between the trained label embedding and sample embedding using the trained model. The results reflected the known renin transcription level: the homogeneous WT renin cells have the highest score, followed by the homogeneous renin-expressing tumoral cells and the renin-expressing primary cells. Conversely, non-renin-expressing cells have the lowest scores.

SUMMARY: In conclusion, we identified the chromatin configurations defining the identity and recruitment of renin cells and developed a computational score to quantify it.

Session Title: Epigenetics Poster Session III

PB2326 The role of exogenously induced mitochondrial DNA variation on the nuclear epigenome and transcriptome

Authors:

P. Win[1], S. Zeng[2], J. Xie[2], C. Newcomb[2], D. E. Arking[2], C. A. Castellani[1,2]; [1]Western Univ., London, ON, Canada, [2]Johns Hopkins Univ Sch. of Med., Baltimore, MD

Background: Mitochondrial DNA copy number (mtCN) reflects the quantity of mtDNA and serves as a proxy for mitochondrial (mt) function. Exogenous environmental stimuli leads to mtCN variation, which in turn, has been shown to influence nuclear DNA (nDNA) methylation and gene expression. We show that exogenous environmental chemical alteration of mtCN modfies nDNA methylation and gene expression in a dose-dependent manner and is often reversible. Characterization of these relationships allows for the identification of mtCN associated CpG sites and genes as well as their underlying biological mechanisms.
Methods: Exogenous mtCN altering chemical compounds were applied to HEK293T cells in culture, these included resveratrol (Resv), acetaminophen (Acet) and ethidium bromide (EtBr) at multiple doses (N=111). EtBr removal following exposure for four recovery timepoints was also tested. DNA and RNA was extracted, and methylation was profiled via the Illumina Methylation EPIC Beadchip. RNA sequencing was performed on the Illumina NovaSeq. Linear mixed and negative binomial regression analyses were used to assess the relationship between mtCN and methylation/gene expression, with nDNA measures as the dependent variable. Integrated analysis between differentially methylated and expressed genes was performed to determine significant CpG-Gene pairs. *In silico* enrichment analyses was performed to identify relevant shared pathways.
Results: Acet and Resv exposure resulted in dose-dependent mtCN increases, and EtBr led to dose-dependent mtCN decrease. 332 CpGs were associated with mtCN ($p<1e-7$). 2686, 1895 and 170 genes were differentially expressed after Acet, Resv and EtBr treatment, respectively ($p<1e-6$). EtBr recovery CpGs/gene variation correlated with mtCN changes and in many cases, mtCN, nDNA methylation, and gene expression recovered to initial levels within 96 hours of drug withdrawal. Integration of methylation and gene expression identified 423 pairs including associations between cg0918651 and nearby *NUDT3*, *UQCC2*, and *C6orf1* ($p<6e-9$). Voltage-gated ion channel activity ($p<6e-7$), and RHO GTPase cycle ($p<4e-6$) pathways were overrepresented in integrated analyses.
Conclusion: Environmentally induced changes in mtCN levels correlate with nDNA methylation and gene expression changes suggesting that the mechanism driving these changes is not independent. Further, we identify that in many cases, these changes are reversible to baseline mtCN and methylation/gene expression levels and are overrepresented by ion channel and cell cycle related pathways.

Session Title: Epigenetics Poster Session I

PB2327 Tissue-specific DNA methylation signatures of alcohol use disorder in human brain.

Authors:

M. Minto[1], C. Willis[1], B. Quach[1], S. Han[2], R. Tao[2], A. Deep-Soboslay[2], B. T. Webb[1], R. D. Mayfield[3], E. O. Johnson[1], J. E. Kleinman[2], D. B. Hancock[1], L. J. Bierut[4], J. D. White[1]; [1]RTI Intl., Research Triangle Park, NC, [2]Lieber Inst. for Brain Dev., Baltimore, MD, [3]Univ. of Texas at Austin, Austin, TX, [4]Washington Univ Sch Med, St Louis, MO

Alcohol Use Disorder (AUD) is a common psychiatric disorder in the United States and has a growing number of associated genetic loci. SNP-based h^2 for AUD is 5-10%, and long-term alcohol use has been associated with epigenomic-driven neuroinflammatory responses that may promote reward in addiction. Previously, we have shown differential DNA methylation (DNAm) at CpG sites across the genome in the nucleus accumbens (NAc) and dorsolateral prefrontal cortex (DLPFC) of AUD cases and controls. We observed high heterogeneity for many of the differential DNAm sites, suggesting the potential for both tissue-specific and shared associations with AUD. To help tease apart tissue-specific vs. shared associations, we used a linear mixed modeling approach on Illumina EPIC methylation array data from 115 decedents (58 cases with 2+ DSM-5 AUD symptoms, 57 controls with no AUD symptoms) of European ancestry to simultaneously model within-subject differences in DNAm across brain tissues and between-subject differences in AUD status. DNAm array data were pre-processed separately for NAc and DLPFC with 768,826 CpGs common across both regions. While no CpGs surpassed FDR < 0.05, at nominal $p < 0.001$, we identified 171 CpGs associated with AUD with shared effects across brain regions and 542 CpGs with evidence of interaction between brain region and AUD status, i.e., tissue-specific associations. Differentially methylated regions were identified using comb-p and ipDMR, which revealed a tissue-specific AUD-associated DMR near *TRIM10* which is important in cytokine signaling and immune response to inflammation. Future studies would benefit from a larger sample size with more ancestrally diverse representation to detect robust, statistically significant associations. Nonetheless, these findings suggest that distinct DNAm sites may influence the neurobiological state of AUD status within and across addiction-relevant brain regions.

Session Title: Epigenetics Poster Session II

PB2328 Tissue-specific epigenetic differences in adults born preterm with very low birth weight compared with their same-sex. siblings

Authors:

H. Hauta-alus[1,2,3,4], J. Ronkainen[1], J. Kuula[2,3], D. Czamara[5], A. Heiskala[1], S. Sandboge[6,2], J. Björkqvist[2], N. Kaseva[2], K. Räikkönen[4], K. Pietiläinen[4], S. Sebert[1], E. Binder[5], E. Kajantie[7,1,8]; [1]Univ. of Oulu, Oulu, Finland, [2]Finnish Inst. for Hlth.and Welfare, Helsinki, Finland, [3]Univ. of Helsinki and Helsinki Univ. Hosp., Helsinki, Finland, [4]Univ. of Helsinki, Helsinki, Finland, [5]Max-Planck-Inst. of Psychiatry, Munich, Germany, [6]Univ. of Tampere, Tampere, Finland, [7]Natl. Inst. for Hlth.and Welfare, Helsinki, Finland, [8]Norwegian Univ. of Sci. and Technology, Trondheim, Norway

Preterm birth and very low birth weight (VLBW; ≤1500 g) increase the long-term risks for poor health and chronic diseases, however, the mechanisms remain unknown. One suggested pathway is epigenetic modifications such as DNA methylation (DNAm), but few studies have assessed other tissues than blood. We examined whether DNAm in blood or fat differs between VLBW adults and their siblings. The current analysis is based on the Adults Born Preterm Sibling Study and included 78 adults born preterm (<37 gestational week) with VLBW with 76 same-sex sibling-controls born at mean gestational age 40 weeks with mean birth weight of 3361g, all born between years 1976-1996. Epigenome-wide DNAm at cytosine-guanine dinucleotide (CpG) sites were examined from blood and fat tissue by Illumina EPIC 850K at mean age of 29 years. Mixed model was conducted adjusting for age, sex, batch, estimated cell composition and maternal smoking. None of the DNAm differences in blood attained epigenome-wide significance. In fat tissue 440 CpG sites were differentially methylated with false discovery rate [FDR] $p<0.05$ and 86 CpG sites with epigenome-wide significance of $p<9.4 \times 10^{-8}$ between VLBW and their sibling-controls after adjustments. Top sites were annotated to genes related to fat metabolism (e.g. *FADS2*, cg00264176: coefficient (standard error) 0.08 (0.01), FDR $p=9.1 \times 10^{-15}$; *ACSL3*, cg14157824: 0.05 (0.01), $p=6.1 \times 10^{-11}$) and neural development (e.g. *KIF26A*, cg08277679: 0.05 (0.01), $p=1.7 \times 10^{-12}$; *QPRT*, cg05127221: 0.06 (0.01), $p=4.9 \times 10^{-11}$) among other functions. Our results suggest tissue-specific DNAm differences in VLBW adults compared with their siblings with pronounced associations in fat tissue rather than blood. The differentially methylated CpG sites observed were related to genes that have central roles in fatty acid and cholesterol metabolism, cell growth and nervous system development indicating possible pathways for adverse metabolic disturbances of VLBW adults.

PB2329 Transcription factor activation induces re-replication and site-specific copy gain of the interferon receptor cluster

Authors:

J. Wilson, M. P. Ludwig, L. Porritt, J. C. Black, K. D. Sullivan; Univ. of Colorado Anschutz Med. Campus, Aurora, CO

Transient site-specific copy gains (TSSGs) are an evolutionarily conserved phenomenon in which specific genomic loci undergo targeted re-replication during S phase in response to stress conditions or alterations in the local epigenetic environment prior to resolution in G2. Furthermore, TSSGs are frequently found in repetitive gene families and regions amplified in tumors, suggesting a potential role as predecessors to inherited copy number alterations. However, the connection between the cellular stress signaling and generation of the TSSG remains unclear. Here, we report a novel TSSG locus at the interferon receptor (*IFNR*) cluster on chromosome 21, as well as the identification of the signaling cascade leading to the induction. We stimulated cells with various activators of the innate immune response, screened for copy-number gains using fluorescent in-situ hybridization (FISH), and determined that, regardless of stimuli, cells underwent rereplication of the *IFNR* locus at a rate of 10-15%, consistent with other TSSG. To identify the cause of this induction, we analyzed the induced pathways that were conserved across tested stimuli at both the RNA and protein level and identified three putative pathways. Next, we used a combination of pharmacological and genetic experiments to determine the components of innate immune activation required to generate TSSGs at the *IFNR* cluster. The results of these experiments identified a key transcription factor that is both necessary and sufficient for TSSG induction. Cut & Run sequencing analysis for this transcription factor under two stress conditions sufficient to induce TSSGs revealed a strong peak directly upstream of the *IFNR* cluster in both. Furthermore, pharmacological inhibition of the pathway upstream of the transcription factor prevents this binding and suppresses TSSGs. Together, these data suggest that activation and binding of this transcription factor to the locus is required for TSSG generation at the *IFNR* cluster.

PB2330 Transcriptional and Epigenetic Consequences of Early-life Seizures

Authors:

S. Townsend[1], J. J. Westfall[1], S. Sran[1], T. A. Bedrosian[2]; [1]The Ohio State Univ., Columbus, OH, [2]Nationwide Children s Hosp., Columbus, OH

Early-life seizure neuronal activation induces brain plasticity and long-term behavioral changes. In particular, the developing brain is highly plastic compared to the adult brain. Neuronal activity is known to remodel the epigenome and alter gene expression. Yet, little work has been done to correlate transcriptional and epigenetic changes in distinct neuronal populations of the developing brain to behavioral phenotypes. In this proposal, we will bridge this gap in knowledge by using single-cell multiomics techniques to investigate epigenetic and transcriptional changes observed in developing hippocampal neuronal populations post-seizure induction. Widespread neuronal activation can be reliably induced using pentylenetetrazol (PTZ), a GABA-A receptor antagonist that rapidly induces generalized seizures by suppressing the function of inhibitory synapses. I will assay hippocampal and cortical cells for gene expression and chromatin accessibility (10x Genomics Multiome) at multiple timepoints (1-hr, 1-day, 1-month) post-seizure induction to identify differentially expressed genes (DEGs) and differentially accessible chromatin regions (DARs) within cell types. So far, we have processed and begun to analyze data from our acute seizure paradigm where mice were exposed to PTZ or Saline on postnatal day 7. Following seizure induction, brains were harvested at the 1hr and 24hr timepoints. The hippocampus and surrounding cortex were harvested from each brain at either 1hr or 24hr post-injection, giving rise to four experimental groups: Saline 1hr, Saline 24hr, PTZ 1hr, and PTZ 24hr. Tissue from multiple mice were pooled into one aggregate sample per experimental group and processed using the 10x Genomics Single-Cell Multiome ATAC+ Gene Expression kit. Libraries were sequenced on an Illumina NovaSeq 6000 and processed via the Cellranger-ARC pipeline according to manufacturer recommendations. Downstream analysis was performed following standard workflows in Seurat and Signac. Mice exposed to PTZ had increased neuronal activity as denoted by increased Immediate Early Gene (IEG) expression in the treated group at the 1hr timepoint. From the go enrichment analysis, we observed changes in key pathways associated with synapse organization, sodium ion transport, and cytoplasmic translation. I am now analyzing chromatin accessibility data and expect to see changes in transcription factor binding that correlate to the changes in biological processes observed from the go-analysis.

PB2331 Transcriptional networks in placenta and fetal brain reveal extensive sex differences in a mouse model of polychlorinated biphenyl mixture exposure.

Authors:

K. Chau, K. Neier, A. Valenzuela, R. Schmidt, P. Lein, J. Lasalle; Univ. of California, Davis, Davis, CA

Neurodevelopmental disorders (NDDs), including autism spectrum disorders, affect as many as 1 in 10 children born in the United States, with males being at highest risk. Because complex interactions between genetic, hormonal, and environmental factors contribute to the risk of NDDs especially during prenatal life, understanding dysregulated gene pathways affected by multiple risks is important. In an NDD enriched-risk human prospective study “Markers of Autism Risk in Babies: Learning Early Signs” (MARBLES), detectable concentrations of multiple polychlorinated biphenyls (PCB) congeners in maternal gestational blood samples were associated with adverse neurodevelopmental outcomes and alterations to methylation patterns of neurodevelopmental genes in term placenta. In a mouse model of prenatal exposure to this mixture of PCB congeners observed in the MARBLES cohort, there were enhanced repetitive behavior and significant deficits in sociability and ultrasonic vocalizations at the lowest dose (0.1 mg/kg) specifically in males. To understand the molecular genetic basis of sexual dimorphism and dosage effects in this human-relevant PCB risk model, we exposed C57Bl/6J females to varying doses (0, 0.1, 1, 6 mg/kg) of the humanized PCB mixture prior to timed mating. At embryonic day 18, brain and placenta samples were collected for RNA sequencing and Whole Genome Bisulfite Sequencing (WGBS). Differential expressed genes (DEG) analysis of PCB effects in RNA-seq data using limmaVoom showed sex-specific dose responses, with females uniquely showing non-monotonic dosage effects that were greatest at 0.1 mg/kg, but males showing more DEGs overall. A weighted gene co-expression network analysis (WGCNA) was applied to investigate groups of highly correlated genes affected by PCBs and revealed that broad pathways of cellular and nucleotide metabolism including DNA repair are disrupted with exposures to PCBs and show sexual dimorphism and non-monotonic dosage effects in both placenta and fetal brain. Comethyl, a novel pipeline developed by the lab for weighted gene correlation network analysis of WGBS data, is in progress to identify comethylated regions correlated with PCB exposures. Lastly, a multi-omics integration of gene expression and DNA methylation will be performed to identify epigenomic signatures of gene expression and DNA methylation in the placenta that will be compared to human NDDs for their predictive value.

Session Title: Epigenetics Poster Session III

PB2332 Transcriptome and acetylome profiling identify crucial steps of neuronal differentiation in Rubinstein Taybi syndrome

Authors:

J. Van Gils[1], S. Karkar[2], A. Barre[2], S. Nothof[3], R. Chevalier[3], N. Broucqsault[3], C. El Yazidi[3], P. Fergelot[1], F. Magdinier[3], D. Lacombe[1]; [1]Dept. of Med. Genetics, Univ. Hosp. of Bordeaux and INSERM U1211, Univ. of Bordeaux, Bordeaux, France, [2]Bordeaux Bioinformatic Ctr. CBiB, Univ. of Bordeaux, Bordeaux, France, [3]Marseille Med. Genetics, INSERM U 1251, MMG, Aix Marseille Univ., Marseille, France

Rubinstein-Taybi syndrome (RTS) is a rare and severe genetic developmental disorder characterized by multiple congenital anomalies and intellectual disability. *CREBBP* and *EP300*, the two genes known to cause RTS, are transcriptional coactivators that possess a catalytic lysine acetyl transferase (KAT) domain and play a major role in chromatin remodeling. Loss of CBP or p300 function results in a deficit in KAT activity. Altered histone acetylation leads to inappropriate modulation of gene activity, in particular during development. In RTS patients, nothing is known on the functional link between histone acetylation and transcriptomic profiles during neuronal differentiation. To address this question, we derived induced pluripotent stem cells (hiPSCs) from RTS patients carrying a recurrent *CREBBP* mutation known to inactivate the KAT domain. We differentiated these cells into cortical and pyramidal neurons. We compared their acetylome by LS-MS/MS and transcriptome by RNA-seq to cells derived from healthy donors at three different timepoints during neuronal differentiation. No morphological differences were observed throughout the neuronal differentiation procedure between RTS patients and controls, but maturation appeared as impacted at the molecular level. We identified 25 specific acetylated histone marks that are specifically altered in RTS. All four core histones are regulated by CBP but H2B and H3 sites are the most impacted. Altered acetylation occurs at a very early stage and is maintained throughout neuronal differentiation for the majority of these 25 specific histone marks. By transcriptomic analyses, we identified the transition between neural progenitors and immature neuron as a critical step during the differentiation process, with an increase of differentially expressed genes (DEGS) in RTS compared to controls. More specifically, these analyses showed an impact on genes involved in neuronal differentiation and brain development, illustrating a delayed maturation process in RTS. The identification of pathophysiological mechanisms, particularly at the neuronal level in RTS, remains a major challenge for a better understanding of the cognitive impairment in patients. Our data highlight specific histone acetylation changes and a crucial phase of differentiation as a hallmark of RTS neuronal development. Overall, this opens new perspectives in the definition of epigenetic biomarkers for RTS, whose methodology could be extended to all chromatinopathies.

Introduction: Linking inherited DNA variation to the disease risks is one of the main goals in modern predictive medicine. Large-scale projects such as the UK Biobank, FinnGen and Biobank Japan have made a substantial contribution to the understanding of human biology and the advancement of personalized medicine. The growing ethnic diversity of genetic studies resulted in the discovery of population-specific susceptibility loci that could not be identified with studies limited to a single ancestry. Inclusion of previously underreported populations into biobank initiatives improves fine-mapping accuracy of previously identified GWAS signals and novel risk gene discovery efforts. **Methods:** A cohort of 4,800 residents of three areas in Russia - St. Petersburg (N=1,600), Orenburg (N=1,600) and Samara (N=1,600) were recruited in 2012-2013 through an ambulatory visit to local hospitals and polyclinics. Additional independent cohort of 138 samples were recruited in 2017-2018 for participation as controls in a local study of early childhood starvation effects. DNA was extracted from blood samples of 4,723 individuals and genotyped using a custom FinnGen ThermoFisher Axiom microarray. Additional genotypes were imputed using Haplotype Reference Consortium (HRC) data. Directly genotyped and imputed variants with DR2 > 0.8 were included in the downstream analysis. Final dataset included 4,145 individuals and 11,077,763 variants. **Results:** We identified multiple distinct subpopulations within the Russian population, displaying notable genetic affinities towards both Finns and Asians. Furthermore, we observe a substantial prevalence of unique Finnish variants throughout Russia and Asia, indicating their likely origin as common ancestral Finno-Ugric variants. Consequently, we establish the feasibility of replicating these distinctive Finnish variants using a relatively modest cohort of Russian individuals. Finally, we provide access to allele frequencies and genetic associations in the Russian population across 465 phenotypes through the Biobank Russia portal. We present replication of many previous associations and report new significant results in smoking initiation, blood pressure increase during pregnancy and abdominal obesity. **Conclusion:** In this study, we present the first analysis of a diverse population spanning across many admixed ancestries. Our comprehensive analysis encompasses over 465 distinct phenotypes, providing a foundational framework for understanding origins of Finno-Ugric populations and transferability of genetic risks between European and Asian populations.

PB2334 Unique genome wide methylation patterns within HIV disease

Authors:

V. Ramsuran, T. Aurumugam, W. Smidt; Univ. OF KWAZULU-NATAL, Durban, South Africa

Despite more than 40 years of research, the human immunodeficiency virus (HIV) is still a major health concern. Advances in the field have helped us understand various aspects of the virus, and this has led to the development of antiretroviral therapy (ART), which has extended life expectancy and it is starting to decrease new infections. However, getting rid of HIV with ART treatment in a large epidemic, such as in South Africa, is a costly and complex activity. In addition, drug resistance levels are increasing at alarming rates. New treatment options, such as dolutegravir, are promising but appear to have some serious side effects. In these circumstances, it is increasingly important to focus attention on developing an HIV vaccine and a cure. HIV host genetics has made significant advances in HIV cure research. In our recent work, we demonstrated the importance of an epigenetic mechanism, DNA methylation, plays on HIV disease. We previously showed specific human genes have methylation patterns that control HIV disease progression. In this study, we explored a rare cohort of females (N=120) followed up from pre-HIV infection to post-HIV infection and followed throughout various fiebig stages and are HIV treatment naïve. We then have these individuals followed post-ART treatment. This cohort from about 15 years of followup through various HIV stages of disease was used to explore the role genome-wide DNA methylation has on HIV infection and disease progression, with a total of 400 samples. Using the Infinium MethylationEPIC v2.0 array, which covers more than 850,000 methylation sites. Our results show specific unique genes associated with either HIV infection or HIV disease. We report unique methylation patterns within the HIV-negative timepoint compared to the HIV-positive timepoint from the same patients. We also developed a prediction algorithm that uses methylation levels as a determinant of viral load. Using our dataset, we can predict viral load (R^2=0.92; p=0.00001). These data provide several novel target sites for potential innovative therapeutic strategies that could be explored in the future.

Session Title: Epigenetics Poster Session III

PB2335 Using Long-Read Sequencing to Identify Methylation Differences Related to Alzheimer's Disease

Authors:

R. Genner[1,2], M. Meredith[3], K. Billingsley[1], P. Alvarez[1], L. Malik[1], B. Paten[3], W. Timp[2], M. Jain[4], C. Blauwendraat[1]; [1]Ctr. for Alzheimer's and Related Dementias, NIH, Bethesda, MD, [2]Johns Hopkins Univ., Baltimore, MD, [3]UC Santa Cruz Univ. Genomics Inst., Santa Cruz, CA, [4]UC Santa Cruz, Santa Cruz, CA

DNA methylation is an epigenetic mechanism that involves adding a methyl group to cytosine residues in DNA and is generally associated with transcriptional repression. Methylation differences affecting gene transcription levels have been shown to play a role in the development and progression of neurodegenerative diseases including Alzheimer's disease (AD). Methylation levels have traditionally been measured using bisulfite conversion followed by methylation arrays and short read sequencing techniques, however these methods detect only short-range methylation patterns, are not optimized for identifying methylation in traditionally challenging genomic regions, and do not allow for phased haplotype specific methylation detection.

New "long-read" sequencing approaches have been developed by PacBio and Nanopore that can directly sequence reads ranging from 10kb to 1Mb+ in length. This results in increased sequencing accuracy and resolution which is particularly helpful for analyzing complex regions of the genome. Long-read sequencing can also directly detect base modifications such as 5MC methylation, allowing for additional genetic information to be extracted such as haplotype phasing for the detection of allele-specific methylation differences. NIH's Center for Alzheimer's Disease and Related Dementias (CARD) has developed protocols designed to streamline and automate the tissue processing and long-read sequencing of thousands brain samples from individuals with and without AD. Generation of this sequencing data provides a unique opportunity to analyze genome-wide, population scale methylation patterns and assess the methylation levels of poorly resolved genomic regions in human brain tissue.

We are currently using computational methods and algorithms to identify allele-specific, cell type-specific and genome-wide methylation differences in long-read sequencing data from the first ~250 brain samples. We are also conducting benchmarking experiments to compare methylation detection in samples run on Nanopore R9 flow cell series with the updated R10 series, which reports improved read accuracy. We found that methylation levels are comparable across CpG islands, promoter regions, and genome-wide methylation levels for three cell lines and one brain sample.This information will provide new insights into the epigenetic mechanisms of the brain and the underlying etiology of AD that could eventually lead to the development of novel and improved targets for treatment strategies.

Unique DNA methylation (DNAm) patterns, known as “episignatures”, are associated with specific genes/pathways in neurodevelopmental disorders (NDD). We analyzed episignature profiles (EpiSignTM classifier v.4) in 164 NDD cases from four cohorts: (i) validation (n=71), cases with pathogenic/likely-pathogenic variants in genes with known episignatures; (ii) uncertain (n=13), cases with VoUS; iii) unsolved (n=24), cases with uninformative CMA/ES; (iv) discovery (n=56), aimed at identifying novel disease-associated episignatures. We found the expected episignature in 65/71 cases in the validation cohort. Exceptions included a *SMARCA2*:M856V variant in the Nicolaides-Baraitser syndrome-associated domain, with a methylation profile for the allelic disease Blepharophimosis-impaired intellectual development syndrome (BIS). The patient was later re-diagnosed with BIS. Interestingly the extreme case of the unique *SMARCA4*:M886V methylation profile overlapped with the *SMARCA2*:M856V. In silico tools showed that M856 and M886 are structural homologs, further supporting that their mutation to Valine exert analog effects. Another interesting finding was the DNAm pattern of R37H-Kleefstra variant and G11R in the N-terminal domain of *SMARCB1* protein that matched the C-terminal ARID1A/B:c.6200 sub-signature. Clinical presentation of the latest corresponded to the described R37H-*SMARCB1*.All these variants reside very near in the BAFopahty complex. In a patient with Rubinstein Taybi syndrome 2 (EP300), we found a GNAS methylation pattern suggestive of Pseudohypoparathyroidism 1B, as secondary finding. In the uncertain cohort, 8/13 cases did not match the methylation profile of the reported VoUS, suggesting that these were benign variants. Among these, a VoUS in *ARID1B* (Coffin-Siris 1) showed a Cornelia de Lange (CdL) episignature, the initial clinical diagnosis. In the unsolved cohort, a second CdL-case with uninfrometive-ES matched the CdL episignature. Another showed an ATRX-methylation profile, subsequently revealing a deletion of *ATRX* ex3-4 missed by ES. TRIP12-episignature was useful to underpin the genetic diagnosis in family with two similarly affected brothers having two different *de novo* variants (*TRIP12*:L1044Ffs*3, *FBN*:A1728V). In the discovery cohort, we defined three robust novel episignatures for NDD genes: *TLK2*, *CAPRIN1*, *ZMYM3*.Episignature analyses have improved variant classification, supported new disease associated gene as functional analyses, and unraveled novel gene interactions in the BAFopahty complex.

Session Title: Epigenetics Poster Session II

PB2337 Whole-genome bisulfite sequencing of cell-free fetal DNA from low volume plasma samples facilitates investigations of methylomic signatures associated with autism risk factors

Authors:

L. Williams[1,2,3,4], O. Sharifi[1,3,4], R. J. Schmidt[1,2,3], J. M. Lasalle[1,2,3,4]; [1]Univ. of California Davis Sch. of Med., Davis, CA, [2]Perinatal Origins of Disparities Ctr., Davis, CA, [3]MIND Inst., Sacramento, CA, [4]Univ. of California Davis Genome Ctr., Davis, CA

Background: The etiology of autism spectrum disorder (ASD) is complex, involving an interplay of genetic and environmental factors. Many proposed environmental risk factors for ASD have been implicated to act through epigenetic mechanisms, such as DNA methylation, during the perinatal development window. Cell-free fetal DNA (cffDNA), which can be found in maternal plasma, has shown promise as an accessible source of fetal DNA to investigate the perinatal period. However, the investigation of patterns of perinatal epigenetic dysregulation associated with environmental exposures and ASD has been historically challenging. Previous efforts to interrogate the perinatal fetal epigenome required high volumes of maternal plasma, and relied on methylation arrays of narrow genomic breadth.
Objective: A comprehensive understanding of ASD etiology requires the tools for scalable, genome-wide methylation profiling of fetal DNA from the perinatal period. We aim to perform low-pass whole genome bisulfite sequencing (WGBS) and comethylation network analysis on 1mL of maternal plasma as a proof of principle for the application of these methods in studies of ASD.
Methods: Twenty 1mL blood plasma aliquots were collected from pregnant women during 3rd trimester or at delivery. Cell-free DNA was isolated from these aliquots and subjected to bisulfite conversion. Libraries were generated from bisulfite converted cffDNA and pooled for sequencing on the NovaSeq S4. The CpG_Me pipeline was employed to perform QC and generate cytosine reports, which were used as input for comethylation network analysis via the Comethyl package.
Results: An average of 4.30ng of cfDNA was isolated from each blood plasma sample, with 14 of these samples used for WGBS. An average of 411.4M total reads for each sample was observed, with a mean coverage of 85.1% and average depth of 10.9X. These data were sufficient to generate comethylation networks from ~260k CpG-containing regions. Multiple comethylation module were found to have significant associations with the gestational timepoint at which plasma was collected and such modules were annotated.
Conclusion: This pilot study validates the feasibility of performing WGBS on cffDNA collected from low volumes of maternal plasma, and empowers researchers to identify associations between differences in fetal DNA methylation in the perinatal period and neurodevelopmental outcomes. Our group is in the process of applying this technique to cffDNA collected from a high-risk ASD cohort with known perinatal exposure data, which will enable us to identify patterns of epigenetic dysregulation associated with both perinatal exposures and ASD outcomes.

Session Title: Epigenetics Poster Session III

PB2338 Whole-genome bisulfite sequencing of motor neurons reveals cell specific enhancers and enables the identification of motor neuron derived cell-free DNA

Authors:

C. Harvey[1], E. Hanon[2], A. Weimer[3], C. Caggiano[4], T. Moll[1], C. Dos Santos Souza[1], S. Zhang[5], A. Barcons[1], K. Ning[1], K. Kenna[6], I. Timpanaro[6], C. van Dijk[6], N. Zaitlen[4], L. Cooper-Knock[7]; [1]Univ. of Sheffield, Sheffield, United Kingdom, [2]Univ. of Exeter, Exeter, United Kingdom, [3]Stanford Dept. of Genetics, Palo Alto, CA, [4]UCLA, Los Angeles, CA, [5]Stanford Univ., Palo Alto, CA, [6]Univ. Med. Ctr. Utrecht, Utrecht, Netherlands, [7]Univ. Of Sheffield, Sheffield, United Kingdom

Background
The cardinal feature of amyotrophic lateral sclerosis (ALS) is the loss of upper and lower motor neurons, which causes progressive weakness and death. Vital to understanding the mechanism of ALS and finding successful treatments is understanding the selective vulnerability of motor neurons. A key regulator of cell specificity is cell specific epigenetic modifications which enable expression of cell specific genes.
In order to understand the unique epigenetic regulation in motor neurons we performed whole genome bisulfite sequencing (WGBS) in induced pluripotent stem cell (iPSC) derived motor neurons to capture genome wide methylation state. We then analysed these methylation profiles alongside a DNA methylation atlas of cell types from Loyfer et al. (2023) to identify motor neuron specific hypo and hypermethylated regions. We then analysed these regions to identify motor neuron specific regulatory regions such as enhancers.
A key use of a reference methylome is that it can be used with a deconvolution algorithm to infer the cellular composition of a mixture from its methylation state. Cell free DNA (cfDNA) in blood plasma is composed of DNA from recently lysed cells, and quantifying the motor neuron derived DNA within that has previously been identified as a promising biomarker in ALS (Robichaud et al. 2021). We used our data to test the feasibility of motor neuron-derived cfDNA as a biomarkerObjectives
To identify motor neuron specific hyper and hypomethylated regions, then to use these regions to identify motor neuron specific enhancers and regulatory regions.
Test the feasibility of motor neuron derived cfDNA as a biomarker of ALS.MethodsWe integrated whole genome bisulfite sequencing of iPSC-derived motor neurons derived from three healthy donors with the methylation atlas from Loyfer et al. (2023) to identify motor neuron specific regions.
We optimised a deconvolution algorithm using synthetic mixes of cfDNA from healthy donors and motor neuron derived DNA and describe its accuracy.
Finally, we will use our optimised deconvolution algorithm on WGBS sequenced cfDNA from 12 ALS patients and 12 controls, previously published in (Caggiano et al. 2021).ResultsWe identify 5281 regions uniquely hypomethylated and 5037 uniquely hypermethylated regions specific to motor neurons.
With our optimised deconvolution algorithm we demonstrate it is feasible to detect motor neuron derived DNA present at 1% of cfDNA

Parker[1]; [1]Univ. of Michigan, Ann Arbor, MI, [2]Washington Univ., Saint Louis, MO, [3]Univ. of Michigan, Canonsburg, PA, [4]10x Genomics, Pleasanton, CA, [5]Inst. of Clinical Med., Kuopio, Finland, [6]Dept. of Med., Kuopio, Finland, [7]Inst. of Biomedicine, Kuopio, Finland, [8]Univ North Carolina, Chapel Hill, NC, [9]Univ Michigan, Ann Arbor, MI, [10]Dept. of Publ. Hlth.and Welfare, Helsinki, Finland, [11]NIH, Bethesda, MD

Aging progressively alters the cellular epigenomic landscape and is associated with increased risk for complex diseases such as cancer, Alzheimer's disease, and type 2 diabetes. Genome-wide association studies have identified hundreds of genetic variants associated with these diseases, the majority of which occur in noncoding regions of the genome. Together, these findings suggest that aging-related epigenomic changes are one component of disease risk. Here we use skeletal muscle biopsies from 284 Finnish adults aged 20 to 79 years (mean 60 years) and single nucleus ATAC-seq to identify patterns in chromatin architecture that are associated with age. To find age-related chromatin patterns in an unbiased way without assuming a linear relationship we use Auto-Regressive Integrated Moving Average (ARIMA) models. Of the 13 skeletal muscle cell types identified via clustering, we selected the five most abundant (Type 1, 2a, and 2x muscle fiber, endothelial, and mesenchymal stem cells) for analysis. We then identified between 149,751 and 289,430 peaks within each of the five selected cell types and, using a generalized linear model, adjusted the sample-specific peak accessibility for body mass index and technical covariates such as batch. Then, we used the ARIMA modeling framework and found that between 6.2% and 15.5% of the tested peaks were age-associated. We used unsupervised clustering to classify age-associated peaks according to their pattern of association (increasing accessibility, decreasing accessibility, or dynamic with age). Breakpoint analysis of these three categories showed that in all cell types the chromatin landscape is changing at its greatest magnitude around 60 years of age. To determine if age-associated peaks are preferentially associated with particular biological pathways, we performed gene ontology (GO) enrichment analysis leveraging the GO terms assigned to nearby genes. These analyses showed both expected results, such as skeletal system development in skeletal muscle fiber, and several other robust signals in increasing, decreasing, and dynamic age-associated peaks. Analyses are ongoing to determine whether variants associated with cell type-relevant complex traits are enriched in age-associated peaks. We are also working to explore the associations of age-associated peaks with chromatin state (transcribed, enhancer, poised, etc.) in order to better understand the context of these peaks with non-linear age dependent dynamics. Together, these results highlight age-associated epigenomic differences in five skeletal muscle cell types, giving us insight into cellular development and aging across the human lifespan.

Hlth., Univ. of Toronto, Toronto, ON, Canada

Introduction: Digital tools are emerging to support the delivery of genetic services, including pre-test counseling, consent, collection of family and medical history, education, results disclosure and post-test counseling. Research has shown that such tools generally improve patient-reported outcomes related to decision-making, knowledge, and psychosocial well-being. However, patients' perspectives and preferences for how these tools are used to facilitate patient-centered care are not well understood. To address this gap, we aimed to better understand patients' opinions and preferences towards the use of digital tools in genetic service delivery.

Methods: Semi-structured interviews were conducted with individuals who received genetic testing for themselves or for their child. Participants were recruited from the Canadian Organization for Rare Disorders (CORD) or were previously enrolled in a Toronto-based cancer genetics research study. Participants were asked about their experiences with and preferences for the use of digital tools in the delivery of genetic services and completed a demographics survey. Thematic analysis was used to interpret the qualitative data.

Results: A total of 30 participants were interviewed. Of these, 17 (57%) received genetic testing for themselves,13 (43%) for their child, and 20 (67%) identified as female. Overall, participants reported positive experiences with digital tools in medical settings and welcomed the shift towards the use of these tools. They desired more agency over their healthcare journey and control of their health information, including their genetic test results. Participants imagined that through the use of a digital platform that they referred to as a 'digital binder', they could access, review and share their health-related information including personal and family histories and test results. Participants anticipated that increased access would enable patients to feel like equal and empowered partners in their care. Balancing a desire for digitally-enabled agency and sustained personal connections with providers, participants anticipated that digital tools could be tailored to each patient's circumstances and needs, enabling a personalized and partnered model of care. They recommended that digital tools be used as a supplement to current models of care rather than as a replacement.

Conclusion: Digital tools, like a 'digital binder' can supplement traditional genetic service delivery and have the potential to enhance patient-centered care, if used appropriately. These findings can inform the implementation and evaluation of digital health tools in genetics service delivery.

Univ. of Newfoundland, St. John's, NL, Canada, [6]Sunnybrook Hlth.Sci. Ctr., Toronto, ON, Canada, [7]Patient Partner, Toronto, ON, Canada, [8]Patient Partner, Vancouver, ON, Canada, [9]Univ. of Toronto, Toronto, ON, Canada, [10]Mem. Univ. of Newfoundland, St. John's, ON, Canada, [11]BC Cancer, Vancouver, BC, Canada, [12]Patient Partner, St.John's, ON, Canada, [13]BC Cancer / Univ British Columbia, Vancouver, BC, Canada

Introduction: Hereditary cancer syndromes (HCS) are one of the most common forms of inherited diseases, with Hereditary Breast and Ovarian Cancer Syndrome (HBOC) and Lynch Syndrome (LS) being the most prevalent. HCS patients are genetically more susceptible to developing cancer in their lifetime and often require consistent, lifelong screening and monitoring. Various facets of patients’ lives may be indirectly affected by their diagnosis and care. However, limited evidence describes the range of psychosocial impacts of HCS following a positive genetic diagnosis. The goal of this study is to describe the psychosocial & lifestyle impacts of HCS. Methods: Patients with a confirmed molecular diagnosis of HBOC or LS participated in semi-structured qualitative interviews. Patients were recruited from hereditary cancer clinics across 3 provinces with varying HCS health systems in Canada. Interpretive description was used to analyze the data. Results: Qualitative interviews were conducted with 73 patients (51 females, 21 males, 1 gender-diverse; age ranges 25-80yrs) diagnosed with HBOC (n= 39) or LS (n= 34). Cancer worry, the fear of oneself or one’s family members developing cancer, was a common concern for many patients rooted in a loss of control: “I worry I don’t have control”. As a result of their increased risk for cancer, patients described heightened symptom monitoring and concerns that unlikely symptoms (e.g. cold symptoms) were cancer-related. This cancer worry expanded to family members, and many parents expressed carrier guilt over possibly passing on their HCS to future generations. To cope with their cancer worry, patients described changes to their outlook to focus on the positive aspects of their diagnosis. To take control of their cancer, patients noted changes to their lifestyle, such as improving diet, exercise, and social activities. Additionally, some patients sought risk-reducing prophylactic surgeries to reduce their cancer risk, though they noted subsequent psychosocial and lifestyle impacts, such as challenges with body image and delaying family planning. Other strategies to gain control included joining patient groups, seeking professional therapy, or discussing their HCS journey with friends and family with similar lived experiences. Conclusion: A HCS diagnosis has broad psychosocial and lifestyle implications. Cancer worry is commonly expressed by many patients. In turn, this fear of developing cancer triggers changes to patients' lifestyles to take control of their cancer risk. This work emphasizes the need to provide multidisciplinary support to patients and families living with HCS beyond the point of diagnosis.

PB2342 "The reason you have anxiety is because you have this genetic disease": sources of anxiety and depression among individuals with inborn errors of immunity.

Authors:

K. Lewis[1], B. Beers[2], H. Davidson[2], M. Setzer[3], R. Gore[1], M. Kamen[4], C. Jodarski[5], H. Orellana[2], N. Reynolds-Lallement[2], D. Snyder[6], J. Yan[2], M. Walkiewicz[4], M. Similuk[7]; [1]Med. Sci. & Computing, NIH, Bethesda, MD, [2]NIH, Bethesda, MD, [3]NIH, Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, [4]NIAID, Bethesda, MD, [5]NIH, Washington, DC, [6]Natl. Inst.s of Mental Hlth., Bethesda, MD, [7]NIH, Bethesda, MD

Background: Inborn errors of immunity (IEI) affect as many as 1/2,000 live births. Genomic testing is often completed to ensure unequivocal diagnosis, optimal treatment, and accurate risk assessment. Roughly half of individuals with an IEI may report mild levels of anxiety, depression, or both. We aimed to describe sources of patients' anxiety and depression to inform the way providers address these concerns. **Methods:** Eligible participants were adults diagnosed with IEI who underwent genomic sequencing and had scores on a screening assessment in a range consistent with mild depression and/or anxiety (T-score >52.5 on Patient Reported Outcome Measurement Information System (PROMIS) 29 Profile v2.1) and above average adaptation (average >3.7 on Psychological Adaptation Scale) on a prior survey. Potential participants were contacted three times. Interviews were conducted by two interviewers using a semi-structured guide with questions about sources and experiences of anxiety and depression. Interviews were recorded and transcribed. Transcripts were coded and analyzed using an inductive, semantic thematic approach. **Results:** Twenty individuals (57.1%) participated. They were 32.3 years old on average. The most frequent diagnoses were common variable immunodeficiency (n = 5, 25%) and GATA2 deficiency (n = 5, 25%). Roughly half were women (n = 13, 65%) and seven had undergone hematopoietic stem cell transplant (35.0%). The most common theme was a bidirectional relationship between mental health and physical health. Most participants emphasized that uncertainty about their symptoms and prognosis caused feelings of anxiety and depression. Many felt lonely, isolated, or experienced social disruption due to their IEI (i.e., missing school or work for care or social distancing) which led them to feel anxious or depressed. Some recommended that providers assess patients' mental health, particularly because of the interrelatedness of their IEI and their mental health. As one participant said, "...They would help insofar as associating the fact that the depression had to do more with my fear of my disease than anything else. For a long time, I just felt like I separated those two things in my head."**Conclusions:** Participants endorsed symptoms of anxiety and depression as important considerations. It may be helpful for clinicians to acknowledge that aspects of IEI (i.e., chronic symptoms, uncertain prognosis, rarity) can contribute to feelings of anxiety and depression. We suggest that providers routinely screen patients with IEI for anxiety and depression and refer for further care, as needed. This study was limited by sample size and participant self-selection.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2343 A playbook for the implementation of genetics services and research in a developing country: a 10 year-experience from DR Congo

Authors:

A. Lumaka Zola[1,2], P. LUKUSA[1], K. Devriendt[3]; [1]Univ. of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [2]CHU LIEGE, Liege, Belgium, [3]Univ Hosp Leuven, Leuven, Belgium

Genomic medicine is an emerging discipline of medical science that requires accessing the genomic information of an individual and interpreting this information in relation to the present or future phenotype. Despite the enthusiasm and expectations generated by this discipline, the uptake in Low and Middle-Income Countries (LMIC) remains limited or very slow.
Since 2009, the Center for Human Genetics of Kinshasa (Democratic Republic of Congo, DRC) and the Center for Human Genetics of the KULeuven (Belgium) engaged in the implementation of genomic medicine in the DRC. The following steps were undertaken: (1) establishing both intra and extra-mural clinical service with pediatricians, (2) establishing a manual DNA extraction laboratory, (3) training clinicians and laboratory personnel both in the country and overseas, (4) creating visibility through publications in international peer-reviewed journals, (5) establishing international collaborations with research and philanthropic partners, while (6) applying for international grants.
As a result, a local network of hospitals and specialized schools is developed in the DRC; DNA extraction is supporting multiple research and clinical activities; nine Ph.D. and one lab technician have been trained in human genetics; more than 40 publications in genetics made in international peer-reviewed journals; a partnership is established with philanthropic programs such the Illumina iHope program (about 100 families have received clinical Whole Genome Sequencing), the UDNI and Wilhelm foundation (Champions Initiative), H3Africa (150 families tested with Whole Exome Sequencing through the NIH-funded DDD-Africa project); and international grants have supported the training and the purchase of additional laboratory equipment.
Altogether, this effort has created access to genomic services and provided the country with professionals that are able to handle genomic data and integrate genomic information into care in a LMIC. Without being perfect, our playbook will encourage those that are hesitant and lead to better uptake of genomic medicine.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2344 † A roadmap for precision prevention in primary care using a PRS enabled preventive intervention to promote lung cancer screening and smoking cessation

Authors:

L-S. Chen[1], T. Chen[2], G. Pham[3], L. Bierut[4], C. Amos[5], R. Hung[6], X. Lin[7], H. Zhang[8]; [1]Washington Univ. Sch. of Med., St. Louis, MO, [2]Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, [3]Washington Univ. Sch. of Med., St. Louis, MO, [4]Washington Univ Sch Med, St Louis, MO, [5]Baylor Coll. of Med., Houston, TX, [6]Sinai Hlth., Univ. of Toronto, Toronto, ON, Canada, [7]Harvard T.H. Chan Sch Pub Hlth, Boston, MA, [8]Natl. Cancer Inst., Cambridge, MA

Background: Lung cancer (LC) poses a significant global health challenge. Early detection and targeted intervention are crucial to reduce its morbidity and mortality. Polygenic risk scores (PRS) offer a robust tool for stratifying disease risk among populations and identifying high-risk individuals. However, their use remains limited in prevention practices in primary care with diverse populations. We aim to develop a PRS-based strategy for a precision prevention intervention to reduce lung cancer mortality. **Methods**: We developed a LC PRS for clinical application, calibrated on 2,504 individuals from the 1000 Genomes Project Phase 3 (1000G) and validated on over 340,000 patients of diverse ancestry from the UK Biobank (UKBB) and Genetically Informed Smoking Cessation Trial (GISC). We identified 101 SNPs out of 128 predictive SNPs from Hung et al. (2020) and constructed PRS using multi-ancestry summary statistics from Byun et al. (2022). We performed a Principal Component Analysis in 1000G and adjusted the PRS for genetic ancestry by regressing out the top five genetic PCs. We estimated the global cutoff points for adjusted PRS in 1000G, further validated in UKBB and GISC, and calculated the corresponding odds ratios (ORs) of LC for risk stratification across a diverse patient population. **Results**: Our methodology harmonizes the PRS distribution among different ancestries for equitable risk assessment without categorizing patients into discrete ancestry groups. To motivate lung cancer screening in eligible patients, we categorized their PRS into “risk”, “high risk” and “very high risk” groups based on the 1000G PRS distribution. Relatively to the “at risk” group, the overall ORs of LC, were 1.30 and 1.68 for the other two risk groups in UKBB. Notably, the OR for the “very high risk” group was significantly larger among non-European ancestry patients, though the case count was potentially insufficient to fully support this distinction. **Conclusion**: Our research offers an innovative PRS-enabled precision prevention intervention framework in primary care, especially for high-risk patients with actionable recommendations such as lung cancer screening and smoking cessation. The implementation and effectiveness of the PRS-enabled behavior change intervention, *RiskProfile*, will be evaluated in 1,625 diverse primary care patients and 140 physicians via two clinical trials. We also explore the translational roadmap for PRS, discuss barriers, potential solutions, and provide an innovative perspective on genetic risk-based health interventions.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2345 A systematic review of international adult Neurofibromatosis 1 surveillance frameworks.

Authors:

J. Chiang[1], S. Rana[2], C. Low[2], J. Koh[3], J. Ngeow[1]; [1]Natl. Cancer Ctr. Singapore, Singapore, Singapore, [2]NUS Yong Loo Lin Sch. of Med., Singapore, Singapore, [3]KK Women's and Children's Hosp., Singapore, Singapore

Background: Neurofibromatosis 1 (NF1) is an autosomal dominant tumour-predisposition condition commonly diagnosed in childhood and fully penetrant by adulthood. Long-term surveillance is cost-prohibitive and may cause variations in the monitoring of NF1 patients in high and low-income countries. Instrumental to adult NF1 care is the implementation of a surveillance framework by a multidisciplinary clinic. We aim to systematically review international surveillance strategies to 1) investigate any association between a country's socioeconomic status and differences in strategies used, 2) extract any existing surveillance framework for the implementation of a multidisciplinary adult NF1 clinic.
Methods: We searched PubMed, Embase, Web of Science and Cochrane. Relevant clinical information on the surveillance of clinical manifestations in adult NF1 patients worldwide was reviewed, extracted, and synthesised.
Results: We identified 51 papers reporting on 7724 individuals. Multiple imaging modalities are actively employed in developed countries for surveying adult NF1 patients. Interestingly, we did not find any relevant papers from less-developed countries. Internationally, there is also a lack of data on a consolidated surveillance framework to set up a multidisciplinary adult NF1 clinic. To address this, we provide a surveillance framework set by the National Cancer Centre Singapore for implementation in a multidisciplinary adult NF1 clinic in Asian countries.
Conclusion: This systematic review suggests that there is robust data on surveillance techniques for adult NF1 in high-income countries, but not for lower-income countries. There is also a lack of data internationally on surveillance frameworks to set up multidisciplinary adult NF1 clinics. Our provided framework will facilitate more effective monitoring of underserved patients in Asian countries. In addition, more research is warranted into the monitoring and surveillance of adult NF1 in lower-income countries.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2346 † A systematic way to find children with undiagnosed genetic diseases.

Authors:

Z. Tang, L. Jeffries, S. Lakhani; Yale Univ., New Haven, CT

Background: Although individually uncommon, rare diseases collectively affect 3-5% of the population and account for approximately half of total pediatric inpatient spending. Despite advances in molecular genomics, many patients still have descriptive diagnoses based on clinical signs and symptoms (i.e. infantile spasms or heterotaxy syndrome) and lack clear molecular genetic explanations. These patients may further be lost in "diagnostic odysseys" in search of a precise diagnosis that can lead to better prognostics, management, and family planning. Several advanced genetic diagnostic programs like Yale's Pediatric Genomics Discovery Program (PGDP) are freely available, but recruitment is patient-initiated and thus vulnerable to various healthcare access barriers inherent to the diagnostic odyssey. Thus, we sought to develop a reproducible, electronic health record (EHR)-based screening method to identify children with potentially undiagnosed rare diseases.
Methods: We developed a screening tool based on approximately 400 ICD-10-CM diagnostic codes, then queried the Yale New Haven Health System (YNHHS) EHR for hospitalized children between 2017-2022 with at least one screening code. Then, we manually reviewed patient charts to exclude patients with likely non-genetic or already confirmed genetic diagnoses. We used Pearson chi-square for categorical data, a multinomial regression model for predictors of PGDP enrollment, and Kruskal-Wallis one-way analysis of variance with pairwise comparisons with Bonferroni correction for multiple comparisons.
Results: Our EHR screen identified 1,648 potential undiagnosed patients. Manual chart review of the first 169 revealed that 4% were already enrolled in PGDP and 42% were previously unknown patients with potentially undiagnosed genetic disorders. A higher proportion of our screened cohort were Black (24%) and Hispanic (31%) relative to the general population or those enrolled in PGDP (p=0.033).
Conclusions: Our EHR screen identified a large number of previously unknown undiagnosed children as appropriate candidates for advanced diagnostic genetic evaluations. The missed group had over-representation of Blacks and Hispanics, suggesting that these groups are more likely to miss receiving precise genetic diagnoses.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2347 Adherence to risk management guidelines in individuals with hereditary cancer conditions in Singapore

Authors:

S. Jonnagadla[1], A. Lee[2], J. Yuen[1], J. Ngeow[1,2]; [1]Natl. Cancer Ctr. Singapore, Singapore, Singapore, [2]Nanyang Technological Univ., Singapore, Singapore

Background: Cancer remains the leading cause of death in many countries including Singapore. Up to 10% of cancer is associated with an inherited predisposition. There are globally established cancer risk management guidelines for inherited cancer conditions that include earlier, more frequent screening to detect cancer early or risk-reducing surgeries to prevent cancer. A preventive model of healthcare can reduce cancer morbidity, mortality and improves an individual's health-related quality of life. Assessing adherence to risk management is essential for service improvement and economic benefits to the patients and healthcare systems. This study aims to report adherence to risk management in individuals identified with inherited cancer conditions at the Cancer Genetics Service at the National Cancer Centre Singapore.
Methods and results: Medical charts of individuals with inherited cancer conditions identified between January 2014 to June 2022 were reviewed. Information on cancer screening, preventative surgeries and cancer detected post-genetic testing was collected for 489 eligible patients. The overall adherence to cancer screening and preventative surgeries was 88.9%, comprising of 308 (62.9%) fully adherent and 126 (25.9%) partially adherent patients. Adherence was higher in females (91.8%), individuals without family history of cancer (94.2%), individuals older than 60 years (96.3%), and individuals previously diagnosed with cancer (90%). Twenty-seven individuals (5.5%) were diagnosed with tumours/cancer through screening recommendations post-genetic testing. There were 226 individuals (46.2%) with hereditary breast and ovarian cancer syndrome. Of which, 38.2% females with this condition opted for bilateral mastectomy, 80.4% were managed with annual breast screening and 138 females (85.2%) underwent bilateral salpingoophorectomy. There were 74 (15.1%) Lynch syndrome carriers who were similarly adherent to colonoscopy and gastroscopy (77.5% and 75.9% respectively). Fifteen females (30%) with Lynch syndrome underwent prophylactic surgery to reduce their risk of endometrial and/or ovarian cancer.
Conclusion: The findings from this study indicate high adherence rates to recommended risk management among individuals with inherited cancer conditions in Singapore. This demonstrates value in identifying these high-risk individuals through genetic testing as carriers can avoid cancer morbidity and mortality. Genetic testing and counselling with emphasis on the benefits and utility of risk management strategies should be adopted to increase adherence in males and less adherent groups.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2348 An approach for standardizing and optimizing the process for genomic test order creation, sample intake, report generation, and result delivery for clinical whole genome sequencing including integration with tertiary analysis platforms.

Authors:

S. Lagu, S. Gabriel, N. Lennon, T. Desmet, J. Medrim, R. Onofrio, S. Matthews, K. Lewis, J. Tamulynas, D. Toledo, H. L. Rehm; Broad Inst. of MIT and Harvard, Cambridge, MA

The Broad Clinical Labs (BCL) is a CLIA-licensed and CAP-accredited clinical laboratory that to-date has provided over 200,000 clinical whole genomes (cWGS) to partner laboratories and clinical research programs. As genomics services become highly utilized and BCL's customer base increases, there is a need to be able to scale operations and to provide an improved user experience to our users across the clinical research and clinical diagnostic space. The solution also needs to be compliant with stringent patient privacy and information security regulations that ensure safety of patient data.

The vision behind our novel Sample Intake, Delivery and Reporting System (SIDR) is to provide an optimized, secure and compliant, self-service solution for users. This solution will provide a standardized process for order creation, sample intake and delivery of end results. The users will also be able to track real time sample status as it is being processed and data is analyzed thus minimizing repetitive manual touchpoints. The SIDR user-interface (UI) will provide both internal and external customers the ability to place their orders directly or organizations can use the API backend that will provide an automated ordering process for bulk orders. SIDR is a key component of the end to end data delivery system and will provide integrations with external platforms such as the terra.bio data repository and the Fabric genomics platform for clinical interpretation and reporting.

SIDR v1 was released earlier this year, allowing users to place orders for a variety of clinical whole genome sequencing based tests. These tests, broadly defined by their intended use include: a technical clinical genome (data and variants created under the clinical quality system) for users who are doing clinical research or have their own tertiary analysis capabilities; a screening genome that incorporates board-certified geneticist interpretation and report sign out of variants in defined gene lists such as actionable findings recommended by ACMG, and a diagnostic genome that ingests patient (and parental) phenotypic information to provide an indication-driven interpretation. A proprietary, genome-backed newborn screening panel has also been launched through the platform. We will present here the technical architecture of SIDR and the business processes that have been created to deliver clinical data files and reports to authorized users. This framework, and the lessons learned in building it, is broadly applicable to any group offering genomic services to the community.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2349 APHMG Undergraduate Medical Education Core Competencies in Genetics and Genomics: A framework and implementation example.

Authors:

L. Massingham[1], S. Nunez[2], J. A. Bernstein[3], D. P. Gardner[4], A. Parikh[5], E. T. Strovel[6], M. Ashfaq[7], R. J. LeClair[8], F. Quintero-Rivera[9]; [1]Warren Alpert Med. Sch. of Brown Univ., Providence, RI, [2]Yale Univ. Sch. of Med., New Haven, CT, [3]Stanford Univ Sch Med, Stanford, CA, [4]Marian Univ. Coll. of Osteopathic Med., Indianapolis, IN, [5]Univ. Hosp. Cleveland Med. Ctr., Cleveland, OH, [6]Univ Maryland, Baltimore, MD, [7]UTHlth.Houston McGovern Med. Sch., Houston, TX, [8]Virginia Tech Carilion Sch. of Med., Roanoke, VA, [9]Univ. of California Irvine (UCI), Irvine, CA

Discoveries in the field of genetics and genomics are expanding at a remarkable pace. This gained scientific knowledge is being translated into clinical practice with genomic information now being routinely used for preventative, diagnostic, and therapeutic decisions. As adoption of genomic medicine continues to evolve, health professionals will be required to stay abreast of genetic discoveries and technologies. Implementation of these advances within their scope of practice will be indicated. Therefore, medical school genetics curriculum must be periodically updated to ensure future physicians have the knowledge and tools necessary to provide optimal care for their patients. In 2022, the Association of Professors of Human and Medical Genetics (APHMG) updated the medical school genetics core competencies that were initially developed in 2013 (PMID: 36040446). The competencies were reviewed and updated through a structured approach incorporating a modified Delphi method. The updated APHMG core competencies will be presented to bring further awareness of this tool to those involved in medical genetics education (including teaching, leadership, and curriculum development, implementation, and assessment). The competencies are concise, specific, and assessable. Additionally, there are new updates that incorporate recent advances in clinical practice and promote equity and inclusion in clinical care. Competency based education provides the framework to shape the educational components into more clear and organized goals. One mechanism chosen by APHMG is to utilize these competencies as a framework to compile a Question Bank of board-style questions that are mapped to each of the 2022 competencies. This question bank is available on the APHMG Genetics Education Resource Exchange (www.aphmg.org/) for members to utilize in their courses in an easily accessible and searchable format. Use of these competencies across the undergraduate medical curricula will foster the knowledge, skills, and behaviors required in medical practice across a range of specialties.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2350 Assessing the Demographics of Clinical Genome Resource Members: an initial step toward enhancing diversity in an international consortium.

Authors:

E. Riggs[1], D. I. Ritter[2,3], B. VanHoute[1], J. Bulkley[4], M. DiStefano[5], M. Elnagheeb[6], I. McGregor[7], J. Berg[6], T. Klein[8], J. Morales[9]; [1]Geisinger, Danville, PA, [2]Baylor Coll. of Med., Houston, TX, [3]Texas Children's Hosp., Houston, TX, [4]Kaiser Permanente Ctr. for Hlth.Res., Portland, OR, [5]The Broad Inst., Boston, MA, [6]UNC Chapel Hill, Chapel Hill, NC, [7]Natl. Human Genome Res. Inst., Bethesda, MD, [8]Stanford Univ., Stanford, CA, [9]NHGRI, Bethesda, MD

The Clinical Genome Resource (ClinGen) is an NIH funded effort to create a central resource of clinically relevant genes and variants to improve genomic medicine. As part of the ClinGen Justice, Equity, Diversity and Inclusion (JEDI) initiative, we are committed to increasing diversity within our workforce. To identify areas for improvement and enhance JEDI principles across the consortium, we developed a survey to establish baseline characteristics of our consortium membership. Survey development was iterative and included evaluating multiple similar surveys, obtaining input from ClinGen working groups and external advisors, and guided interviews with both US-based and international participants. The survey was disseminated to 2098 ClinGen members in Nov - Dec 2022; 768 members responded (36.6% response rate). Overall, 64% (n=488) of ClinGen respondents are from the USA and 73% (n=544) self-identified as white. Sixty-five percent (n=497) of respondents identify as women, and 48% (n= 369) are between 25-44 years old. A broad range of professionals contribute to ClinGen, with the largest single group being clinical laboratory geneticists (21%, n= 145). The survey highlighted several gaps that we are actively addressing. For example, respondents self-identifying as Black/African-American (2%, n=17) or Hispanic/Latino (7%, n=49) were under-represented (using the 2020 US census data as a comparator), reflecting a systematic lack of representation in the ClinGen workforce. We are currently planning targeted outreach to organizations such as the Society for Advancement of Chicanos/Hispanics & Native Americans in Science with the goal of increasing participation. Though the majority of respondents identified as women, we identified a higher ratio of men in leadership roles; 45% of working group chairs were men though they made up 34% of total respondents. This constitutes ~30% fewer women chairs than expected (assuming that the proportion of women chairs should be equal to the proportion of women in ClinGen). We also found a lower ratio of Hispanic/Latino and Black/African American individuals in leadership roles (3% and 1%, respectively) compared to their overall representation in the consortium. We are issuing guidance to promote rotation of chairs so that under-represented participants can be promoted to leadership positions, as well as emphasizing education and awareness to ensure that expert panels are composed of diverse individuals at the outset. We aim for the leadership of ClinGen to reflect its participants , with the ultimate goal of enhancing diversity across the consortium in alignment with our JEDI Action Plan.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2351 Assessing the Diagnostic Odyssey in Pediatric Autism.

Authors:

K. Parsons[1], Z. Liu[1], M. K. Higashi[1], P. Kruszka[2], H. Raynes[3]; [1]Gene Dx, Stamford, CT, [2]GeneDx, Samford, CA, [3]Mount Sinai, New York, NY

Autism spectrum disorder (ASD) in the United States has an estimated prevalence of 21.5 cases per 1,000 children at 4 years of age (PMID: 36952289). The cumulative incidence of Autism Spectrum Disorder (ASD) up to 8 years suggests a prolonged diagnostic odyssey (PMID: 36952289). Identifying a genetic cause can inform patient care, making a compelling case for genetic testing. However, patients often endure a series of tests that may prolong the diagnostic odyssey. The purpose of this study was to describe the genetic testing workflow for ASD in a real-world setting and quantify cost of this diagnostic odyssey. A retrospective ASD cohort (2003-2021) was curated from a deidentified longitudinal dataset of 3.9 million patients from a major health system in New York State. Demographic and clinical variables were obtained from structured data. International Classification of Diseases (ICD-9/10) codes and Current Procedural Terminology (CPT) codes associated with a clinical ASD diagnosis and genetic tests were identified. Patients without procedures within 3 years prior to diagnosis and those older than 10 were excluded. Procedure charges were obtained from de-identified claims data for 2022.The cohort with an autism diagnosis (ICD-10 code) and a prior symptomatic code was 733. The most common CPT code was chromosomal microarray (141), followed by karyotype (120), FMR1 testing (112) and X-linked disability gene panel (94). Most patients had several testing procedures, with the majority of patients beginning their diagnostic journey with FMR1 testing (59%). The most frequent combination of tests was FRM1, Karyotyping and CMA. A sizable group of patients were tested by these methods as well as X-linked disability gene sequencing. The most expensive test was next generation sequencing (NGS) for X-linked disability genes (average charges $4,377 (95% CI $3,455-$5,408). Given that most ASD patients undergo numerous tests, total charges for several combinations were calculated. The most common pattern of tests in our cohort (FMR1, Karyotyping, and CMA) results in total charges of $3,410. Adding NGS increases this to $6,787. Our data suggests that a minority of children with ASD undergo genetic testing. Among those who do, most had tests with low diagnostic yields (0.5-2.0 % for FMR1 and 10-15% for CMA (PMID: 31182824)). Our results suggest that ASD patients and their caregivers face a significant diagnostic odyssey when stepwise testing is employed, representing a considerable cost burden. These results stress the need for clinical practice to align with current recommendations and to consider routine exome testing to reduce the ASD diagnostic odyssey.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2352 BAP1 tumor predisposition syndrome expert provider survey results.

Authors:

L. Byrne[1], C. Porteus[1], A. Kumar[1], H. Hanson[2], C. Cebulla[1], M. Abdel-Rahman[1]; [1]The Ohio State Univ., Columbus, OH, [2]SouthWest Thames Ctr. for Genomics, St. George's Univ. Hosp., London, United Kingdom

Objective: *BAP1* germline likely pathogenic/pathogenic variants (GPV) are associated with the hereditary tumor predisposition syndrome, BAP1-(TPDS) with an increased risk for uveal and cutaneous melanomas, mesothelioma, renal, and potentially other cancers. The phenotype and surveillance of BAP1-TPDS is still unclear. Thus, we created a survey to assess the current practices and challenges of medical providers of individuals with *BAP1* GPV. Methods: We invited healthcare providers from different specialties with expertise in the care of individuals with *BAP1* GPV to fill out a survey. Health care providers were selected based on either previous report(s) on *BAP1* GPV individuals and/or referring individuals with *BAP1* GPV to our study. Results: Out of 112 providers contacted, 51 (46%) completed the survey. Forty-three (84%) were physicians, 7 (14%) were Genetic counselors and one PhD geneticist. Twenty (39%) reported their specialty as Genetics and 11 (22%) Ophthalmology, and the majority work in an academic medical center and have 16 or more years' experience. The majority (55%) reported seeing ≥ 5 *BAP1* GPV individuals, with an additional 27% seeing more than one but <5. Regarding tumors that should be included in screening, there was high concordance on the four main cancers: uveal melanoma (94%), cutaneous melanoma (90%), renal cancer (88%) and mesothelioma (84%). However, there was less agreement for other cancers such as basal cell carcinoma (47%), bile duct cancer (25.5%), breast carcinoma (13%), ovarian carcinoma (13%), hepatocellular carcinoma (10%), and meningioma (6%). For cancer surveillance, variations in the age of onset, frequency and modality were reported. With respect to germline genetic testing of *BAP1*, 92% of providers would offer testing where there is known familial GPV, 90% for an individual with two BAP1 associated tumors, 86% for an individual with one BAP1 associated tumor and one in a first or second degree relative, 65% to an individual with early age of onset of a *BAP1* associated tumor (40 or younger), and 31% following identification of somatic *BAP1* mutation in a tumor. Conclusions: Although, most providers with experience in management of individuals with germline variants in *BAP1* agree on the association of *BAP1* GPV with four main cancers (uveal and cutaneous melanomas, renal cell carcinoma and mesothelioma), the contribution to predisposition to other cancers is still not clear. However, there is still variation in many of the aspects of preventive surveillance strategies for individuals with *BAP1* GPV including the age of onset to start surveillance for each cancer and the frequency and modality of such surveillance.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2353 † Barriers and Successes in Providing Genetic Cancer Risk Information to Families of Patients who are Deceased: Experiences of the Genetic Risk Analysis in Ovarian Cancer (GRACE) Study

Authors:

J. Hunter[1], Y. Prado[2], A. Reyes[2], J. Zepp[2], M. Maiyani[3], J. Sawyer[3], L. White[3], S. Vertrees[4], A. Rope[5], S. Weinmann[2], S. Lee[6], N. Henrikson[7], H. Feigelson[3]; [1]RTI Intl., Research Triangle Park, NC, [2]Kaiser Permanente Ctr. for Hlth.Res., Portland, OR, [3]Kaiser Permanente Colorado, Aurora, CO, [4]Kasier Permanente Ctr. for Hlth.Res., Portland, OR, [5]Genome Med., San Francisco, CA, [6]Columbia Univ., New York, NY, [7]Kaiser Permanente Washington Hlth.Res. Inst., Seattle, WA

The Genetic Risk Assessment in Ovarian Cancer (GRACE) study aims to identify families with an increased susceptibility for cancer by offering genetic testing to individuals with a prior diagnosis of ovarian cancer (OC). One goal of the study is to test the feasibility of providing genetic information to relatives of individuals who are deceased. Search of tumor registry data at two health care systems (Kaiser Permanente Northwest and Colorado) identified cases of OC diagnosed 1998-2020 who either did not have genetic testing or had genetic testing limited to *BRCA1/2* and could benefit from testing with a comprehensive panel of cancer risk genes. Of all patients with a diagnosis of OC identified, 943 were deceased (roughly half of the total 1874 cases), 72% of which had no genetic testing and an additional 10% had testing of BRCA1/2 only, representing a significant care gap for receipt of genetic risk information for these families. However, challenges arose in recruitment of families of individuals who are deceased. First, legal and regulatory guidance on family contact and health information disclosure impacted who the study team could contact and what information could be communicated about the patient's cancer history. Second, planned germline genetic testing of archived pathology specimens was not always successful. Despite these challenges, recruitment of families of individuals who are deceased has moved forward; when testing of the pathology specimen is not successful or feasible, first-degree relatives of the individual are directly offered germline testing. To date, relatives of 25 individuals who are deceased have been contacted, with at least 1 member from 12 of the families consenting to testing, a 48% recruitment success rate for families. This uptake of testing by families of patients who are deceased reflects a strong interest in genetic risk information. However, practical barriers must be addressed to provide genetic risk information on a broader scale. Overall, the GRACE study can inform implementation of future programs across health care systems, providing life-saving information to prevent and mitigate the burden of ovarian and other hereditary cancers.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2354 Building awareness, respect, and confidence about genetics through science education partnerships.

Authors:

R. O'Malley, N. Vincenten, R. Bowman, G. McNeil, H. Kim, T. Wu, M. Gelbart; Harvard Med. Sch., Boston, MA

The Building Awareness, Respect, and Confidence through Genetics (ARC) project (2016-2021) empowered high school teachers to facilitate dialogue about genetics advances and societal impacts within classrooms and in their communities. Components included a) professional development workshops, b) new curricula resources refined through input from teachers, c) building a community of practice to support teachers, and d) sharing and learning within schools and communities about recent advances in genetics, including their potential benefits and ethical, legal, and social implications. The five-year project supported 17 in-person and two virtual workshops. Teacher attendees (n=396) collectively reached an average of 5,100 students annually. Seven (7) lesson plans and 19 distance learning resources were created, the latter in response to educators' needs during the COVID-19 pandemic.

An evaluation based on pre- and post-workshop surveys as well as annual follow-ups found that a) teachers' interest in teaching genetics is very high; b) teachers' confidence in conversations about genetics topics increased after workshop participation; c) teachers' knowledge increased in all measured topic areas; and d) according to teachers, personal genetics topics interest and engage students. Anecdotal evidence indicates that lessons learned in class spread beyond the classroom setting through conversations with peers and family members. The most prevalent barrier to implementation by educators was lack of time.

The project resource library continues to grow with new or revised resources for educators, to ensure that up-to-date classroom-ready materials for teaching genetics are free and easily accessible online. Future studies would benefit from evaluating project impacts on the students themselves in addition to teacher perceptions.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2356 Carrier screening testing: Assessing advantages and limitations through a small consultant group.

Authors:

K. Rocha[1,2], M. Lazar[1,2], M. C. Varela[1,2], K. Bagatini[1,2], D. G. Franco[1,2], V. N. V. Takahashi[1,2], J. Y. T. Wang[1,2], M. R. Passos-Bueno[1,2]; [1]Human Genome and Stem Cell Res. Ctr., Univ. of São Paulo, São Paulo, Brazil, [2]Dept. of Genetics and Evolutionary Biology, BioSci.s Inst., Univ. of São Paulo, São Paulo, Brazil

In order to evaluate the benefit of offering a carrier screening investigation to larger segment of the Brazilian population, we have reassessed the results of individuals referred to our laboratory for carrier screening testing in the last years. Using a panel containing 234 to 340 genes associated with recessive and X-linked conditions we have performed 79 carrier-screening tests, comprising, altogether, 53 potential couples. For 27 couples, both partners were genotyped, while for the remainder, only one partner (21 female / 5 male) was tested. 62,3% of couples reported consanguinity or have been born in small nearby towns; 56,6% reported a previous, in most cases, undiagnosed genetic condition affecting themselves, their offspring, or another family member and, 24,5% informed both (consanguinity and a previous condition). Among consanguineous couples which both partners were tested, we have identified shared pathogenic variants in 47,1%, including all those who declared a deceased child or pregnancy loss. It was identified pathogenic variants in same gene in three out of nine non-consanguineous couples (both genotyped): one had reported a deceased child; one had likely pathogenic variants in *USH2A* and one was an IVF case with egg donation (*GJB2* gene). Though small, this cohort indicates the relevance of offering a broader program of carrier screening that might include not only at-risk families or manifestly consanguineous couples, but also couples from small towns. Although continentally large, Brazil has several isolated populations that might benefit from a carrier-screening program. Besides, the inclusion of fertility clinics should also be considered.
FAPESP/CEPID 13/08028-1

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2357 Cascade testing, reach, and acceptability or health system contact of at-risk relatives: pilot trial results.

Authors:

N. Henrikson[1,2], J. Zepp[3], P. Blasi[4], A. Scrol[4], M. Anderson[1], J. Ewing[1], J. Ralston[5], S. Fullerton[2], K. Leppig[6]; [1]Kaiser Permanente Washington Hlth.Res. Inst, Seattle, WA, [2]Univ. of Washington, Seattle, WA, [3]Kaiser Permanente Northwest Ctr. for Hlth.Res., Portland, OR, [4]Kaiser Permanente Washington Hlth.Res. Inst., Seattle, WA, [5]Kaiser Permanente Washington Hlth.Res. Instisute, Seattle, WA, [6]Kaiser Permanente of Washington, Seattle, WA

Cascade testing can improve outcomes for at-risk relatives of people with pathogenic variants associated with cancer risk, yet many relatives never learn of their risk. We piloted a new direct contact program where the care team contacts relatives to offer cascade testing for hereditary cancers. We co-designed the program with patients and families; key requirements included pre-test consent of probands and relatives to participate in the program and that the program should complement, not replace, existing patient-mediated disclosure. We assessed feasibility, acceptability, and limited effectiveness of the program. METHODS We conducted a single-arm, prospective mixed-methods intervention study at one U.S. integrated health system. We recruited adult probands awaiting pre-test genetic counseling for cancer risk; offered to contact at-risk relatives after testing; and contacted relatives to recommend cascade testing. We surveyed all study participants at 6-8 weeks to assess relative uptake of genetic testing and program acceptability. We assessed proband genetic testing outcomes using administrative data. We conducted semi-structured interviews with program participants and triangulated the results with survey data. RESULTS We invited 148 probands to participate in the study; 37% (n=55) enrolled. Enrolled probands were mean age 58; 75% female (n=41), 88% White race (n=45); and 7% Hispanic. The majority (69%, n=37) were married; 58% (n=31) reported college education or more. Half of probands (n=28, 51%) requested direct contact of relatives and provided consent to contact 101 relatives; 44% (n=45) of relatives consented to be contacted. We interviewed 32 participants from 22 families. Survey and qualitative data found high program acceptability for both probands and relatives. 83% of probands reported the program helped their family and 56% reported that relatives only learned of their risk because of the program. Of 35 probands with test results returned, 5 received pathogenic findings. At 6-8 weeks (n=40 relatives), 3 (8%) had received genetic testing; one of these three relatives reported a cancer risk-associated pathogenic variant. Five additional relatives (15%) reported plans to have genetic testing. CONCLUSIONS The direct contact program was acceptable and successfully reached at-risk relatives. The program worked as intended as a complement to patient-led disclosure. Future implementation efforts should seek to balance family preferences for pre-test consent and focusing outreach efforts on patients and families with confirmed pathogenic findings.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2359 Clinical genetics and genetic counselling external quality assessment (EQA) provision.

Authors:

M. Tabiner[1], K. Rack[1], R. Hastings[2], Z. Deans[2]; [1]GenQA, Oxford, United Kingdom, [2]GenQA, Edinburgh, United Kingdom

Background/Objectives: GenQA offers global external quality assessments (also known as proficiency testing) for the entire clinical genomics service. Clinical Genetics educational case scenarios allow an external assessment of patient consultations and counselling whilst over a hundred other programs assess laboratory processes, interpretation of results and reporting procedures. Since 2014, clinicians have been able to participate in a customised EQA program and subsequently review their clinical practice, learn from peers and demonstrate continuing professional development. EQAs for all clinical genetics disciplines are now available: dysmorphology; cardiovascular disorders; monogenic disorders; oncogenetics; inborn errors of metabolism. A separate program focussing exclusively on Genetic counselling is also offered. A new pilot EQA for Genomic multi-disciplinary team (MDT) working will be introduced in 2023.

Methods: Annual online multi-stage case scenarios which follow the patient pathway and reflect real clinical cases are provided for each EQA. Information regarding the clinical presentation of the proband is provided on a bespoke website, followed by specific questions about the initial consultation. Further details are provided sequentially and access to subsequent stages is blocked until all answers in a stage have been submitted. Participants in the Clinical Genetics EQAs must request appropriate genomic investigations and then interpret the results provided to establish a clinical diagnosis. There are also questions assessing the consequences of the diagnosis and content of the post-test appointment. Submissions are marked according to professional standards by an expert panel of international clinicians. A tailored score report with feedback comments and a participation certificate are provided to each centre.

Results: Satisfactory participation in these EQAs evidences training to a recognised level and demonstrates ongoing professional competency. The detailed EQA Summary Reports provide the expected answers and learning points for the case scenarios together with an overview of performance. These can be used for benchmarking the quality of clinical services provided.

Conclusion: These EQAs provide a mechanism for continuous assessment against agreed quality standards and therefore provide valuable training and educational opportunities for Clinical Geneticists and Genetic Counsellors. Participation in EQA can refine best practice and ultimately improve the quality of care for patients.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2360 Clinical Genome Resource Variant Classification and Curation Interface Workshops: Collaboration with Genetics Organizations in Low and Middle Income Countries.

Authors:

D. Ritter[1], F. Ali[1], A. Dalal[2], M. Hegde[3], R. Julius[4], A. Lumaka[5], A. Moirangthem[6], J. Morales[7], S. Phadke[6], A. Santani[8], K. Riehle[1], S-A. Yang[1], M. Mandell[9], M. Wright[9], T. Klein[9], S. Plon[1]; [1]Baylor Coll. of Med., Houston, TX, [2]Ctr. for DNA Fingerprinting and Diagnostics, Hyderabad, India, [3]PerkinElmer, Waltham, MA, [4]H3Africa CC, Univ. of Cape Town, Cape Town, South Africa, [5]Univ. of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [6]Sanjay Gandhi PGIMS, Lucknow, India, [7]NHGRI, Bethesda, MD, [8]Lets Get Checked, Monrovia, CA, [9]Stanford Univ., Palo Alto, CA

The Clinical Genome Resource (ClinGen) is an NIH funded effort creating a central resource of clinically relevant genes and variants to improve genomic medicine. Dissemination of ClinGen's work is critical to ensure broad uptake. Recently ClinGen has focused on multiple educational approaches including educational workshops of genomics professionals to increase understanding of variant classification and use of ClinGen tools. Here we report the results of our recent outreach efforts to genetics professionals in low and middle income countries (LIMCs). In the last year, two dedicated workshops were held on variant classification using the ClinGen Variant Curation Interface (VCI). An in-person satellite workshop to the annual meeting of the Society for Indian Academy of Medical Genetics in India (83 participants) focused on ACMG/AMP variant classification and use of the VCI. Following an overview of classification guidelines and the VCI, participants were randomly divided into ten groups to work as teams on curating progressively challenging variants within test instances of the VCI. Although no post-workshop survey was given, feedback on better understanding of variant classification was received and we identified 14 new active user accounts from India in the production version of the VCI. We built on this experience for a virtual workshop with genetics trainees and professionals from Human Hereditary & Health Africa (H3Africa). The 3hr workshop provided a brief orientation to the ClinGen VCI and Allele Registry. The 61 participants were divided into country-based breakout rooms (from 6 countries) of 5-10 people with a "ClinGen lead" experienced in VCI curation. Information from the post-workshop survey (n=34, 55% response rate) revealed that participants were split between those with no or little experience versus those with substantial experience in variant classification (ACMG Classification: 12 inexperienced vs 22 experienced). Post workshop, 30/34 respondents would likely use the VCI, 30/32 requested annual VCI training, and 29/24 preferred future workshops be structured in shorter sessions over multiple days. Open text responses described a preference for teams based on prior experience. We identified 15 active user accounts established after the workshop, with a total of 3 affiliations from laboratories in Africa. These efforts showed that whether in-person or virtual, interactive training workshops resulted in VCI user uptake among 20% (29/144) of participants. Engagement with international genetic organizations has helped develop a workshop model to aid in uptake of genomic resources supporting genomic medicine in LMICs.

Hlth., Univ. of Toronto, Toronto, ON, Canada

Introduction: Guidelines prioritize medically actionable secondary findings (SFs), but a broader spectrum of medically relevant results can be returned. We characterized the clinical utility of all types of medically relevant SFs by evaluating yield and changes to patient management. **Methods:** Observational intervention study in an RCT (Incidental Genomics RCT, NCT03597165). Adult cancer patients had genomic sequencing (GS) with return of primary cancer findings and option to learn multiple categories of SFs: medically actionable, Mendelian, early-onset neurodegenerative, carrier status, common disease risk, and pharmacogenomic (PGx) variants. Variants in patients' chosen categories were classified following ACMG/AMP criteria. P and LP variants were reported as SFs and returned by study genetic counselors (GC). GS reports and consult letters with recommendations from study GC and medical geneticist were sent to patients and their family doctors. Yield and clinical management changes were collected through chart review and patient-reported surveys up to 1 year after SF return. **Results:** Participants (n=139) were 85.7% female, average 55.1 years old, and 60.7% White/European. Overall, 100% of participants had ≥1 SF reported; 98.5% had multiple SFs. Yield was highest for PGx variants (97.8% of participants), followed by carrier status (90.1%), common disease risk (89.4%), Mendelian (27.4%), medically actionable (15.2%), and early-onset neurodegenerative (2.6%) variants. 1.4% of participants had SFs in ACMG-recommended genes. Overall, 19.4% of participants had a change in medical management attributed to their SFs, mainly appointments with specialists (11.5%) and family doctors (8.6%). Management changes were completed among 47.6% (10/21) of patients with medically actionable findings (e.g., medical genetics consultation), 29.4% (10/34) with Mendelian findings (e.g., imaging), 66.7% (2/3) with early-onset neurodegenerative findings (e.g., medical genetics consultation), 1.7% (2/118) with carrier status findings (e.g., family doctor appointment), 2.2% (3/135) with PGx variants (e.g., medication change), and 2.2% (2/118) with common disease risk variants (e.g., ophthalmologist consultation). **Conclusions:** Yield of SFs was high, largely due to reporting carrier status, PGx and common disease risk variants. SFs demonstrated clinical utility by prompting changes in patient management, including results that were not considered medically actionable. This implies potential benefits of returning a wide range of SFs; longer-term studies are needed to determine if management changes improve health outcomes.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2362 Clustering of heritability beliefs across diseases, traits, and individuals.

Authors:

S. Persky; Natl. Human Genome Res. Inst., Bethesda, MD

Introduction: Individuals' beliefs about the extent to which diseases and traits are heritable varies depending upon life experience, exposure to educational content, and broader biological and social belief systems. Heritability belief patterns can reflect intuitions and normative ideas underlying their formation and suggest ways beliefs might generalize based on shared underlying characteristics. In a practical sense, these beliefs are associated with behavioral and psychological response to health risks. Moreover, they have been tied to differential support for structural health policy programs with health equity implications.
Method: Data from an online survey panel (N=742) on heritability beliefs (rated 0-100%) for 30 traits and diseases were assessed for emerging clusters using hierarchical clustering. Individual cases were assessed using k-means cluster analysis for 4 participant clusters which were evaluated for demographic differences in membership.
Results: Four clusters of traits and diseases emerged with varying average perceptions of heritability; A) phenotypes with little perceived behavioral influence (type 1 diabetes; height), M=75, SD=18, B) common complex diseases (e.g., type 2 diabetes), M=49, SD=17, C) behavioral traits (e.g., tendency to eat in the absence of hunger) and cancers with well-known behavioral factors (e.g., melanoma), M=20, SD=19, D) biological characteristics (e.g., brain structure), M=60, SD=23. Participant cluster membership varied significantly by self-reported racial group, sexual minority status, gender, parental status, and age. Cluster membership did not differ by education, ethnicity, or BMI. Participant cluster 1 had high heritability beliefs across each trait/disease type and had disproportionately high gender and sexual minority and female membership. Cluster 2 was marked by relatively low heritability beliefs for biological characteristics alongside average heritability beliefs for other condition types and had high rates of female and parent membership. Cluster 3 had high heritability beliefs for trait clusters A and D, low for B and C and was disproportionately populated by White, male, non-parent individuals. Cluster 4 had the lowest levels of all heritability beliefs and had a high proportion of Black and male members.
Conclusion: Heritability beliefs across diseases and traits cluster relatively neatly in accordance with common conceptions of genetic and behavioral causal factors. Notably, participant clusters were unrelated to formal education and membership patterns suggest important sociocultural and lived experience forces underlying belief formation.

PB2363 † Community engagement in the development of genomic medicine research: Enrollment experience from the BabySeq Project

Authors:

S. Walmsley[1,2], B. Zettler[1,2], C. R. Horowitz[3,4], C. Genetti[5], S. Edwards[6], R. C. Green[1,2,7,8], I. A. Holm[5,8]; [1]Dept. of Med., Mass Gen. Brigham, Boston, MA, [2]Ariadne Labs, Boston, MA, [3]Dept. of Med., Icahn Sch. of Med. at Mount Sinai, New York, NY, [4]Dept. of Population Hlth.Sci. and Policy and Inst. for Hlth.Equity Res., Icahn Sch. of Med. at Mount Sinai, New York, NY, [5]Div. of Genetics and Genomics, The Manton Ctr. for Orphan Disease Res., Boston Children's Hosp., Boston, MA, [6]E.WE Fndn., Huntsville, AL, [7]Broad Inst., Cambridge, MA, [8]Harvard Med. Sch., Boston, MA

Introduction: Partnering with community and clinical stakeholders in research design and conduct may help develop studies that are practical, engaging and encourage diverse participation in research. We studied whether these stakeholder partnerships could increase diversity of participants in the BabySeq2 Project: a randomized controlled trial of genome sequencing (GS) in infants.
Methods: We convened a diverse Community Advisory Board (CAB) with representation from all recruitment cities (Boston, MA; New York, NY; Birmingham, AL) to provide input via virtual quarterly meetings with study staff. We also built partnerships with pediatricians in general practices, briefly trained them in genomics, and embedded research assistants from local communities at their practices to recruit families. CAB input was influential in several key domains. 1) We revised the protocol to require the consent of only 1 parent/guardian as the CAB felt a 2-parent requirement would be exclusionary. 2) We simplified and clarified consent language. 3) The CAB contributed to the formative research (qualitative and survey) used to develop protocols and recruitment procedures. 4) We changed the infant sample type from a venous draw to a heel stick. 5) We changed randomization to occur before sample collection and to not collect samples from the control group due to concerns of potential distress from unnecessary and uncomfortable testing, and skepticism over how secondary samples were used or destroyed.
Data Analysis: We compared the uptake rate and demographics (race; ethnicity; education; household income) of families recruited in BabySeq1, our prior study of newborn GS, with recruitment to date in BabySeq2. We analyzed between-group differences using Fisher's exact test.
Results: The overall uptake rate of BabySeq2 is significantly higher than BabySeq1 (13.8% vs. 6.9%, $p<0.001$). Additionally, families in BabySeq2 are significantly more likely to identify as non-White (91.9% vs. 17.6%, $p<0.001$), Hispanic (35.1% vs. 7.4%, $p<0.001$), have an education below a bachelor's degree (65.6% vs. 8.3%, $p<0.001$), and have a household income under $150,000 (92.9% vs. 43.7%, $p<0.001$).
Discussion: The uptake rate of the current BabySeq2 study is nearly double that of BabySeq1, and the currently enrolled cohort is significantly more diverse and nationally representative than in BabySeq1. Early recruitment experiences suggest that engaging with local communities and clinicians and recruiting in diverse practices can increase uptake and diversity in genomic research.

PB2364 Concept and Awareness of Genetic Counseling among Intersex Individuals in Pakistan.

Authors:

Z. Tariq, M. Rida, T. Ahmed, I. Yasin; Kinnaird Coll. for Women Univ., Lahore, Pakistan

The embodiment of gender with respect to the assigned biological sex plays an important role for a person to be recognized as male, female, or intersex i.e., atypical sex due to sexual variation at the chromosomal, gonadal, hormonal, or genital level. Biological perspective of intersexuality is not understood by many stirring extreme discrimination, violation, and stigmatization for the innate carnal ambiguities in intersex individuals. Altered genetic make-up might be the fundamental reason that might also be unknown to affected individuals whom could be informed, and supported through genetic counseling. This cross sectional study was conducted to determine the socio-economic factors, social dilemmas, depression, and genetic counseling scope among intersex individuals. A survey-based questionnaire having 50 questions including Hamilton Depression Rating Scale (HDRS) was filled by 90 intersex individuals. Descriptive Statistics, Univariate and Bivariate analyses, Pearson Correlation Tests, and Linear Regression Analysis using SPSS version 21 were applied. 33.33% male, female, and intersex genders each were assigned at birth. However, with the gonadal and hormonal changes, 6.7% considered themselves males, 40% females, and 53.3% intersex. One sample T-test indicated significant association of depression score (p=0.000), lack of support score (p=0.000), and awareness and need of genetic counseling score (p=0.00). One-way ANOVA confirmed significant association of marital status (p=0.006), societal discrimination (p=0.024), and familial support (p=0.02) in development of depression, and education (p=0.047), income (p=0.042), and governmental facilities (p=0.049) in lack of support. Genetic counseling awareness and need was significantly correlated with genetics knowledge (p=0.000), will to undergo genetic counseling (p=0.003), availability and accessibility (p=0.021), previous genetic counseling experience (p=0.000), and scope of genetic counseling (p=0.003). Linear Regression analysis confirmed the significant role of availability and accessibility (p=0.001), and previous genetic counseling experience (p=0.000) in the need and awareness of genetic counseling among the targeted population. To our knowledge, this is the first study on intersex individuals in this aspect worldwide. Severe gender-based societal discrimination and stigmatization of the intersex community leading to lack of support and development of depression in these individuals has been found. Poor genetic counseling services are another major drawback in providing relevant support to these individuals for which significant work has to be done.

PB2365 Consultagene: design and experience of a tele-genetic academic platform supporting genetic consultation, patient and provider education, and research engagement.

Authors:

D. Riconda, K. C. Worley, A. M. Wallis, C. A. Shaw, C. M. Holder, S. A. Nassef, S. A. Darilek, S. R. Lalani, B. Vuocolo, R. A. Sierra, P. L. Magoulas, S. M. Huguenard, B. H. L. Lee, Consultagene Group; Baylor Coll. of Med., Houston, TX

Introduction: Increasing use of genetic testing in medicine expands the need for genetic engagement and education for patients, caregivers, providers, and research participants. We designed an education platform for our academic medical department that is agnostic to use or configuration of Electronic Health Record systems and that supports different uses. **Methods:** The Consultagene platform is implemented with a secure computational infrastructure and supports different user roles (genetic provider, referrer, and client) with different types of interaction including content and activities for educational only, patient consultative, peer-to-peer and research engagement. Educational content was developed by our experienced geneticists and genetic counselors with focus group input from community members and reviewed for utility and understanding by platform users. **Results:** We have successfully implemented this platform in outpatient pediatric, adult, and prenatal genetic services. To date, 877 pediatric and 1456 prenatal/preconception educational journeys have been referred through the platform. We surveyed patients/parents on their satisfaction and understanding of two of our core educational videos. The majority (75 to 94%) of participants responding had positive assessments of the content and 73% reported improved understanding of the material. These numbers have been stable over time. Consultagene is being used for engaging in research studies including Project GIVE (UG3TR004047) where the platform is being used for outpatient genetic evaluation and return of WGS results for children living along the Texas-Mexico border. Since May of 2022, the PIs have engaged pediatricians at the University of Texas Rio Grande Valley (UTRGV) and community front-line providers in referring over 75 Hispanic individuals with undiagnosed rare genetic diseases and have accepted 50 pediatric patients for evaluation. Providers such as these who lack local access to geneticists are seeking peer-to-peer engagement with the platform as independent providers. **Conclusion:** The Consultagene platform supports genetic engagement in clinical practice, peer-to-peer consultation, and research applications with educational journeys that can be configured for different use cases. The materials and access are valued by patients and physicians. The platform enables genetic engagement that can reach to the populated but remote regions of Texas hundreds of miles from any genetics services.

Lerner-Ellis[15]; [1]Univ. of Toronto, Toronto, ON, Canada, [2]Unity Hlth.Toronto, Toronto, ON, Canada, [3]St. Michaels Hosp. & Univ. of Toronto, Toronto, ON, Canada, [4]St. Michael s Hosp., Toronto, ON, Canada, [5]Unity Hlth.Toronto - St. Michael s Hosp., Toronto, ON, Canada, [6]The Marvelle Koffler Breast Ctr.-Mount Sinai Hosp., Toronto, ON, Canada, [7]Zane Cohen Ctr. for Digestive Diseases, Mount Sinai Hosp., Toronto, ON, Canada, [8]Bhalwani Familial Cancer Clinic, Princess Margaret Cancer Ctr., Toronto, ON, Canada, [9]Odette Cancer Ctr., Sunnybrook Hlth.Sci. Ctr., Toronto, ON, Canada, [10]The Marvelle Koffler Breast Ctr., Mount Sinai Hosp., Toronto, ON, Canada, [11]Dept. of Family & Community Med., Univ. of Toronto, Toronto, ON, Canada, [12]Sanofi, North Bergen, NJ, [13]Dept. of Med. Genetics, The Univ. of British Columbia, Vancouver, BC, Canada, [14]Dalla Lana Sch. of Publ. Hlth., Univ. of Toronto, Toronto, ON, Canada, [15]Pathology & Lab. Med., Mount Sinai Hosp., Sinai Hlth., Toronto, ON, Canada

Background: Genomic sequencing (GS) can generate a large volume of incidental results (IR), which have varying levels of clinical actionability. Although preference studies show that patients want all types of results, there is limited real-world evidence evaluating preferences of patients undergoing sequencing and actual return of IR. Here, we report preferences and changes in preferences among patients undergoing GS and return of all types of IR. Methods: We conducted analysis of preference data generated within the Incidental Genomics Trial (NCT03597165). Participants were adult cancer patients who previously received uninformative cancer panel results. Patients were offered GS and randomized to receive either cancer (control) or cancer+incidental results (intervention). Intervention participants chose between 5 IR categories: 1) actionable 2) common disease SNPs (i.e. polygenic risks), 3) Mendelian disorders, 4) early-onset brain disorders and 5) carrier status. Participants made selections at a pre-test counseling appointment and had the option to change preferences at a 1-week check in appointment. We analyzed preferences and changes using descriptive statistics. Results: 144 participants were randomized into the intervention arm, and were predominantly female (86%) of European ancestry (60%) with breast cancer history (57%). At the pre-test counseling appointment, participants were very interested in all categories, even those without clinical actionability. Nearly all participants (99%;142/144) chose actionable findings, 92% (133/144) chose carrier status, 90% (129/144) chose polygenic risks, 87% (125/144) chose Mendelian diseases and 81% (117/144) chose brain diseases. Three quarters (74%;106/144) chose all categories. At the 1-week follow up, 13% (18/144) changed preferences. The most common changes were for early-onset brain diseases: 8 participants added this category while 4 removed it. Conclusions: The majority of our participants selected to receive all types of IR, including those without actionability. A minority of patients changed selections at the follow-up appointment. Overall, the early-onset brain disease category had the least interest and most preference-sensitive changes, which aligns with current clinical practices that employ extensive genetic counseling protocols for patients undergoing testing for early-onset brain diseases. Our results emphasize the need for incorporating patient preferences, along with clinical evidence and costs, into future guidelines and highlight the importance of dynamic genetic counseling that provide patients an opportunity to reflect and change preferences.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2367 Cytogenomic characterization of breakpoints involving chromosome 8 in some Egyptian patients.

Authors:

S. Abd Allah[1], M. Mekkawy[1], A. kamel[1], E. Ashaat[2], M. Yousry[2], O. Eid[1], A. Mohamed[1]; [1]Human Cytogenetics, Natl. Res. Ctr., Cairo, Egypt, [2]Clinical genetics, Natl. Res. Ctr., Cairo, Egypt

Structural abnormalities of chromosome 8 have been reported in at least 1300 patients. Deletions of chromosome 8 may occur as an individual abnormality or with other chromosomal defects. Deletions of the short arm mostly occur with partial duplication for more proximal segments of 8p.
We report 5 patients with chromosome 8 rearrangements, presented to the Human Genetics Clinics and referred to the Cytogenetics department at the National Research Centre, Egypt.
The patients underwent clinical examination, IQ evaluation, anthropometric measurements, and imaging analysis. Karyotyping was performed for the patients and parents using GTG banding technique on peripheral blood lymphocytes. Fluorescence in situ hybridization (FISH) analysis was conducted using 8p & 8q subtelomeres probe set, whole chromosome painting 8 probe and other necessary probes when needed. Chromosomal microarray (CMA) analysis was performed using Genome-Wide Human SNP Array 6.
The patients' ages ranged from 4-10 years old. They were 3 males and 2 females. All exhibited distinctive dysmorphic features and intellectual disabilities (ID) ranging from mild to severe. They also had variable associated anomalies affecting the limbs, brain and heart. The karyotype analysis revealed in female and male siblings 46,XX,der(12) and 46,XY,der(12) respectively that were derived from maternal balanced translocation 46,XX,t(8;12)(q24.3;p13.3); add(18)(p11.3) in a female patient that was also inherited from maternal balanced translocation 46,XX,t(8;18)(p21;p11.3); add(8)(p23) in two male patients that were de novo.
CMA identified the extent and size of deletion and/or duplication in the affected patients; 15 Mb duplication in 8q24.3 that was associated with 3Mb deletion in 12p13.3 in two siblings, duplication of 8p21-8p23 that was combined by deletion in 18p11.3, another patient had 7.1Mb deletion in 8p23.3-8p23.1 followed by intermediate intact segment then 34 Mb duplication in 8p23.1- 8q21.3 (inverted duplication deletion). FISH analysis using the suitable probes confirmed CMA results in all patients and their parents.
We can conclude that breakpoints seem to be more concentrated at three intervals: interval 1 is at the telomeric end; intervals 2 and 3 are in 8p23 close to the beta-defensin gene cluster (DEFB) and olfactory receptor (OR) low-copy repeats (LCRs). CMA is a crucial tool for precise detection of breakpoints and the involved genes which are crucial for proper genotype-phenotype correlation. FISH analysis is essential in patients with chromosomal abnormalities due to parental balanced translocations for detection of copy number variants in the subtelomeres.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2368 Degree of uncertainty predicts emotional reaction to mock polygenic risk score results

Authors:

C. Jodarski[1], R. Gore[1], J. Yan[1], M. Kamen[2], K. Lewis[1], N. Reynolds-Lallement[1], S. Byers[1], B. Beers[1], M. Yavi[1], E. Ballard[1], C. Zarate[1], J. Austin[3], M. Walkiewicz[2], M. Similuk[1]; [1]NIH, Bethesda, MD, [2]NIAID, Bethesda, MD, [3]Univ British Columbia, Vancouver, BC, Canada

Psychiatric illnesses typically result from a complex interaction of genetic and environmental factors. Due to advances in the understanding of the many genetic factors contributing a small effect towards risk, polygenic risk scores (PRS) could be used to quantify an individual's risk of developing a psychiatric illness. While this technology is not currently being used on a clinical basis, it is important to evaluate how the individuals who may use PRS react to their results, so that appropriate pre- and post-test counseling can be provided. Therefore, this project aimed to identify factors that may be related to a positive or negative emotional response amongst individuals with treatment resistant depression (TRD), who received a hypothetical PRS result.

An online survey was sent to participants who underwent remote genetic counseling and genome sequencing one week after their initial appointment. The survey included a hypothetical scenario depicting a mock PRS for depression (randomized to low, average, or high risk PRS report). Affective response to the result was measured via the 12-item Feelings About Genomic Testing Results scale (FACToR), and potential domains of personal utility were evaluated using the 17-item Personal Utility Scale (PrU). Participants were also asked to identify which type of mock result they received, as a knowledge check.

We analyzed 64 responses from the 160 individuals who were invited to participate (40% response rate). Most participants (65.6%) correctly identified the type of mock PRS results received, and the remainder (34.4%) were unsure. The type of mock result received (low, average, or high risk) did not impact the degree of positive or negative emotions reported by participants ($p=0.17$ and 0.37, respectively). However, multiple linear regression (MLR) identified that increased uncertainty about PRS results and concerns about PRS technology were correlates of negative emotions towards PRS results ($\beta=0.54$, 0.29, respectively, all $p<0.01$). Additionally, MLR identified that greater perceived utility of results and less uncertainty were correlates of positive emotions towards PRS results ($\beta=0.42$, -0.25, respectively, all $p<0.05$).

These results suggest that while the degree of risk predicted by mock PRS result itself does not influence the type of emotional reaction experienced by participants in this study, the degree of uncertainty individuals feel about this result does. Given this knowledge, it will be important for those undergoing PRS testing to receive adequate counseling surrounding the test's utility and limitations so that results can be better understood within their personal and familial contexts.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2369 † Democratizing Gene Therapy Education for Patient Communities.

Authors:

V. Bonham, T. Jackson, H. Ramirez, K. Amini, R. Willard, A. Buscetta; NHGRI, Bethesda, MD

As novel and complex genetic therapies continue to emerge and gain approval from the US Food and Drug Administration, it is important for patient communities to have access to open-source, accurate, and understandable patient education materials (PEMs). Engagement with individuals living with the disease, support persons, and community advocacy groups is essential to understand their educational needs and gaps. Their voices should be heard by the research and scientific community, who are developing and implementing new genetic therapies. The Democratizing Education for Sickle Cell Disease Gene Therapy project used rational democratic deliberation and a community dialogue approach to engage stakeholders to create high-quality educational materials for gene therapy for sickle cell disease (SCD). A deliberative stakeholder engagement model was used to guide this project, employing both deliberative democracy and stakeholder engagement processes. Deliberative democracy is an inclusive approach to reaching consensus decision-making through participative and representative engagement. Community engagement encompasses individuals, constituent groups, and entities that play a role in developing and implementing new genomic technologies. We will examine the model employed by this project to engage patients, advocacy groups, researchers, clinicians, industry, and government representatives to create open-source PEMs for SCD gene therapy. Partnerships with community-based advocacy groups to disseminate these gene therapy education materials will be described. The method of using content syndication to republish to other websites and ensure regular updates that preserve their scientific accuracy will be presented. As the field of gene therapy advances, patient education content updates can be shared in real-time, thus providing the community with access to the most up to date and high-quality PEMs on gene therapy treatments and techniques.

Hayeems[5,6]; [1]Div. of Clinical & Metabolic Genetics, Dept. of Paediatrics, The Hosp. for Sick Children, Toronto, ON, Canada, [2]Program in Genetics and Genome Biology, SickKids Res. Inst., Toronto, ON, Canada, [3]Dept. of Genetics, Children's Hosp. of Eastern Ontario, Ottawa, ON, Canada, [4]Children's Hosp. of Eastern Ontario Res. Inst., Univ. of Ottawa, Ottawa, ON, Canada, [5]Program in Child Hlth.Evaluative Sci., SickKids Res. Inst., Toronto, ON, Canada, [6]Inst. of Hlth.Policy, Management and Evaluation, Univ. of Toronto, Toronto, ON, Canada, [7]Children's Hosp. of Eastern Ontario Res. Inst., Ottawa, ON, Canada

BACKGROUND: Genome-wide sequencing (GWS; including exome and genome sequencing) is increasingly recommended as a diagnostic test for rare diseases (RD), but timely access in many jurisdictions remains limited to those referred to medical geneticists. Enabling access to GWS for non-geneticist providers has the potential to expedite diagnosis for affected families and reduce wait times for the geneticist-led model of care that has limited capacity. However, evidence to guide the implementation of GWS into the practice of non-geneticists is lacking.
SETTING: Genome-wide Sequencing Ontario (GSO) is a harmonized multi-institutional service developed to deliver GWS for RD across Ontario, Canada. GSO's two-year pilot demonstrated the effectiveness of a hub-and-spoke model of delivery—where sequencing and informatics is done centrally with distributed analysis and reporting at two institutions—ensuring quality, consistency, efficiency, and sustainability province-wide. A diagnostic yield of 31% was achieved across sequencing strategies (singleton, duo, trio), and was significantly higher when the patient phenotype included developmental delay/intellectual disability. The mean overall turnaround time was 54.4 days (SD: 29.6), with 92% of cases reported in less than 12 weeks.
DESIGN: A mainstreaming model of care that enables a selected group of non-geneticist subspecialists to order clinical GWS will be developed, implemented, and evaluated by the GSO study team. To enable co-design, non-geneticist providers will be drawn from specialty areas that care for patients who meet eligibility criteria, including pediatric neurology and developmental pediatrics. Patient partners and knowledge users will be included in the sampling frame. Using a multi-phase mixed methods design, we will: (i) conduct semi-structured qualitative interviews and expert consultations to explore barriers and facilitators to the uptake of GWS among non-geneticist providers; (ii) co-design, test, and implement a mainstreaming model of care; and, (iii) measure both GWS outcomes (i.e., diagnostic utility, clinical utility, and timeliness) and implementation outcomes (i.e., acceptability, feasibility, fidelity, costs, sustainability, and penetration of the new delivery model) at the level of both providers and patients.
INTERPRETATION: Findings from this work will provide evidence related to the performance of GWS in a service delivery model that includes non-geneticist care providers. Outcomes will inform provincial and cross-provincial policy and implementation planning related to the organization and delivery of clinical-grade genome diagnostics for RD.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2371 Developing a programmatic evaluation for programs focused on improving access to genetic services for underserved populations

Authors:

M. Lyon[1], D. Maiese[1], L. Creel[2]; [1]American Coll. of Med. Genetics and Genomics, Bethesda, MD, [2]Univ. of Colorado Anschutz Med. Campus, Sch. of Med., Dept. of Med., Div. of Hlth.Care Policy and Res., Aurora, CO

Due to the scarcity of genetic services and resources in parts of the United States, the Health Resources and Services Administration (HRSA)/ Maternal and Child Health Bureau (MCHB)/ Genetic Services Branch (GSB) funds the seven Regional Genetics Networks (RGNs), the National Coordinating Center for the Regional Genetics Networks (NCC), and the National Genetics Education and Family Support Center (NGEFSC) to improve access to genetic services for underserved populations. Through a regional infrastructure that covers up to eight states per network, the system provides education and workforce development (e.g., general genetics and genetics policy) to individuals, families, and health care and public health professionals. The system also focuses on linking patients to genetic services and supports telehealth training and service delivery. The RGN/NCC/NGEFSC system uses common performance measures to assess the five objectives set forth in the RGN Notice of Funding Opportunity. In this evaluation, medically underserved is defined as living in a geographic region designated by HRSA as a Health Professional Shortage Area. ZIP Codes are collected to determine the reach of the system into medically underserved communities. The goal of this cross-regional evaluation is to assess the system's year-to-year progress toward reaching underserved populations and connecting individuals and families to needed genetic services. Since 2017, the RGNs, NCC, and the Family Center have collected data from a variety of sources through a mixed-methods approach. Data collected includes registration data, agreements with clinics to provide data, and follow-up surveys to RGN participants. Data are compiled by each program and submitted to NCC via REDCap to create annual reports to HRSA about the system's reach. This data set includes the number of individuals that received education or training on genetics; linkages created to connect patients to genetic services; providers trained or aided with TA in telehealth; and RGN-supported clinics that use telehealth modalities. Through a consensus-building process among the RGNs, NCC, Family Center, and HRSA, we have streamlined REDCap, and agreed upon definitions for each data element with reference documents to assist programs in understanding how data should be counted. Using the data collected through this evaluation, we provide publicly available data on the outcomes of our system (nccrcg.org/our-impact), which includes educating over 8,000 providers and reaching more than 4,000 individuals and families, thus reaching people in every state and territory.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2372 Development of a comprehensive framework for understanding the scope of undiagnosed disease

Authors:

D. Adams[1], E. Macnamara[2], C. Tifft[3], C. Toro[1], W. Gahl[4]; [1]NIH, Bethesda, MD, [2]NIH, Bethesda, MD, [3]NIH Office of the Clinical Director, Bethesda, MD, [4]NHGRI (NIH), Bethesda, MD

INTRO: The NIH Undiagnosed Diseases Program (UDP) has now been enrolling participants since 2008, and as part of the Undiagnosed Diseases Network (UDN) since 2015. Participants have diseases that remain undiagnosed after extensive standard of care evaluation. This period has also seen the emergence of a global undiagnosed disease community. The root causes for diagnostic failure are complex. Examples include undefined new diseases, lack of diagnostic resources and atypical phenotypes. A comprehensive system for categorizing the circumstances leading to failed diagnoses is needed, both to understand the scope of the associated medical need and to prioritize research and clinical resources.
METHODS: The study authors utilized their experience with the UDP and UDN to construct a framework for describing mechanisms leading to the failure to reach a diagnosis. Individual UDP cases were used to refine the framework by studying real-world examples. Mapping of 314 past, diagnosed UDP cases to causes of diagnostic failure generated preliminary estimates of the relative contribution of individual factors across the cohort.
RESULTS: The patients evaluated by the UDP and UDN represent a subset of all undiagnosed disease patients. There is a bias toward diseases with manifestations of sufficient duration to persist through standard of care and subsequent UDN clinical evaluations. Prospective participants may be excluded if they have not had a standard of care workup. Geographic biases arise from a largely US study cohort. Of the 314 cases, 257 (82%) were associated with a gene-associated disease—likely reflecting program enrollment priorities. For these reasons, quantitative information about the frequency of individual contributors to diagnostic failure was specific to the UDP/UDN cohort and not generalizable. Despite these limitations, the process allowed for the generation of a standardized vocabulary for use in prospective work.
CONCLUSIONS: We present a framework for categorizing pathways by which undiagnosed disease patients come to the end of available clinical evaluation without having achieved a diagnosis. Further work will be required to understand the relative contributions of framework elements in a broad spectrum of healthcare settings. To accomplish that goal, new collaborations and data sources will be needed to augment the UDP/UDN experience. We anticipate that further development and study of the framework will allow for refined targeting of efforts to mitigate delays and diagnostic failures.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2373 Disclosure of genetic test results for stroke among stroke-free West Africans

Authors:

A. Fakunle[1], A. Okekunle[2], O. Asowata[2], O. Akpa[2], J. Akinyemi[2], F. Sarfo[3], A. Akpalu[4], R. Obiako[5], K. Wahab[6], R. Akinyemi[2], B. Ovbiagele[7], M. Owolabi[2]; [1]Osun State Univ., Osogbo, Nigeria, [2]Univ. of Ibadan, Ibadan, Nigeria, [3]Kwame Nkrumah Univ. of Sci. and Technology, Kumasi, Ghana, [4]Univ. of Ghana, Accra, Ghana, [5]Ahmadu Bello Univ., Zaria, Nigeria, [6]Univ. of Ilorin, Ilorin, Nigeria, [7]Univ. of California, San-Francisco, CA

Background: Genetic testing is an essential component of human genetics. With the recent revolution in genetic testing and its promising contribution towards mitigating the burden of stroke in sub-Saharan Africa, it is crucial to assess Africans' perception, preference, and attitude towards the disclosure of stroke genetic test results.
Objective: This study evaluated the preference, perceptions, and attitudes towards the disclosure of genetic testing results for stroke among stroke-free controls in the SIREN-SIBS Genomics Study.
Methodology: We employed a quantitative data collection technique to assess the perception, preferences, and attitudes of stroke-free controls in Ghana and Nigeria towards disclosure or non-disclosure of different tiers of stroke genetic results using the SIREN questionnaire. Multivariable regression model was used to investigate sociodemographic factors that influence Africans' preferences, perceptions, and attitudes towards the disclosure of genetic testing results for stroke.
Results: A total of 351 stroke-free controls were included in the current study. Respondents' mean (SD) age was 51.26 (14.68) years, with a male preponderance (58.0%). The majority of the respondents (66.1%) were against the opinion that getting the results of the genetic test for stroke is of no use, while 95.6% claimed that they prefer a face-to-face disclosure of their genetic results. More than half (66.0%) had a negative attitude towards disclosing genetic test results for stroke. Age >70 years was associated with a negative attitude towards disclosure of genetic test results for stroke [odds ratio (OR) 4.19; 95% confidence interval 1.04-6.88].
Conclusion: These findings necessitate culturally sensitive interventions for continuing education to improve individuals' attitudes towards the disclosure of genetic test results for stroke in Africa.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2374 Disease-related and recreational genetic testing in Australia: insights into associated health and sociodemographic factors from an analysis of 45,061 participants of the 45 and Up Study.

Authors:

J. Steinberg, D. Goldsbury, H. Tanha, Y-J. Kang, A. Smit, K. Dunlop, L. Petelin, P. Ngo, C. Tang, H. Hui, N. Meagher, M. Merritt, M. Weber, A. De Fazio, A. Cust, K. Canfell; The Univ. of Sydney, Sydney, Australia

Genetic testing has considerable promise for precision health, with tests increasingly available for disease risk and tailored treatment. Australia presents an example of a high-income country with universal healthcare, but only limited nationally re-imbursed genetic testing, with many tests covered by health services or directly by individuals. To help realise the potential of genetics, it is thus important to understand current patterns of testing, including differences by socioeconomic status.

We conducted a large-scale analysis of self-reported genetic testing and its association with sociodemographic and health characteristics (including family history for multiple diseases) in Australia, using the 45 and Up Study (a longitudinal cohort of 267,357 participants aged 45+ years, recruited 2005-2009) and linked NSW Cancer Registry data.

Among 45,061 participants who completed follow-up questionnaires in 2020, 9.2% (95%CI 8.3-10.0%) reported ever having a genetic test, with 3.9% (3.0-4.8%) reporting a disease-related test (risk, diagnosis, or treatment) and 5.2% (4.3-6.1%) a recreational test (ancestry/diet/fitness/other). Estimates adjusted to match national education or income levels were similar (e.g. any genetic test: 8.4-9.5%).

Variation between population subgroups was substantial. For example, disease-related testing was significantly associated with relatively younger age (e.g. 5% age 60-69 vs 2% age 80+ years, adjusted odds ratio (aOR) 2.50), a record of breast (aOR 4.14) or bowel cancer (aOR 2.50), cardiovascular disease (aOR 1.37), family history of breast (aOR 1.67) or ovarian cancer (aOR 2.41), but also university education (aOR 1.48 vs school only; all above estimates adjusted for all characteristics analysed and significant after multiple-testing correction).

As cancer is a key area for disease-related testing, we also specifically considered participants with a linked cancer diagnosis record. Here, disease-related testing was strongly associated with a more recent cancer diagnosis (e.g. 2015-2019 vs pre-2005: aOR 1.95). Associations with family history increased strongly when multiple generations were affected, or when restricting the analysis to participants with the same cancer. However, there remained consistent evidence for an association between testing and higher education (disease-related testing: aOR 1.37 for university vs school only, $p<0.05$).

In summary, our results provide detailed insights into current access to genetic testing and how it differs between population subgroups in a high-income country, re-enforcing the need for further research on equitable access to genomic technologies.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2375 Dissecting racial disparities in the implementation of pediatric whole genome sequencing as a first-line diagnostic test: insights from SeqFirst.

Authors:

J-H. Yu[1], K. MacDuffie[1,2], O. Sommers[1], K. Anderson[1], M. Sikes[2], L. Kruidenier[2], H. Gildersleeve[1], A. A. Scott[2], K. Buckingham[1], A. Snook[3], P. Kruszka[3], D. E. Miller[1], J. X. Chong[1], D. Veenstra[1], K. M. Dipple[1,2], T. L. Wenger[1,2], D. Doherty[1,2], M. J. Bamshad[1]; [1]Univ. of Washington, Seattle, WA, [2]Seattle Children's, Seattle, WA, [3]GeneDx, Stamford, CT

Background: Racial disparities in access to genetic services, whole genome sequencing (WGS), and a precise genetic diagnosis (PrGD) are well-documented and contribute to inequitable outcomes among infants and children with a suspected genetic condition. The SeqFirst Study aims to improve equitable access to a PrGD by offering WGS as a first-line diagnostic test to families of infants and toddlers without an obvious environmental explanation for their condition. SeqFirst enrollment through a quaternary Children's Hospital NICU suggests that BIPOC patients/families with genetic conditions may be less likely than white families to receive genetic services. Such access disparities might be due to a range of structural and social determinants that manifest in interactions between family, providers, and institutions (e.g., family's distrust, provider bias). **Methods:** Semi-structured key informant interviews with n=9 neonatologists and n=10 neurodevelopmental providers involved in SeqFirst recruitment were conducted to investigate factors underlying observed racial disparities in access to a PrGD as well as attitudes toward genetic research, testing, and experience of SeqFirst recruitment. **Results:** Despite intentions to avoid discriminating between BIPOC and white families, providers articulated a range of considerations and practices that may lead to disparities. Providers were adamant that race does not and should not matter; yet thought it may influence their ability to detect dysmorphic features contingent on medical training and experience serving racialized populations. Race was thought to complicate evaluations along with infant age, size, development, and parent availability at bedside. Nearly all identified parent-provider language discordance and differences in "medical literacy" as challenges to offering genetic tests and services. Together these factors characterized newcomer families in contrast to those who are English-proficient, highly educated, wealthy, privileged, and self-advocating. Limited institutional resources (e.g., suboptimal interpreter services, availability of referral pathways) and social determinants (e.g., occupationally-constrained parent availability) left families vulnerable to access disparities. **Discussion:** A constellation of factors and practices that interact throughout a family's healthcare journey may contribute to racial disparities in access to genetics. Efforts are needed not only to address biases in provider training but also institutional resource constraints and barriers caused by social determinants to achieve equitable access to genetic testing and services.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2376 Do the Benefits Outweigh the Barriers?: Clinical Implementation of Parent-of-Origin Genomic Analysis

Authors:

A. Roston[1], A. Virani[1], K. Schrader[2]; [1]Univ. of British Columbia, Vancouver, BC, Canada, [2]BC Cancer / Univ British Columbia, Vancouver, BC, Canada

Background: Parent-of-origin assignment (POAga) is an emerging genetic testing modality, in which DNA can be reliably assigned to either paternal or maternal origin, even in the absence of parental testing. The ability to determine inheritance from a single genetic test represents a paradigm shift in clinical genetics, as it mitigates the need for the 'trio-based' testing approach during variant segregation. However, there are several barriers that may hinder its translation from the research laboratory to the clinic. Benefits: POAga promises numerous benefits for patients, families, and the healthcare system. First, POAga can inform screening and management recommendations for variants whose effects depend on the contributing parent. This will be especially beneficial to those without available parents, including patients who are adopted, elderly, or who have immigrated. Additionally, POAga prediction will likely assist in curating variants of uncertain significance (VUS), which are known to disproportionately affect patients of non-Western European ancestry. At the family level, POAga data helps direct cascade testing to one side of the family, and allows for more refined genetic counselling and screening recommendations. Finally, this ability to refine surveillance recommendations among patients may ultimately lead to decreased healthcare costs and improved resource stewardship. Barriers: Because POAga predicts the genotypes of untested parents, parental autonomy and confidentiality must be considered. As an additional concern, the ability to predict parental carrier status within a single test will lead to a duty to warn parents of pathogenic results, and on an unprecedented scale. POAga also provides the greatest direct benefit to a relatively small proportion of individuals (e.g. variants with parent-of-origin effects *and* unavailable parents). Compounding this issue is the fact that POAga relies on cutting edge, high-cost technologies; therefore, it is very likely that, at least in the initial stages, there will be unequal access to this testing modality. Finally, the initial implementation of POAga, which will require significant user education and policy changes, will likely lead to temporary increases in system costs. Conclusions: Overall, while a promising new technology with numerous clinical benefits, POAga warrants a careful discussion of its ethical and practical implications.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2377 Equity and human rights perspectives on multigene panel testing for cancer: Health insurance coverage in Japan and Switzerland.

Authors:

K. Nakasato[1], C. Manz[2], K. Kato[1]; [1]Osaka Univ. Graduate Sch. of Med., Suita, Japan, [2]Univ. of Lausanne, Lausanne, Switzerland

Advancements in genomic medicine have led to prospects in a wide range of clinical fields, including oncology. In particular, developments in next-generation sequencing (NGS) multigene panel tests have led to the possibility of tailoring treatment to the specific genomic markers of a patient's cancer. However, several practical challenges have yet to be fully addressed. One of these potential challenges is whether and under which circumstances multigene panel testing for cancer is covered by health insurance, which can have broader implications for health equity and human rights. Such discussions have often been centered around countries at the forefront of implementing precision cancer medicine into routine care such as the United Kingdom and the United States. Comparatively, less is known about the situation in countries like Japan and Switzerland, which have a strong foundation in genomic research and national health insurance but have not implemented genomic medicine to the same extent. As such, we investigated the approaches to insurance coverage for cancer multigene panel testing in Japan and Switzerland. Results have shown that while there is an overlap between the two countries regarding the use of multigene panel tests, there are noticeable differences in the circumstances under which these tests are covered by national health insurance. With these results, we will discuss the implications for policy-making decisions for equitable access to genomic medicine, as well as broader discussions on non-discrimination in health care.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2378 Ethical considerations for returning sex chromosome aneuploidy as a secondary finding.

Authors:

A. Buscetta, J. Aickareth, H. Ramirez, J. Floyd, V. Bonham; NIH/NHGRI, Bethesda, MD

The American College of Medical Genetics and Genomics (ACMG) has published recommendations for reporting secondary findings (SF) in clinical exome and genome sequencing. These recommendations include a minimal list of pathogenic and likely pathogenic variants, which is updated annually. The ACMG recommendations are often used as a guideline and educational resource for research groups who are returning results. The ACMG encourages the community to submit nominations of actionable genes to be considered for inclusion. They state these recommendations are not inclusive or exclusive of all procedures or tests and professional and clinical judgment is warranted in specific clinical circumstances. Currently, sex chromosome aneuploidies (SCA) are not included on the ACMG list. Approximately, 75-90% of SCA cases are undiagnosed during an individual's lifetime. With advances in prenatal testing, studies have shown better outcomes with earlier diagnosis of an SCA. Given the variation in phenotype and severity of SCAs, it is important to consider the diagnosis and the impact on the individual prior to returning the result. Three ethical principles to help guide decisions to return SF have been proposed: validity, value, and volition. Validity and value concern the accuracy and usefulness of the diagnosis to the person. Volition centers around whether or not the person wants to receive the information, i.e. informed consent. We present a case report of a research participant living with sickle cell disease (SCD), who consented to whole genome sequencing (WGS) and receiving SF. The participant was found to have a variation in the copy number of sex chromosomes, which indicated the presence of XXY or Klinefelter syndrome. Prior to contacting the patient to obtain a new sample for CLIA confirmation, an ethics consultation was received to weigh potential risks and benefits of returning this result. The following relevant considerations were discussed: clinical actionability, fertility issues, and psychosocial effects. The final ethical analysis determined there was enough direct clinical value and personal utility to support disclosing the results, however, not enough to deem this ethically obligatory. We examine the ethical dilemma of returning secondary results for sex chromosome aneuploidy.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2379 Evaluation of Genetic Counseling Services by Genetics Teams in Korea

Authors:

I. Choi[1], H. Shin[2], M. Kang[2], H. Bae[3], S. Hwang[4], G-H. Kim[2], B. Lee[4]; [1]Univ. of Ulsan Coll. of Med., Seoul, Korea, Republic of, [2]Asan Med. Ctr., Seoul, Korea, Republic of, [3]Asan Med. Ctr. Children s Hosp., Seoul, Korea, Republic of, [4]Asan Med. Ctr. Children's Hosp., Seoul, Korea, Republic of

In South Korea, the provision of clinical genetics services started with the opening of genetics clinics in the 1990s. Despite the increasing number of geneticists, the number of geneticists remains insufficient compared with the number of patients requiring genetics services. It is important for medical geneticists and genetic counselors to collaboratively provide genetic counseling services. This study aimed to examine Korean patients with rare genetic disorders and their families who visited the medical genetics center in a tertiary general hospital in terms of their perception and satisfaction regarding genetic counseling services. In addition, the genetic counseling service model of a genetics team, which involves collaboration between medical geneticists and genetic counselors, was evaluated. Among the study participants, 164 participants (80.8%) were aware of the genetic counseling services and 135 participants (66.5%) were aware of the role of genetic counselors. The score of satisfaction with genetic counseling services provided by the genetics team was 8.19 ± 1.68 out of 10. The satisfaction score was highest for the item informing about the medical expense support program (4.46 ± 0.93 points out of 5), followed by the items providing medical knowledge about diseases (4.34 ± 0.74 points), helping with making decision about diagnostic work-up/options for genetic testing (4.34 ± 0.82 points), explaining about the ways of being inherited and the recurrence risk within the family (4.24 ± 0.84 points), providing psychosocial support (3.96 ± 0.97 points), and informing about additional resources, including patient support groups, special education, and rehabilitation (3.43 ± 1.24 points). In conclusion, genetic counseling services provided by collaboration between medical geneticists and genetic counselors were effective in providing information and can be helpful in diagnosing, treating, and managing patients. As a genetic team approach, collaboration between medical geneticists and certified genetic counselors would be useful in providing information and in diagnosing, treating, and managing patients.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2380 Exploring precision medicine through the lens of the LGBTQ+ community.

Authors:

D. Diaz Caro[1], B. Rolf[2], D. Kochhar[3], M. Campion[4]; [1]Columbia Univ. Irving Med. Ctr., New York, NY, [2]Univ. of Washington, Seattle, WA, [3]Seattle Univ., Seattle, WA, [4]Stanford Univ., Stanford, CA

Background: For the benefits of precision medicine (PM) to reach all patients, initiatives must understand and address the needs of all underrepresented populations. Previous studies have explored the perspectives of ethnic and racial minorities regarding barriers, facilitators, concerns, and benefits of PM; however, no study has surveyed individuals that identify as lesbian, gay, bisexual, transgender, queer, and/or other marginalized sexual and gender identities (LGBTQ+). This study aims to address this gap by exploring the perspectives that LGBTQ+ community members have about PM. **Methods:** Participants were identified through a LGBTQ+ community center recruitment survey that gathered demographics and introduced PM via an educational video. Participants were randomly selected for interviews using a stratified sampling approach. Semi-structured interviews were conducted via videoconferencing with 12 participants that self-identified as LGBTQ+. The interviews gathered information on understandings of PM, perceptions of PM initiative trustworthiness, benefits, expectations, concerns, and foreseeable barriers and facilitators for PM participation. Interview recordings were transcribed, and content analysis was conducted to identify themes. **Results:** Interviewees had varying levels of understanding of PM prior to participating in our study. Expectations of PM encompassed addressing general and LGBTQ+ specific health concerns and social inequities that affect health outcomes. Barriers to the adoption of PM included negative past experiences in healthcare, negative social and personal implications of identity disclosure, and lack of access and resources. A major concern identified was the potential misuse of LGBTQ+ identity for discriminatory practices. Interviewees indicated that they would view PM initiatives as trustworthy if barriers and concerns were addressed through a demonstrated commitment to accountability, credibility, accessibility, inclusivity, transparency, and privacy. Facilitators included qualities that would demonstrate trustworthiness such as endorsement from trusted LGBTQ+ practitioners or institutions, inclusive content, and the dissemination of information through community trusted sources. **Conclusion:** The study findings identified specific areas that future PM initiatives need to address in order to foster inclusivity and recognition of the LGBTQ+ community. Further research should investigate the perspectives of LGBTQ+ individuals participating in PM initiatives and include a broader spectrum of intersecting identities not characterized in this study.

PB2381 Exploring the Impact of Secondary Genetic Findings on the Psychosocial Wellbeing of Caregivers of Cleft Children

Authors:

A. Oladayo[1], V. Sule[2], Y. Oshodi[3], A. Adekunle, A[4], W. Adeyemo[4], O. Ogunlewe[4], A. E. Ajadi[3], B. Aikomo[3], O. Aiyelomi[3], A. Babatunde[3], T. Busch[5], A. Alade[5], M. Olujitan[1], E. Aladenika[5], W. Awotoye[6], L. Gowans[7], M. Eshete[8], C. Campbell[5], D. J. Caplan[1], O. Adeagbo[1], P. Mossey[9], A. Adeyemo[10], J. Murray[5], A. Prince[5], A. Butali[1]; [1]Univ. of Iowa, Coralville, IA, [2]Uiowa, Coralville, IA, [3]Univ. of Lagos, Lagos, Nigeria, [4]Univ. of Lagos/ Lagos Univ. Teaching Hosp., Lagos, Nigeria, [5]Univ. of Iowa, Iowa City, IA, [6]Univ. of Iowa, Iowa, IA, [7]Kwame Nkrumah Univ. of Sci. and Technology, Kumasi, Ghana, [8]Addis Ababa Univ., Addis Ababa, Ethiopia, [9]Univ. of Dundee, Dundee, United Kingdom, [10]NIH, Bethesda, MD

Introduction: Caregivers with children affected by orofacial clefts (OFCs) in low- and middle-income countries often experience significant emotional and psychological problems, including social stigma. The discovery of secondary findings (SFs) of potential health importance from whole-genome sequencing (WGS) may further exacerbate this since genetics and heritability may raise additional ethical and social issues. However, little is known about the experiences of caregivers and the impact of receiving SFs in the context of OFCs in sub-Saharan Africa. Our study aimed to determine if identifying SFs will affect the psychosocial well-being of caregivers of cleft children in Nigeria. **Methods:** Two Focus Group Discussions were conducted with 22 purposively sampled caregivers of children who underwent WGS analysis and attended the cleft clinic at the LUTH, Lagos, Nigeria. We investigated participants' experience regarding genomic testing, knowledge about SFs, psychosocial impact and coping strategies. Audio recordings from discussions were transcribed verbatim and analyzed using content analysis. **Results**: The average caregiver age was 34.3 ± 11.3 years, and 19 out of the 22 participants were females. Four themes and thirteen subthemes emerged**.** These include **pervasive burden** {child care practices, financial hardship hindering follow-up on SFs, physical and mental health impact and effect on family unit}, **concern** {causes of cleft, acting on SFs and community treatment of affected child}, **coping strategies** {holding on through faith, family support and peer support at cleft clinic} and **need for psychological support** {coping with cleft diagnosis, associated stigmatization and requirement of caring for a cleft child}. Although WGS results sparked relief and concerns, caregivers reported that SFs might potentially exacerbate existing stress. **Conclusion:** Caregivers faced numerous difficulties, including psychosocial issues, as they cared for a child with a cleft. However, they were able to draw strength and optimism from peers at the cleft clinic. Promoting a healthy collaboration between care providers and caregivers could lay the foundation for improving their understanding and utility of testing results while linking them to appropriate resources that could provide needed psychosocial support and alleviate the negative caregiver experience associated with OFCs in limited resource settings. Similar studies could provide evidence to plan for mental health care for caregivers of cleft children in the presence of genetic risks. Thus, it is recommended that this study is repeated in other regions across the continent.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2382 Fighting genetics harms with education: a course on genetics, ethics, and society

Authors:

R. Ungar, R. Patel, A. L. Pyke, E. Greenwald, A. Adijoelja, J. Gomez-Stafford, A. Narain, N. Hunter, P. Goddard, T. Mackenzie, D. Cotter, M. Chakraborty, D. Martschenko; Stanford, Stanford, CA

Despite decades of scientific activism, we are still grappling with the misuse of genetics to justify racist, sexist, ableist, and transphobic ideology. However, few training opportunities provide students with the tools to understand how society and science are related, or to interrogate their own roles as part of the scientific system.
To address this gap, we as a group of trainees ideated, designed, and led a course using contemporary design principles with the following learning goals:
1. Connect the historical context of genetics research to its modern-day practice
2. Evaluate the social and ethical implications of genetics research
3. Analyze how societal norms and structures, along with personal identities, biases, and responsibility, impact the conduct of scientific research
We first designed this as a six-session, discussion-based mini-course in Spring 2022, and focused on the history of genetics; race and ancestry; forensic genetics; and reproductive genetics. We then expanded this to a ten-week course in Spring 2023, and added new topics, including behavioral genetics; sex and gender; genetics and (dis)ability; and scientific activism. We situated our discussions of these topics in the language of positionality, reflexivity, and social responsibility, which enabled students to ideate actionable solutions for social harms. We have released all of our learning goals, slides, and related materials here: bit.ly/stanford-genethics.
We conducted an IRB-approved survey to evaluate the impacts of this course. Following our class in Spring 2022, every student strongly agreed that "research is influenced by society", and many shared that it was important to them that research "does not re/create harm". Despite the discussion of difficult topics, this course empowered students; all students agreed they "can make a change towards a more equitable, inclusive, and just scientific research and structure"; one student mentioned they "learned how to be a better advocate for more ethical science". It is important to note 73% of our students identified as underrepresented in STEM, which highlights the need to better engage the broader academic community. We will provide additional insights gained from Spring 2023, as our course was still in progress at time of abstract submission.
To achieve the collective goal ASHG set to "consistently acknowledge and oppose harms and injustices" we propose an educational model that can be adopted and iterated on at other institutions or workshops. We argue this training is an important step to enable collective action towards equitable and inclusive scientific research.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2383 Fragile X Syndrome: Evaluation of a documentary used to share genomic research findings in Cameroon.

Authors:

K. Kengne Kamga[1,2], M. Lebogang[2], N. Seraphin[3], A. Wonkam[4], J. De Vries[2]; [1]Regional Hosp. Limbe, Limbe, Cameroon, [2]Univ. of Cape town, Cape town, South Africa, [3]Univ. of yaounde 1, Yaounde, Cameroon, [4]Dept. of Genetic Med., JHU, Baltimore, MD

Fragile X Syndrome (FXS) is the most common genetic cause of intellectual disability and Autism Spectrum Disorder (ASD). Recently, a large family in Cameroon with FXS was studied, and a documentary on FXS was created to share the research findings. This paper reports on the post-production evaluation of the FXS-documentary. Between March 2022 and January 2023, we surveyed individuals from communities in Cameroon's western and southwestern regions. Our survey consisted of a 17-question questionnaire. To participate, we obtained consent from individuals and let them watch the 10-minute documentary on FXS and complete the questionnaire. We used EPI info 7 for quantitative data, while Nvivo 12 was used for qualitative data. Our statistical significance was set at $p \leq 0.05$. Our survey gathered information from 42 individuals residing in the southwest and western regions of Cameroon. Most participants were female and had completed at least a high school education. The participants had diverse occupations, with healthcare workers (33.3%), students (19.0%), artists (16.7%), people in business (4.8%), and farmers (4.8%) being among the most well-represented. The survey revealed that 76.2% of participants watched the entire FXS-documentary, while 23.8% were unable to do so. The participants provided qualitative feedback on the FXS-documentary, highlighting three main themes: the documentary's ability to enhance genetic knowledge, the importance of community involvement, and its effectiveness as a counselling tool. Only 38.1% of participants expressed dissatisfaction with the documentary's language, background noise, and video quality. It's worth noting that non-English speaking viewers may face challenges accessing the FXS-documentary since it's only available in English. Nonetheless, the FXS-documentary received favorable reviews with an impressive rating of 4.4 stars. All participants were willing to share the FXS-documentary with their friends, family, and colleagues. This documentary on FXS can serve various purposes, including being a genetic counselling tool, lecture support material, and audiovisual material for community engagements. Hence documentaries could be used with personalized genetic counselling services to provide comprehensive support and guidance to affected individuals.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2384 Framing the conversation about prognoses for children with genetic neurodevelopmental conditions

Authors:

E. Turbitt[1], M. Bourne[1], A. Gokoolparsadh[1], A. McEwen[1], D. Amor[2]; [1]Univ. of Technology Sydney, Sydney, Australia, [2]Murdoch Children's Res. Inst., Parkville, Australia

Background: Conversations about prognosis for genetic neurodevelopmental conditions are becoming more frequent; however, there is a lack of evidence and guidance on how to approach these conversations.
Aim: We aimed to investigate what parents want to discuss about their children's prognosis with a focus on aspects such as expected intellectual functioning and autism features. We further aimed to investigate how parents receive prognostic information from clinicians, and online, and their preferences for these conversations.
Methods: This was a mixed-methods study, using qualitative interviews and an environmental scan of online information. The semi-structured interview data with parents were analysed using reflexive thematic analysis. We conducted a content analysis of online information.
Results: We interviewed 32 parents from across Australia. Parents had a child with a genetic neurodevelopmental condition, such as Fragile X syndrome (28%), 22q11.2 deletion syndrome (16%) or Angelman syndrome (16%). Parents found conversations about their child's prognosis stressful and emotional, with a preference to discuss their child's potential strengths as well as challenges. They reported that conversations about prognosis often focused on the child's potential deficits and that online information they encountered was similarly framed negatively. Our content analysis of online information confirmed parents accounts: 95.3% was coded as negative, while only 4.7% was positive/neutral.
Conclusion: Our data provide evidence of an over-emphasis of deficit-framed prognostic information about genetic neurodevelopmental conditions. The initial exposure to negative information may adversely affect parents' psychological well-being and expectations, which future research could address. Health professionals could consider strengths-based framing of prognostic information gained from current and emerging technologies when returning results to families.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2385 Generative methods for Pediatric Genetics Education.

Authors:

R. Waikel, T. Patel, A. Othman, S. Ledgister Hanchard, P. Hu, D. Dat, B. D. Solomon; Natl. Human Genome Res. Inst., Bethesda, MD

With the advancement of generative artificial intelligence (AI), there has been much effort to validate the effectiveness of these generated data (e.g., how well ChatGPT generates programming code). Analogous to these studies, to help address patient privacy concerns and the limited ancestral diversity of medical teaching images, we propose the use of generative AI images in medical education. Specifically, we sought to determine whether generative AI could help train pediatric residents to recognize two genetic conditions: Noonan and Kabuki syndromes. To generate fake images, publicly available images of real syndromic individuals were collected and used to finetune StyleGAN2-Ada. This finetuning used vector representations of the syndromic images. By varying these vector representations, we generated images of fake individuals transformed from unaffected to affected with the genetic condition of interest. Recruited pediatric residents provided opinions about facial diagnosis and classified 20 images following exposure to one of 4 possible educational interventions: text description of the genetic condition, text and real images, text and generative AI images, or text and generative AI transformation image strips, displaying a series of 5 images from unaffected to affected. When provided a text description of the facial dysmorphology, pediatric residents had a higher baseline average accuracy when classifying Noonan images (65.3%) compared to Kabuki images (48.2%), suggesting more familiarity with Noonan syndrome. The addition of real images significantly raised the accuracy for Noonan to 74.3% and Kabuki to 60.3%. Generative images also improved accuracy, particularly for Kabuki syndrome, with an accuracy of 57.0% (single image) and 59.6% (transformation image strip). Most participants reported educational images regardless of type to be helpful in classification, although generative images were rated as less helpful than real images. This difference could reflect an inherent bias against AI methodologies, as performance between groups was more similar than reported usefulness. We conclude that generative AI images can serve as an educational tool particularly for rarer conditions, such as Kabuki syndrome.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2386 Genetic knowledge and acceptability of genetic risk communication among hematologic malignancy survivors

Authors:

N. Sharafeldin, A. Lively, A. Grimm, N. Balas, L. Francisco, L. Hageman, S. Bhatia; Univ Alabama at Birmingham, Birmingham, AL

Background: Gene-based personalized interventions carry the potential to be more effective in inducing changes in outcome. Hematologic malignancy (HM) patients are at increased risk of adverse cognitive outcomes post-treatment. Clear evidence, however, is lacking on patient genetics knowledge, their receptiveness to genetic risk communication, and its influence on deciding to participate in interventions that mitigate adverse cognitive outcomes. Methods: HM patients enrolled in the Cognitive Training and Attitudes towards Genetics study completed a self-administered survey post-treatment. Genetic knowledge was measured using a previously published structured survey measuring factual and clinical genetic knowledge and scores were compared to historical cohorts. Attitudes towards risk communication were measured using a hypothetical scenario that randomized patients to having low or high genetic risk for cognitive impairment. Logistic regression was used to assess associations of sociodemographic variables with knowledge scores and measure likelihood of intervention uptake based on genetic risk information.
Results: A total of 133 HM patients completed the survey: median age 55y (23-74), 60% females, 73.7% non-Hispanic Whites (NHW) and 21% African American, 47.4% had a college degree or higher, and 20.3% had a household income of 100K or more. Average total correct score was 61.1%, 54.8% for factual and 76.5% for clinical knowledge. Scores were statistically lower among HM survivors compared to the general population ($p<0.001$) but higher than other chronic disease patient populations ($p=0.0013$). Older age was associated with lower total scores (OR=0.36, 95%CI: 0.15, 0.86, $p=0.021$), while higher education level was associated with higher factual (OR=3.79, 95%CI: 1.61, 8.88, $p=0.002$) and race other than NHW with lower clinical scores (OR=0.34, 95%CI: 0.13, 0.87, $p=0.024$). A total of 57% considered genetic testing for post-treatment outcomes somewhat or extremely important, 88% felt confident they understood the questions, and 76.5% found it not hard to use genetic information to make decisions on using interventions. Perceived high genetic risk for impairment was significantly associated with higher likelihood of affecting patients' decision to use an intervention (OR=2.36, 95%CI: 1.13, 4.93, $p=0.022$). Conclusion: Discrepancies in knowledge scores among hematologic cancer survivors present an opportunity to improve patient knowledge levels. These findings show patients are amenable to genetic risk communication and support the potential utility of incorporating genetics in risk-based management of cancer survivors.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2387 Genetic return of results in a population-based cohort: Enrollment experience from the PopSeq Project

Authors:

K. Christensen[1], S. Walmsley[2,3,4], C. Blout Zawatsky[2,3,4], G. Splansky[5,6], R. Bowles[5,6], L. Clayson[5,6], M. Valentino[5,6], K. Swenson[5], M. Lebo[7,4,8], K. Machini[7], H. Zouk[7,8], M. Hickingbotham[9], A. P. Carson[10], N. Heard-Costa[5,6], R. C. Green[2,3,4,8]; [1]Dept. of Population Med., Harvard Med. Sch. and Harvard Pilgrim Hlth.Care Inst., Boston, MA, [2]Dept. of Med., Mass Gen. Brigham, Boston, MA, [3]Ariadne Labs, Boston, MA, [4]Broad Inst., Cambridge, MA, [5]Boston Univ. Chobanian & Avedisian Sch. of Med., Boston, MA, [6]Framingham Heart Study, Framingham, MA, [7]Lab. for Molecular Med., Mass Gen. Brigham, Cambridge, MA, [8]Harvard Med. Sch., Boston, MA, [9]Dept. of Population Med., Harvard Pilgrim Hlth.Care Inst., Boston, MA, [10]Dept. of Med., Univ. of Mississippi Med. Ctr., Jackson, MS

Background: Genetic testing is often conducted in large-scale human studies; however, there is little empirical evidence around genetic return of results (gRoR) within the context of large-scale population studies. Most published data has been collected through biobanks affiliated with academic medical centers. Here we present data collected from the PopSeq Project: a prospective study of gRoR in population-based cohorts.
Methods: Framingham Heart Study (FHS) participants were sequenced as part of the NHLBI Trans-Omics for Precision Medicine (TOPMed) program and consented to re-contact for actionable results. Results were returnable if a pathogenic or likely pathogenic variant was identified in a gene included in the American College of Medical Genetic and Genomics v2.0 secondary findings list. Living participants with variants previously unknown to the study were contacted by a FHS affiliated geneticist (MD) by phone. If a participant elected to move forward, the MD facilitated CLIA confirmation and a clinical disclosure. If participants declined the reason was recorded.
Results: Of 4,197 FHS participants sequenced, 109 (2.6%) were identified to have returnable results, of which 42 (38.5%) were deceased. Living individuals with returnable results included 29 of 67 (43.3%) participants from the Original and Offspring cohorts, recruited in 1948 and 1971, respectively; and 38 of 42 (90.5%) participants from the Omni and Generation 3 cohorts, recruited in 1994 and 2002, respectively. Of the 67 living participants with returnable results, the study team was able to reach 39 (58.2%) for notification, of which 34 (87.2%) agreed to gRoR. Thus far, results have been clinically confirmed for 20 (58.8%) individuals. It took a median of 3 (1-8) contact attempts per participant to reach them for pre-test counseling. The reasons for decline were already being aware of their genetic result, no interest in the study, did not think testing was relevant due to already being affected, and wanting to prioritize non-medical issues.
Discussion: The PopSeq Project is the first study to conduct gRoR research in a population-based cohort. Analyses found that many FHS participants with actionable results had died by the time variants were identified. Of those still living, the majority were interested in clinical confirmation after being notified, and reported decliner reasons were similar to other published studies. Similar efforts are underway within the all-African American Jackson Heart Study. These results can help inform the development of protocols for population-based studies interested in gROR.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2388 Genomics return of results to participants in the All of Us Research Program

Authors:

P. Jain[1], M. Begale[1], M. Bryant[2]; [1]Vibrent Hlth., Fairfax, VA, [2]Vibrent Hlth., Mt. Pleasant, SC

"Participants have access to their information" is a core value of the All of Us Research Program (AoURP). "Retention", broadly defined as the number of enrollees actively participating in program activities, has emerged as a crucial program metric. Genetic Return of Results (gRoR) is a central tool to achieve both of these programmatic priorities. gRoR has two core components: health-related genetic results and engagement (non-health related) genetic results. This session will describe the program's strategy for returning both engagement and health-related genetic results through the Genomics Platform (GP). The main objective of returning genetic results is to provide value to participants by giving them access to insightful information based on their genetics. The return of genetic results is optional and affirmatively consented participants choose which types of results they want to receive. By providing both health-related and non-health-related (or engagement) genetic results as options, the AoURP enables participants to choose which results they find most interesting, valuable, or engaging.

The GP is an AoURP-branded, web-based user experience that houses the genetics results modules. Participants will be able to navigate from their participant portal to the GP, and from there, choose which types of results they would like to see within two categories: health-related results or genetic ancestry and trait results.

Aims of the program we will present: Aim 1: Develop and deploy the Genomics Platform (GP), a secure information and content management platform that will deliver genetic results to All of Us Research Program (AoURP) participants through a web-based user experience.

Aim 2: Make engagement and health-related genetic results available to eligible participants

Aim 3: Ongoing monitoring of the GP, including the Genetics Engagement Module (GEM) and Health-Related Genomics Module (HGM) return of results.

Additionally, the GEM content and informing loops have been subjected to comprehension testing, to assess whether participants understand key concepts or important takeaways, from the materials. Special attention was given to the genetic ancestry content.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2389 *Global genomic pathogen surveillance: online training and pandemic preparedness.*

Authors:

l. jackson[1,2], COG-Train; [1]Univ. of Exeter, Exeter, United Kingdom, [2]Univ. of Cambridge, Cambridge, United Kingdom

Training in genomics and bioinformatics is at peak demand due to its increased use in public health applications such as disease surveillance. The pandemic forced the development of innovative methods to continue providing training while generating more affordable and equitable access to scientists who are in great need for genomics skills development. COG-Train, a partnership between Wellcome Connecting Science and COG-UK, pioneered a truly global delivery of a SARS-Cov-2 genomics training programme focused on increasing capacity for application of pathogen genomic surveillance in emergency response at global scale. The programme brought together scientists based in Africa, Asia and Latin America to develop a series of free online-based educational initiatives covering topics from genomic sequencing techniques to bioinformatic analysis and application of genomics in public health. Our three main training courses (MOOCs, Distributed Classrooms and Virtual Courses) have provided training to over 13,000 participants from &gt150 countries, predominantly from our three target regions in the global south (Africa, Asia and Latin America). The majority of participants were early-mid career researchers working on pathogen genomics and microbiology, although there were also numerous individuals working in public health and in more senior roles. Week-long intensive courses in viral bioinformatics, delivered virtually in Asia and Latin America provided more advanced bioinformatics training, enabling 60 early career scientists to develop their own SARS-CoV-2 analysis pipelines and to establish best practices on how to share their skills with others. A blended learning format and distributed classroom model spanning Africa, Asia and Latin America, supported scientists with intermediate experience to learn concurrently on how to manage a viral genome sequencing pipeline, extract and interpret results. This mixed format facilitated engagement from scientists regardless of their location, experience and resources. Such a global approach to pathogen genomics and bioinformatics is key to building capacity and regional networks which may be crucial for future epidemic and pandemic response to infectious diseases. Lessons from this program can inform the teaching of human genomics and bioinformatics in the Global South.

PB2390 How do patients with hereditary cancer syndromes navigate the healthcare system? A qualitative comparative study

Authors:

C. Butkowsky[1,2], J. Sam[1], E. Reble[1], M. Clausen[1], S. Rajeziesfahani[3], B. Sparkes[3], R. Gopalakrishnan[1], V. Aguda[1], M. Aronson[4], J. C. Carroll[2], D. Bishop[5], L. Dawson[3], A. Eisen[6], T. Graham[6], J. Green[3], C. Mighton[1,2], J. Pauling[7], C. Pavao[8], P. Pechlivanoglou[2,9], C. Remocker[8], S. Savas[3], S. Sun[10], T. Tiano[7], A. Tilley[5], K. Thorpe[1,2], K. Schrader[10], H. Etchegary[3], Y. Bombard[1,2]; [1]St. Michael's Hosp., Toronto, ON, Canada, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Mem. Univ. of Newfoundland, St. John's, NL, Canada, [4]Zane Cohen Ctr., Sinai Hlth.System, Toronot, ON, Canada, [5]Patient Partner, St. John's, NL, Canada, [6]Sunnybrook Hlth.Sci. Ctr., Toronto, ON, Canada, [7]Patient Partner, Toronto, ON, Canada, [8]Patient Partner, Vancouver, BC, Canada, [9]The Hosp. for Sick Children, Toronto, ON, Canada, [10]BC Cancer, Vancouver, BC, Canada

Background: Hereditary cancer syndromes (HCS) account for 5-10% of all cancers. HCSs such as hereditary breast and ovarian cancer syndrome (HBOC) or Lynch syndrome (LS) can increase one's lifetime risk of cancer by over 80%. HCS patients therefore require lifelong follow-up care, including screening and appointments with a wide range of specialists. However, it is unknown what patients' care experiences are after receiving a molecular diagnosis of HCS, a major factor influencing clinical utility of genetic testing.
Aim: To understand the care experiences and needs of HCS patients following receipt of a molecular diagnosis of HCS.
Methods: HCS patients who received a positive genetic test result for HBOC or LS were purposely sampled from clinics in Ontario (ON), Newfoundland and Labrador (NL), and British Columbia (BC), reflecting variation across genetic testing services, screening and follow-up programs. Semi-structured interviews were completed with interpretive description used for analysis.
Results: Qualitative interviews were conducted with 73 patients (51 females, 21 males, 1 gender-diverse; age range 25-80 yrs) diagnosed with HBOC (n= 39) or LS (n= 34). Several key themes emerged including navigation, advocacy, and access. HCS patients expressed difficulties in navigating recommended follow-up care, and often mentioned a lack of guidance and knowledge from their healthcare professionals. Several patients highlighted the need for adequate communication about screening practices following risk-reducing surgeries and the importance of trust in care. Patients often had to self-advocate for referrals and screening appointments and noted differences in access to these services across jurisdictions. Importantly, access to genetic services, specialists and eligibility for prevention programs were described as sometimes limited for HCS patients. Participants commented that their circle of care (i.e., number and diversity of specialists involved in care) was likely smaller than those with a previous cancer diagnosis and noted impacts on access to support services.
Conclusions: This is the first study to compare HCS patients' experiences with care after receipt of genetic testing, a determinant clinical utility. We found that HCS patients face numerous healthcare challenges. Receiving adequate guidance from healthcare professionals, getting timely access to screening, professional and informational supports and trust in care were most widely discussed among participants. Identifying the needs and challenges for patients with HCS can optimize care experiences and ultimately improve patient outcomes and the value of genetic testing.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2391 How to conduct equitable genetics research to include underrepresented populations: A systematic review of best practices.

Authors:

V. Aguda[1], S. Grewal[1], K. Cheung[2], V. Jha[3], E. Reble[1], M. Clausen[1], D. Lightfoot[1], A. Lofters[4], N. Persaud[1], M. Aronson[5], A. Pollett[5], H. Feilotter[6], J. Lerner-Ellis[5], Y. Bombard[3,1]; [1]Unity Hlth.Toronto, Toronto, ON, Canada, [2]Boston Univ., Boston, MA, [3]Univ. of Toronto, Toronto, ON, Canada, [4]Women's Coll. Hosp., Toronto, ON, Canada, [5]Mount Sinai Hosp., Toronto, ON, Canada, [6]Queen's Univ., Kingston, ON, Canada

Introduction: The genetics community at large has recognized that current data sources and analytical approaches are inherently biased toward individuals of European ancestry. Underrepresentation of genomes from diverse ancestries results in uncertainty about the interpretation of benign versus disease-causing genetic variation leading to a higher rate of inconclusive test results in those populations and risk prediction models that do not transfer across genetic ancestries. Without a genetic diagnosis, access to personalized treatment and management options, as well as cascade testing for relatives, is restricted, often in populations who are already under-referred to genetic services. As genetic information is increasingly translated into clinical care, promoting equitable practices is paramount to prevent genetic technologies from further exacerbating existing health disparities. While the lack of diversity in genetic research has been well characterized, there are limited guidelines for researchers on best practices for conducting equitable genetic research. In this study, we aim to systematically review and synthesize the literature on best practices for conducting equitable genetic research. **Methods:** A systematic review is being conducted. The review has been registered in PROSPERO (CRD42023384475). Medline, EMBASE, and Cochrane Databases were searched for articles that described strategies, guidelines, contextual factors, and best practices for conducting equitable research in genetics. Grey literature was also searched. Data extraction is being conducted by two reviewers. Quality assessment is being conducted using established critical appraisal tools from the Joanna Briggs Institute. Mixed methods are being used for a descriptive synthesis. **Results:** The searches returned 5366 articles. Title and abstract screening are ongoing. To date, 286 studies have proceeded to full-text screening. Preliminary themes from articles in full-text screening include increasing awareness and access to research opportunities, aligning research goals and questions with the priorities of communities, providing culturally-sensitive research materials, and the importance of co-design and collaboration rather than tokenistic participation. Full-text screening, data extraction, critical appraisal, and synthesis are expected to be completed by October 2023. **Conclusions:** This evidence synthesis is the foundation for the development of best practices for how genetic research with diverse patient populations can be done in a manner that is culturally safe, equitable, and ultimately benefits all involved.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2392 † Identifying patients at-risk for breast/ovarian cancer within Kaiser Permanente Mid-Atlantic States - the evaluation of genetics referrals and testing from a FHS-7 best practice advisory alert

Authors:

C. Jonas, P. Suwannarat, S. Basra, E. Watson, C. M. Boyd, A. Deneal, D. Canedo, S. Gustafson, K. Hsieh, S. Kim; Mid-Atlantic Permanente Med. Group, Rockville, MD

Background: Ovarian cancer patients are often diagnosed at a late stage, and the disease is associated with high mortality. According to the CDC, 10% of ovarian cancer cases are due to a hereditary genetic variant. In 2021, Kaiser Permanente Mid-Atlantic States (KPMAS) created an electronic health record based Best Practice Advisory (BPA) alert to identify patients who may be at higher risk for breast/ovarian cancer. This BPA displays based on a documented family history of certain cancers. Patients scoring more than 1 on the Family History Screening 7 (FHS-7) are offered a Genetics referral for genetic counseling. Results: During Sept. 1, 2021-Sept. 30, 2022, there were 5,466 OB/GYN visits with the BPA acknowledged, resulting in 2,769 (51%) Genetics referrals and 1,480 (53%) completed virtual genetic counseling visits. Genetic testing was ordered in only 24% of genetic counseling visits (n=348), but testing was completed 86% of the time (n=301/348; 86%)—indicating that if patients in this cascade are offered genetic testing, a large majority complete it. These results prompted the study team to examine the other 76% (N=1,131) of visits in which genetic testing orders were not placed. Results showed: 50% (n=561) of patients did not meet NCCN criteria for testing, 25% (n=278) met NCCN criteria but were told to encourage their affected relative to test first, 24% (n=275) met NCCN criteria but declined testing, and 1% (n=17) had already tested. Among the group told to encourage their affected relative to test, none had evidence of returning the relative's genetic testing results. Conclusions: Our results show a key drop off at the point of ordering genetic testing. Specifically, patients who met testing criteria were instructed to encourage an affected relative to test first and were not offered testing themselves (n=278; 19% of 1,480 total completed visits). As a result, none of these eligible patients completed genetic testing. While testing an affected family member is preferred, it is not always possible. Failing to test patients who meet criteria increases the chance that at-risk individuals are not identified and is a missed opportunity to offer genetic information. Recommending contacting affected family members that might be more appropriate for initial genetic testing is a long-accepted practice that may need to be revisited.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2393 Impact of SeqFirst in hospitalized neonates

Authors:

T. Wenger[1], K. MacDuffie[1], A. Keefe[1], M. Sikes[1], L. Kruidenier[2], O. Sommers[1], H. Gildersleeve[1], K. Buckingham[1], J. Chong[1], D. Veenstra[3], K. Dipple[4], D. Miller[1], D. Copenheaver[5], J. Juusola[6], K. Retterer[7], K. McWalter[8], A. Snook[8], P. Kruszka[8], J. H. Yu[1], M. Bamshad[1]; [1]Univ. of Washington, Seattle, WA, [2]Seattle Children's Hosp., Seattle, WA, [3]Univ of Washington, Seattle, WA, [4]Seattle Children s Hosp. and Univ. of Wash, Seattle, WA, [5]Gene Dx, Gaithersburg, MD, [6]GeneDx, Clarksburg, MD, [7]Geisinger, Danville, PA, [8]GeneDx, Bethesda, MD

The SeqFirst neo project aims to improve access equity to genomic testing of hospitalized neonates by offering rapid whole genome sequencing (rWGS) to infants not fully explained by prematurity, infection or trauma. Our group previously reported that enrolled infants (n=126) had a diagnostic yield of 50% at the time of rWGS. In order to better understand the impact of the SeqFirst approach versus conventional care, we reviewed the electronic health record for the first 12 months of life for 1) infants enrolled in SeqFirst (n=126) and 2) controls - consisting of all infants admitted to the NICU during the study period who were medically eligible for SeqFirst but instead received conventional care (n=113). Additionally, we explored the impact on families via parental questionnaires at enrollment, after rWGS, 6 and 12 months after enrollment. (Response rates per questionnaire 74.8-86.4%) Semi-structured 1:1 interviews were also conducted with neonatologists who cared for infants enrolled in SeqFirst. Infants in the control group who received conventional phenotype-driven care had a diagnostic rate of 8.8% in the NICU. After 12 months of follow up, only one additional genetic diagnosis had been made in the outpatient setting (9.7%). Precise genetic diagnosis in living infants led to similar rate of change in management for infants in SeqFirst group (89%) and those who received conventional care (87.5%). Among infants who died during the study period, those who were enrolled in SeqFirst were more likely to have a precise genetic diagnosis compared to those who received conventional care (67% vs. 22%). Parental questionnaires suggested low decisional regret and a positive impact on families for infants who received a precise genetic diagnosis as well as those who had nondiagnostic rWGS. Semistructured interviews with eight neonatologists who had patients enrolled in SeqFirst described the positive impacts they observed compared to conventional care, including expanded testing and quick access to results which helped guide medical management. Neonatologists additionally reported that the experience with SeqFirst had lingering impacts on their practice, broadening their awareness of the value of genetic testing and boosting their willingness

PB2394 Improving access to exome sequencing in a medically underserved population through the Texome Project: A summary of the first 60 cases.

Authors:

B. Vuocolo[1,2], R. German[1,2], C. Bacino[1,3,4], C. Murali[3,1], S. Lalani[1,3], S. Baskin[5], E. Roeder[5], C. Schmid[5], S. McLean[5], R. Littlejohn[5], O. Juarez[5], M. Stuebben[5], M. Nutter[5], B. Mitchell[5], D. El Achi[5], L. Vossaert[6,4], N. Owen[1,4], C. M. Eng[1,4], P. Liu[1,4], Z. Liu[1,2], D. Mao[1,2], S. Yamamoto[1,2], S. Kim[1,2], S. Pasupuleti[1,2], H. Bellen[1,2,7], M. Wangler[1,2]; [1]Baylor Coll. of Med., Houston, TX, [2]Jan and Dan Duncan Neurological Res. Inst., Houston, TX, [3]Texas Children's Hosp., Houston, TX, [4]Baylor Genetics Lab., Houston, TX, [5]Baylor Coll. of Med., San Antonio, TX, [6]Baylor Coll. Med., Houston, TX, [7]Howard Hughes Med. Inst., Houston, TX

Exome sequencing has been proven to be a useful clinical tool in ending diagnostic odysseys, but health insurance and other systemic barriers prohibit individuals in underserved communities from equitably accessing this genetic testing. The Texome project is an NIH-funded research study that reduces barriers to genetic evaluation by offering exome sequencing to patients with undiagnosed, rare diseases who have financial barriers to obtaining exome sequencing clinically. Participants receive a genetic evaluation, CAP/CLIA exome sequencing, and return of results free of charge. To date, there have been 132 applications reviewed by the Texome clinical team, and 104 have been accepted into the study, with an acceptance rate of 78.8%. Diverse regions of Texas are represented in our cohort, and a majority of patients are publicly insured (53.1%) and identify as Hispanic/Latino (68.1%). To date, 60 individuals have undergone exome sequencing, with an etiologic diagnosis confirmed in 18 (30%) of cases; 17 were solved by proband-only ES with Sanger confirmation of available parents, and one additional case was solved after reflexing to trio ES and discovering a recently-described de novo RHOB variant. Of these solved cases, 5 (27.8%) are confirmed or presumed to be inherited (3 autosomal recessive and 2 dominant). There is an even distribution of solved cases between the adult and pediatric patients. Variants in ITGA2B, RHOB, ZIC2, CTCF, ERCC4, B4GALT7, and SHANK3 were identified in adult patients of Texome, ending decades-long diagnostic odysseys and contributing to the genotypic and phenotypic understanding of these disorders. For cases that remain unsolved, we are utilizing advanced bioinformatics pipelines to identify novel variants or genes that may cause disease. Findings from the Texome project support the need for expanding access to genetic testing and services in underserved populations and highlight the utility of proband exome sequencing with Sanger confirmation as a first-tier test in medically underserved populations.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2395 Increased Rate of Return of Secondary Findings: Impact of the ACMG v3.1 Gene Lists.

Authors:

M. Kamen, M. Similuk, S. Byers, J. Yan, B. Seifert, R. Ghosh, C. Jodarski, R. Gore, K. Lewis, N. Reynolds-Lallement, B. Beers, E. Damskey, H. Orellena, J. Johnston, L. Biesecker, M. Walkiewicz; NIH, Bethesda, MD

Background: In June of 2022, the American College of Medical Genetics and Genomics (ACMG) released the ACMG Secondary Findings (SF) v3.1 list. The SF v3.1 policy statement announced 5 new genes to be included in the minimum SF gene list. This was a minor update to the 2021 ACMG SF v3.0 list. There are limited empirical estimates of the extent to which these additions will increase the SF molecular diagnostic rate, particularly considering the relatively high allele frequency (1.0%-2.5%) of the pathogenic c.424G>A *TTR* variant among individuals of West African ancestry. We sought to address this gap by reviewing the study cohort recruited to the National Institute of Allergy and Infectious Diseases (NIAID) Centralized Sequencing Program (CSP) to determine the impact on the rate of return for the ACMG SF v3.1 vs v3.0.
Methods: We analyzed the genomes of a cohort of families with heterogenous clinical phenotypes enrolled in the CSP. We applied ACMG's Standards and Guidelines for the Interpretation of Sequence Variants to evaluate pathogenicity. We returned pathogenic and likely pathogenic variants to study participants per SF guidelines. Specifically, we looked at all coding variants with a minor allele frequency of ≤1%. Notable exceptions were variants with autosomal recessive modes of inheritance in *BTD* and *HFE* with a minor allele frequency extended to 5%, the pathogenic *GAA* variant, NM_000152.5 c.-32-13T>G as well as the pathogenic *TTR* variant c.424G>A.
Results: We applied the 2021 SF v3.0 guidelines to the genomic analysis of 1,091 families and detected 35 total SF (3.2% SF rate; 95% CI [2.2%,4.4%]). Subsequently, we applied the 2022 SF v3.1 updated guidelines to the analysis of 748 additional families and detected 30 total SF (4.0% SF rate; 95% CI 2.7% to 5.6%). Among the 5 new genes included in the SF v3.1 update, we identified the high frequency TTR c.424G>A variant in 9 families, (1.2%; 95% CI [0.55%,2.27%]) and this made up all new SF not reflected in the v3.0 list. While SF v3.0 vs v3.1 guidelines increased the rate of SF return from approximately 3.2% to 4.0%, this difference was not statistically significant (95% CI [-0.37%,0.56%], Chi-squared = 0.008, P = 0.93).
Discussion: These data suggest providers may expect an increase in the SF rate of return, largely driven by the frequency of the pathogenic c.424G>A *TTR* variant. The associated hereditary transthyretin amyloidosis has reduced penetrance and is mitigated by FDA-approved treatments, making it an attractive target for opportunistic screening and personalized treatment. The small sample size limits further analysis but provides preliminary evidence to support further characterization of SF yield and outcomes.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2396 Insurance Record-Based Analysis of the Burden of Disease in Patients with Galactosemia in the US

Authors:

D. Gallo[1], N. Longo[2], J. L. Fridovich-Keil[3], R. Chang[4], J. B. Spencer[5], B. Moy[1], A. G. Ellis[6]; [1]Jaguar Gene Therapy, LLC, Lake Forest, IL, [2]Dept. of Pediatrics, Univ. of Utah Spencer Fox Eccles Sch. of Med., Salt Lake City, UT, [3]Dept. of Human Genetics, Emory Univ. Sch. of Med., Atlanta, GA, [4]Children's Hosp. of Orange County, Div. of Metabolic Disorders, Orange, CA, [5]Dept. of Gynecology and Obstetrics, Emory Univ. Sch. of Med., Atlanta, GA, [6]Stratevi, LLC, Boston, MA

Objective: Classic galactosemia is a rare genetic disease that can cause severe lifelong complications. Data on the lifetime clinical trajectory of disease are limited. This study helps characterize the real-world burden of disease among US galactosemia patients. **Methods:** Data from MarketScan (January 2006 - September 2022) were analyzed. Patients were identified using International Classification of Diseases, 9th Revision and 10th Revision codes for galactosemia (271.1 and E74.21, respectively). Pediatric and adult galactosemia patients were matched with up to 2 individuals from the general population (controls) based on year of birth, sex, region, insurance type, and years of continuous enrollment. The prevalence (n, %) of 17 conditions among the galactosemia patients was compared with demographically matched controls. The list of conditions was generated based on a prior analysis of a US claims database (Symphony Health) and input from clinical experts. The prevalence of conditions by age groups and by sex was examined. **Results:** 1,957 galactosemia patients and 3,431 matched controls were included. The average age was 23, and 51% of patients were male. The prevalence of all conditions was greater in the galactosemia cohort compared with matched controls and was significantly higher for 16 conditions. Of note, developmental delay, bone health disorders, neurological complications, and intellectual disabilities were each at least twice as high for the galactosemia cohort vs. controls. Furthermore, conditions not previously associated with galactosemia were observed to be higher in the galactosemia cohort, including liver illness. The prevalence of specific conditions differed between younger and older age cohorts, indicating different manifestations of disease across ages. For example, dietary counseling and complications and liver illness were common among people <1 year of age and significantly higher for patients with galactosemia. In people 40-69 years of age, blood related disorders, kidney related disorders, liver illness, malaise and fatigue, and neurological complications were common and significantly higher in the galactosemia cohort. Among females, larger differences in gonadal complications and bone health were observed starting in adolescence and into adulthood. **Conclusion:** The prevalence of 16 selected comorbid conditions is significantly higher among patients with galactosemia than for a general population of matched controls. The prevalence of conditions varied across age groups, providing insights into the lifetime burden of disease and raising awareness of previously unexpected complications in adults.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2397 Measuring and Maximizing Outcomes in Population Genomic Screening: a High-Touch Recontact Pilot

Authors:

K. Tangney, D. Erwin, D. Brockman, S. Zarkesh Esfahani, N. M. Johnson, J. Lee, A. Khan, A. Collins, A. Nguyen, R. Garcia, C. L. Neben, S. Topper; Color Hlth., Burlingame, CA

Population genomic screening can provide crucial health information to millions at risk for hereditary conditions, but its impact depends on follow-up care utilization for which there is limited longitudinal data. At Color Health, we provide population screening and genetic counseling for common hereditary conditions through employee benefits programs, research studies, and healthcare providers. To assess how people navigate clinical recommendations after receiving genetic results and counseling, we recontacted 200 Color Health participants by phone who received a positive genetic result 1-3 years prior for familial hypercholesterolemia (FH), hereditary breast and ovarian cancer (HBOC), or Lynch syndrome (LS). We collected participant-reported actions since receiving results, and connected them to local resources or an in-house care advocate if further care navigation was indicated or requested.

Of 200 selected participants, 37% (n=74) were re-contacted. The average age of participants was 50 years (range 22-84), 47% (n=35) self-identified as female, 70% (n=52) were non-Hispanic White, and all were English-speaking. A total of 34 participants (46%) had a HBOC pathogenic variant (PV), 27 (36%) had a LS PV, and 13 (18%) had a FH PV. Of 11 HBOC females eligible for screening or prevention, 36% (n=4) reported initiating breast MRI, 55% (n=6) reported risk-reducing mastectomy, and 55% (n=6) reported bilateral salpingo-oophorectomy. Of 13 eligible HBOC males, 54% (n=7) reported initiating PSA, and 46% (n=6) initiated male breast cancer screening. Initiation of screening and prevention was higher with the 27 LS participants - 70% (n=19) initiated colonoscopy screening and 47% (n=7 females) reported risk reducing hysterectomy - but lower with the 13 FH participants - 31% (n=4) initiated or altered their lipid treatment.

Within two weeks of initial receipt, many participants shared results with a provider (65%; n=49) and at-risk relatives (73%; n=54). During recontact, 3 additional participants chose to share results. A total of 10 participants sought care navigation: 7 were connected to local resources by genetic counselors and 3 had help navigating health insurance or connection to a local primary care provider by care advocates.

This pilot showed that many population screening participants (57%; n=42) reported initiating a recommended screening, prevention or treatment after receiving a high-risk genetic result and post-test counseling. Accessible population screening combined with genetic counseling and care advocacy can be effective in identifying and empowering high-risk individuals to take appropriate next steps in their healthcare.

Pasupuleti[1,2], S. Yamamoto[1,6,7,2], H. Bellen[1,2,7,8], M. Wangler[1,2,7]; [1]Dept. of Molecular and Human Genetics, Baylor Coll. of Med., Houston, TX, [2]Jan and Dan Duncan Neurological Res. Inst., Texas Children's Hosp., Houston, TX, [3]Texas Children's Hosp., Houston, TX, [4]Baylor Genetics Lab., Houston, TX, [5]Dept. of Pediatrics, Baylor Coll. of Med., San Antonio, TX, [6]Dept. of NeuroSci., Baylor Coll. of Med., Houston, TX, [7]Program in Dev.al Biology, Baylor Coll. of Med., Houston, TX, [8]Howard Hughes Med. Inst., Houston, TX

The Texome Project is a genomic medicine implementation program for communities that lack access to genetics services in Texas. The Texome Project provides whole exome sequencing (WES), AI-optimized bioinformatics analysis, and model organisms to diagnose and study genetic disease in medically underserved groups. To date, 60 CAP/CLIA WES results have been disclosed to participants since beginning enrollment in December 2021. We present 5 cases where WES led to a change in medical management that would not have been indicated without access to genomic medicine. Case 1) A 7-year-old male was evaluated for global developmental delay, hypotonia, strabismus, atrial septal defect, and seizures. WES found a pathogenic variant in *ATP1A3* associated with alternating hemiplegia of childhood 2. The patient was started on flunarizine, a calcium channel blocker, and has not reported any further hemiplegic episodes. Case 2) A 40-year-old female with bilateral carotid paragangliomas, intellectual disability, and dysmorphic features was enrolled in the Texome Project. A variant in *DNMT3A* was uncovered on WES. This result represents a possible diagnosis of Heyn-Sproul-Jackson syndrome and was linked to the patient's paragangliomas and resulted in a recommendation to begin annual thyroid exams to screen for recurrent malignancies. Case 3) A 7-year-old male with autism, developmental delay, and a family history of hypocalciuric hypercalcemia was enrolled in the Texome Project. WES reported a pathogenic variant in *CASR* indicating a molecular diagnosis of hypocalciuric hypercalcemia type I. This finding resulted in a referral to follow with nephrology for monitoring. Case 4) A 9-year-old female with intellectual disability, autism, mild dysmorphic features, and epilepsy. She received WES, which reported a pathogenic variant in *GNB1* associated with Intellectual developmental disorder 42. Given this finding, the patient was recommended to seek physical therapy, occupational therapy, and a sleep study to better manage their condition. Case 5) A 5-year-old female presented with spasticity, cerebral palsy, toe walking, and recurrent urinary tract infections. After enrollment into the Texome Project, WES uncovered a pathogenic variant in *ADAR* consistent with Aicardi-Goutières syndrome 6. Tofacitinib, a JAK inhibitor, was recommended and administered by the patient's rheumatologist. The family has reported a positive response to treatment, with lessening spasticity. These cases demonstrate the clinical utility of whole exome sequencing in medically underserved groups to end diagnostic odysseys and provide management recommendations.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2399 Narrative explorations of rare and undiagnosed genetic diseases: Elucidating lived experiences of the diagnostic odyssey.

Authors:

I. Simeone, C. Dvorak; Hayward Genetics Ctr., Tulane Univ. Sch. of Med., New Orleans, LA

Background: It is estimated that approximately 72% of rare diseases have a genetic etiology, and many patients facing such diseases are misdiagnosed or remain undiagnosed for several years. Previous studies have characterized the negative psychosocial, financial, and emotional burdens on these patients and their families, suggesting an unmet need for psychological support among this population.
Purpose: Considering the role of family dynamics in shaping the lived experience of these patients, there exists a paucity of scholarly work on the sociological dimensions of rare and undiagnosed genetic diseases. Patients facing rare, complex, and difficult-to-diagnose genetic diseases often undertake a protracted and unpredictable "diagnostic odyssey" in seeking answers. What happens when a genetic disease does not fit within any existing paradigms? How can patients (and their caregivers) facing ultra-rare genetic diseases look to narrative and storytelling as a source of support?
Methods: To address these questions, our study was anchored by close readings of two illness memoirs, *The Family Gene: A Mission to Turn My Deadly Inheritance into a Hopeful Future* by Joselin Linder and *This Boy We Made: A Memoir of Motherhood, Genetics, and Facing the Unknown* by Taylor Harris. We aimed to call attention to the unique voices of patients who may feel overlooked and burdened by the complexity of their medical histories and elusive nature of their genetics.
Results: Illness memoirs written by writers grappling with rare and undiagnosed genetic diseases reveal ubiquitous themes of incomprehensibility, medicalization of family and kinship, and liminality; figurative language such as metaphor and anthropomorphism allows for these writers to effectively adopt a "style" for their illness, better allowing them to grapple with their lived experiences. Beyond the utility of the illness memoir for patients to generate their own "language of illness," such narratives—particularly those that may enrich a reader's understanding of how best to support patients despite having limited/no answers—can be a foundational tool in the educational experience of medical students.
Conclusion: Existing at the margins of established disease taxonomies, rare and undiagnosed genetic diseases are defined foremost by the "inexpressibility topos" inherent in navigating an illness sphere for which there exists no precedent, language, or greater "illness community" to lean on. Future research may focus on characterizing the beneficial effects of a "narrative intervention" (writing, reading, or verbally telling stories) across all participants in the therapeutic relationship.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2400 Neurodevelopmental Comorbidities in Newborn Screening Conditions.

Authors:

Z. Talebizadeh, G. Tona, Y. Unnikumaran, A. Brower; American Coll. of Med. Genetics and Genomics, Bethesda, MD

Newborn screening (NBS) is a large-scale public health program in the US that screens 3.8 million newborns for up to 81 genetic conditions each year. Many of these conditions have comorbidities, including autism, neurodevelopmental disorders (NDD), and intellectual/developmental disabilities (IDD). These comorbidities can have a significant impact on health outcomes across the lifespan. Most screened conditions are inborn errors of metabolism (IEM). PKU, the first condition identified by NBS, is an inherited metabolic disorder that can cause developmental delays and IDD if not treated. The Newborn Screening Translational Research Network (NBSTRN) is a program funded by the National Institute of Child Health and Human Development since 2008. NBSTRN is charged with developing, maintaining, and enhancing tools, resources, and expertise supporting NBS research. One of the tasks led by NBSTRN is to provide direction for developing question/answer sets used in the Longitudinal Pediatric Data Resource (LPDR) to create consensus-based, and standardized common data elements (CDEs) for NBS conditions. There is a growing interest in the NBS community to assess neurodevelopmental trajectories through long-term follow-up studies. This could be streamlined by employing uniform CDEs. To address this unmet need, we conducted a landscape analysis. Our objective was to identify CDEs that can be used to study neurodevelopmental trajectories for NBS conditions having NDDs as comorbidity. We used a mixed methods approach (data mining, focus group, and literature reviews) to conduct a feasibility assessment, including the identification of needs and priorities. Data mining included examining health information from a completed, 10-year natural history study of IEMs, called Inborn Errors of Metabolism Collaborative (IBEMC). 44 IEM conditions are currently included in the Recommended Uniform Screening Panel. Deidentified data from the IBEMC projects are available for secondary data analysis in LPDR. The IBEMC data dictionary was reviewed to identify NDD-related CDEs. PubMed search and MedGen review were conducted to estimate the prevalence of NDD-related comorbidities in NBS conditions. Furthermore, existing CDE repositories were evaluated to identify a list of NDD-related CDEs. Branching logic was developed to assist with prioritizing the adoption of these CDEs in NBS research studies. Our findings can inform future efforts toward advancing research infrastructure for this established public health program. The renewed awareness of the risk of NDDs after a positive NBS and diagnosis could lead to improving treatment guidelines for mental health conditions.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2401 Novel applications of the *All of Us* Research Program platform in a course-based undergraduate research experience.

Authors:

K. McDougal; Towson Univ., Towson, MD

Course-based Undergraduate Research Experiences (CUREs) are opportunities for students to design and conduct authentic research projects within the framework of an academic course. CUREs expose a larger number of students to research than traditional research experiences and can be beneficial for individuals from populations underrepresented in research spaces. The *All of Us* Research Program is a large, unique data resource accessible to researchers at all stages of their careers through a centralized cloud-based platform. This creates an interesting and valuable opportunity to expose students to research experiences in biomedical genomics using expansive data from diverse populations. A CURE using the *All of Us* Researcher Workbench has been run in three different iterations. The first was a Registered Tier design using electronic health record, survey, wearable, and demographic data types. Then, once genomic data was released, a Controlled Tier design was implemented using limited genotype array data combined with the data types used in the previous Registered Tier version. Finally, the most recent iteration was a Controlled Tier design where students performed genome-wide association studies using whole genome sequencing data in concert with the electronic health record, survey, and demographic data types. In all iterations students worked in pairs to design a research proposal on the topic of their choice, performed the research in the *All of Us* Researcher Workbench, and reported their findings in a poster presentation. This CURE is an example for those at other institutions who wish to utilize the *All of Us* platform to enhance student exposure to authentic research experiences in biomedical genomics with a precision medicine focus.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2402 Offering return of results at the time of enrollment improves uptake of genomic screening among participants of a diverse biobank

Authors:

E. Soper[1], S. Suckiel[2], E. Kenny[1], N. S. Abul-Husn[3]; [1]Icahn Sch. of Med. at Mount Sinai, New York, NY, [2]Icahn Sch. of Med. at Mount Sinai, New York City, NY, [3]23andMe, Sunnyvale, CA

Background: Genomic screening for actionable variants can uncover disease risk, allowing intervention with the aim of improving health outcomes. Biobank-based return of results (RoR) offers an opportunity to implement genomic screening at scale. However, the ideal timing for offering RoR to participants remains unknown. We compared RoR uptake among participants of a diverse biobank in New York City who could consent to RoR at enrollment or at a later time.
Methods: The study population consisted of 127 adult participants of the Bio*Me* Biobank enrolled between 8/2/2016 - 2/7/2020 with an unconfirmed research finding (*TTR* V142I pathogenic variant). The Bio*Me* research protocol was amended 10/1/2018 to allow RoR. Participants enrolled after that date (N=56) could opt in/out of RoR at consent. Participants enrolled prior to this (N=71) were not offered RoR at consent, but could subsequently update their consent to opt in/out of RoR. We outreached to participants to collect a new sample for clinical confirmation of the research finding. Individuals who had consented to RoR at enrollment were informed of the presence of a research finding and asked to provide a new sample if they wished to proceed with clinical confirmation. Those enrolled prior to the protocol amendment could not be informed about a research finding, but were offered the opportunity to re-consent for RoR with concurrent sample collection for clinical confirmation. Using Fisher's exact test, we compared the uptake of RoR, defined as receiving a clinically confirmed result, among both groups overall, and among the subset of individuals from each group who we successfully recontacted.
Results: 52 of 56 participants who were consented for RoR at enrollment, and 70 of 71 who were not, were eligible for outreach (i.e., living and had not opted out of RoR). Overall, RoR uptake was 2.9x higher among those opting in to RoR at enrollment (33%) compared to those not previously consented for RoR (11%, p=0.006). In the subset of individuals we successfully recontacted, RoR uptake was 2.4x higher among those opting in to RoR at enrollment (44%) compared to those not previously consented for RoR (18%, p=0.016).
Conclusions: A significantly higher proportion of participants received results when offered the option of RoR at the time of enrollment into Bio*Me*. Crucially, we were able to inform participants of a potential genomic finding at outreach if they had already consented to receive this information. These findings highlight the importance of engaging participants about RoR at the time of biobank enrollment to maximize the reach of genomic screening.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2403 Participants and stakeholders views on feedback of genetics research findings of the H3Africa kidney disease research network, Ghana**.**

Authors:

G. Larbie Gafa[1], V. Boima[2,1], I. Rockson[1], S. T. Chatio[3], A. Ghansah[4], B. L. Salako[5], A. Ojo[6], P. Tindana[7], D. Adu[1,2]; [1]H3-Africa Kidney Disease Res. Network, UGMS, Accra, Ghana, [2]Dept. of Med. and Therapeutics, Univ. of Ghana Med. Sch., Coll. of Hlth.Sci., Univ. of Ghana, Accra, Ghana, [3]Navrongo Hlth.Res. Ctr., Ghana Hlth.Service, Navrongo, Ghana, [4]Noguchi Mem. Inst. for Med. Res., Univ. of Ghana, Legon, Ghana, [5]Coll. of Med., Univ. of Ibadan, Ibadan, Nigeria, [6]Kansas Univ. Med. Ctr., Kansas, KS, [7]5. Dept. of Hlth.Policy, Planning and Management, Sch. of Publ. Hlth., Coll. of Hlth.Sci., Univ. of Ghana, Legon, Ghana

Genetics and genomics research raise important ethical issues, particularly those related to obtaining valid consent, engaging with relevant communities in the implementation of research and feedback of research findings. There is evidence that variants of the Apolipoprotein L1 gene in Africans and people of African descent increase the risk of developing chronic kidney disease (CKD). A study carried out by the H3Africa Kidney Disease Research Network showed that 28.2% of the study participants carried 2 *APOL1* high-risk variants. It is also known that relatives of subjects with CKD may be at increased risk of developing CKD. Should participants and their relatives be informed about their risk of developing CKD? What findings should be given and who should be involved in the feedback process? The aim of this study was to seek the views of research participants, families and stakeholders on feedback of genetic research findings. This research employed an exploratory qualitative study approach for data collection. The study explored the views of genetic/genomic researchers, participants, families and members of research ethics committees on what count as good ethical practice in deciding what, who and how to return genetic research findings of the kidney disease research in Ghana through in-depth interviews, focus group discussions and deliberative workshops. Data was coded and structured with NVivo software and thematically analysed. There was a consensus that relevant individual and aggregate genetics results should be fed back to participants and communities. Most participants preferred to receive their personal results from a doctor or a research scientist. There is an ethical imperative to return validated clinically relevant individual genetic research results to the kidney disease research participants and families and aggregate results to communities. We recommend the H3Africa Kidney Disease Research Network to educate participants and families on the concept of risk variants, train Genetic Counsellors and explore innovative strategies to support the feedback process.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2404 Poor foundation in genetics and related disciplines a clog in the progress of bioinformatics and computational biology in Nigeria

Authors:

I. Uzoma[1], J. Iloekwe[2], I. A. Taiwo[3]; [1]Molecular-Haematology Lab., Dept. of Med. Lab. Sci., Univ. of Nigeria Nsukka, Enugu, Nigeria, [2]Sch. of Sci. and Technology Pan-Atlantic Univ., Lekki, Lagos, Nigeria, [3]Human Genetics Res. Group, Genetics Res. Unit, Dept. of Cell Biology and Genetics, Faculty of Sci., Univ. of Lagos, Akoka., Lagos, Nigeria

The advent of genomics is associated with a rapid rise in biological data needing the use of mathematics, statistics, and computer algorithms to handle and examine the huge biological information stored in databases. Despite the seemingly obvious relevance of bioinformatics and computational biology in the current age of genomics, growth in the field of computer-aided management and study of biological data has been sluggish in Nigeria. Some scientists have deliberated on the state of bioinformatics and computational biology in Nigeria; some have addressed possible factors militating against advancement and progress in this area, but none has addressed the fundamental issue which might be the major limiting factor responsible for the slow progress poor foundation in genetics and related disciplines because of rigidity in our curricula at the pre-tertiary and tertiary institutions. Empirical indications point to the need to overhaul our academic curricula at all stages in Nigeria and other underdeveloped countries with a view to aligning our educational systems with the emerging truths of genomics, bioinformatics, and computational biology.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2405 Preliminary Findings from a Pilot Study of Disability Identity Among Parents of Pediatric Participants in the Undiagnosed Diseases Network

Authors:

K. Mintz, S. S. Lucas-Griffin, H. Tabor; Stanford Univ. Sch. of Med., Stanford, CA

Rare and undiagnosed genetic conditions often contribute to individuals experiencing a range of functional limitations and disabilities. Yet few, if any, studies have explored experiences of disability in this population. We present preliminary findings from a qualitative study of experiences of disability identity among parents of children enrolled in the Undiagnosed Diseases Network (UDN). Twenty parents of children aged 3 to 17 enrolled in the UDN participated in the study. Each parent completed two qualitative, semi-structured interviews. We suggest that the experiences of parents in the study exemplify three ways in which clinical genetics and genomics researchers might partner with families in navigating living with significant disabilities. First, researchers may consider expanding the scope of research questions to emphasize improving a patient's quality of life, even if curing a genetic condition is unlikely. Second, researchers might help individuals and families better confront the difficulties they face applying for and receiving services for disability-related needs, for example by providing a letter documenting their disabilities. Such assistance is critical since many government programs require individuals to have a widely recognized diagnosis before receiving services. Third, many individuals interviewed found the labels associated with disability and chronic illness used in research stigmatizing. This suggests that clinical genetics and genetics research communities should carefully examine and potentially revise the language used to categorize patients and research participants. Taken together, these preliminary findings provide opportunities for genomic research studies to critically reflect on the appropriate role of and approaches to reciprocity between investigators and participants in genetics and genomics research.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2406 Prenatal gene editing for neurodevelopmental disease: ethical and scientific considerations.

Authors:

R. Major[1], E. Juengst[2]; [1]Univ. of North Carolina, Chapel Hill, NC, [2]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Neurodevelopmental disorders are notoriously difficult to identify and treat early enough to make a meaningful difference in symptom alleviation. However, as prenatal diagnostic technologies become more powerful and prevalent, there may be opportunities to target diseases before they manifest. Ultrasounds, genetic screenings, exon sequencing, and whole genome sequencing could be used to detect the vast majority of neurogenetic diseases while a fetus is still in-utero. Gene editing trials are quickly making their way into the clinic and have already shown great promise in the treatment of blood and eye diseases. Although much debate exists around heritable gene editing, few have considered the ethical implications and promise of prenatal gene editing. Prenatal gene editing is particularly contentious because there are two patients to consider: the fetus and the pregnant person. This presentation will explore the ethical and scientific considerations of prenatal gene editing by reviewing current ethical perspectives and guidelines on analogous examples of fetal medicine and assessing these considerations in the context of neurodevelopmental disorders for which prenatal gene editing may be considered. The goal of this presentation is to provide a roadmap of sorts for the field to navigate the ethical and scientific landscapes of prenatal gene editing for neurodevelopmental disease.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2407 Prevalence of ACMG secondary findings: Implications for population health and health disparities.

Authors:

M. Macneal[1], M. Higashi[1], T. Brandt[1], J. Ge[1], W. Walker[2], D. Veenstra[3], R. Essner[2]; [1]GeneDx, Stamford, CT, [2]AdventHlth., Orlando, FL, [3]Univ of Washington, Seattle, WA

Background: Exome sequencing (ES) and genome sequencing (GS) are widely used to diagnose genetic disorders. An additional benefit of ES/GS is the detection of secondary findings (SFs) unrelated to the primary diagnosis but with medical actionability (PMID: 36143288). The American College of Medical Genetics and Genomics (ACMG) has published a guideline for reporting secondary findings (PMID: 34012068), with a recent update (ACMG SF v3.1) listing 78 genes (PMID: 35802134), including the Centers for Disease Control and Prevention's (CDC) Tier 1 conditions for primary screening: Lynch syndrome, hereditary breast and ovarian cancer syndrome, and familial hypercholesterolemia (FH) (PMID: 25577298). While population genomic screening for these disorders is likely to be cost-effective in U.S. adults younger than 40 years (PMID: 37155986), studies have shown lower implementation rates among racial and ethnic minority groups, rural communities, uninsured or underinsured people, and those with lower education and income (PMID: 35482015).
Objective: Establishing the frequency and prevalence of medically actionable SFs across racial and ethnic groups will strengthen health system efforts to design effective prevention and health improvement programs.
Methods: Deidentified ES and GS SF data (N=104066) were analyzed from the GeneDx diagnostic testing database dating back approximately ten years. This database is enriched for individuals presenting with typical ES/GS testing indications (e.g. pediatric neurodevelopmental disorders, congenital anomalies). ACMG SF frequencies were stratified by imputed ancestry.
Results: The overall prevalence of SFs was 2.35% (N=2567), with the East Asian population at a rate of 3.29%, which is statistically significant when compared to other imputed races. Statistically significant prevalence differences by imputed race were found in the following genes: *TTN* (Black and South Asian), *TTR* (Black), *HFE* (White), *APOB* (East Asian), *MYH7* (East Asian).
Limitations: Not able to distinguish founder effects among white patients (e.g. Ashkenazi Jewish, Finnish)
Conclusions: The frequency of *APOB* mutations (CDC Tier 1) are significantly higher in East Asian families, suggesting an elevated risk for FH. Higher frequencies in several groups confirms some known associations, but reveals possible novel increased disease prevalence. As self-reported race is not always available or accurate, imputed ancestry presents an opportunity to enrich sample sizes for research and population health programs. Narrowing our analysis to only SFs reduces the likelihood of confounding with pediatric illness and primary reason for testing.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2408 Primary care patient and provider attitudes about population-based genetic testing and a chatbot to support informed decision-making.

Authors:

S. Andrews[1], R. Moultrie[1], O. Kutsa[1], K. Williams[1], K. Carpenter[2], A. Parker[2], J. Hunter[1], B. Biesecker[1]; [1]RTI Intl., Research Triangle Park, NC, [2]Univ. of Florida Coll. of Med., Jacksonville, FL

The three CDC Tier 1 conditions (Hereditary Breast and Ovarian Cancer, Lynch Syndrome, and Familial Hypercholesterolemia) are estimated to affect 2 million people in the US; however, an estimated 90% are unaware of their genetic risk. Population-based genetic screening is a promising approach to increase identification. Genetic counselors play an essential role in genomic medicine; however, leveraging their expertise for population-level screening is not feasible or financially sustainable. Digital tools such as chatbots are a promising, scalable approach to provide pretest genetic counseling for population-level genetic screening. From May to July 2022, we conducted semi-structured interviews with patients (N=20) and primary care providers (PCPs, N=9) from primary care clinics at an academic medical center that serves a large, diverse metropolitan city. Interviews assessed attitudes about predictive genetic testing, openness to population-level genetic screening, and reactions to a chatbot as a tool to facilitate patient informed decision-making. Rapid qualitative analysis methodology was used to analyze interview data. Most patients were receptive to population screening but had concerns about privacy and discrimination based on results, possible anxiety about results, and fear of invasive procedures (e.g., blood draws). To support decision-making about genetic testing, patients expressed the need to know: potential harms; how results will be stored; procedures involved (e.g., saliva vs blood draw); and how to interpret results. PCPs expressed the need to inform patients that: early disease identification through genetic testing can improve morbidity and mortality; results could have implications for family members; and testing is completely voluntary. Moreover, PCPs expressed the need for clear follow-up procedures and concerns about insurance coverage among patients with a positive result. Finally, PCPs stressed the importance of education to ensure understanding that a negative result does not mean they will never have heart disease or cancer. Both patients and PCPs reacted positively to the chatbot as a tool to educate patients about genetic testing. They reported the tool was easy to navigate and had sufficient information to make an informed decision about genetic testing, though using a chatbot might be difficult for elderly people who are less comfortable with technology. This work provides important information about receptivity of patients and PCPs to population screening and the potential for chatbots as a tool to facilitate decision-making around the implementation of large volume, population-level genetic screening.

PB2409 Process steps and resource requirements associated with innovative genetic testing: A time and motion study in the clinical sequencing evidence-generating research (CSER) consortium

Authors:

L. Desrosiers[1,2], H. Smith[3,1], J. Bensen[4], J. Chau[5], C. Finnila[6], L. Hindorff[7], H. Hoban[8], N. Kelly[9], F. Lynch[10], B. Rolf[11], N. Sahin Hodoglugil[8], M. Wasserstein[12], T. Yip[13], K. Hassmiller Lich[4]; [1]Baylor Coll. of Med., Houston, TX, [2]Texas Children's Hosp., Houston, TX, [3]Harvard Med. Sch. and Harvard Pilgrim Hlth.Care Inst., Boston, MA, [4]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [5]NIH/NIAID, Bethesda, MD, [6]HudsonAlpha Inst. for Biotechnology, Huntsville, AL, [7]NIH/NHGRI, Bethesda, MD, [8]Univ. of California San Francisco, San Francisco, CA, [9]Children's Hosp. at Montefiore and the Albert Einstein Coll. of Med., Bronx, NY, [10]Kaiser Permanente Northwest, Portland, OR, [11]Univ. of Washington, Seattle, WA, [12]Albert Einstein Coll. of Med., Bronx, NY, [13]UCSF, San Francisco, CA

Background As the material cost of genomic sequencing (GS) (e.g., exome and genome) declines, use of GS in clinical care has expanded. In addition to material costs, clinical GS requires personnel time and care delivery infrastructure, the costs of which are understudied. The NHGRI Clinical Sequencing Evidence-Generating Research (CSER) consortium consisted of 6 projects investigating implementation of GS innovations (GSI) in care of diverse populations, thus providing a unique setting to explore resource requirements for GSI implementation.
Methods Detailed process flow diagrams were generated for each project and 11 process steps common across the projects were defined (cPS). In 5 of 6 projects, at least 20 patients were followed and data on personnel role and time were collected for each project's detailed process steps (dPS). We calculated the mean time for each dPS and summed means at the cPS to compare across projects.
Results Data are collected for 15 prenatal, 113 pediatric, and 24 adult patients (n=152), of which 107 (70%) were medically underserved or underrepresented (MUS-UR) and 48 (32%) had complex GS results. Across projects, GSI averaged 202 min (Range of Averages (ROA): 83-341 min). Genetic counselors (GCs) spent the most time (mean 131 min; ROA: 57-241 min) per patient, followed by research coordinators (mean 38 min; ROA: 0-77 min) and MDs (mean 25 min; ROA: 0-86 min).
cPS8 "Review, prepare, and return results to patients" took the most time (mean 69 min; ROA: 35-115 min) followed by cPS5 "Pre-test clinic visit" (mean 50 min; ROA: 11-86 min). cPS10 "Hand-off to next step" required the least time (mean 4 min; ROA: 1-7 min).
For MUS-UR patients, genomic innovations averaged 204 min (ROA: 81-341 min) compared with 208 min (ROA: 82-364 min) for patients not designated as MUS-UR. GC time averaged 132 min (ROA: 56-246 min) for MUS-UR and 132 min (ROA: 47-262 min) for not MUS-UR. GSI for patients with complex results averaged 244 min (ROA: 88-372 min) compared with 174 min (ROA: 68-305 min) for non-complex (NC) results. There was a 52 min increase in average time required for cPS8 in complex (Avg: 101 min) versus NC results (Avg: 49 min).
Conclusion In addition to direct costs associated with GSI, implementation also requires resources in the form of staff and provider time. A large portion of this time spent by GCs. Our analysis likely underestimates the time required in clinical (vs. research) settings, and we did not capture all steps within each project (e.g., laboratory processes) due to practical limitations. Implementation of GSI will require decision makers to consider personnel resources, particularly for patients with complex results.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2410 Providing trainees hands-on experience in clinical genetics research through a case report writing workshop increases trainee engagement in clinical genetics.

Authors:

J. Owens[1], R. Hopkin[1], V. Viswanath[2], L. Alvey[3], A. Shillington[4]; [1]Cincinnati Children's Hosp., Cincinnati, OH, [2]Univ. of Cincinnati Sch. of Med., Cincinnati, OH, [3]Univ. of Cincinnati Coll. of Med., Cincinnati, OH, [4]Cincinnati Children's Hosp., Cincinnatti, OH

Nearly all clinical geneticists have interesting patients and multiple small projects they would like to publish if they had time. Meanwhile, the number of trainees pursuing careers in clinical genetics has struggled to match the recent increased demand for genetics services. To increase medical student interest and engagement with clinical genetics, we created a “Report Writing Workshop” from our local genetics student interest group to provide an opportunity for medical students to obtain hands-on experience in writing and publishing small clinical projects.Twenty 1st and 2nd year medical students volunteered to write ten case reports. The workshop aimed to break down the writing process into small, approachable tasks and allow participants to make autonomous decisions allowing ownership over their work. 16 potential case reports were collected from genetics attendings and residents, who had intended to write the cases themselves in the future. Medical students were asked to choose 2-3 projects that were most interesting to them. Participants placed themselves in groups or were assigned to groups based on mutual interest in cases. The workshop included five ~90 minute meetings that respectively focused on an introduction to report development, literature review, chart review, writing an introduction, and writing a clinical history. The first 10 minutes of meetings summarized the topic of the meeting, with the remainder of the time provided for teams to work on data gathering and writing. In developing the discussion for each paper, groups worked independently to provide answers to targeted take home points that the report added to the field. These answers were combined and organized together for publication. Participants provided the core content of the manuscript to a genetics fellow, who reviewed and edited their work to reflect the terminology and content expected for academic publication. All 10 case reports will be submitted to medical genetics journals, and all 20 students intend to present their work at ASHG in 2023.This scalable approach allowed for a large cohort of medical students to be mentored by a small group of genetics fellows overseen by a single attending. We attribute success of the workshop to the quality cases that merited publication, the group dynamics that added a social component to maintain momentum, and breaking down the process into specific small steps for each section. In our experience, it benefited the attendings by moving their projects forward, improved the fellows ability to provide medical education and mentorship opportunities, and increased medical student interest in clinical genetics.

Ctr., Mount Sinai Hosp., Sinai Hlth., Toronto, ON, Canada, [16]Sanofi, North Bergen, NJ, [17]British Columbia Cancer Agency, Vancouver, BC, Canada, [18]Dept. of Med. Genetics, The Univ. of British Columbia, Vancouver, BC, Canada, [19]Dalla Lana Sch. of Publ. Hlth., Univ. of Toronto, Toronto, ON, Canada

Introduction: Genomic sequencing (GS) is an effective diagnostic test, but questions remain about which types of clinically relevant secondary findings (SFs) should be returned. Guidelines call for further evidence on health outcomes of returning SFs. Other studies have returned limited SFs and without controls; evidence is lacking on outcomes of simultaneously returning all SFs. We conducted an RCT (Incidental Genomics trial, NCT03597165) to evaluate outcomes and costs of returning all clinically relevant SFs. Here, we report preliminary findings on psychological and behavioral outcomes. **Methods:** Adults with cancer were recruited and randomized. Participants in both arms had GS with cancer results. Intervention arm participants could choose to learn multiple types of SFs: medically actionable, Mendelian, early-onset neurodegenerative, carrier status, common disease risk variants, and pharmacogenomic variants. The primary outcome was distress, measured by the Hospital Anxiety and Depression Scale (HADS) 2 weeks after return of results. Secondary outcomes included patient-reported medical (e.g., appointments, screening) and lifestyle behaviors (e.g., diet, exercise), 2 weeks, 6 weeks, 6 months, and 1-year post-return of results. HADS at 2-weeks was compared between arms with an ANCOVA model to adjust for baseline scores. Proportions of participants reporting medical and lifestyle behaviors were compared at all timepoints with chi-square tests or Fisher's exact test. **Results:** Participants (n=287) were 87.1% female, 57.5% White/European, and average 57.2 years old. The adjusted mean difference in HADS anxiety in the intervention arm compared to the control arm was -0.19 (95% CI -1.1 to 0.68, p=0.7), implying less increase. The CI excludes the minimal clinically important difference (MCID: 2.5). The adjusted mean difference in HADS depression in the intervention arm compared to the control arm was 0.02 (95% CI -0.67, 0.71, p=0.96), with the CI also excluding the MCID (2.5). A difference in health behavior uptake was not observed at 6 months. There was higher uptake of medical behaviors (e.g., appointments) in the intervention arm at 6 weeks (14.8% vs. 3.1%, p=0.002). There was higher uptake of lifestyle behaviors in the intervention (e.g., diet changes) arm at 2 weeks (7.4% vs. 0%, p=0.002) and 12 months (4.4% vs. 0%, p=0.03). **Discussion:** We did not find strong statistical evidence that returning SFs increased distress relative to GS with primary findings only, however we found evidence that SFs led to higher uptake of medical and lifestyle-related behaviors. These findings suggest returning SFs is safe and effective for influencing health behaviors.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2412 Racial Disparity in the Diagnosis of Mitochondrial Disease

Authors:

D. McGinn[1], C. Muraresku[2], K. Valverde[3], M. Falk[2], R. Ganetzky[2]; [1]Children s Hosp. of Philadelphia and Perelman Sch. of Med. at the Univ. of Pennsylvania, Philadelphia, PA, [2]Children's Hosp. of Philadelphia, Philadelphia, PA, [3]Univ. of Pennsylvania, Philadelphia, PA

Background: Primary Mitochondrial Diseases (PMD) caused by inherited disruption of oxidative phosphorylation are collectively the most common inborn error of metabolism with broad variability including age at presentation and severity. A 2020 North American study of individuals with PMD reported >85% were white, significantly discrepant from the 2020 US Census where 61% self-reported as white. Here we present results of an investigation of potential racial disparities in ascertainment and disease severity in individuals with PMD to determine if patients of color are underdiagnosed. **Methods:** We retrospectively reviewed electronic health records on 337 patients with molecularly confirmed PMD under an IRB-approved study. Only probands with sufficient available demographic, diagnostic setting (inpatient/outpatient), and symptom data were included. Symptom severity was assessed using a multisystem aggregate severity score index [SSI], where lower scores indicate more severe disease. Potential confounders including socioeconomic status, distance to the hospital, and insurance coverage were also collected. **Results:** 207 patients met inclusion criteria: 53.6% were female; Mean age was 18.1 years; 74.9% were white, 11.1% Hispanic, 9.7% Asian, and 7.2% Black; Mean age at PMD diagnosis was 9.72 years; 75.8% were diagnosed as an outpatient; average SSI was 13.55. Notably, Black (mean SSI=12.0, p=0.013) and Hispanic (mean SSI=12.5, p=0.016) patients had more severe symptoms compared with white patients with non-Hispanic backgrounds (mean SSI=14.2). Notably, Asian, Black, and Hispanic patients were significantly more likely to be diagnosed as inpatients (40%, 40%, and 35%, respectively) compared with white PMD patients (20%). Self-identified patients of color were more likely to be diagnosed with PMD in the inpatient setting. Additionally, Black and Hispanic patients tended to have more severe symptoms as compared with those from other backgrounds. **Conclusions:** This data supports the premise that patients of color tend to require a higher diagnostic threshold to achieve a diagnosis of PMD; previous reports demonstrating a higher prevalence of patients self-reported as white may be influenced by ascertainment bias; and people of color are likely under-diagnosed within the PMD community, representing a critical but previously unrecognized health disparity. Given a major barrier to diagnosis is obtaining a referral to a mitochondrial medicine clinic, overcoming this disparity requires wide-scale education of healthcare providers regarding the pan-racial occurrence of PMD.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2413 Rapid whole-genome sequencing in children in acute care in a universal health care system: Physicians underestimate parental expectations and concerns about the impact on their child's care

Authors:

C. Azuelos[1,2], C. Varin-Tremblay[1,2], J. L. Michaud[1,2], A-M. Laberge[1,2]; [1]CHU Sainte-Justine, Montreal, QC, Canada, [2]Université de Montréal, Montreal, QC, Canada

Purpose: The use of rapid whole genome sequencing (rGS) in the investigation of rare disease is used increasingly as a diagnostic tool for children in acute care. Parental and physician experiences of rGS in a universal health care system need to be better understood to ensure its appropriate use. This study aims to assess parental and physician perspectives about rGS and the impact of results on clinical care.
Methods: A 2-year prospective provincial multi-center study is ongoing in the four pediatric academic centers in Quebec, Canada. Children are eligible if they are aged 0-18 years and hospitalized for an acute condition with a high likelihood of genetic etiology. In addition to rGS, parents and physicians complete questionnaires at recruitment and one-month after disclosure of results. Parental questionnaires include sociodemographic data, understanding of rGS, expectations, and concerns about rGS results. Physician questionnaires include their assessment of parental understanding and concerns and their own expectations of test results.
Results: By April 2023, parents and physicians had completed questionnaires at recruitment for 39 children. They had similar assessments of the likelihood of identifying a genetic cause with rGS (p=0.89). Parents understood rGS well (mean knowledge score 4.38/5). Parental expectations about the impact of rGS results for their child are significantly higher than physicians' expectations for getting a clearer prognosis (4.08 vs 2.85; p=0.0001), guiding management (4.42 vs 2.26; p<0.0001), influencing the level of care (4.21 vs 1.33; p<0.0001), identifying an actionable secondary finding (3.22 vs 1.13; p<0.0001) and enabling genetic counseling (3.84 vs 2.90; p=0.0018). Physicians also underestimate parents' level of worry about rGS results (1.73 vs 2.50; p=0.03).
Conclusion: Parents understand rGS and have high expectations about the impacts of test results. Physicians tend to underestimate parental expectations and concerns. Data collection is ongoing and further analyses will include comparison with parental and physician perspectives post-disclosure of rGS results. These findings will inform the implementation of rGS in clinical care in our province, to reduce the discrepancies between physician and parent expectations.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2414 Results of survey about concerns and motivation of the Latvian general population and researchers towards citizen-science research projects in the field of genomics.

Authors:

V. Rovite[1], A. Svandere[1], S. Mezinska[2], K. Kaleja[1], R. Peculis[1], N. Kante[1]; [1]Latvian BioMed. Res. and Study centre, Riga, Latvia, [2]Univ. of Latvia, Faculty of Med., Riga, Latvia

Introduction. Citizen-science is research carried out by citizens or amateur scientists in cooperation with scientists or within the framework of specific scientific projects, based on scientifically developed methods. Examples of citizen-science include bird watching and counting, collecting environmental data, performing astronomical observations and reporting these data to scientists. Citizen-science makes science accessible to the public and promotes public trust. The study aimed to evaluate the concerns and motivation of the Latvian general population and researchers towards citizen-science research projects in the field of genomics.Methods. We developed a specific survey that consisted of seven citizen-science research project examples (vignettes) that included various levels of participant involvement, use of data and relation to genetic research. After each research project vignette description survey participants need to answer questions about their motivation and concerns to participate. The same vignettes were used for the researcher survey, but the researchers were asked to answer questions on their potential motivation or concerns using such citizen-science research data for their research studies. The survey data was analysed according to specific vignettes where we analysed what was the most frequent motivation and concerns in specific types of studies for potential research participants from the general population. We also looked at how the concerns and motivation differed for the same individual for different types of studies and what were the main principal differences in opinions of researchers and citizens. Results and conclusions. For researchers the greatest motivation to use citizen-science were possibility to obtain more data with lower costs, but concerns were regarding the quality and traceability of data collection. For general public the most relevant motivation to participate in citizen-science activities was personal benefits or potential help to society in future, but concerns were the lack of time to contribute to these activities and data protection issues.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2415 † Scientists' views on whether genome editing warrants unique governance guidelines.

Authors:

R. Cadigan[1], M. Waltz[1], M. Flatt[2], A. Davis[1], J. Conley[1], G. Henderson[1], G. Inamine[1], E. Juengst[1]; [1]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Cuyahoga Community Coll., Highland Hills, OH

Advances in genome editing technology such as CRISPR have revolutionized biomedical research. As human clinical trials get underway, early results have been both promising and cautionary. They also reinvigorate questions as to how best to regulate such research to address ethical concerns while also encouraging important biomedical advances. Governance efforts, like the International Commission on the Clinical Use of Human Germline Genome Editing and a World Health Organization Expert Advisory Committee, have been established to provide guidance on conducting genome editing research and its translation to the clinic. To gain insight into how these international governance efforts align with the views of practicing scientists, we conducted interviews with over 60 international scientists involved in genome editing to explore their perceptions of the ethical issues associated with human genome editing research and how such research should be governed. Our ongoing analyses of these interviews have yielded noteworthy and sometimes contradictory perspectives on the question of whether genome editing research warrants unique governance guidelines. While scientists may agree with descriptions of genome editing technology as unparalleled and exceptional with unique ethical implications, many simultaneously reject calls for special forms of governance, arguing that genome editing is no different than other emerging technologies and can be adequately governed by existing regulatory mechanisms. In this presentation, we will analyze this contradiction by exploring the ways in which scientists accept or reject the idea of genome editing as an exceptional technology and how this relates to their thoughts on governance. Debates on whether existing regulations are sufficient, especially within the context of heritable editing and so-called ‘rogue’ editing, will be presented. We will conclude with a discussion of the implications that these scientists’ rhetorical contradictions may have for future genome editing governance efforts at national and global levels.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2416 "Should I let them know I have this?": Experiences with genetic discrimination amongst patients with hereditary cancer syndromes.

Authors:

R. Gopalakrishnan[1], J. Sam[1], C. Butkowsky[1,2], E. Reble[1], M. Clausen[1], S. Rajeziesfahani[3], B. Sparkes[3], V. Aguda[1], M. Aronson[4], D. Bishop[5], L. Dawson[3], A. Eisen[6], T. Graham[6], J. Green[3], C. Mighton[1,2], J. Pauling[7], C. Pavao[8], P. Pechlivanoglou[2,9], C. Remocker[8], S. Savas[3], S. Sun[10], T. Tiano[7], A. Tilley[5], K. Thorpe[1,2], K. Schrader[10], H. Etchegary[3], Y. Bombard[1,2]; [1]St. Michael's Hosp., Toronto, ON, Canada, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Mem. Univ. of Newfoundland, St. John's, NL, Canada, [4]Zane Cohen Ctr., Sinai Hlth.System, Toronto, ON, Canada, [5]Patient Partner, St. John's, NL, Canada, [6]Sunnybrook Hlth.Sci. Ctr., Toronto, ON, Canada, [7]Patient Partner, Toronto, ON, Canada, [8]Patient Partner, Vancouver, BC, Canada, [9]The Hosp. for Sick Children, Toronto, ON, Canada, [10]BC Cancer, Vancouver, BC, Canada

Introduction: Hereditary cancer syndromes (HCS) represent approximately 1 in 10 of all cancer patients. Among HCS, Hereditary Breast and Ovarian Cancer Syndrome (HBOC) and Lynch Syndrome (LS) are the most prevalent. HCS patients are genetically predisposed to developing cancer, and require complex care which may include genetic testing, screening and prophylactic surgery. In addition to medical burdens, many patients are concerned about stigmatization based on their HCS diagnosis; this study aims to describe experiences with genetic discrimination that patients may face on their care journey.
Methods: Semi-structured qualitative interviews were conducted with HCS patients residing in Ontario, British Columbia and Newfoundland & Labrador, Canada. All interviewees had a confirmed molecular diagnosis of HBOC or LS. Interpretive description was used to analyze the data.
Results: Across Ontario (n=26), British Columbia (n=23) and Newfoundland & Labrador (n=24), 73 patients with HBOC (n=39) and LS (n=34) were interviewed. The sample consisted of 51 females, 21 males and 1 gender diverse individual. Overarchingly, patients worried about whether to share their HCS genetic diagnosis with others due to fears of being judged, stigmatized or discriminated against. Genetic discrimination regarding insurance coverage was of particular concern; patients discussed experiences where they were denied coverage, received lesser coverage or paid higher fees upon disclosing their HCS status. These experiences extended to various insurance types, including life, health and disability insurance. Patients noted that insurance companies had roundabout ways of soliciting family health and genetic testing history without explicitly asking if an individual was positive for a certain cancer-associated gene. Beyond the insurance space, patients were also wary of genetic discrimination by employers, family and friends as they felt sharing their HCS diagnosis may limit personal and professional opportunities. For example, patients did not want employers to question their job performance nor did they want family members to comment on their appearance after being branded as “sick.” Lastly, many patients said they were unaware of the Genetic Non-Discrimination Act and expressed interest in learning more about the Act.
Conclusion: Genetic discrimination is a concern for many HCS patients, especially in terms of impacts on insurance coverage. Despite non-discrimination legislation, patients are uncertain of their rights and wary about sharing their diagnosis with others. This work emphasizes the need to address genetic discrimination experienced by HCS patients.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2418 Sickle cell trait insights from the *All of Us* research program.

Authors:

H. Ramirez[1], F. Wossenseged[1], D. Seddighi[1], A. J. Buscetta[1], Y. Wang[2], P. Joseph[2], V. L. Bonham[1]; [1]NIH/NHGRI, Bethesda, MD, [2]NIH/NIAAA, Bethesda, MD

Sickle cell trait (SCT), HbAS, is one of the most common hemoglobin mutations in the world, with an estimated prevalence of 300 million carriers globally. In the United States, more than 3 million individuals have SCT. Since 2006, all newborns in the United States have been screened for SCT in all 50 states, but adults' knowledge of their carrier status and documentation in their electronic health record is unknown. The hematology research community has called for increased large scale epidemiological and genomic research on SCT, including large population-based studies. In addition, there is limited research on clinical complications that may be associated with SCT carrier status. To address this gap, electronic health record (EHR) and whole genome sequencing (WGS) data from the NIH *All of Us* (AoU) Research Program was used to identify SCT carriers. Carrier status was determined using ICD-9 and ICD-10 codes (282.5 and D57.3, respectively) in the EHR and by genomic analysis ("AT" genotype of rs334). As of February 2023, the total cohort within the *AoU* database included 409,420 participants, of which 254,700 participants (62.2%) have EHR data and 245,400 (59.9%) have WSG data available. Of those with EHR data, a cohort of 1,061 (0.42%) participants were identified as SCT carriers via ICD diagnosis. We determined that 750 (70.6%) participants within the EHR cohort (n=1061) also have WGS data. Through genomic analysis, 595 (79.3%) participants were confirmed as sickle cell carriers with heterozygous genotype of rs334. Furthermore, of the 245,400 participants with WGS data within the *AoU* research program, 5,484 (2.2%) SCT carriers with heterozygous genotype of rs334 were identified. Further investigation of this cohort will be done to determine how many participants also have EHR data available in the *AoU* database. We will report on the association of nine clinical outcomes and carrier status (carrier vs. non-carrier). We will utilize a matched control cohort without known history of SCT or other hemoglobinopathies. The nine clinical outcomes of interest were identified from a 2018 systematic review, Clinical Outcomes Associated with Sickle Cell Trait (PMID: 30383109). The discrepancies between EHR-reported SCT carriers and those identified and verified via genomic analysis in the *AoU* population informs the need for adult screening for SCT, comprehensive education, and guidelines for communication of rare health risk for newly identified carriers.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2419 System Requirements to Support Primary Care Pediatricians in the Return of Genome Informed Risk Assessment

Authors:

J. Connolly[1], D. Karavite[1], S. Terek[2], M. Harr[3], H. Hakonarson[1], R. Grundmeier[4]; [1]Children's Hosp. of Philadelphia, Philadelphia, PA, [2]The Children s Hosp. of Philadelphia, Philadelphia, PA, [3]Children S Hosp. of Philadelphia, Philadelphia, PA, [4]Childrens Hosp. of Philadelphia, Philadelphia, PA

Purpose: Genome informed risk assessment (GIRA) - informed by polygenic risk scores, family history, and patient history - is a new testing modality that has the potential to improve healthcare by identifying individuals at risk for common conditions. However, returning GIRA results in clinical practice requires assessment of the needs and capabilities of providers and healthcare systems. As part of an electronic Medical Records and Genomics (eMERGE) network initiative, we conducted a systems requirement assessment to inform the design of a comprehensive return of GIRA results and clinical decision support system for pediatric primary care providers (PCPs).
Methods: PCPs from ten practices affiliated with Children's Hospital of Philadelphia were eligible to participate. We administered a seven-phase interview comprised of surveys and semi-structured interview questions to elicit PCP responses across a spectrum of sociotechnical requirements for a system to manage GIRA results. Interviews were conducted with 20 primary care providers (PCPs) from ten practices within a single health system.
Results: Twenty participants completed the interview process (19 doctors, 1 nurse practitioner). Results demonstrated that PCPs are interested in being involved in the process of returning genetic testing results to patients, but require a comprehensive system that delivers actionable recommendations, supports patient education, streamlines communication, and facilitates multi-disciplinary collaboration. Further, analyses highlighted the need to integrate risk reports with clinical decision support tools that can accommodate different clinical scenarios and provider workflow preferences.
Conclusion: These findings underscore the point that the return of genetic testing results and decision support for PCPs extends beyond the electronic health record, and include systems and processes for information delivery, patient education, communication, and collaboration.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2420 Systematic use of NGS as significant impact factor for diagnosis of rare diseases in national health care system

Authors:

M. Vinkšel[1], B. Peterlin[1], K. Writzl[2], A. Maver[1]; [1]Univ. clinical centre Ljubljana, Ljubljana, Slovenia, [2]Clinical Inst. of Med. Genetics UMCL, Ljubljana, Slovenia

Rare diseases are numerous, heterogeneous and diverse and are in 80% of genetic origin, mostly chronic diseases, and many cause early death. Due to the low prevalence of individual rare disease, lack of knowledge, scarcity of expertise and life-treating nature, rare diseases to emerge as a public health priority worldwide. Novel technologies such as NGS approaches has transformed approach to the diagnosis, which is now more comprehensive, timely and focused on a patient. In Slovenia, NGS was implemented for a systematic use in a national health care system in 2012 for pediatric and adult patients, who presented with a hypothesis of any genetic disease. An overall diagnostic yield of 34% was achieved. Diagnostic yield across diverse organ systems was 23%-56,7%. For cases with a clinical diagnostic hypothesis for monogenic disease genetic etiology was established in 47%. For unclear diagnostic hypothesis or for diagnostic hypothesis with a possible monogenic etiology approximately one third of the referrals were resolved. Among reported 1517 genes 945 genes were clinically actionable. Therefore, NGS approaches should be consider as first tier diagnostictool in the national health systems due to its importance for ending diagnostic odyssey, provision of optimal medical care and prevention.

PB2421 The Clinician-reported Genetic testing Utility InDEX (C-GUIDE): Development and validation for prenatal care

Authors:

R. Hayeems[1,2], S. Luca[1], B. Xiao[1], C. Armour[3,4], C. Boswell-Patterson[3], K. Boycott[3], D. Dyment[3], J. Lazier[3], L. Chad[1], T. Kolar[5], W. J. Ungar[1,2]; [1]The Hosp. for Sick Children, Toronto, ON, Canada, [2]Univ. of Toronto, Toronto, ON, Canada, [3]Children's Hosp. of Eastern Ontario, Ottawa, ON, Canada, [4]Univ. of Ottawa, Ottawa, ON, Canada, [5]British Columbia Children's Hosp., Vancouver, BC, Canada

Background: Integrating new genetic tests into clinical practice requires evidence of clinical utility. Our team previously developed and validated a measure of clinical utility, the Clinician-reported Genetic testing Utility InDEX (C-GUIDE), in a rare disease pediatric population. However, the utility of genetic testing for clinical decision-making and patient care is patient population-specific. In prenatal care, genetic test results may trigger decisions related to pregnancy interruption, monitoring, delivery, or neonatal management. Therefore, it is important to define and measure clinical utility for this specific population.
Aim: To develop and validate a measure of clinical utility for genetic testing in prenatal care.
Methods: First, we modified the wording of C-GUIDE to suit the prenatal context. Face and content validity were assessed by 19 geneticists and genetic counsellors who routinely order prenatal genetic testing. Feedback on the wording and relevance of each item was obtained through audio-recorded interviews and a survey in which participants were asked to accept, modify or reject items. Feedback was synthesized to inform revisions. Next, to test the construct validity of C-GUIDE Prenatal, 4 geneticist raters completed C-GUIDE on a retrospective sample of cases that received prenatal genetic testing. They also completed a global assessment of utility using a single anchor item. Construct validity was assessed using a generalized estimating equations model.
Results: Most C-GUIDE items were considered relevant. Clarification regarding the timepoint at which utility was to be assessed (i.e., pre- vs. post-natal) and the index patient in question (i.e., fetus or pregnant person) was required. Recommended items were added. Of the 101 retrospective cases reviewed in the validation study, genetic results were positive and informative in 32 cases, negative and informative in 38 and negative and uninformative in 31. On average, a 1-point increase in the global item score was associated with an increase of 1.2 in the C-GUIDE score ($p=0.04$). Compared to uninformative results, informative positive and informative negative results were associated with an increase of 11.1 ($p<0.001$) and 5.5 ($p<0.001$) in the C-GUIDE score, respectively.
Conclusions: The significant positive associations between C-GUIDE total and the global item score and between C-GUIDE total and result type, in the hypothesized direction, provide evidence of construct validity. This tool may contribute to a body of evidence pertaining to the clinical utility of prenatal genetic testing, in turn informing adoption and coverage decisions.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2422 The Estonian Biobank's MyGenome Portal: A comprehensive platform for return of results to over 200,000 biobank participants.

Authors:

N. Pervjakova[1], L. Leitsalu[1], K. Metsalu[1], K. Kruusmaa[1], P. Pärkson[1], K. Teder[1], K. Kaasla[1], L. Sissas[1], K. Fischer[2], V. Kukushkina[1], P. Kleemann[1], A. Reigo[1], H. Alavere[1], K. Krebs[1], S. Reisberg[3], G. Hudjashov[1], V. Pankratov[1], M. Nelis[1], L. Sirje[1], K. Maal[1], K. Läll[1], D. Sokurova[1], R. Mägi[1], S. Kasela[1], L. Luitva[1], A. Metspalu[1], M. Metspalu[1], L. Milani[1]; [1]Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, [2]Inst. of Mathematics and Statistics, Univ. of Tartu, Tartu, Estonia, [3]Inst. of computer Sci., Univ. of Tartu, Tartu, Estonia

The MyGenome Portal (MGP) of the Estonian Biobank is a research platform with multiple objectives: provide individual results to over 200,000 biobank participants; ensure transparency regarding the use of participants' data; improve public health and genomic literacy; serve as a platform for research; and support precision medicine initiatives. The MGP is structured into three sections: personalized results, educational content, and studies. The portal incorporates dynamic consent that allows participants to choose specific categories for the return of results and which research projects they wish to join.

The personalized results section currently provides participants with reports on type 2 diabetes (T2D) and coronary artery disease (CAD) as well as pharmacogenomics, caffeine metabolism, and ancestry at different resolutions. For T2D and CAD, the reports incorporate 10-year and lifetime cumulative risk calculations based on polygenic risk scores, lifestyle factors, and prevalent diseases. The pharmacogenomics report covers 26 medications with high-evidence recommendations. The educational section complements the personalized results by providing respective background information. The interactive components and visual aids of the reports together with the educational section empower participants to gain a comprehensive understanding of the topics covered, facilitating informed decision-making regarding their health.

The dedicated research section serves as a digital solution for data collection. Among the first projects is an investigation into the perceived impact of genetic information reported through the portal. The research section will expand to include questionnaires, randomized clinical studies, and other research initiatives. The development of the MGP involved consulting with expert groups and a qualitative study to assess user experience. Participants expressed satisfaction with the user-friendly interface and overall concept of the portal. They also expressed interest in receiving personalized reports and recommendations for a healthy lifestyle. Next, a preliminary launch is planned with 10,000 participants, with the full launch scheduled by the end of 2023 (October 2023).

Beyond facilitating the communication of personalized risk information, the MGP acts as a testbed for precision medicine initiatives. The study group within the MGP enables the creation of various sub-populations that represent the general population, allowing estimation of the impact on public health. The MGP empowers individuals, and promotes research, contributing to the ongoing transformation of healthcare.

Hlth., Univ. of Toronto, Toronto, ON, Canada

Background. Genetic testing is increasingly used in mainstream care across medical disciplines, leading to increased demand for genetics services. Combined with workforce shortages, this has resulted in growing waitlists and pressure on care delivery. E-health tools are one scalable and patient-centred solution; however tools developed to date are limited in scale and none integrate all components of genetics service delivery. The Genetics Navigator is an interactive patient-centred digital platform that collects medical and family history, provides pre- and post-test genetic counseling, and returns results. The study objective is to measure the effectiveness of the Genetics Navigator across pediatric and adult populations when integrated with usual care by a genetics clinician compared to usual care alone. **Methods and analysis.** One hundred and thirty-two participants (66 patients and 66 parents of patients eligible for genetic testing) will be recruited from three Ontario genetics clinics. Participants will be randomly assigned to the intervention or usual care. Those randomized to the intervention will use the Genetics Navigator in the pre-test period before meeting with their genetics clinician, and either before, during, or after results disclosure by their genetics clinician. Participants randomized to usual care will meet with their genetics clinician in the pre-test period and for results disclosure. The primary outcome is patient/parent distress 2 weeks after results disclosure. Secondary outcomes include knowledge, decisional conflict, anxiety/depression, empowerment, quality of life, personal utility, satisfaction, acceptability, health and digital literacy, and mental health resource use. Quantitative outcomes will be measured with validated surveys and compared between study groups for patients and for parents using inferential statistics and regression models. A sub-set of participants will be interviewed to explore user experience, using interpretive description to analyze the data. We will also conduct a cost-effectiveness analysis to assess the incremental cost of the Genetics Navigator compared to usual care per QALY gained from the perspective of the public payer for the patient and parent groups. **Conclusion.** Rigorously-evaluated patient platforms that digitize genetic services are needed. This study will provide robust evidence on the effectiveness of the Genetics

Navigator, a patient-centred e-health navigation platform to support end-to-end genetics service delivery across pediatric and adult populations.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2425 The Genomic Medicine Action Plan (GMAP) is a scalable, EHR-integrated utility-messaging tool for patients and their non-genetics providers receiving clinical genomic screening results.

Authors:

R. Wildin, D. Gerrard, P. vanWoert, D. Leonard; Univ. of Vermont Hlth.Network, Burlington, VT

Genetic test laboratory reports do not communicate clinical use guidance consumable by all patients and their non-genetics providers, creating a barrier to efficient and effective application for preventive health. In our genomic population health screening test implementation, our clinical laboratory creates and includes a GMAP messaging document along with reference lab reports when placing them in the electronic health record (EHR) and mailing a printed copy for patients. The GMAP: - Contains clear and concise messages written for patients and their primary care providers - Describes specific action recommendations and key education messages simultaneously for each of zero to many reported pathogenic or likely pathogenic variants (variants of uncertain significance [VUS] are not reported). - Is evidence-based and implements pre-defined care pathways for health risk results - Is integrated in one EHR lab result with a searchable text version of the associated test reports and their PDF versions - Reiterates program-related opportunities for free genetic counseling, cascade testing, for low-cost partner testing, and encourages sharing with healthcare professionals and relatives. The GMAP also: - Is revised and reissued when a variant classification is changed by the testing laboratory, indexed for patient-record global text search in the EHR (since 2022), and built in Epic for each patient from reusable formatted text blocks stored as Epic smart phrases - Provides telephone and email contacts for help from genetics professionals - Is empirically associated with a very low uptake of offered free genetic counseling - Is associated with increased self-reported genomic practice competency among primary re providers ordering the test. In addition to the core GMAP template, examples of real cases posing special challenges to clear and concise messaging will be presented, along with adaptations made from 2019 through 2023. Challenging examples including complex genotypes (e.g. in CYP21A2), possibly mosaic variants, deleted genes representing hematologic neoplasm, and reclassification of variants from VUS (not reported) to likely pathogenic or pathogenic or vice versa. The real-world examples illustrate our scalable approach to maximize utility of genomic screening results and minimize patient and non-genetics provider confusion. The GMAP model provides a reference solution for optimizing the critical information transfer of actionable information for clinical and personal utility. This may benefit other programs implementing large gene-count adult population health screening programs in a clinical, EHR-reported environment.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2426 The G-Test: Genetic Testing Eligibility Screening Tool for Prostate Cancer

Authors:

E. Chen, Y. Moo, J. Hoo, D. Chen; Arbelos Genomics, Chino, CA

Precision medicine is vital in effective treatment and improved cancer patient outcomes. Multi-gene panel cancer testing has significantly transformed the clinical methodology for testing at-risk patients and their families with hereditary cancer. Among all cancer types, prostate cancer has been a prevalent malignancy affecting many men worldwide. Previous studies demonstrate around 15% of individuals diagnosed with advanced prostate cancer carry a germline pathogenic variant; the National Comprehensive Cancer Network (NCCN)Version: 1.2023 recommends prostate cancer patients undergo germline genetic testing when the result can potentially impact treatment strategies. Over the past decade, however, most prostate cancer patients have not received germline genetic testing due to various factors. One major challenge is that physicians face difficulties comprehending the risk assessment principle. We aimed to increase the accessibility of prostate cancer genetic tests for patients by simplifying the patient eligibility determination process. By studying the latest NCCN guidelines on genetics and molecular analysis principles, we developed an algorithmic screening tool by posing questions specific to cancer stage, patient family history, and tumor characteristics. Questionnaire answers are processed and stored in a backend database with patient testing qualifications accessible to physicians through web interface queries. To test our model, we performed a retrospective study on 30 model patients' records, twenty of which are eligible for cancer genetic testing and the remaining ten are not as determined by NCCN guidelines. We have five primary care physicians review the records of 30 model patients and let them determine each eligibility for genetic testing using the NCCN guidelines, then the designed screening tool. The results show an increase in identifying eligible patients from 11.2 out of 20 cases to 16.3 out of 20 cases. We have then introduced the screening tool in outpatient urology settings and will continue to evaluate the change in the genetic test ordering rate. Simplifying the patient eligibility determination process for physicians allows broader access to genetic tests, enabling a larger pool of qualified patients to undergo testing and potentially benefit from personalized treatment approaches.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2427 The impact of recurrent 16p12.2 deletions on health in general population and personalized management of undiagnosed adult CNV carriers in the Estonian Biobank.

Authors:

M. Nõukas[1], M. Palover[1], A. Reigo[1], H. Alavere[1], L. Leitsalu[1], M. Jõeloo[1], I. Xenarios[2,3], A. Reymond[4], N. Tõnisson[1,5], K. Männik[2]; [1]Estonian Biobank, Inst. of Genomics, Univ. of Tartu, Tartu, Estonia, [2]Hlth.2030 Genome Ctr., Fondation Campus Biotech, Geneva, Switzerland, [3]Lausanne Univ. Hosp., Geneva, Switzerland, [4]Ctr. for Integrative Genomics, Univ. of Lausanne, Lausanne, Switzerland, [5]Dept. of Clinical Genetics in Tallinn, Tartu Univ. Hosp., Tartu, Estonia

The role of recurrent 16p12.2 deletions has previously been described in children with neurodevelopmental and psychiatric problems, but extensive phenotypic heterogeneity is also known. Here, we further plan to expand the knowledge on how: i) the recurrent 16p12.2 deletions affect health in the adult population and ii) to disclose these CNV findings to individuals at high genetic risk for complex health problems.

We detected 106 carriers (ages 22-83) of 16p12.2 deletions in the Estonian Biobank (EstBB; n=195,904) and mapped their disease traits using linked electronic health registries (EHRs). We further collect in-depth phenotype information from 16p12.2 deletion carriers through recall visits, return genetic risk findings, provide counseling tailored to their presented health conditions and evaluate the impact of disclosed genetic finding on their health and social support.

According to EHRs, depression (35%; 37/106) and anxiety disorders (22%; 17/106) were the most common neuropsychiatric diagnosis in adults with 16p12.2 deletion. Notably, mental and behavioural disorders due to use of alcohol (14%; 15/106) were frequently detected. Only 1 out of 106 carriers of recurrent 16p12.2 deletion was aware of their genetic diagnosis. Amongst the carriers of 16p12.2 deletion recontacted so far, 24 EstBB participants have consented for disclosure.

The study adds a population view to the knowledge of the understudied relationship between the recurrent 16p12.2 deletions, neuropsychiatric and other phenotypic traits in adults. Although not yet considered actionable in current guidelines, recall visits may relieve the anxiety in symptomatic CNV carriers.

OF FERRARA, Ferrara, Italy, [6]RTI interNatl., Durham, NC, [7]Victorian Clinical Genetics Services, Melbourne, Australia, [8]RTI Intl., Research Triangle Park, NC, [9]Rady Children s Inst. for Genomic Med., Coronado, CA, [10]Columbia Univ., New York, NY, [11]Genomics England, London, No, United Kingdom, [12]Albert Einstein Coll. of Med., Bronx, NY, [13]Genomics England Ltd., Gig Harbor, WA, [14]Harvard Med. Sch., Boston, MA

CONSORTIUM NAME: International Consortium on Newborn Sequencing (ICoNS)
BACKGROUND: Newborn sequencing (NBSeq) has the potential to offer a lifetime of personalized health care and disease prevention that is specific to each individual genome. When fully realized, NBSeq will mark a disruptive transition into personalized medicine and public health. A number of research projects and commercial offerings are already underway to explore the implementation of newborn sequencing in clinical settings.
OBJECTIVES: Given the proliferation of clinical implementation efforts, we sought to create the first organization specifically dedicated to communicating and sharing progress and best practices in the implementation of NBSeq. Initial topics for consideration included gene selection for initial panels, variant interpretation, patient communication and planning for clinical follow up.
METHODS: Principal investigators from 8 separate groups that were already conducting or imminently planning to conduct NBSeq research began regular meetings and agreed to establish the International Consortium on Newborn Sequencing (ICoNS). ICoNS was created to harmonize activities leading to evidence-based best practices for implementing newborn sequencing.
RESULTS: We have established ICoNS as an alliance of active investigators in NBSeq research with an annual interdisciplinary conference. An initial conference featuring 19 presentations was held in October 2022 in Boston, MA with over 300 attendees from 35 countries, and the next conference is planned for October 5-6, 2023 in London. Discussions of organization and governance are underway.
CONCLUSION: ICoNS presents an opportunity to gather multi-disciplinary governmental, academic and industry stakeholders and experts from around the world in order to accelerate and harmonize research progress and real-world implementation in NBSeq.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2429 The landscape of clinical sequencing in diverse populations: lessons learned from the Clinical Sequencing Evidence-generating Research (CSER) consortium.

Authors:

Z. Bly[1], L. Aviles-Santa[2], L. Biesecker[3], G. Cooper[4], S. Fullerton[5], B. Gelb[6], C. Horowitz[6], G. Jarvik[7], D. Kaufman[8], M. Norton[9], S. Plon[10], B. Powell[11], C. Sillari[1], A. Slavotinek[12], P. Tarczy-Hornoch[13], B. Wilfond[14], L. Hindorff[1], B. Korf[15]; [1]NIH/NHGRI, Bethesda, MD, [2]Natl. Inst. of Minority Hlth.and Hlth.Disparities, Bethesda, MD, [3]NIH NHGRI, Bethesda, MD, [4]Hudson Alpha Inst. for Biotechnology, Huntsville, AL, [5]Univ. of Washington, Seattle, WA, [6]Icahn Sch. of Med. at Mount Sinai, New York, NY, [7]Univ Washington Med Ctr., Seattle, WA, [8]NIH - NHGRI, Chevy Chase, MD, [9]Univ California San Francisco, San Francisco, CA, [10]Baylor Coll. Med., Houston, TX, [11]Univ North Carolina at Chapel Hill, Chapel Hill, NC, [12]Cincinnati Children`s Hosp. Med. Ctr., Cincinnati, OH, [13]Univ of Washington, Seattle, WA, [14]Seattle Children's Res. Inst., Seattle, WA, [15]Univ Alabama at Birmingham, Birmingham, AL

Background: Clinical Sequencing Evidence-Generating Research (CSER) was a national consortium funded by the National Institutes of Health committed to researching and supporting genomic sequencing in a clinical context. Since Phase 1 of CSER began in 2009, over 500 articles have been published by CSER investigators. The second phase of CSER (2017-2023) focused on generating evidence for clinical utility of genome sequencing. Seven clinical sites and a Coordinating Center, comprising 19 sub-sites across 11 states in the United States, worked collaboratively to recruit over 5,200 participants (~75% from diverse populations). Publications were authored by sites and/or by 8 cross-CSER working groups with members from across these different sites. **Methods:** In 2020, CSER investigators developed a schema to categorize the publications with respect to the clinical workflow and the corresponding roles of patients, providers, and laboratories. CSER papers were categorized into 1 of 7 "boxes" - e.g. Assessment and Referral, Sequencing and Analysis, or Return of Results and Counseling -- based on a list of over 40 relevant research questions. CSER papers published from 2017-2023 were categorized by three individuals, with each paper considered by two individuals, and discrepancies resolved by consensus. **Results:** Of the 209 papers evaluated 31% fell into the Sequencing and Analysis category and another 31% fell into the Return of Results and Counseling category. The categories with the fewest papers were case level papers in the Medical Problem (5%) or Interpretation in Light of Clinical Question (2%) boxes. The research questions most frequently addressed by CSER-related work are 1) how can reports and resources be communicated to participants of diverse backgrounds (n=48), 2) how can clinical sequencing data contribute to better understanding variant function (n=48), and 3) what is the impact of a diagnosis on subsequent care (n=47)? This reflects the multidisciplinary scope and goals of CSER as a program focused on clinical sequencing in diverse populations as well as ethical, legal and social (ELSI) matters. **Conclusions:** The categories and themes in the schema analysis highlight CSER's dedication to improving clinical sequencing at all stages of the patient, provider and laboratory experience, improving outcomes for diverse populations, and engaging with relevant stakeholders. The data generated also allow for identification of potential gaps in the consortium's research and sharing of lessons learned with the broader community.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2430 The PRAGMatIQ study: Implementation of rapid genome sequencing for hospitalized children in a publicly funded health care system

Authors:

C. Varin-Tremblay[1], G. D'amours[1], J. M. Gauthier[1], S. Gravel[2], S. Lévesque[2], N. Anastasio[2], J-F. Soucy[1], F. F. Hamdan[1], A-M. Laberge[1], J. L. Michaud[1]; [1]CHU Sainte-Justine, Montreal, QC, Canada, [2]CHU Sherbrooke, Sherbrooke, QC, Canada

Background: The use of rapid genome sequencing (rGS) in ill children with a suspicion of a monogenic condition has shown favorable results with regards to diagnostic yield, clinical utility, and reduced cost of care across multiple studies. Data from the use of this technology in publicly funded health care systems are scarce.
Objectives: Pediatric RApid GenoMics in Quebec (PRAGMatIQ) is a multi-center study that aims to assess, in real-world clinical practice, the medical, behavioral and economic impacts of rGS in inpatient children in the province of Quebec.
Design & Methods: Children admitted to an inpatient unit, including pediatric wards and pediatric and neonatal intensive care units, in one of the four pediatric tertiary hospitals of Quebec with an unexplained clinical presentation and a suspicion of a monogenic condition are eligible to participate in the study. Over a period of three years, 750 trios will be enrolled by medical geneticists and will receive rGS. Medical chart review and questionnaires for patients and clinicians will be used to assess the medical, behavioral and economic impacts of rGS.
Results: A pilot study involving 82 families was completed in one of the centers between January 2019 and December 2020. The PRAGMatIQ study, which started in November 2022, has enrolled 83 patients and their parents as of May 2023. Preliminary results show that rGS is beneficial for ill children across all pediatric units, age range and clinical presentations. So far, rGS has led to a molecular diagnosis in 40.2% of patients and impacted the clinical management in 31% of patients. There is evidence that negative results can also be informative to clinicians and have an impact on patient management. The median turnaround time of 20 days from patient enrollment to report of results is exposing the challenges of Quebec's health care system in implementing rGS. Additional data will become available in the upcoming months.
Conclusions: This province-wide study demonstrates how rGS can be implemented in a publicly funded healthcare system and can benefit ill children and their families. Variations in turnaround times highlight real-world challenges. Different strategies are being considered to reduce these delays.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2431 The role of multidisciplinary genomic teams in precision medicine: an implementation science guided systematic review

Authors:

A. Ma[1,2], R. O'Shea[2], L. Wedd[3,1], C. Wong[1], R. Jamieson[2,1,3], N. Rankin[4,2]; [1]Sydney Children's Hosp. Network, Sydney, Australia, [2]Univ. of Sydney, Sydney, Australia, [3]Children's Med. Res. Inst., Sydney, Australia, [4]Univ. of Melbourne, Melbourne, Australia

Introduction

Genomics and precision medicine hold promise for enhancing healthcare, especially in the era of advanced therapeutics. However, there is a great need for an implementation science based approach, that takes into account the health services, practitioner and patient needs and barriers, before the benefits of precision healthcare can be accessed by all.

Due to the increasing complexity of genomic data interpretation, and need for close collaboration with clinical, laboratory, and research expertise, genomics often requires a multidisciplinary approach. This systematic review aims to establish the evidence for effectiveness of the genomic multidisciplinary team, and the implementation components of this model that can inform precision care.

Methods

Databases were searched for papers examining the genomic multidisciplinary approach for diagnosis and management, and implementation outcomes regarding effectiveness, adoption, efficiency, safety, and acceptability (Proctor et al.). A narrative synthesis of these outcomes and themes were mapped against the Genomic Medicine Integrative Research (GMIR Horowitz et al.) framework to inform practice, and identify evidence-practice gaps in the literature.

Results

A total of 1039 studies were screened, and 17 papers met selection criteria. All studies pointed towards the effectiveness of the genomic MDT approach, with 10-78% diagnostic yield depending on clinical context, and an increased yield of 6-25% attributed to the MDT approach itself, due to improved expert clinical-laboratory collaboration. The genomic MDT was also found to be highly efficient, especially in interpretation of variants of uncertain significance, timeliness for a rapid result, made a significant impact on management, and was acceptable for adoption by a wide variety of subspecialists. Only one study utilized an implementation science based approach to the genomic MDT.

Conclusions

The genomic MDT approach appears to be highly effective and efficient, facilitating higher diagnostic rates and improved patient management. However, key gaps remain in health systems readiness for this collaborative model, and there is a lack of implementation science based research especially addressing the adaptability, scalability and sustainability of this model.

PB2432 † The Sickle Cell Women and Girls (S.W.A.G) Project of Accra, Ghana: An Evidence-Based Study at the Ghana Institute of Clinical Genetics

Authors:

S. THOMAS[1], A. Asare[2], R. Attah[3], L. Agyiri[2], J. Ayete-Nyampong[4], E. Anku[2], J. A. Osae-Larbi[5], C. R. Sudfeld[1], A. Benneh-Akwasi Kuma[2], E. V. Asare[2]; [1]Harvard Sch. of Publ. Hlth., Boston, MA, MA, [2]Ghana Inst. of Clinical Genetics, Accra, Ghana, [3]Univ. of Ghana, Accra, Ghana, [4]Korle Bu Teaching Hosp., Accra, Ghana, [5]West African Genetic Med. Ctr., Accra, Ghana

ABSTRACT The Sickle Women and Girls (S.W.A.G.) Project is a NIH-funded research initiative, with collaborators between the United States and Ghana. In this study, we are investigating the reproductive health experiences among women and girls (13-25 years of age) with sickle cell disease (SCD) in the Greater Accra Region. Women and girls of reproductive age living with SCD is highly prevalent in throughout Ghana, with one in three Ghanaians having either sickle cell trait or SCD, such as: HbAS, HbSS, or HbSC. Due to reproductive-related conditions, examining SCD, at the intersection of maternal-child health requires critical attention. This study utilized a qualitative research design, consisting of 42 semi-structured interviews at the Ghana Institute of Clinical Genetics. We sought to investigate how women and girls with SCD transition through adolescents, involving social and cultural stigmatizations, menstruation health, perceptions of contraception, and perceptions of testing partners for sickle cell trait. Data was collected by a team of six research assistants (who spoke both English and Twi local language). Data was analyzed using NVIVO 12 qualitative software. Results show two thematic patterns, including: 1) increased social and emotional isolation due to disease stigmatization; 2) and female adolescents' desiring increased knowledge and support for transitioning from pediatrics to adult care for SCD treatment and family planning. Overall, our study provides further evidence for intervention that calls researchers to bridge the gap between the clinical aspects of SCD, while also uplifting the social, emotional, and mental health needs of SCD across the African Diaspora.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2433 The social construction of genomics and blindness in Nigeria: The Eyes of Africa (EOA) study.

Authors:

O. Olawoye[1], K. Salami[2], T. Realini[3], M. Hauser[4], A. Ashaye[1]; [1]Dept. of Ophthalmology,Coll. of Med. Univ. of Ibadan, Nigeria, Ibadan, Nigeria, [2]Dept. of Sociology Univ. of Ibadan, Ibadan, Nigeria, [3]Dept. of Ophthalmology, West Virginia Univ., West Virginia, VA, [4]Duke Univ Med Ctr, Durham, NC

Background: Genomics is an emerging field that has great potential to improve our understanding of ocular diseases and public health practice. **Purpose**: This study explored the social construction of genomics and blindness in two different communities in Nigeria. **Methodology**: This qualitative study utilized in-depth interviews (IDIs) to generate data from both members of the Nigeria Association of the Blind (NAB) and members of the Gbedu community in Oyo State of Nigeria. It utilized a multiple descriptive interview design to depict and understand research participants' views about genomics and blindness. The design also enhanced an in-depth understanding of participants' perception and interpretation of genomics and blindness in their context uncovering the meaning they give to their perception of a social phenomenon. Eighteen sighted and 12 blind participants were purposively interviewed in the community. Audio recordings of the IDI sessions were transcribed and labelled appropriately. Data were reviewed and edited to ensure proper interpretation and construction of accurate meaning and then processed using the NVIVO version 12 Pro. Both deductive and inductive approaches were employed. **Results:** Our study revealed some level of knowledge regarding the hereditary basis of some ocular diseases. However, this was tempered by many fallacious beliefs such as maternal versus paternal contributions to inheritance, and supernatural/religious underpinnings among both the blind and sighted in the community. Both groups of participants preferred saliva-based sample collection over blood-based. Although the participants (blind and sighted) were willing to participate in genomics testing for ocular diseases, they expressed concern for the individual and community benefits in both the short and long term. Participants expected a return of individual results if they participated in a genomic study. There was also a disconnect between the perceived causes of blindness (processed food, use of spectacles in early life, supernatural fallacies) and evidence-based causes of blindness. **Conclusion**: Knowledge limitations, fallacies, and participant expectations influenced the attitude of participants towards genomics in ocular sciences; therefore, this should be addressed with appropriate community engagement programs. It is important that participants' opinions about anonymity are respected to engender greater support and participation in genomics research. The development of actionable genomics procedures in ocular diseases should be sensitive to the needs and preferences of the study participants.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2435 Towards Representative Genomic Research: The Children's Rare Disease Cohorts Experience

Authors:

Z. Frazier, E. Brown, S. Rockowitz, T. Lee, B. Zhang, A. Sveden, N. Chamberlin, K. Dies, A. Poduri, P. Sliz, M. Chopra; Boston Children's Hosp., Boston, MA

Background: Due to racial, cultural and linguistic marginalization, some populations experience disproportionate barriers to genetic testing in both clinical and research settings. It is difficult to track such disparities due to non-inclusive self-reported race and ethnicity categories within the electronic health record (EHR). Inclusion and access for all populations is critical to achieve health equity and to capture the full spectrum of rare genetic disease. Objective: We aimed to create revised race and ethnicity categories. Additionally, we identified racial and ethnic under-representation amongst three cohorts: (1) the general Boston Children's Hospital patient population (general BCH) (n=3,067,921), (2) the BCH patient population that underwent clinical genomic testing (clinical sequencing) (n=1,791), and (3) Children's Rare Disease Cohort research initiative (CRDC) participants (n=3,627). Design and Methods: Race and ethnicity data was collected from the EHRs of the general BCH, clinical sequencing, and CRDC cohorts. We constructed a single comprehensive set of race and ethnicity categories. EHR-based race and ethnicity variables were mapped within each cohort to the revised categories. Then, the numbers of patients within each revised race and ethnicity category were compared across cohorts.
Results: There was a significantly lower percentage of Black or African American /African, non-Hispanic/non-Latine individuals in the CRDC cohort compared with the general BCH cohort (4.60% vs 9.72%, $p < 0.0001$), but there was no statistically significant difference between the CRDC and the clinical sequencing cohorts (4.60% vs 5.82%, $p = 0.1794$). There was a significantly lower percentage of multi-racial, Hispanic/Latine individuals in the CRDC cohort compared to the clinical sequencing cohort (7.36% vs 11.52%, $p < 0.0001$). White, non-Hispanic/non-Latine individuals were over-represented in the CRDC compared to the general BCH cohort (71.88% vs 66.80%, $p < 0.0001$) and the clinical sequencing cohort (71.88% vs 65.96%, $p = 0.0002$).
Conclusion: We highlight underrepresentation of certain racial and ethnic populations in sequencing cohorts compared to the general hospital population. We propose a range of measures to address these disparities, to strive for equitable future precision medicine-based clinical care and for the benefit of the whole rare disease community.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2436 Transforming Genomics Research through Community Engagement and Return of Results: A Case Study from French Polynesia

Authors:

H. Babiker[1], K. Wasik[1], S. LeBaron von Baeyer[1], K. Fox[2], P. Tristan[3], T. Mairai[1], V. Wheeler[4]; [1]Variant Bio, Inc., Seattle, WA, [2]Indigenous Futures Inst., Univ. of California San Diego, La Jolla, CA, [3]Lille Catholic Univ., Lille, France, [4]Australian Natl. Univ., Canberra, Australia

Many communities around the world are wary of genomics research, and for good reasons. All too often, researchers have failed to address local priorities and power inequities when designing and executing these studies. What is more, findings are rarely communicated to participating communities. Here, we highlight an approach that seeks to address colonial and ongoing legacies of extractive research by performing in-depth community engagement, respecting local cultural protocols, and sharing meaningful benefits as well as population-level genomic and health results first and foremost with participating communities. The study was conducted in French Polynesia where ~1100 individuals participated in a sample and data collection campaign spanning genomics, transcriptomics, metabolomics, and extensive biomedical health evaluation. In the course of the study we made multiple findings with significant implications for public health in French Polynesia. For instance we discovered that more than a quarter of the adult population of French Polynesia is estimated to have gout (compared to 0.9% in metropolitan France and 3.9% in the US). We will discuss how appropriate community engagement enabled us to conduct the study and gather data, and how these results are currently shaping the discourse around treatment of gout and public health across the Polynesian archipelago.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2437 Understanding ableism in abstracts for genetic and genomic autism research

Authors:

N. Sugden[1], J. Kee[2], C. Gunter[1]; [1]Natl. Human Genome Res. Inst., Bethesda, MD, [2]Thomas Jefferson Univ., Philadelphia, MD

In recent years, genetic and genomic autism research has come under increasing scrutiny, moving to the center of debates about autism acceptance and the future of research and care. Psychiatric and neurodevelopmental genetic research is especially ethically fraught because of its historical association with eugenics, leading to current-day concerns over its use to guide reproductive decision-making via family histories and prenatal testing or screening for a number of neurodevelopmental conditions. Many critiques of genetic and genomic autism research hinge on the idea that such research is often ableist: that it values abled over disabled and nonautistic over autistic life, and assumes that autistic children and adults require interventions in order to meet societal expectations rather than vice versa. The language of research is an indicator of its evolving priorities and ethics. Research documentation, including abstracts in grant applications, are subject to both formal requirements and explicit and implicit norms. Prospective and ongoing research is a space of uncertainty, promise, and persuasion, where prospective grantees feel the requirement to "sell their science." For these reasons, the language of research cannot be taken to straightforwardly correspond to individual researchers' beliefs and behavior. Nevertheless, the presence of widespread or egregious ableist language may indicate structural and institutionalized ableism - and evaluating the language of research can prompt researchers and research institutions to reflect on the way they discuss and pursue their work and lead to changes that promote greater inclusion and equity. We conducted a mixed-methods analysis of 541 abstracts associated with NIH-funded genetic and genomic autism research since 1980, to reveal the prevalence of ableist language and discourse about autistic people and to identify when they are more likely to be used. In our pilot study of 100 abstracts, 66% contained ableist language or discourse, including ideas about deficits and risk as well as the use of the outdated term "mental retardation." Analysis of the full sample is revealing more detailed patterns over time and between types of research and funding.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2438 Understanding parental/caregiver perspectives during pediatric genome-wide sequencing: A scoping literature review

Authors:

P. Murali[1], J-H. Yu[2]; [1]Univ. of Washington, Seattle, WA, [2]Univ. of Washington Sch. of Med., Seattle, WA

Background: Genome-wide sequencing (GWS) has changed the landscape of pediatric genetics, enabling accurate risk assessment and targeted treatments. However, the needs and perspectives, of parents/caregivers of pediatric patients preceding, during, and following GWS remain poorly understood. An examination of these needs is critical to providing informed care that incorporates parent/caregiver values, addresses their concerns, and fosters collaborative decision-making in the context of pediatric GWS. Therefore, we conducted a scoping literature review to characterize parent and caregiver perspectives and needs in pediatric GWS. Methods: Based on scoping review methods by Arksey and O'Malley, a literature search was conducted across PubMed, Cinahl, Embase, Psycinfo, and Web of Science for English-language primary research articles reporting on the experiences, perspectives, and needs of parents/caregivers of pediatric patients who have undergone GWS. Results: An initial search yielded 574 articles of which 49 met inclusion criteria. Preliminary findings focused on impact of diagnosis, test features, support needs and engagement, and ethical considerations. Regarding diagnostic impact, parents expressed positive attitude towards results of testing regardless of positive, negative, or uncertain findings. An understanding of etiology provided closure and a sense of relief. Regarding test features, parents expressed a need for clear and understandable information following treatment and intervention following GWS. Some expressed disappointment when GWS results did not result in treatment changes. Parents emphasized the importance of support from healthcare professionals and peer networks to cope with the challenges associated with GWS. Finally, parents faced ethical dilemmas related to incidental findings as well as potential implications for other family members. Discussion: This scoping review highlights the multifaceted nature of these experiences for patients based on the type of result, the medical specialty in which GWS was conducted and the severity of disease in the impacted child, among others. These experiences inform parent/caregiver needs as they navigate the process of GWS diagnostic testing that should be better understood by clinicians, genetics counselors, and policymakers to ensure appropriate support and guidance. Furthermore, these knowledge gaps emphasize the need for future research to explore parental perspectives in diverse populations, the long-term impact of GWS on families, and the effectiveness of interventions aimed at supporting parents and caregivers throughout the diagnostic journey.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2439 Usability of a pre-test genetic counseling video for familial hypercholesterolemia as part of RESEQUENCE-GC.

Authors:

E. Brown[1], C. Pendleton[1], C. Applegate[1], C. Tichnell[2], B. Murray[1], B. Rivers[1], R. McClellan[1], A. Barth[1], L. Yanek[2], C. Taylor[1], J. Day[1], C. James[3]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Johns Hopkins Univ, Baltimore, MD, [3]Johns Hopkins Hosp, Baltimore, MD

Familial hypercholesterolemia (FH) is an autosomal semi-dominant condition characterized by high LDL-C levels and an increased risk for coronary artery disease (CAD). If untreated, risk of early onset CAD is significantly elevated. Therefore, the Centers for Disease Control and Prevention (CDC) classifies FH as a Tier 1 condition for genomic application. Multiple cardiac guidelines also recommend patients receive genetic counseling in addition to genetic testing. Despite these recommendations, access to genetic counselors may be limited due to increased need for interpretation of genetic testing results in the setting of ongoing workforce shortage. RESQUENCE-GC is an NHGRI-funded trial to evaluate the utility of a pre-test genetic counseling video instead of the traditional genetic counseling visit providing pre-test education for patients with a personal or family history of hereditary cardiac conditions including FH. Here we describe the development and assessment of the FH videos. Two 8-minute educational animated videos were developed using principles from the Cognitive Theory of Multimedia Learning for the FH panel and targeted familial variant testing. Videos were created using Maxon Cinema4D, Adobe Creative Cloud, and TechSmith Camtasia Studio. Flesch-Kincaid Grade Level was 8.9 and 9.4 for the videos. For evaluation, the videos were sent to both the general population recruited via a usability testing company (UserHappy) and members of a patient support group (Family Heart Foundation). Participants were emailed a questionnaire that included 8 true/false pre-video knowledge questions, one of the two videos, free response feedback, engagement questions [User Engagement Scale; scores for each question range from 1-5, where 5 indicates highest agreement] and the same 8 true/false questions for post-video assessment. In total, 78 individuals participated from the patient support group (N=24) and the general population (N=54). Participant knowledge increased for both videos. Participants answered 84% of questions correctly pre-test which increased to 89% post-test (mean change score 0.043±0.13, p=0.002). In terms of user engagement, on average for both videos individuals indicated they found the video worthwhile (4.3±0.8) and would feel comfortable making a genetic testing decision post-video (4.3±0.8). These data suggest a pre-test genetic counseling video visit may be a suitable alternative for cases where a traditional pre-test genetic counseling visit is challenging. This option may help increase accessibility to genetic counselors and decrease wait-times with an end result of more people gaining access to genetics services.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2440 Using computational phenotype trajectories to inform a holistic model of care for rare diseases

Authors:

T. Groza[1], K. Stevens[1], D. Gration[2], K. Togher[2], S. O'Neil[3], J. Rogers[4], S. Jamuar[5,6], W. Lim[6,7,8], G. Baynam[1]; [1]Rare Care Ctr., Perth Children's Hosp., Nedlands, Australia, [2]Western Australian Register of Dev.al Anomalies, Subiaco, Australia, [3]Child and Adolescent Hlth.Services, Nedlands, Australia, [4]Linear, Nedlands, Australia, [5]KK Women s and Children s Hosp., Singapore, Singapore, [6]SingHlth.Duke-NUS Inst. of Precision Med., Singapore, Singapore, [7]Genome Inst., Singapore, Singapore, [8]SingHlth.Duke-NUS Genomic Med. Ctr., Singapore, Singapore

Rare diseases (RD) are a worldwide health care challenge, collectively affecting at least 1 in 16 people. Patients and families living with suspected RDs often spend more than five years on a diagnostic odyssey. While advances in genomic sequencing coupled with the adoption of standardised terminologies and an increasing willingness to share data internationally have enabled progress in this field, for many patients the effort will ultimately be futile; more than 50% of RD patients do not receive a molecular diagnosis. The management of the phenotypic presentation of the condition thus becomes critical for the patient and family well-being. Devising care pathways, for both diagnosed and undiagnosed patients - covering prognosis, surveillance, coordinated clinical care or family planning - is essential to support emotional relief and appropriate access to resources. This is the primary aim of the Rare Care Centre, which has developed a transformative, community co designed cross-sector Model of Care, to provide holistic care and support in an integrated and responsive service.

The Model of Care is underpinned by computational models of disease that capture the various dependency relationships governing phenotypes and produce phenotype trajectories that map a more accurate view over prognosis and functional consequences. For example, an unmanaged *hydrocephalus* leads to *cortical damage*, which could lead to *blindness* and hence impact *education*. Having this relationship externalised and interpreted in a given temporal context can lead to an appropriately informed care plan - e.g., by performing cerebrospinal fluid shunting - known to improve the hydrocephalus - as well as planning for specific education programs.

Lowering the granularity of the currently available computationally-tractable knowledge and shifting the focus to phenotypes opens new avenues for studying specific genotype-phenotype relationships, including the underpinning biological processes that are disrupted. More importantly, coding phenotype trajectories and their insights into the specific time points that trigger management events enable the Rare Care team to proactively intervene and deliver a more personalised care plan, for both diagnosed and undiagnosed patients.

Our framework for RD management - currently developed for lysosomal storage disorders - covers a deeper understanding of the relationships between phenotypes and an encoding of actionable knowledge spanning across the multidimensional needs that impact not only the patients' physical and mental health, but every aspect of their lives, including education, finances, social activities and employment.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2441 Using e-Technology Among Populations of Advanced Age to Investigate Genetic Mechanisms of Exceptional Longevity in the SuperAgers Family Study

Authors:

A. Montgomery[1], S. Milman[2], S. Shokouhi[1], N. Barzilai[3], P. Jain[1], A. Shuldiner[4]; [1]Vibrent Hlth., Fairfax, VA, [2]Albert Einstein Coll. of Med., Bronx, NY, [3]Einstein Coll. of Med., Bronx, NY, [4]Regeneron, Tarrytown, NY

Background/Objective: Although 95% of older adults in the US have at least one chronic condition, individuals who live past the age of 95 demonstrate delayed onset of age-associated disease. Previous studies show that healthy aging is strongly influenced by genetics; however, the genetic basis for exceptional longevity and healthspan remains primarily unknown. The SuperAgers Family study aims to investigate genetic, phenotypic, and biological mechanisms related to healthy aging and exceptional longevity. The current pilot phase will determine feasibility and identify best practices in using e-technology to conduct nationwide, remote health research among individuals of advanced age.
Methods: SuperAgers aged 95 or older, their offspring, and offspring's spouses are invited to join the study via e-mail or mail. All participants use a web-based platform via computer or mobile device to enroll, confirm age, and complete study surveys. Manual linkage of SuperAgers and offspring profiles initiates receipt of a saliva DNA kit by mail. Participants collect samples at home and return them by mail. Research staff provide support as needed by phone or via secure computer-assisted telephone interview. Qualitative process evaluation was conducted to evaluate the study workflow.
Results: Preliminary data from SuperAgers (n = 118) and offspring/spouses (n = 110) were included in process evaluation. Collectively, participants had an average age of 84 years (± 15 SD), 66.23 % were female, and 96.05 % were non-Hispanic White. During eligibility screening, 3.1% of participants misidentified themselves as either SuperAger, offspring, or spouse, leading to incorrect group assignments. Further, 35.9% of participants entered incorrect SuperAger identifying information causing failure of the family member linkage process. Workflow adjustments were made to prevent recurrence of identified errors.
Discussion: Process evaluation of the SuperAgers Family Study pilot revealed participant entry errors occurring during eligibility screening and family member linkage processes. As a result, workflow safeguards were successfully implemented to prevent repeat errors. These findings may inform development of best practices for conducting digitally delivered research studies in aging populations.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2442 Values-Based Policymaking in Prenatal Human Gene Editing

Authors:

R. Isasi[1], K. Riggan[2], Y. Bombard[3], N. Bonhomme[4], K. Meagher[5], M. Michie[6], K. Musunuru[7], K. Ormond[8], S. Rubeck[9], R. Feys[1], M. Allyse[2]; [1]Univ. of Miami Miller Sch. of Med., Miami, FL, [2]Mayo Clinic, Rochester, MN, [3]Univ of Toronto, Toronto, ON, Canada, [4]Genetic Alliance, Washington, DC, [5]BioMed. Ethics Res. Program, Mayo Clinic, Rochester, MN, [6]Case Western Reserve Univ. Sch. of Med., Cleveland, OH, [7]Univ. of Pennsylvania, Philadelphia, PA, [8]Stanford Univ and ETH-Zurich, Zurich, Switzerland, [9]Dept. of Bioethics, Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Human gene editing technologies in both the research and clinical contexts continue to progress rapidly. Recent experiments in translation in reproductive settings have emphasized the need for more values based and patient-centered governance mechanisms for translation of prenatal gene editing. Several national and international bodies have called for such governance; however, they have been technocratically framed around moratoria or other forms of suppression. We propose a values-based governance approach that moves beyond traditional technocratic considerations of safety and efficacy and considers collective normative deliberation about the ethics of prenatal intervention. Importantly, we call for special consideration to emerging translational justice challenges. Based on international policy comparative study combining soft (e.g., professional guidelines) and hard laws (e.g., statutes), we will analyze normative frameworks to assess underlying normative underpinnings of proposed policy approaches, professional feasibility of proposals, and values and priorities around the potential translation of prenatal gene editing in humans. We further outline a framework for incorporating translational justice considerations within governance structures for gene editing in both research and clinical settings.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session II

PB2443 Voluntary workplace genetic testing in a large healthcare system: Does testing prompt employee health behavior changes or use of health services?

Authors:

E. Charnysh[1], A. Vogle[1], W. Uhlmann[2], A. Prince[3], R. Ferber[4], S. McCain[4], K. Sanghavi[1], W. Feero[5], C. Lee[1], J. Roberts[6]; [1]The Jackson Lab. for Genomic Med., Farmington, CT, [2]Univ. of Michigan Sch. of Med., Ann Arbor, MI, [3]Univ. of Iowa, Iowa City, IA, [4]Univ. of Michigan, Ann Arbor, MI, [5]Maine-Dartmouth Family Med. Residency, Augusta, ME, [6]Univ. of Michigan Sch. of Publ. Hlth., Ann Arbor, MI

Some employers are offering voluntary genetic testing through workplace wellness programs, known as workplace genetic testing (wGT). Little is known about the perspectives of employees offered wGT or its potential impact on their health behaviors and use of health services. From Dec. 2021 to May 2022, we conducted a web survey (n=776) of employees at a large healthcare system who were offered wGT through a third-party vendor that included genetic tests for hereditary cancer and cardiovascular disease risk as well as medication response (pharmacogenomics - PGx). This study reports on findings from the 418 respondents (53.9%) who reported receiving results (female, 88.3%; white, 83.0%; college or graduate degree, 80.6%). Across these 418 respondents, 211 unique positive results were reported among 159/418 (38.0%) individuals. Specifically, 125/418 (29.9%) of these respondents reported receiving at least one PGx result, 48/418 (11.5%) reported at least one result indicating an increased risk of cancer, and 38/418 (9.1%) reported at least one result indicating an increased risk of heart disease. Notedly, 39/418 (9.3%) reported receiving more than one positive finding among the three categories. Regarding health behavior changes following wGT, 29/159 (18.2%) individuals with positive (pos) results reported making changes to their diet, and 27/159 (17.0%) reported making changes to their physical activity/exercise. This was comparable to those with negative/unknown (neg/unk) results: 41/259 (15.8%) reported diet changes and 43/259 (16.6%) reported physical activity changes. Respondents with both result types reported using health services or making plans for healthcare utilization as a result of learning their test results, including making an appointment with a provider (pos all: n=32/159 [20.1%]; neg/unk all: n=49/259 [18.9%]), cancer screening (pos cancer: n=10/48 [20.8%]; neg/unk for cancer: n=101/370 [27.3%]), surgeries/cancer prevention procedures (pos cancer: n=6/48 [12.5%]; neg/unk for cancer: n=55/370 [14.9%]), heart disease screening (pos cardio: n=10/38 [26.3%]; neg/unk for cardio: n=97/380 [25.5%]), and making changes to use of medications (pos PGx: n=21/125 [16.8%]; neg/unk for PGx: n=44/293 [15.0%]). Findings suggest undergoing wGT prompted a range of health behavior changes, regardless of test results, in a subset of employees, as well as the use of health services related to the prevention of cancer and heart disease. Future planned analyses within this dataset will seek to identify factors influencing behavioral responses to wGT. This is the first study to report on behavior and healthcare service utilization outcomes for wGT.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session III

PB2444 What are patient perspectives on privacy and trust in digital genomic tools? A qualitative study

Authors:

V. Jha[1], S. Saeedi[2], M. Clausen[3], D. Assamad[4], S. Grewal[5], D. Hirjikaka[5], W. Lee[4], S. Luca[4], A. Shaw[6], R. Hayeems[4], Y. Bombard[7], on behalf of the Genetics Navigator Study Team; [1]Univ. of Toronto, Toronto, ON, Canada, [2]McGill Univ., Montreal, QC, Canada, [3]St. Michael s Hosp., Toronto, ON, Canada, [4]The Hosp. for Sick Children, Toronto, ON, Canada, [5]St. Michael's Hosp., Toronto, ON, Canada, [6]Unity Hlth., St. Michaels Hosp., Toronto, ON, Canada, [7]Univ of Toronto, Toronto, ON, Canada

Background: Digital tools have emerged as a promising solution to increase efficiency and capacity of genomic services. Patient facing digital tools can improve access, decrease wait times, and boost patient engagement. However, along with digital healthcare comes a radical change in the storage of personal health information (PHI) which can raise concern about privacy and security risks. As patient facing digital genomic tools continue to develop, it is important to understand and incorporate patients' perspectives on privacy and security.**Aim:** To assess patient perspectives on privacy and security in digital genomic tools.Methods: A qualitative study was conducted using semi-structured interviews with patients or parents of patients who underwent genetic testing. Participants were either recruited from the Canadian Organization for Rare Disorders or had previously participated in a Toronto-based cancer genetics study. Interviews focused on features that would make a digital genomics platform feel secure and trustworthy. Interview transcripts were analyzed using thematic analysis and interpretive description.Results: Thirty participants who previously received genetic testing for themselves (n = 17) or their child (n = 13) were interviewed (n=20 females, n=15 above 50 years old). Overall, participants were willing to store and access genomics personal health information (PHI) in a patient-facing digital platform. The main benefits of digital genomics services identified by participants were the ability to access and control their own PHI. Participants emphasized that a digital genomics platform should prioritize patient control of information to give patients more agency and increase efficiency in their care. Participants expressed that the benefits, such as patient empowerment and personalized care, outweighed the perceived risks, such as potential data leaks. Participants described factors that increased their risk tolerance, including the digitization of other sensitive matters such as banking information. In order to minimize risks, participants emphasized transparency about what security measures are in place and who has access to their PHI. Participants described this information as a prerequisite, which should be easily found on a consent form or a page on a digital platform.Conclusions: Patients are willing to access their genomic information digitally as long as security measures are clearly explained and patients are able to access and control their own information. These findings inform the design of digital genomic platforms to enhance patients' sense of security, which is critical for the uptake and usage of any platform.

Session Title: Genetic Counseling, ELSI, Education, and Health Services Research Poster Session I

PB2445 Where we stand on gene therapy: The current capabilities, the public opinion, and the policy.

Authors:

M. Svoboda[1], M. Dinulos[2]; [1]Geisel Sch. of Med. at Dartmouth, Hanover, NH, [2]Dartmouth Hitchcock Med Ctr, Lebanon, NH

The incessant advancements in genomic sequencing, nucleic acid editing, and gene delivery have recently produced the first approved gene therapies that are now available to the public. While these new technologies promise unprecedented opportunities in both biomedical research and clinical practice, they also present novel ethical dilemmas with practical implications for patient care, making us reconsider issues like decision-making delegation, the boundary between a “treatment” and an “enhancement,” and even species identity. The further we move the limits of our knowledge, the more frequently we encounter new limits that are of ethical nature instead: the question of “What can we do?” becomes “What should we do?”

Using the findings presented by studies in genetics available to date, we describe the extent of the technological advancements in gene therapies on the basic, translational, and clinical level. While there are currently several approved both in- and ex-vivo gene therapies, many more are undergoing clinical trials and yet even more are in the translational pipelines or basic research, promising an explosion of novel capabilities to tackle diseases with known genetic basis.

We then explore the public opinion of gene therapies and discover that in general, while somatic cell editing for patients with known serious pathologies is supported, embryonic and germline cell editing is met with mixed and mostly unfavorable views. The support further declines when interventions described as “enhancements,” as opposed to “treatments,” are considered.

Lastly, we turn to reconcile the technological advancements and public opinions with the current policy regarding gene therapies with specific focus on the most contentious aspect thereof, heritable germline editing, and we find the existing policy insufficient to govern these practices. To facilitate a fruitful discussion in anticipation of future scientific advances, we suggest a specific set of guidelines, under which heritable genome editing in humans may be theoretically permissible. We conclude that these standards have not yet been, and perhaps never may be, met and further discourse is needed before such therapies are approved.

PB3001 A draft diploid reference pangenome construction from a distinct Arab population

Authors:

N. Nassir[1], M. Almarri[1], M. Kumail[1], N. Mohamed[1], m. AlObathani[1], B. Jamalalail[1], S. Hanif[1], h. Elsokary[1], D. Satsangi[1], H. Al Suwaidi[1], M. Hamdi[2], A. Abu Tayoun[1], A. Albanna[1], H. Khansaheb[2], S. Duplessis[1], A. Alsheikh-Ali[1], M. Uddin[3]; [1]Mohammed bin rashid Univ. of medicine and Hlth. Sci.s, Dubai, United Arab Emirates, [2]Dubai Hlth.Authority, Dubai, United Arab Emirates, [3]Mohammed Bin Rashid Univ. of Med., Dubai, United Arab Emirates

Current reference genomes do not adequately represent the ethnic diversity of humans, with near absent representation of Arab populations. The recent pangenome initiative identified a massive intra and inter-population genetic diversity from *de novo* genome assemblies. However, the pangenome consortium lacks representation from the Arab population. In this study, we sequenced 25 deeply phenotyped healthy adults from the United Arab Emirates (UAE) using Pacific Bioscience (70X High fidelity reads with N50=18.70 kb, median Q=32.8) and Oxford Nanopore (54X ultralong reads; N50=59.57 kb, median Q=16.4) yielding high-quality *de novo* assemblies covering 97.88% of CHM13 (QV66.78). Preliminary analysis from a trio suggests our assemblies are highly contiguous (NG50=146.01 Mb) compared to 40 Mb for current pangenomes, spanning 3.03, 2.97Gb for maternal and paternal haplotypes, respectively. The assembly exhibits low switch (0.015204, 0.00008) and Hamming (0.020121, 0.000055) error rates, likely reflecting high LOH stretches due to population consanguinity. Initial mapping to GRCh38 revealed a significant number of population-specific variants not reported in other ethnicities. Furthermore, we identified 4.65 Mb of new sequence (outside of hg38) from the trio, which may contain novel genes and regulatory elements. This represents the most contiguous diploid human genome to date, revealing extensive unreported structural variation and enabling high-quality haplotyping of clinically relevant alleles in this underrepresented population. Our study provides a foundational resource for future genetic research and precision medicine initiatives in the UAE and other populations with similar genetic backgrounds.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3002 A genetic assessment of the likelihood of patrilocal mating in Neanderthals

Authors:

N. McAllister; Univ. of Michigan, Ann Arbor, MI

There is no current consensus on common mating practices in Neanderthals. Mating practices provide important information about the social organization of a species, making comparisons of Neanderthal and ancient *Homo sapiens* practices an important piece in understanding the differences in social behavior between us. The issue of patrilocality, or the movement of females into the male partner's household, has captured the interest of paleoanthropologists and resulted in a topic of debate. Evidence for patrilocality comes from a sample of 13 closely related Neanderthals at the remote eastern boundary of their range. It is unclear if the conclusion of patrilocality is generalizable to other times/regions of Neanderthal occupation. We study this question by inferring pairwise coalescent times in a set of 16 Neanderthal individuals from across the temporal and spatial range of their occupation. We account for the low (< 2x) coverage in these individuals by integrating over uncertainty in the genotype calls. As autosomes and sex chromosomes spend different proportions of coalescent history in males and females, differences in coalescent times between autosomes and sex chromosomes reflect different population histories of males and females. Under patrilocality, we assume that the migration rates of males are lower than the migration rates of females, resulting in differences in the time to most recent common ancestor of X-chromosomes and autosomes, even after accounting for differences in the chromosomes' effective population size. Our results can help indicate whether patrilocality was a common practice among Neanderthals outside of the remote eastern boundary region and whether or not the mating practices of Neanderthals are comparable to ancient *Homo sapiens*.

PB3003 A likelihood-based framework for demographic inference from genealogical trees

Authors:

C. Chiang[1], J. L. Cahoon[1], B. L. Dinh[1], D. Ortega-Del Vecchyo[2], C. D. Huber[3], M. D. Edge[1], N. Mancuso[1], C. Fan[1]; [1]Univ. of Southern California, Los Angeles, CA, [2]Natl. Autonomous Univ. of Mexico, Queretaro, Mexico, [3]Penn State Univ., University Park, PA

Methods to infer demographic history from genetic data typically rely on extracting low-dimensional features from the underlying gene genealogies. As a result, the likelihood functions in these methods incompletely capture the observed information and are often degenerate or divergent, leading to poor optimization or unstable inference. Here we propose a novel framework called the genealogical likelihood (gLike) that addresses these limitations by deriving the full likelihood of a genealogical tree under any hypothesized demographic history. It is motivated by the fact that a genealogical tree does not specify the populations of its ancestral lineages, and a large number of possible trajectories of their population memberships may exist that are compatible with the observed coalescences throughout the history. Employing an innovative graph-based structure, gLike is able to summarize the relationships between all such trajectories and efficiently compute the exact marginal probability under a parameterized demographic model. Through extensive simulations of multiple admixtures as well as admixed demographic models from stdpopsim, we show that when the true genealogy is known, gLike has excellent accuracy (mean estimation error < 5%) in estimating dozens of demographic parameters, such as ancestral population sizes, admixture timing, and admixture proportions. Moreover, when using genealogical trees estimated from genetic data with tsinfer+tsdate, we show that gLike outperforms conventional demographic inference methods that leverage only the allele frequency spectrum. Furthermore, our framework traces ancestral histories by analyzing solely a sample from the admixed population, removing the need to have sampled the ancestral populations that may no longer exist. To illustrate the utility of gLike on real data, we performed demographic inference using estimated genealogical trees based on 1,000 individuals each from the Latino American and Native Hawaiian populations of the Multiethnic Cohort, yielding parameter estimates that align with established historical knowledge of their past demographic history. For example, we found the Native Hawaiians to be more recently admixed than the Latinos, with a slightly smaller initial population size. Overall, our proposed gLike framework harnesses the complete genealogical information to offer exceptional sensitivity and accuracy in inferring complex demographies.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3004 A multivariate fixation index for measuring genomic differentiation of human populations

Authors:

I. Jordan, G. P. Yerradoddi, S. Sharma; Georgia Inst. of Technology, Atlanta, GA

Univariate variance partitioning methods (e.g. Wright's fixation index Fst) are used to measure genetic differentiation among populations, whereas multivariate methods (e.g. principal component analysis) are used to classify individuals' population origins. Univariate genetic differentiation methods average information across loci, refining the precision of single locus estimates, whereas multivariate classification methods accumulate information across loci, resulting in high precision for population origin assignments. We have developed a multivariate fixation index for measuring genomic differentiation of human populations, which combines the variance partitioning and classification approaches to yield a more accurate picture of the apportionment of human genomic diversity. Our multivariate method leverages the correlation structure of human genomic variation, accumulating information across loci, to estimate the within and between population genomic variance components based on multilocus data. In other words, the multivariate fixation index allows us to characterize the relative similarity for random pairs of genomes drawn from the same versus different populations, rather than the relative similarity for random pairs of loci within versus between populations as measured by the univariate fixation index. We applied our multivariate approach to whole genome sequence data from the 1000 Genomes Project, partitioning variation among populations within regions and among regions. The multivariate fixation index reveals human populations to be substantially more genomically differentiated than can be seen using univariate methods, consistent with the fact that pairs of individuals from the same population tend to be far more closely related than pairs of individuals from different populations.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3005 A new model-based method controlling for gene flow using ancient genomes obtains less biased estimates of the selection coefficient

Authors:

X. Li[1], J. Novembre[2]; [1]Univ. of Chicago, Chicago, IL, [2]Univ Chicago, Chicago, IL

Studying genetic signatures of natural selection using ancient DNA may help identify functionally important variants. However, the complex demographic history of humans can hide selection signals or lead to spurious discovery. In particular, gene flow from diverged populations can cause rapid shifts in allele frequencies that may be mistaken as selection signatures.

To address this limitation, we developed a new method to infer selection while controlling for the effects of gene flow. We model the allele frequency change of a target population as a function of genetic influx from other source populations, drift, and selection. First, we infer the posterior distribution of migration proportion parameters using SNPs from putatively neutral regions. Second, conditioning on the migration proportions, we estimate the selection coefficients for variants in interest. At each step, to obtain the posterior distribution efficiently, we use variational inference.

To test this method, we applied our method to simulated data. In these simulations, compared to a method that does not account for migration, our approach obtains a more accurate and unbiased selection coefficient. For instance, in the case of 30% pulse migration, an initial frequency of 0.01 in the target population, and a selection coefficient of 0.001, the approach without considering gene flow infers on average a 3-fold larger selection coefficient estimate ($s=0.0034$ vs. $s=0.0012$). In addition, when we simulate neutrally evolving alleles using a realistic demographic model, the approach that does not account for gene flow obtains a 11.4% false positive rate while our method obtains a well-controlled 3.6% false positive rate.

We applied our method to publicly available data from 481 individuals from the Carpathian Basin, including samples ranging from 5000 BCE to 900 CE (Mallick et al., 2023). Our method fits two major events of gene flow: 1) from Steppe-like ancestry during the Bronze Age and 2) from Xiongnu-like ancestry in the Medieval period. Correcting for these gene flow events, we identify selection signals associated with light skin pigmentation and immune response. For instance, our method recovers a well-studied selection signal at rs1426654 (posterior mean of $s= 0.024$ with 95% credible interval [0.00078, 0.047]) while a method that does not account for gene flow does not have enough power (posterior mean of $s= 0.021$ with 95% credible interval [-0.0090, 0.050]).

While gene flow among populations has been shown to be pervasive across human history, our new method can be a powerful way to infer selection using ancient DNA without biases from gene flow.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3006 A novel approach, LASeQTL, shows local ancestry has widespread effects on regulation of gene expression and improves functional annotation of GWAS signals

Authors:

H-H. Chen[1,2], W. Zhu[3], L. Petty[2], H. Polikowsky[3], J. McCormick[4], S. Fisher-Hoch[4], H. Highland[5], K. North[5], E. Gamazon[2], J. Below[2]; [1]Academia Sinica, Taipei, Taiwan, [2]Vanderbilt Univ. Med. Ctr., Nashville, TN, [3]Vanderbilt Univ., Nashville, TN, [4]Univ. of Texas Sch. of Publ. Hlth., Brownsville, TX, [5]Univ. North Carolina at Chapel Hill, Chapel Hill, NC

Expression quantitative trait loci (eQTL) are powerful genetic predictors of molecular phenotypes and are the basis of many functional characterizations of genetic associations with disease. Yet, to date most eQTL studies have been performed in populations with predominantly European ancestries. Here, we leverage genetic and RNA sequencing data from 645 whole blood RNA samples from the Cameron County Hispanic Cohort to conduct eQTL mapping on haplotype-specific expression while considering local ancestry. To accomplish this, we developed a novel approach to map local ancestry-specific (LAS) eQTL, LASeQTL. Global genetic ancestry analysis identified an average of 49.0% Amerindian (AMR), 45.7% European (EUR), and 4.6% West African ancestry in our samples. Here, we focus on EUR and AMR specific eQTLs. In total, we identified over 3 million cis-eQTLs for 8,523 genes (FDR-adjusted p-value<0.05), of which 4,724 genes have at least one LASeQTL. Interestingly, in 1,411 of these genes, 37,544 LASeQTLs exhibited opposing effect directions on expression between the EUR and AMR ancestral haplotypes. Highlighting the genome-wide differences in genetic regulation by ancestral haplotypes, the median genetic correlation of LAS gene expression was 0.50 between EUR and AMR in the CCHC among heritable genes (heritability>0.05), and 0.53 for highly heritable genes (heritability>0.4); in contrast, a high concordance was observed between CCHC local European specific gene expression and GTEx (European >84.6%), median genetic correlation was 0.59 for heritable genes and 0.91 for highly heritable genes. To demonstrate the importance of our approach, we further performed colocalization analysis with our identified ancestry-specific eQTLs and the Hispanic/Latino type 2 diabetes GWAS from DIAMANTE (n=33,808); eight GWAS signals colocalized with our LASeQTLs whereas only one signal was colocalized with the GTEx eQTLs. Such differences may explain the differential predictive value of functionally oriented models of disease risk in admixed populations and the inconsistent GWAS and TWAS findings across diverse populations. In conclusion, we represent the first profile of a local ancestry-specific regulatory landscape of gene expression in Hispanic/Latinos, and demonstrate its importance on functional interpretation of previous genetic studies' findings, continuing to emphasize the importance of diversity in genetic research.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3007 A Pangenome Reference of 36 Chinese populations

Authors:

S. Xu; Fudan Univ., Shanghai, China

Human genomics is witnessing an ongoing paradigm shift from a single reference sequence to a pangenome form, but populations of Asian ancestry are underrepresented. Here, we present the first effort of the Chinese Pangenome Consortium (CPC) with a collection of 116 high-quality and haplotype-phased *de novo* assemblies based on 58 core samples representing 36 minority Chinese ethnic groups. With an average 30.65× high-fidelity long-read sequence coverage, an average contiguity N50 of more than 35.63 Mb, and an average total size of 3.01 Gb, the CPC core assemblies add 189 million base pairs of euchromatic polymorphic sequences and 1,367 protein-coding gene duplications to GRCh38. We identified 15.9 million small variants and 78 thousand structural variants, of which 5.9 million small variants and 34 thousand structural variants were not reported in a recently released pangenome reference[1]. The CPC data demonstrate a remarkable increase in the discovery of novel and missing sequences when individuals are included from underrepresented minority ethnic groups. The missing reference sequences were enriched with archaic-derived alleles and genes that confer essential functions related to keratinization, UV response, DNA repair, immunological responses, and lifespan, implying great potential for tracing missing links in human evolution and recovering missing heritability in complex disease mapping.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3008 A reference panel to improve genotype imputation for Native Hawaiians

Authors:

B. Dinh[1], X. Sheng[1], E. Tang[1], F. Chen[1], E. Young[2], K. Taparra[3], L. R. Wilkens[4], L. Le Marchand[4], I. Hall[5], N. Stitziel[2], C. A. Haiman[1], C. W. K. Chiang[1]; [1]Univ. of Southern California, Los Angeles, CA, [2]Washington Univ. in St. Louis, St Louis, MO, [3]Stanford Univ., Stanford, CA, [4]Univ. of Hawai'i, Honolulu, HI, [5]Yale Univ., New Haven, CT

Imputation is now a fundamental component to conduct powerful association studies. In recent years, public imputation reference panels have increased their size, representation, and accessibility. Recent findings have shown that the state-of-the-art reference panel from the TOPMed consortium now imputes comparably for minority populations such as African Americans and Latinos as it does for individuals of European ancestries, an improvement over previous reference panels. Nevertheless, the accuracy and effectiveness of imputation remain low among global populations whose ancestries are not adequately represented in TOPMed. We created an imputation reference panel comprised of 10,721 whole-genome sequenced individuals from the Multiethnic Cohort (MEC), with multi-ancestry representations from five ethnic groups: African Americans (1,270), Native Hawaiians (1,065), Japanese Americans (3,106), Latinos (4,141), and non-Hispanic whites (1,139). In total, we constructed the reference panel based on 82M SNPs and 5M indels passing quality control measures. Despite being approximately 10% the size of TOPMed, we find that our reference panel outperforms TOPMed for populations not well-represented such as Native Hawaiians (NH) and Japanese Americans (JA). We imputed 3,276 NH and 4,176 JA individuals genotyped on the MEGA array and find that both populations showed improved imputation accuracy with the MEC panel. For example, for alleles with 1-5% frequency, the mean imputation Rsq for NH and JA are 0.921 and 0.908, respectively, compared to 0.886 and 0.751 when imputed on the TOPMed imputation server. Comparing to genotypes from 100 held-out sequenced individuals, we also confirmed that NH and JA individuals benefited from the MEC reference panel, with an increase of 0.03 and 0.13 in squared-Pearson's correlation coefficient (r^2), respectively. These improvements are stronger for NH more enriched with Polynesian ancestries (0.05 increase in r^2 compared to TOPMed), suggesting that our reference panel may also benefit other Pacific Island populations enriched with Polynesian ancestries in general. As this improvement due to increased representation does not require sequencing a prohibitive number of individuals, our study highlights the urgent need to generate genomic resources that will enable better association studies for underserved populations across the globe.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3009 A scan of selective signals in whole-genome sequencing data from Canary Islanders

Authors:

J. Lorenzo Salazar[1], R. Gonzalez-Montelongo[1], L. Rubio-Rodriguez[1], A. Muñoz-Barrera[1], D. Jáspez[1], A. Díaz-de Usera[1], V. Garcia Olivares[1], A. Iñigo Campos[1], B. Guillen-Guio[2,3,4], I. Marcelino-Rodríguez[2,5], A. Corrales[2,6], D. Comas[7], C. Flores[1,2,6]; [1]Genomics Div., Inst. of Technology and Renewable Energy (ITER), Granadilla de Abona, Spain, [2]Res. Unit, Hosp. Univ.rio Ntra. Sra. de Candelaria, Santa Cruz de Tenerife, Spain, [3]Dept. of Population Hlth.Sci., Univ. of Leicester, Leicester, United Kingdom, [4]NIHR Leicester BioMed. Res. Ctr., Leicester, United Kingdom, [5]Publ. Hlth.and Preventive Med. Area, Univ. de La Laguna, Santa Cruz de Tenerife, Spain, [6]CIBER de Enfermedades Respiratorias (CIBERES), Inst. de Salud Carlos III, Madrid, Spain, [7]Departament de Ciències Experimentals i de la Salut, Inst. de Biología Evolutiva (CSIC-UPF), Univ.t Pompeu Fabra, Barcelona, Spain

Rationale. The genetic uniqueness of the contemporary Canary Islands (Spain) population is explained by historic admixture during and after the conquest of the islands in the XV century. Ancestry influences from Iberians (IBS) and North Africans (NAF) constitute the main genetic components that are recognized in the population. Studies with SNP array data have revealed a few loci that are enriched in one of the genetic ancestries in the current inhabitants and some of these loci showed evidence of selection.
Objective. To use whole genome sequencing (WGS) to systematically scan for regions evidencing putative natural selection in the genome of the contemporary Canarian population.
Methods. WGS at ~30x from 100 unrelated Canary Islanders (CAN) and 100 NAF (Illumina HiSeq2500, HiSeq4000, and NovaSeq6000, paired-end 150 bp), and 100 IBS (The 1000 Genomes project) have been processed. Small germline genetic variation was characterized using BWA-GATKv4 (hg19) based pipelines. Putative signals of selection were identified from genetic neutrality and diversity tests (D-Tajima, PBS, iSAFE) at different window sizes. Values at the extremes of the distributions were prioritized, functionally annotated, and used in the enrichment analyses by combining GREAT, Open Targets Genetics, and Ensembl.
Results. Approximately 25 million variants were identified in CAN, of which ~18% were not present in dbSNP (avsnp150) and 43% were not described in TOPMed freeze3. A focus on the top 0.1% of the D-Tajima distribution revealed more than 1,300 putative regions of selection. This includes the highly polymorphic region encompassing HLA (*TSBP1*), as well as other well-known regions under natural selection (*LCT*). The enriched terms in the prioritized genetic regions include autoimmune, ophthalmologic, and oncologic diseases, among others.
Conclusion. Our results support the existence of a genuine gene pool in the current Canary Islanders. Further studies to evaluate the relationship between the putative signals of selection, disease links, and the admixture sources are underway.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3010 A significant difference in the prevalence of genotypes and alleles in SNPs known to be associated with strength, endurance and injury propensity in the local population compared to the prevalence in global databases

Authors:

D. Bercovich[1,2], H. Salem[3]; [1]Tel Hai Academic Coll., Tel Hai, Israel, [2]Galile Genetic Analysis - GGA Ctr., Kazerin, Israel, [3]Ariel Univ., Ariel, Israel

There are number of SNPs that are known in the literature where different genotypes in the same SNPs may influence people's optimal athletic ability and determine whether they are suitable for strength type sports or more suitable for endurance sports type and their susceptibility to injuries after sports activities (such as muscle injury or the ability to recover and the susceptibility to inflammation in the Achilles tendon). In this study, we examined the prevalence of these SNP genotypes and alleles frequencies in about 3600 individuals from the Israeli population from all ethnic groups and compared the prevalence of these genotypes and alleles to those known in databases (such as dbSNP). A large number of differences were found in the prevalence of genotypes known to affect these traits, such as SNP rs1042713, in which the genotype affecting suitable for endurance, the AA genotype, is found worldwide at a prevalence of 20% and in the Israeli population only 3%. Also, in SNP rs12594956, the AA genotype that affects this trait is found worldwide at a prevalence of 50% and in Israel only by 31% . in the rs679620 SNP, the CC genotype, which is known to predict susceptibility to Achilles tendon inflammation, is found worldwide at a prevalence of 39% and in the Israeli population only 25%. The work will present differences in SNP prevalence related to strength and endurance tendency to muscle injuries and inflammation of the Achilles tendon.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3011 A symphony of genes: Exploring the diverse landscape of human copy number variable Y-chromosomal ampliconic genes.

Authors:

M. Loftus[1], P. Hallast[2], P. Ebert[3], F. Yilmaz[2], The Human Genome Structural Variation Consortium, T. Marschall[3], C. Lee[2], M. K. Konkel[1]; [1]Clemson Univ., Clemson, SC, [2]The Jackson Lab. for Genomic Med., Farmington, CT, [3]Heinrich Heine Univ., Düsseldorf, Germany

The human Y chromosome is essential to sex determination and fertility. Most of the Y chromosome is comprised of the male-specific region (MSY) that does not recombine with the X chromosome. Across the MSY there are seven ampliconic regions, which collectively contain nine multi-copy ampliconic genes (*BPY2*, *CDY*, *DAZ*, *HSFY*, *PRY*, *RBMY1*, *XKRY*, *VCY*, and *TSPY*). These ampliconic genes perform pivotal roles in male-specific functions, particularly spermatogenesis, and their aberrant expression has been associated with a multitude of diseases, including a variety of cancers. Unfortunately, studies for some of these genes have faced hindrances due to the incomplete assembly of their genomic regions (e.g., the *TSPY* array). The initial assembly of the first human Y chromosome sequence was generated nearly two decades ago, yielding a high-quality, yet incomplete sequence (approximately 53.8% unresolved in GRCh38 Y). Recently, a significant milestone was achieved by the Telomere-to-Telomere (T2T) Consortium, who reported the first complete *de novo* assembly of a human Y chromosome from end-to-end (Rhie et al. - manuscript under review, preprint available on bioRxiv). Combining PacBio HiFi and Oxford Nanopore Ultra-Long read sequencing technologies, we have assembled 43 human Y chromosomes with half of our Y chromosome assemblies encompassing African lineages. From the analysis of these 44 (43 + T2T Y) new assemblies, in conjunction with an exon-centric approach, we find considerable genetic diversity, including copy number variation, of the ampliconic genes. Two ampliconic genes, *RBMY1* and *TSPY* are particularly copy number variable (*RBMY1*: 5 - 11 copies; *TSPY*: 23 - 46 copies). Utilizing chimpanzee as an outgroup, we determined which gene copies are the most ancestral and examined the potential functional diversity of these genes. Lastly, we provide examples of how recombination events (e.g., gene conversion and non-allelic homologous recombination) might maintain the function of ampliconic gene arrays through the purging of low divergence (less than 2%) haplogroup-specific pseudogenes. Our findings not only enhance our understanding of more than 180,000 years of human Y chromosome ampliconic gene evolution, but could lead to the better diagnosis and treatment of associated diseases.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3012 † A timeline of human evolution: Leveraging GWAS and comparative genomic data to contextualize human-evolved diseases and morphological traits

Authors:

E. Kun[1], M. Sohail[2], V. Narasimhan[1]; [1]The Univ. of Texas at Austin, Austin, TX, [2]UNAM, Cuernavaca, Mexico

Higher levels of cognitive function, bipedalism, and other uniquely human traits evolved over millennia, but genomic evidence for these changes has been lacking. Recent high-quality reference genomes of 240 different primates, ancient DNA from archaic hominids, and comparative functional genomic data across primates have identified human gained brain enhancers and promoters (HGEPs), selective sweeps, neanderthal introgressed regions (NIRs), and human accelerated regions (HARs). These correspond to different evolutionary periods and can be associated with traits, contextualizing the evolutionary history of each trait. To do so, we used stratified LD score regression as well as protein coding gene enrichment analysis to integrate these key evolutionarily genomic regions with GWAS of several human traits and diseases and image derived morphological traits of the heart, brain, and skeletal structure. First we examined functional genomic annotations and saw differences in heritability enrichment across stages of development and traits we examined. Virtually all traits with enrichment for overlap in HGEPs were only significant in early time points but not in adults, suggesting that major differences in trait gene expression between humans and primates lie in early development. At least 1 psychiatric, dermatological, and respiratory trait showed enrichment while no immune or metabolic traits did. Similarly, we find significant enrichment for skeletal and brain morphology traits but not heart morphological traits. Next we examined annotations derived from comparative analysis of DNA sequence. Genes associated with various psychiatric traits were especially enriched in HARs, alongside brain visual cortex area and arm-to-leg ratio in line with known human anatomical evolution. Conversely, ancient selective sweeps and NIRs had greater enrichment with immune and reproductive traits, respectively. Further, genes associated with the thalamus, which is responsible for relaying sensory information in the brain, and heart atrial area were specifically enriched in NIRs. As HARs arise from differences between humans and great apes while selective sweeps and NIRs are related to archaic humans, our results paint a temporal map of which traits likely evolved before emergence of bipedal hominids as well as which traits continued to evolve or only began to evolve in more recent human history. Overall, we combined large datasets from comparative, ancient, medical, functional and imaging genomics to investigate the evolution of human traits and connect these to evolutionary timepoints, furthering our understanding of the emergence of human specific biology.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3013 A tree-based algorithm for identifying mutator alleles from genetic variation data

Authors:

L. Zhu, K. Harris; Univ. of Washington, Seattle, WA

Mutator alleles are genetic variants that increase the mutation rate, for example by interfering with DNA repair. Although mutators have been hypothesized to play a role in the rapid divergence of mutation spectra between vertebrate populations and species, they are difficult to detect in sexual organisms because they quickly recombine away from the mutations they beget. In theory, mutator alleles segregating in large genetic variation databases should be detectable via linkage to excess rare variants; here, we describe a tree-based algorithm for identifying this signature. At a mutator locus, edges within the subtree subtending the mutator allele are expected to accumulate mutations at an elevated rate, as are linked edges in adjacent subtrees. Our algorithm uses a tree sequence to identify the "ARG footprint" of a candidate mutator allele, which is essentially the set of tracts inherited identical by descent between each pair of sequences carrying the candidate mutator. We use SLiM simulations to verify that ground-truth ARG footprints show good agreement with the ARG footprints that our algorithm efficiently infers, and we perform a power analysis showing that our approach is capable of identifying mutators of moderate effect sizes from large tree sequences constructed using *tsinfer*. We have started inferring for TOPMed individuals to potentially investigate the presence of mutator activity.

PB3014 Adaptations to diving in the Haenyeo of Jeju, Korea

Authors:

M. Ilardo[1], R. Nielsen[2], J-Y. Lee[3]; [1]Univ. of Utah, Salt Lake City, UT, [2]Univ California Berkeley, Berkeley, CA, [3]Seoul Natl. Univ., Seoul, Korea, Republic of

Around the world, various human populations have adjusted to a marine-based lifestyle by adopting the practice of subsistence breath-hold diving. One such population is the Haenyeo, a group of all female breath-hold divers on the island of Jeju, Korea. Perhaps even more remarkable than their diving abilities are the temperatures at which the dives are performed: in the winter, water surface temperatures dip to 10ºC. We pursued for the first time an investigation of the genetics and diving physiology of the Haenyeo. We measured baseline metrics associated with diving physiology as well as cardiovascular measurements during a series of simulated dives. We then used whole genome sequencing (WGS) data to identify genetic loci that have been under selection in this population and examined whether these loci were associated with candidate phenotypes. We report the demographic history of the Haenyeo as well as physiological and genetic adaptations to diving.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3015 An ancient DNA time-transect of the Western Steppe from 1000 BCE to 1000 CE disproves the Khazar hypothesis of Ashkenazi Jewish origins.

Authors:

A. Shaus[1,2], I. Shingiray[3], C. Lalueza-Fox[4], R. Pinhasi[5], D. Reich[1,6,7,8]; [1]Harvard Med. Sch., Boston, MA, [2]Tel Aviv Univ., Tel Aviv, Israel, [3]Univ. of Oxford, Oxford, United Kingdom, [4]Inst. of Evolutionary Biology of UPF and CSIC, Barcelona, Spain, [5]Univ. of Vienna, Vienna, Austria, [6]Harvard Univ., Cambridge, MA, [7]Broad Inst. of MIT and Harvard, Cambridge, MA, [8]Howard Hughes Med. Inst., Boston, MA

Unlike many literate civilizations of the past, most of the cultures of the Western Steppe during the millennia before and after the turn of the common era left little, if any, written evidence. Hence, the only historical knowledge of these cultures is provided by the writing of often unfriendly neighbors, which is at best fragmentary and certainly tendentious. Additionally, in many cases, the archaeological record of these societies is restricted to isolated burials, which are difficult to characterize and analyze based on frequently limited and fragmentary funerary material culture, and is further complicated by the common presence of intrusive graves from later periods. We report genome-wide data from 105 Steppe individuals from Moldova, Ukraine, Russia, Georgia and Kazakhstan, 83 of which were radiocarbon dated. We trace the intricate effects of centuries-long patterns of migrations, admixtures and population displacements for populations likely to correspond to the historically described Scythians, Sarmatians, Alans, Khazars, and Bulgars. We detect a major population shift beginning with the second half of the 4th century CE, which can be associated with the consequences of the so-called “Hunnic mayhem”, postulated by some historians. By analyzing multiple genomes from the core area of the Khazar Khaganate, we set to rest the “Khazar hypothesis” of Jewish Ashkenazi origins, which postulates that Khazars, converted to Judaism in the 8th and 9th centuries CE, were a major contributing source to present-day Ashkenazi Jews. Instead, we find that Khazar burials have a typical Western Turkic genetic profile, with no evidence at all for recent shared ancestry with present-day or medieval Jews.

PB3016 An SFS-based model of negative selection predicts fine-scale constraint in the noncoding genome

Authors:

E. Koch, D. Lee, V. Seplyarskiy, S. Sunyaev; Harvard Med. Sch., Boston, MA

The availability of whole-genome sequencing data with sample sizes in the hundreds of thousands has led to attempts to map fine-scale selective constraint across the human genome. This is generally done by comparing the probability that a variant is present in a sample to neutral expectations. These depend strongly on mutation rates, and a poor rate map can therefore lead to biased or noisy estimates of selection. For instance, tRNA genes are nearly ten times more mutable than expected based on sequence context, yet they likely constitute an important class of constrained sites in the human genome. We first developed a mutation rate model (Roulette) that includes such local effects and provides better neutral predictions than previous approaches. A second limitation of most current methods is that they ignore the frequency distribution (SFS) of observed variants. Hypermutable sites are highly informative about selective constraint, but the shape of the SFS for these sites depends on the mutation rate due to recurrent mutation. Inference for these sites can be achieved by combining precise rate predictions with modeling of selection's effect on allele frequencies. We developed a method (RaKLette) to move beyond presence/absence by modeling the zero-inclusive distribution of allele frequencies using Roulette. This method uses a multinomial transform of the SFS to account for mutation rate dependence. Multinomial coefficients are then fit using a regression approach that can capture constraint associated with regions of the genome or quantitative covariates. We summarize the effects of selection on a per-mutation level using the KL divergence between neutral and expected allele frequencies. Simulations based on realistic human population histories and distributions of selection coefficients suggest that RaKLette outperforms presence/absence models, with greatest improvements for high mutation rates and strong to moderate selection. We then applied RaKLette to whole-genome sequencing data from gnomAD v3 and compared constraint estimates generated using 1kb windows, enhancer models, and phylogenetic conservation. We provide a per-mutation annotation track along with quantitative estimates of fitness effect for various functional annotations.

PB3017 Ancient DNA from 576 prehistoric people reveals the genetic history of the Sambaqui shellmound builders of Brazil.

Authors:

Y-C. Liu[1,2], M. Okumura[3], K. Sirak[1,2], O. Cheronet[4], N. Rohland[2], R. Pinhasi[4], D. Reich[1,2,5,6]; [1]Dept. of Human Evolutionary Biology, Harvard Univ., Cambridge, MA, [2]Dept. of Genetics, Harvard Med. Sch., Boston, MA, [3]Dept. of Genetics and Evolutionary Biology, Inst. of BioSci.s, Univ. of São Paulo, São Paulo, Brazil, [4]Dept. of Evolutionary Anthropology, Univ. of Vienna, Vienna, Austria, [5]Broad Inst. of MIT and Harvard, Cambridge, MA, [6]Howard Hughes Med. Inst., Harvard Med. Sch., Boston, MA

The shellmounds built by prehistoric hunter-gatherers of southeast Brazil are a prominent feature of the Brazilian coastline; the largest ones were constructed 5000-3000 years before present (BP), with the earliest evidence going back to 8000 BP. Around 1000BP, archaeological research documents a major transition from hunter-gatherers to ceramic-users with the appearance of two types of pottery cultures in the same region, known as Itararé and Tupiguarani, likely to have been associated with Jê and Tupi-Guarani speakers. In the absence of ancient DNA data, the genetic origin and interrelationship of these groups has been unclear, and it remains uncertain whether these early ceramic users were related genetically to the prehistoric hunter-gatherers. We generated genome-wide ancient DNA data for 576 prehistoric individuals dating to 5100-400 BP from coastal shellmound sites in three states (Rio de Janeiro, Paraná, and Santa Catarina) and inland rockshelter sites in two states (São Paulo and Rio Grande do Sul), thereby more than tripling the amount of human ancient DNA data reported from the Americas. We show that coastal shellmound builders are closely related to inland groups dating to 6000 BP and earlier, such as the inland riverine shellmound builders from the Laranjal and the Moraes sites of the Vale do Ribeira de Iguape in southern São Paulo from this time. We find that the genetic structure of shellmound builders correlates tightly with their geographic locations regardless of chronology and material culture, following an isolation-by-distance pattern. We document genetic continuity over 5000 years in the coast even during the lifestyle transition from hunter-gatherers to farmers associated with the Itararé culture, indicating that this culture transition was largely due to local innovation or adoption of ideas rather than to movements of people. This contrasts with many other regions of the world where ancient DNA data often documents large population displacements correlating with significant cultural change and in particular the lifestyle shift from hunting to farming. Our study also reveals that prehistoric groups from the inland rockshelter sites that have been hypothesized to be associated with Jê speakers are indeed more closely related to present-day Jê speakers than to contemporaneous coastal groups, providing support for models that the spread of people related to present-day and historically attested Jê-speakers was mediated by long-distance migration. We detect high amounts of Runs Of Homozygosity and extensive Identity-By-Descent segments throughout the ancient DNA time transect, implying a long-term small effective population size.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3018 Ancient viral detection using metagenomic data from ancient individuals

Authors:

L. Nishimura[1,2], R. Sugimoto[1], H. Kanzawa-Kiriyama[3], K. Shinoda[3], I. Inoue[1]; [1]Natl. Inst. of Genetics, Mishima, Japan, [2]The Graduate Univ. for Advanced Studies (SOKENDAI), Mishima, Japan, [3]Natl. Museum of Nature and Sci., Tsukuba, Japan

Ancient DNAs have been massively sequenced because of the recent development of sequence techniques. Ancient DNAs contain viral genomic information accompanied with host genomes. Researchers have discovered ancient viral sequences in historical samples like bones, teeth, and mummified tissues, providing insights into past pandemics and long-term viral evolution. However, the number of ancient viruses found has been limited. Here, we analyzed whole genomic sequencing (WGS) data from ancient individuals who lived in the Japanese archipelago for thousands of years. We downloaded WGS data of ancient individuals from NCBI database. We used various bioinformatic techniques to detect ancient viruses, including de novo assembly, read alignment, metagenomic profiling, and non-homologous viral detection using bacterial CRISPR immunological memories. We recovered an almost complete sequence of the Siphovirus contig89 (CT89) and compared ancient and modern CT89 genomes, revealing that the most recent common ancestor of CT89 existed around 7,900 years ago. We also detected more than 10,000 candidate ancient viral genomes and some of them did not match modern viral sequences, possibly indicating highly diverged or extinct ancient viral genomes. We then characterized the ancient viromes of each individual, revealing differences between ancient and modern Japanese and European viromes that may reflect different dietary behaviors. Overall, these findings suggest that analyzing ancient viruses can be useful for understanding their existence in the past and long-term viral evolution.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3019 Archaic humans have contributed to large-scale variation in modern human T cell receptor genes.

Authors:

M. Chernyshev[1], M. Corcoran[1], M. Mandolesi[1], S. Narang[1], M. Kaduk[1], K. Ye[1], S. Christopher[1], A. Färnert[1], T. Kreslavsky[1], C. Bernhardsson[2], M. Larena[2], M. Jakobsson[2], G. B. Karlsson Hedestam[1]; [1]Karolinska Inst.t, Solna, Sweden, [2]Uppsala Univ., Uppsala, Sweden

Human T cell receptors (TCRs) are critical for mediating immune responses to pathogens and tumors as well as regulating self-antigen recognition. Yet, variations in the genes encoding TCRs remain insufficiently defined. Detailed analysis of expressed TCR alpha, beta, gamma, and delta genes in 45 donors from four human populations-African, East Asian, South Asian, and European-revealed 175 additional TCR variable and junctional alleles. Most of these contained coding changes and were present at widely differing frequencies in the populations, a finding confirmed using DNA samples from the 1000 Genomes Project. Importantly, we identified three Neanderthal-derived, introgressed TCR regions including a highly divergent TRGV4 variant, which mediated altered butyrophilin-like molecule 3 (BTNL3) ligand reactivity and was frequent in all modern Eurasian population groups. Our results demonstrate remarkable variation in TCR genes in both individuals and populations, providing a strong incentive for including allelic variation in studies of TCR function in human biology.

PB3020 † Associations between genome-wide autozygosity and complex traits in an ancestrally diverse US cohort.

Authors:

E. Johnson[1], S. M. Colbert[2], M. C. Keller[3,4], J. F. Wilson[5,6]; [1]Dept. of Psychiatry, Washington Univ. Sch. of Med., St. Louis, MO, [2]Dept. of Genetics and Genomic Sci., Icahn Sch. of Med. at Mount Sinai, New York, NY, [3]Dept. of Psychology and NeuroSci., Univ. of Colorado Boulder, Boulder, CO, [4]Inst. for Behavioral Genetics, Univ. of Colorado Boulder, Boulder, CO, [5]Ctr. for Global Hlth.Res., Usher Inst., The Univ. of Edinburgh, Edinburgh, United Kingdom, [6]MRC Human Genetics Unit, Inst. of Genetics and Cancer, The Univ. of Edinburgh, Edinburgh, United Kingdom

While inbreeding depression is often considered with respect to Mendelian diseases caused by rare, recessive variants, it has been shown to affect complex traits in humans as well. Even in seemingly outbred populations, the net effect of recessive variants acting on a trait can be estimated by genome-wide autozygosity (the proportion of the genome that is homozygous due to inheritance of alleles identical-by-descent). Prior studies have demonstrated associations between greater autozygosity and generally decreased fitness-related trait values for complex traits such as height, weight, and fertility. Questions that remain include the degree to which rare versus common variants are driving these associations with autozygosity, and the extent to which confounding factors play a role in observed associations. In this abstract, we present data on the relationship between genome-wide autozygosity and complex traits in a large cohort of diverse ancestries from the US (All of Us; max N = 206,819). We focused on traits that were previously associated with autozygosity in work from the ROHgen consortium. In a meta-analysis across ancestries, we found significant associations between greater autozygosity and fewer years of education, shorter height, and greater waist-to-hip ratio, consistent with prior studies. When using broad continental ancestry assignments provided by the All of Us program, there were noticeable ancestry-specific differences in some trait associations with autozygosity (e.g., weight); we suspect these differences may be due to residual population structure and are currently investigating this. Controlling for potential confounding factors, such as religiosity, did not substantially attenuate the observed associations. Consistent with a study in the UK Biobank, we found that the extent to which common or rare variants drive associations between autozygosity and complex traits seems to be trait-dependent; for example, the relationship between educational attainment and autozygosity seemed to be largely driven by rare variants, while results were more mixed for height and weight. Future studies should focus on within-family designs as the gold standard for limiting the potential influence of confounders. Additionally, we note that statistical power was limited for ancestry-specific models and the more fine-grained consideration of genetic ancestry required for follow-up analyses. These constraints exemplify the need for targeted recruitment of more diverse samples.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3021 Assortative mating: Disentangling mate choice from population stratification

Authors:

A. Mas Sandoval, N. Barban; Università di Bologna, Bologna, Italy

Human populations do not mate randomly. Positive assortative mating occurs when individuals tend to mate with other individuals that are similar to them, resulting in a genetic correlation between mates. Nevertheless, this correlation can be driven by at least two different scenarios: population stratification and mate choice. Geographical and sociocultural barriers restrict social interactions and limit the mating opportunities across population strata. Consequently, mate choice is restricted to the network of interactions of an individual. Despite evidence of population stratification in most human populations, the observation of assortative mating is often interpreted as a consequence of mate choice by phenotype.

Here, we aim to disentangle the contribution of mate choice and population stratification to assortative mating. With this purpose we analyze homozygosity to study assortative mating. Population stratification results in higher genome-wide homozygosity than expected in Hardy-Weinberg equilibrium. However, mate choice by phenotype results in increased homozygosity in specific genomic regions associated with the trait. We scan the genome to study the patterns of homozygosity deviations, focusing on genetic variants associated with different complex traits. In addition, following this methodology, we can infer assortative mating patterns from genetic data without information of the mating couples.

We do not find evidence of mate choice driving assortative mating beyond the effect of population stratification in traits previously described to be under active mate choice. Our results highlight the importance of an accurate analysis of the population structure in genetic studies.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3022 † Bayesian inferences of admixture dynamics in Brazil

Authors:

C. Silva de Carvalho[1], M. Gouveia[2], E. Tarazona-Santos[1], H. P. Sant Anna[1]; [1]Univ.e Federal de Minas Gerais, Belo Horizonte, Brazil, [2]NHGRI - NIH, Bethesda, MD

Because Latin Americans mostly result from admixture during the last half-millennium between Europeans, Africans, and Indigenous, their genomes are like a mosaic of fragments (i.e. tracts) deriving from those ancestries. Different methods are being developed to infer admixture dynamics, which is one of the frontiers of the population genetics of Latin Americans. Mutatis mutandi, this is like passing from the era of photographs (i.e. the current picture of admixture Illustrated by na Admixture-like barplot) to that of filmmaking (i.e. how admixture evolved). We are combining two approaches based on Approximate Bayesian Computation to infer admixture dynamics. One approach relies on the distribution of autosomal tract lengths, which has revealed that the low Indigenous ancestry of admixed Brazilians, characterized by short tracts, was mostly introduced immediately after the first arrival of Europeans into the Americas, consistently with the decimation of indigenous in Brazil. Our second approach combines information from autosomal and X-chromosomes using tract lengths, as well as the gradual approximation of X-chromosome variants to Hardy-Weinberg equilibrium, which allows us to infer, in addition to the dynamics of admixture, that of sex/ancestry bias (i.e. different ancestry of mating males and females). This approach applied to data to the city of Salvador, the most African city in Brazil (1,246 unrelated individuals, 50.8%[SE=0.35] of African ancestry) allowed to infer female- and male-mediated contributions of Europeans, Africans, and Indigenous during the 16th-20th centuries. African contribution was mostly mediated by females, and we inferred a sex bias driven by African females and European males reinforced in the 17th century that lasted even after the abolition of slavery. Our model-based approaches illustrate how genomic data on autosomal and X-chromosome may be combined to fill the gaps in the social history of Latin American populations.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3023 Characterization of novel genetic variation in the major secreted airway mucins and associations with respiratory disease

Authors:

E. Plender[1,2], P. Hsieh[1], J. Ebler[3], K. M. Munson[1], A. Sulvari[1], W. K. O'Neal[4], T. Marschall[3], J. D. Bloom[1,2,5], E. E. Eichler[1,6]; [1]Dept. of Genome Sci., Univ. of Washington Sch. of Med., Seattle, WA, [2]Basic Sci. Div., Fred Hutch Cancer Res. Ctr., Seattle, WA, [3]Inst. for Med. Biometry and Bioinformatics, Heinrich Heine Univ. Düsseldorf, Düsseldorf, Germany, [4]Cystic Fibrosis/Pulmonary Res. and Treatment Ctr., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Howard Hughes Med. Inst., Fred Hutch Cancer Res. Ctr., Seattle, WA, [6]Howard Hughes Med. Inst., Univ. of Washington, Seattle, WA

BACKGROUND: Few loci in the human genome have been linked to severe respiratory disease outcomes; mucin genes, however, are potential candidates due to their critical roles in pathogen entrapment. MUC5AC and MUC5B, two secreted mucins in the airway, feature coding variable number tandem repeat sequences (VNTRs) that allow binding to pathogens. Additionally, these loci are implicated in the pathogenesis of asthma. Long-read sequencing (LRS) enables resolution of these repetitive gene structures and detection of novel variants, thereby providing a novel resource for future genome-wide association studies with airway disease. **METHODS:** Long-read assemblies from the Human Pangenome Reference Consortium (HPRC, n=50) and Human Genome Structural Variation Consortium (HGSVC, n=53) were used to characterize variation within *MUC5AC* and *MUC5B,* while non-human primate (NHP) genome assemblies (chimpanzee, bonobo, gorilla, and orangutan) were used to place this variation in an evolutionary context. **RESULTS:** Most human haplotypes of *MUC5B* (90%) yield proteins between 5761-5763 amino acids (aa) in length; however, five human haplotypes predict proteins of 7020aa that include an additional VNTR domain. Species-specific motif utilization and domain copy number was identified in non-human ape alleles. Together, these results challenge the long-held belief that the central exon of *MUC5B* is invariable. *MUC5AC* features far greater variation; in fact, 30 human allelic variants encode 16 distinct proteins with variation observed in cys domain copy number and VNTR copy/domain number. Phylogenetically, we identified three clades of human *MUC5AC* where the three most common variants encode proteins of 5654 (46%), 5742 (33%), and 6326aa (7%). In contrast, most NHP genomes encode larger MUC5AC proteins (6031-7888aa) with novel VNTR domains, suggesting protein size reduction in the ancestral human lineage or varying rates of VNTR expansion across ape lineages. Additionally, striking patterns of linkage disequilibrium in the *MUC5AC/5B* locus in East Asian genomes are evidence of recent positive selection. Together, these findings contextualize the observations that medium-length alleles of *MUC5AC* (5742aa, 33% of haplotypes) are in linkage with GWAS SNPs associated with increased risk for severe pneumonia and shorter-length alleles of *MUC5AC* (5654aa, 46% of haplotypes) are in linkage with those for asthma. **CONCLUSION:** LRS provides the first model for VNTR evolution and variation in the *MUC5AC* and *MUC5B* loci. We are using these findings to develop bespoke methods to capture polymorphisms in these genes and to improve disease associations for respiratory disease outcomes.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3024 Characterizing the impact of deleterious recessive alleles on genetic diversity across the transition between weak and strong selection.

Authors:

S. Sun, R. Hernandez; Univ. of California San Francisco, San Francisco, CA

Understanding how recessive deleterious variants impact neutral genetic diversity through genetic linkage is an outstanding problem in population genomics. To date, studies have focused on co-dominant deleterious variants due to their additive effects which can be very intuitive and easier to model. In the context of linked selection, recessive deleterious variants are capable of driving background selection similar to their co-dominant counterparts and thus, decrease genetic diversity. However, under a weaker selection regime, recessive deleterious variants can greatly increase genetic diversity through the mechanism of associative overdominance. To understand the nature of this transition from strong to weak selection and its impact on genetic diversity driven by recessive deleterious variants, we conducted a systematic forward in time simulation study across a wide range of selection coefficients. We then incorporated demographic models into our simulations to assess how events such as population bottlenecks and expansion further affect these dynamics.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3025 Comparative analysis of molecular variation in the three-prime repair exonuclease 1 TREX1 across mammalian species and in human disease.

Authors:

M. Konate Monnard, M. Shekfeh, J. Krushkal; NCI, Rockville, MD

The three-prime repair exonuclease 1, TREX1, plays a major role in degrading cytosolic DNA, which may be generated through a variety of processes, such as exogenous viral infections, activation of endogenous retrotransposon activities, DNA damage during replication, micronuclei formation, or rupture of mitochondrial membranes. TREX1 inactivation results in DNA accumulation in the cytosol, which activates the cGAS-STING DNA sensing pathway and downstream interferon-mediated innate immune signaling and inflammation. Furthermore, germline pathogenic mutational defects in the TREX1 gene lead to hereditary autoimmune and autoinflammatory disorders. To assess the functional importance of residues along the TREX1 sequence, we analyzed protein sequences of the functional TREX1 isoform, TREX1b, from 167 mammalian species. While placental mammals showed a considerable degree of conservation of the entire TREX1b protein, egg-laying mammals and marsupials each had their own unique C-terminal domains at nearly one-third length of the TREX1b protein. The observed variability in the C-terminal domains in different groups of mammals is notable, as the C-terminus of the human TREX1 plays an important role in TREX1 localization to the endoplasmic reticulum, is subjected to post-translational modifications, and highly penetrant mutations in this region were reported in individuals with systemic lupus erythematosus (SLE) and retinal vasculopathy with cerebral leukodystrophy (RVCL). We will discuss implications of TREX1 variation and conservation across mammalian species and potential effects of TREX1 variants on human disease, which we inferred from existing data on germline TREX1 variants in hereditary autoimmune and autoinflammatory disorders and on somatic TREX1 variants in human cancer cells and tumor samples.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3026 Comparative study of the founder effect in different populations.

Authors:

L. Gagnon, C. Moreau, C. Laprise, H. Vézina, S. Girard; Univ. of Quebec in Chicoutimi, Chicoutimi, QC, Canada

Background/objectives: Populations with founder effects have been particularly useful in demonstrating how past demographic events have shaped current genetic structure and its consequences on human health. Several demographic and historical events can lead to a founder effect. However, the resulting founder effect will be unique in each population. Moreover, there are few comparisons between populations with founder effects in population genetics. For these reasons, we propose to compare five populations with a documented founder effect: the Ashkenazi Jews, the Himba, the Hutterites, the Quebec, and a group of populations from South America (PAGE). These populations were chosen for the variability of their historical and demographic characteristics that have led to different genetic structures. Methods: We propose to characterize the populations using a principal component analysis (PCA) and a uniform manifold approximation and projection (UMAP), segments of runs of homozygosity (ROH), identical-by-descent segments (IBD), and effective population size (Ne). Results and discussion: The analysis of the ROH and IBD segments informs about the population structure. Some populations like the Himba and the Hutterites have longer segments for both types; and the Quebec, PAGE and Ashkenazi Jews have numerous shorter segments. These results can be linked to the Ne analysis which reveals that the populations with longer segments tend to have a bottleneck that is more important whereas populations with shorter segments tend to have a less important or older bottleneck. However, the analysis of population structure with a UMAP shows sub-population structures within some populations with founder effects, namely: the Ashkenazi Jews, the Quebec, and the PAGE group. Therefore, these populations were reanalysed considering the division of the main population with founder effects into more sub-populations. These comparisons, even between sub-populations of the same origin, reveal important differences in IBD sharing, ROH and the effective population size. Conclusion: These analyses will provide a better understanding of the genetic differences between populations with different founder effects. In addition, in some of these populations, there are significant structural differences leading to sub-population divisions. It is therefore essential to take these sub-populations into account to avoid biases and properly design studies on both Mendelian diseases and complex traits.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3027 Comparison and evaluation of HLA calling from African Whole Genome Sequencing data in the UK Biobank

Authors:

Y. Liu[1], Z. Meng[2], Y. Huang[1], L. Xiao[1], Y. Wu[1], S. Tao[1], I. Adrianto[2], A. Levin[2], Q. Wang[1], H. Gui[3,4]; [1]Mental Hlth.Ctr. and Psychiatric Lab., West China Hosp. of Sichuan Univ., Chengdu, China, [2]Dept. of Publ. Hlth.Sci., Henry Ford Hlth., Detroit, MI, [3]Ctr. for Hlth.Policy and Hlth.Services Res., Henry Ford Hlth., Detroit, MI, [4]Behavioral Hlth.Services and Psychiatry Res., Henry Ford Hlth., Detroit, MI

Background: The human leukocyte antigen (HLA) region significantly influences the risk of various diseases, especially immune-mediated diseases like autoimmune, allergy, and neuroinflammation. Fine-mapping of causal variants in this region, approximately 6 Megabases, is a daunting task due to its highly polymorphic nature and complex linkage disequilibrium patterns. HLA imputation has proven successfully in inferring HLA types from regional single nucleotide polymorphisms (SNP) for European or East Asian samples. The refinement of methods and enlargement of reference panels are underway to secure more precise and reliable HLA genotypes and haplotypes. However, a substantial population-scale HLA reference panel for African ancestry is still absent. **Methods:** We applied whole genome sequencing (WGS) from African participants (n=1,000) in the UK Biobank (UKB) to identify each participant's HLA alleles, using the HLA*LA ("linear alignments") software. Subsequently, we contrasted our results with the HLA alleles imputed from SNP arrays using HLA:IMP*2 software, performed by the UKB team itself. The concordance of the two methods was separately evaluated separately for 10 typical HLA genes (3 for class I and 7 for class II). A new reference panel was formulated by the HLA-TAPAS pipeline. **Results:** The consistency of HLA alleles were reported at both 2-digit and 4-digit resolution. While biallelic 2-digit concordance was moderate to good for HLA Class I genes (93% for HLA-A, 67% for HLA-B, and 80% for HLA-C), it significantly dipped for HLA-DP genes (ranging from 29% for HLA-DPA1 to 0.2% for HLA-DPB1). For 4-digit concordance, the biallelic accuracy match is 63-89% for class I genes and 0.2-86% for class II genes. This level of consistency was notably lower than that for European population, and necessitating caution when using imputed HLA types directly for African samples in UKB. **Discussion:** The low concordance rates for imputed HLA genotypes in African sample highlight the exiting issue of diversity deficiency in the currently accessible imputation reference panels. For further study, we will compare existing HLA calls with those from other WGS calling pipelines, and then use updated HLA allelic frequencies to detect the HLA diversity and evolution of the African population in the UK.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3028 Decomposing polygenic adaptation of myopia on the sunlight exposure hypothesis.

Authors:

T. Xia, K. Nakayama; Graduate Sch. of Frontier Sci., The Univ. of Tokyo, Kashiwa-shi, Japan

Myopia is increasingly prevalent worldwide due to modern lifestyles. Spending more time outdoors under bright sunlight can inhibit myopia progression. We hypothesize that residents of high latitude regions, adapted to dim light environments, have a lower tendency to develop myopia. This can be supported by Europeans, who exhibit lower myopia prevalence than East Asians despite similar urbanization and education attainment that increase indoor activities.We aim to investigate the genetic basis of population discrepancies related to the sunlight exposure hypothesis. We computed population branch statistics (PBS) and number of segregating sites by length (nS_L) statistics in 1000 Genomes Project (1KGP) Europeans. We mapped the PBS and nSL outliers in myopia-associated SNPs to genes and conducted KEGG pathway enrichment analysis, "phototransduction" is significant and aligned with our interest. Representative loci for this term were *RHO* and *TSPAN10*. *RHO* encodes rhodopsin in the rod cells that are sensitive to dim light, and *TSPAN10* is significantly associated with both myopia and hair color.We utilized a previously established methodology, improvising the PBS selection index, to identify instances of polygenic adaptation by subtle allele frequency shifts enriched within a functional pathway. Myopia-associated SNPs were mapped to 4,006 nearby genes and subsequently mapped to gene ontology (GO) biological process terms, eventually 260 non-redundant GO terms we obtained. We observed significant shifts in per-gene PBS selection index distributions for 12 GO terms. Our focus was on "camera-type eye development" (GO:0043010) and "visual perception" (GO:0007601) due to their relevance. The most significant locus, *MED1*, has been previously associated with mammalian circadian rhythms.Haplotype and allele frequencies of *RHO*, *TSPAN10*, and *MED1* exhibit a geographical distribution similar to the pigmentation-associated locus, *SLC24A5*. In two-sample Mendelian randomization analyses, causal inferences to myopia were significant for tanning ability and time spent outdoors but not significant for circadian traits. Therefore, the genetic basis of myopia might be influenced by adaptations in pigmentation and light perception pathways.To investigate the overall genetic discrepancy of myopia, we improvised polygenic risk score (PRS) in 1KGP Europeans and concluded that the major population discrepancies were driven by population structure and demographic history. In summary, we suggest that the current prevalence disparity of myopia is collectively influenced by population structure, local adaptation, and pleiotropic effects.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3029 Detecting evolutionary adaptation and admixed ancestry in the Taiwanese Siraya people

Authors:

W-Y. Ko[1], W-C. Pan[1], J-N. Zeng[1], K-T. Lin[1], J-H. Loo[2], Y. Satta[2], M. Lin[2]; [1]Natl. Yang Ming Chiao Tung Univ., Taipei, Taiwan, [2]Mackay Mem. Hosp., New Taipei City, Taiwan

While the indigenous people of Taiwan are of central interest in studying genetic origins of the Austronesian-speaking people who have populated throughout Southeast Asia, Oceania, and the Pacific, it is less known that there were many Plain indigenous tribes (known as "Pingpu" people) who once inhabited in the plains and coastal regions of western Taiwan. The Pingpu people had largely admixed with Han Taiwanese and nowadays it is almost impossible to distinguish them from the Han Taiwanese. Little is known about the time and degree of population admixture and scenarios of evolutionary adaptation in the Pingpu people. Here, we studied genetic ancestry and adaptation of the Pingpu Siraya people by analyzing the whole genome genotyping data in 43 individuals for a total of 2,612, 357 SNPs. We showed that the Siraya are genetically distinct from the Han Taiwanese and phylogenetically grouped together with the Austronesian populations with a strong gene flow occurred recently from the Han Taiwanese. We inferred genetic components and local genetic ancestry for each individual genome. The average proportions are 0.41 (ranging: 0.3 - 0.59) and 0.26 (0.14 - 0.36) for the Han and Austronesian ancestries, respectively. The admixture event was dated as early as 220 years ago (around 1798 AD). Finally, we detected a number of candidate genes targeted by positive selection likely related to brain-volume development and body height, schizophrenia, immunity, or olfactory function. The obtained results of genetic adaptation and admixed ancestry is expected to facilitate the genetic profiling of disease susceptibilities and development of statistical models for disease-risk prediction.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3030 Detecting late-onset disease causing variants in the genomes of Han Taiwanese people

Authors:

J-L. Chen[1], M-L. Kang[1], W-C. Tseng[2], J-H. Loo[3], M. Lin[3], H-H. Lee[1], Y. Satta[4], W-Y. Ko[1]; [1]Dept. of Life Sci. and Inst. of Genome Sci., Natl. Yang Ming Chiao Tung Univ., Taipei, Taiwan, [2]Taipei Veterans Gen. Hosp., Taipei, Taiwan, [3]Mackay Mem. Hosp., New Taipei City, Taiwan, [4]Res. Ctr. for Integrative Evolutionary Sci., SOKENDAI, Hayama, Japan

Identifying genes/genetic variants responsible for disease susceptibilities is a key challenge in studying common diseases. Many of these variants are categorized as late-onset disease causing variants, of which the carriers can often survive through adulthood (and leave offspring). These variants segregate in the population as neutral variants since natural selection is ineffective to remove them from the population, which causes considerable genetic burden in our population. Here, we aim to identify late-onset disease causing genetic variants by examining allele-frequency differences at different age groups of healthy individuals collected by the Taiwan Biobank. We analyzed the whole-genome genotyping data for a total of 509,873 variants in 42,467 individuals (age range: 30-70), and identified a number of candidate variants whose allele frequencies differ significantly along age. While most identified candidate variants are novel findings from this study, we indeed detected a pathogenic mutation in *BRCA1* (rs80357377) and a deletion in *MSH6* (rs587779299) known to be associated with Lynch Syndrome. Interestingly, several variants linked to the haplotype that carries the selection-favored ALDH2 allele appear to increase in frequency with age despite having been reported associated with late-onset diseases (i.e., cardiovascular and chronic kidney diseases). In order to identify possible causal variants, we also conducted linkage disequilibrium (LD) analysis for a subset of 772 individuals whose whole genome sequences are available. To further detect the functional effects of each candidate SNP, we performed multiple runs of phenome-wide association analyses across 27 clinical traits that are related to cardiovascular, renal, hepatic, hematologic diseases and diabetes. Many of the identified candidate SNPs appear to have pleiotropic connections with these traits. The knowledge gained from this study is expected to help inform strategies for disease prevention and treatment.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3031 Detecting recent natural selection in East Asia using ancient DNA

Authors:

L. Colbran, I. Mathieson; Univ. of Pennsylvania, Philadelphia, PA

Identifying regions of the human genome influenced by population-specific selection enables us to identif traits that influence fitness, learn about past selective pressures, and understand their effects on genetic and phenotypic variation. Ancient DNA (aDNA) provides direct access to the evolutionary history of individual variants and has been used extensively to detect and classify occurrences of natural selection. However, this research has focused almost exclusively on Europeans due to their well-understood demographic history and large sample sizes. While populations in East Asia have a similar history—affected by the out-of-Africa migration and the transition to agriculture in parallel with Europeans—they have been exposed to many independent evolutionary pressures. This provides a unique opportunity to study the common effects of shared selective pressures and to identify novel selected loci and traits.

In this study, we take advantage of the recent increase in available aDNA from East Asia to expand aDNA-based studies of selection to these populations. We generalize a previous approach for detecting selection that models present-day populations as a mixture of ancient populations. Since the ancient East Asian populations are admixed, we extend the model to allow both the source and target populations to be admixed. We model 241 individuals from 3 ancient groups dating to the past 33,000 years, and 509 individuals from 5 modern populations, assuming Northern and Southern East Asian sources for the present-day mainland populations, and Northern and Jomon sources for Japanese populations. We fit the expected frequencies of each variant given this history and test for significant deviations using a maximum likelihood approach. We identify novel loci at *POLR3H* and *TEDC1*, in addition to known loci such as the HLA region, *FADS1* and *ALDH1B*.

We also adapt this approach to test for polygenic selection on traits analyzed in genome-wide association studies by counting the proportion of independent trait-increasing alleles seen in each population and applying a similar test. We use the results of GWAS conducted in populations of European ancestry to avoid issues related to population stratification. We test for selection on a wide range of polygenic traits and, for example, find that LDL levels have been subject to selection (uncorrected P = 3.77e-6). Overall, this study provides a comprehensive examination of recent selection in East Asia, incorporating additional population data and new methods. It will enable comparison with results from studies in Europe and increase our understanding of the role of selection on traits across multiple modern populations.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3032 Detection of novel amylase haplotypes and insights into the genetic variation of amylase genes using optical mapping and long-read sequencing.

Authors:

F. Yilmaz; The Jackson Lab. for Genomic Med., Farmington, CT

The amylase locus is a complex region of the genome that contains AMY1, AMY2A, and AMY2B genes that code for the amylase enzyme that breaks down starch. Human-specific duplications of amylase genes were adaptively evolved in response to increased human starch consumption. Copy number variations of these genes are associated with agricultural lifestyles and metabolic disorders such as obesity and diabetes. The true extent of the genomic variation in this locus is still unknown due to the presence of paralogous segmental duplications (>45 kbp) that are difficult to map using conventional methods. We investigated the genetic variation and haplotype structures of the amylase locus utilizing Bionano Genomics optical genome mapping and PacBio HiFi long-read sequencing. We detected 30 haplotypes (H1-H30), with sizes ranging from 111.4 kbp to 376.1 kbp, containing novel duplications and inversions in 81 individuals from Human Genome Structural Variation and Human Pangenome Reference Consortium samples, surpassing the previous discovery of 10 haplotypes. Notably, amylase haplotype prevalence varies significantly between populations. For instance, H1-111.4 kbp, H5-205.6 kbp, H6-205.5 kbp, and H8-205.5 kbp were the most common haplotypes among individuals of African and American descent, while H8 and H10 were dominant among East Asians. Europeans predominantly displayed H1 and H6 haplotypes, whereas H6 was the most prevalent in South Asians. We hypothesize that this locus has evolved rapidly, as evidenced by population divergence and population-specific haplotypes. Further, we characterized the mechanisms that give rise to the variation in the locus. Non-allelic homologous recombination underlies the majority of amylase structural rearrangements, while three FoSTeS events were also identified. The analysis of AMY1 from diploid genomes revealed four copies were the most common (n=11), while two individuals had ten copies. Our study provides the most comprehensive map of amylase gene haplotype structures and novel insights into genetic variation. These findings pave the way for further research into the mechanisms underlying genetic variation at this locus, as well as the roles of amylase genes in human dietary adaptations, metabolic disorders, and nutrition.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3033 Development of an integrated pipeline for comprehensive population genetic analysis

Authors:

N. Park, H. Kim, J. Kim; Konkuk Univ., Seoul, Korea, Republic of

The availability of population genetic variant data resulting from the advances in next-generation sequencing (NGS) technologies has led to the development of various population analysis tools to enhance our understanding of population structure and evolution. Currently, available tools analyzing population genetic variant data generally require different environments, parameters, and formats of input data, which acts as a barrier to the widespread use of such tools by general researchers not familiar with bioinformatics. To address this problem, we developed an automated and comprehensive pipeline PAPipe to perform seven widely used population genetic analyses using population NGS data. PAPipe seamlessly interconnects and serializes multiple steps, such as read mapping, genetic variant calling, data filtering, and format converting, in addition to seven population genetic analyses including population structure analysis, linkage disequilibrium decay analysis, fixation index analysis, population admixture analysis, principal component analysis, phylogenetic analysis, and pairwise sequentially Markovian coalescent analysis. PAPipe can be used to generate extensive results that provide clues or insights to enhance user convenience and data usability. PAPipe is intended for use in the Linux operating system, and the Docker image files are also provided for reducing the challenges in the environment settings.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3034 Diagnostic yield of genome and exome sequencing in the ancestrally diverse CSER Phase II consortium is not associated with genetic ancestry in a variety of clinical settings

Authors:

Y. Mavura[1], D. Crosslin[2], K. D. M. Ferar[3], J. Greally[4], L. Hindorff[5], G. Jarvik[6], S. Kalla[7], B. Koenig[1], M. Kvale[1], P-Y. Kwok[1], M. Norton[1], S. Plon[8], B. Powell[9], A. Slavotinek[1], M. Thompson[10], A. Popejoy[11], E. Kenny[12], N. Risch[1]; [1]Univ. of California San Francisco, San Francisco, CA, [2]Tulane Univ., New Orleans, LA, [3]Univ. of Washington, Seattle, WA, [4]Albert Einstein Coll. of Med., Bronx, NY, [5]NIH/NHGRI, Bethesda, MD, [6]Univ. of Washington Med Ctr., Seattle, WA, [7]Baylor Coll. of Med., Houston, TX, [8]Baylor Coll. Med., Houston, TX, [9]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [10]Hudson Alpha Inst. for Biotechnology, Huntsville, AL, [11]Univ. of California, Davis, Sacramento, CA, [12]Icahn Sch. of Med. at Mount Sinai, New York, NY

Background It has been suggested that diagnostic yield (DY) from genome (GS) and exome sequencing (ES) may be higher among patients with predominantly European ancestry than those whose ancestral backgrounds may not be as well represented in genomic research and reference databases. Here, we examined the association of DY with estimated proportion(s) of genetic ancestry across global reference populations in a large cohort of diverse prenatal, neonatal and pediatric participants in various clinical/ healthcare settings. **Methods** A total of 3015 participants and their families were enrolled at one of 5 independent centers across the US as part of the Clinical Sequencing Evidence-Generating Research (CSER) phase II consortium. The participants were recruited from prenatal, NICU and pediatric clinics and underwent GS or ES for diagnosis. Genetic ancestry proportions were estimated from GS & ES data using Human Genome Diversity Project GS data and ADMIXTURE. Analyses compared the distribution of genetic ancestry between the combined CSER categories of definitive or probable ("positive") diagnostic results versus all others (negative and inconclusive) by Kolmogorov-Smirnov tests and linear associations of ancestry with DY by Cochran-Armitage trend tests within each of the 5 centers. The analyses were conducted overall and stratified by mode of inheritance. We then conducted fixed effects meta-analyses using weighted sum of Z-scores. **Results** Across centers, 18.7% (Min 5.2%, Max 27.9%) had a positive case outcome (DY). The majority of positive cases, 72.9% (Min 60%, Max 90.7%) were of Autosomal dominant (AD) MOI. The average estimated genetic ancestry proportions overall were African: 21%, American: 17.1%, East Asian: 4.5%, European: 46%, Middle Eastern: 7.7%, South Asian: 3.7%. We observed no statistically significant association in overall DY with any of the genetic ancestries for any of the 5 centers or in the meta-analyses. However, we observed a relative increase in Autosomal recessive (AR) homozygous MOI cases with South Asian ancestry (C-A P-value: 0.0011) approaching statistical significance due to consanguinity. There was decreased African ancestry for AD de novo and increased African ancestry for AD unknown MOI possibly due to differences in parental sequencing, but there was no association with AD DY overall. **Conclusion** No geographic genetic ancestry was associated with the likelihood of a positive diagnosis, supporting the possibility that ES and GS in diagnosis of previously undiagnosed but potentially Mendelian disorders across all ancestral populations may be more equitable than hypothesized in a variety of healthcare/ clinical settings.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3035 Discovery of high-impact variants in CARTaGENE whole-genome sequences from diverse populations of Quebec

Authors:

K. Lo[1], S. Gagliano Taliun[1,2], C. Bhérer[3,4,5], S. Gravel[3], G. Lettre[1,2]; [1]Montreal Heart Inst., Montreal, QC, Canada, [2]Dept. of Med., Université de Montréal, Montreal, QC, Canada, [3]Dept. of Human Genetics, McGill Univ., Montreal, QC, Canada, [4]Canada Excellence Res. Chair in Genomic Med., McGill Univ., Montreal, QC, Canada, [5]Victor Phillip Dahdaleh Inst. of Genomic Med., McGill Univ., Montreal, QC, Canada

CARTaGENE (CaG) is a population-based cohort that includes ~43,000 participants recruited in Quebec (Canada) and is characterized by a wealth of longitudinally collected phenotypic information (e.g. questionnaire, health records, imaging, lab results). While the majority of its participants descend from French settlers who immigrated to Quebec in the 17th and 18th centuries, CaG is a cosmopolitan cohort that captures the diverse ancestries of modern Quebec.

We recently completed deep whole-genome sequencing of 1,756, 163 and 131 CaG participants of French-Canadian (FC), Haitian (HAI) and Moroccan (MOR) ancestry, respectively. Following rigorous quality-control measures, we obtained a total of 80,407,530 single-nucleotide variants and small insertions or deletions (indels). For variant annotation, we utilized two resources: the well-established Variant Effect Predictor (VEP) and the more recent Functional Annotation of Variants Online Resource (FAVOR) tools. To prioritize phenotypically interesting variants, we focused on the "VEP high-impact" variants (n=26,874), which encompass frameshift, splice acceptor and donor, start lost, stop gain and stop lost variants. Look-ups in ClinVar revealed that 864 (3%) of these variants are annotated as pathogenic/likely pathogenic. For all the common (minor allele frequency >1%) high-impact variants, we compared CaG and gnomAD allele frequencies, selecting gnomAD non-Finnish European, African/African American and mid-Eastern populations to match the CaG FC, HAI and MOR subsets, respectively. We found 119 FC, 288 HAI and 399 MOR variants with a ratio CaG/gnomAD >2, suggesting a potential enrichment of these variants in these populations. We also identified 50 FC, 71 HAI, and 287 MOR high-impact variants absent from gnomAD. To gain insights into the potential functional implications of these variants, we will conduct phenome-wide association studies, taking advantage of the rich phenotypic information in CaG.

Our findings contribute to a deeper understanding of the genetic diversity and potential disease risk factors within the FC, HAI and MOR populations. These results have implications for personalized medicine, population health research, and the development of targeted interventions tailored to the unique genetic profiles of these populations.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3036 Disentangling clock-like mutation processes in germline and soma

Authors:

N. Spisak, M. de Manuel, W. Milligan, G. Sella, M. Przeworski; Columbia Univ., New York, NY

Decompositions of mutations into "signatures" based on the 96 single base substitution (SBS) types provide insights into mutagenesis in cancer, non-cancerous soma and germline. Among the signatures cataloged in the COSMIC database, two are ubiquitous in the soma and are considered "clock-like," because of their linear increase with age in some cell types: SBS signature 1, which consists primarily of transitions at methylated CpG sites caused by spontaneous deamination, and the much more diffuse SBS signature 5, which is of unknown etiology. The standard view of these signatures is much like Tolstoy's view of happy families: it is often assumed that while each non-clock-like mutational signature has a distinct source, all clock-like mutations are clock-like in the same way. As we show, this need not be the case. Firstly, we introduce a modeling framework that includes different modes of mutagenesis. This model highlights that mutational signatures can exhibit clock-like behavior due to several underlying mechanisms, including DNA replication errors, unrepaired damage, or damage that is repaired incorrectly. Next, we use de novo germline mutations as well as somatic mutations detected in single cells or small monoclonal populations in order to estimate the age-dependency of these mutational signatures in different cell types. In post-mitotic cells such as neurons and oocytes, there is no discernable increase of the number of SBS signature 1 mutations with age, in contrast to what is observed in dividing cell lineages. Thus, the underlying mutagenic process tracks cell divisions. One implication is that we can use the rate of accumulation of CpG transitions in tissues with known turnover rates to learn about division rates in other cell types. In turn, the number of the SBS signature 5 mutations does increase with age in post-mitotic cell types, indicating that the source of mutation is independent of cell division. Instead, SBS signature 5 accumulates with cell-type specific DNA damage rates, implicating errors in DNA repair as a key underlying mechanism.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3037 † Dissecting the genetic and evolutionary sources of phenotypic variation in East Polynesians

Authors:

D. Liu[1], M. Roux[1], G. Rijo de Leon[1], I. Teiti[2], C. Harmant[1], A. Tessier[2], A. Bisiaux[1], V. Richard[2], A. Jaquaniello[1], M. Aubry[2], V-M. Cao-Lormeau[2], E. Patin[1], L. Quintana-Murci[3]; [1]Inst. Pasteur, Paris, France, [2]Inst. Louis Malardé, Papeete, French Polynesia, [3]Pasteur Inst. and Coll. de France, Paris, France

Understanding the links between genetic diversity, local adaptation and phenotypic variation is of upmost importance in evolutionary genetics; yet, most human genomics studies have focused only on European-descent populations. Such an imbalance precludes not only the transferability of genomic findings to other populations, but it provides a partial view of the genetic changes experienced by our species to survive new environments. Polynesia is of particular interest in this context as it has a unique settlement history, made of long-distance voyaging and extensive admixture, and is thought to present among the highest prevalence worldwide of metabolic disorders, raising questions regarding the role of natural selection and genetic drift in driving the genetic architecture of human traits. Here, we generated whole-genome sequencing data for 1,770 individuals originating from 18 East Polynesian islands and collected a wide range of demographic and phenotypic data relating to metabolism and morphology. Our analyses revealed that East Polynesians from all islands carry genetic ancestries that are maximized in present-day Austronesian speakers from Taiwan and the Philippines, Papuans, western Europeans, and East Asians, as well as native South Americans in the Marquesas Islands only. We observed large variation in East Asian- and European-related ancestries within islands, supporting a common history of recent, extensive admixture. We confirmed the high prevalence of obesity and type 2 diabetes in the region: > 50% of the population has a BMI > 32, and > 10% has glycated hemoglobin (HbA1c) levels > 6.5%. Applying multiple linear regression models and controlling for sex, age and island of residence, we found that BMI, HbA1c, cholesterol, HDL, and skin pigmentation (melanin index) are associated with genetic ancestry, suggesting that admixture has contributed to phenotypic diversity in Polynesians. For example, we detected a European-specific *SLC24A5* variant as a strong determinant of skin pigmentation variation in Polynesians. Furthermore, we identified novel variants associated with variation in metabolic and morphological traits, including variants that are private to Pacific populations. Interestingly, we found no signals of selective sweeps on such variants, suggesting a predominant role of genetic drift in driving phenotypic variation in the region. Together, these results highlight how quantitative genomics in understudied populations can increase our understanding of the genetic and evolutionary sources of human phenotypic variation.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3038 Diversity and Representation of South Asian Genomes

Authors:

A. Das, M. C. Schatz; Johns Hopkins Univ., Baltimore, MD

The rapid growth in genomics has not been uniform across the full range of human diversity, leaving the majority of the world's populations poorly represented and resulting in systemic biases that can have serious impacts on clinical interpretations and other analysis. In this work, we aim to utilize recent advancements in genome sequencing and assembly to better understand the variation present in South Asian (SA) populations.

Using high quality short read data from 635 SA individuals in the 1000 Genomes Project and Simons Genome Diversity Project, we investigated the variation between these individuals relative to linear and pangenome references. To do this, we follow a similar pipeline used in the creation of the African Pan-Genome (Sherman et al. 2019) which assembles contigs from reads that were unaligned and/or poorly aligned relative to a chosen reference genome. We then attempt to place the larger contigs in the reference, allowing us to identify variants and novel sequences.

We focus our analysis on the T2T CHM13 genome to rule out spurious contigs created from unresolved regions in GRCh38. Interestingly, when using CHM13 we assemble ~1 Mbp of sequence from unaligned reads and ~15 Mbp of sequence from poorly aligned reads per individual, highlighting widespread population-specific sequence missing. We are able to successfully place more of these contigs against CHM13 than GRCh38, and find that they place evenly across the chromosomes, with those placements overlapping a range of biologically significant regions. We also find the majority of these assembled contigs to be private to the individual they are assembled from.

We similarly evaluated the recently released draft human pan-genome references from the Human Pangenome Reference Consortium, built from 47 individual genomes plus GRCh38 or CHM13. We observe higher alignment rates (+0.3%) of SA reads in pangenomes than in their corresponding linear reference, and find that the contigs assembled from unaligned reads are a subset of those assembled from the corresponding linear references. Nevertheless we still find ~10 Mbp of sequence per individual assembled from poorly aligned reads, including some contigs that are over 60Kbp in size, and many of which still overlap biologically significant regions.

We are currently investigating the transcriptional potential of these contigs using RNA-seq data from these individuals, as well as long read data from ongoing sequencing efforts. These data will help validate our short read results, allow us both to evaluate the functional significance of our novel sequence and investigate the overlap between placed contigs and clinically relevant variants.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3039 † Diversity in the All of Us Research Program: race, ethnicity, and genetic ancestry

Authors:

S. Sharma[1,2], S. Nagar[1], L. Lichtenstein[3], P. Pemu[4,5,6], K. Mayo[7], A. Ramirez[8], A. Able[9,10], A. Green[10], L. Sokny[10], S. Zuchner[11], The All of Us Research Program, SEEC Consortium, L. Mariño-Ramírez[2], R. Meller[4], I. Jordan[1]; [1]Georgia Inst. of Technology, Atlanta, GA, [2]Natl. Inst. on Minority Hlth.and Hlth.Disparities, NIH, Bethesda, MD, [3]Broad Inst. of Harvard and MIT, Cambridge, MA, [4]Morehouse Sch. of Med., Atlanta, GA, [5]The All of Us Res. Program, NIH, Bethesda, MD, [6]SEEC Investigators, Univ. of Miami, Coral Gables, FL, [7]Vanderbilt Univ. Med. Ctr., Nashville, TN, [8]NIH, Mclean, VA, [9]VUMC, Nashville, TN, [10]All of Us Demonstration Projects Subcommittee NIH, Bethesda, MD, [11]Univ. of Miami Miller Sch. of Med., Miami, FL

The NIH All of Us Research Program aims to build one of the world's most diverse population biobanks in support of equitable precision medicine. For this study, we characterized the diversity of the All of Us participant cohort (n=165,072) with respect to race, ethnicity, and genetic ancestry. We evaluated the relationship between All of Us participants' self-identified race and ethnicity (SIRE) and their genetically inferred ancestry, exploring how genetic ancestry changes over space and time in the US and how it is related to health outcomes. Overall, minority racial and ethnic groups are overrepresented in the All of Us participant cohort, particularly for participants who identify as Black or African American. All of Us participants show diverse genetic ancestry, with major contributions from European (66.3%), African (20.7%), Asian (7.4%), and Native American (5.4%) ancestry components. Participant racial and ethnic groups show group-specific genetic ancestry patterns, with a continuum of ancestry proportions within groups. African and Native American ancestry are enriched in the southeast and southwest regions of the country, whereas European ancestry is more evenly distributed across the US. The diversity of All of Us participants' genetic ancestry is negatively correlated with age; younger participants show higher levels of genetic admixture compared to older participants. African, European, and Native American ancestries were found to be associated with numerous health outcomes in the All of Us cohort. African and Native American ancestry are both positively associated with diabetes and hypertension and negatively associated with skin disorders, whereas European ancestry is positively associated with numerous neoplasms and skin disorders. For mental health conditions, African ancestry is positively associated with schizophrenia, while European ancestry is positively associated with anxiety disorder. Our results underscore the diversity of the AoU cohort and suggest how ancestry can be leveraged to support genomic health equity.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3040 Diversity of Y-chromosome haplogroup C in the Japanese population: Inference of its ethnic originhaplogroup C

Authors:

M. Osawa[1], R. Zhang[1], A. Ueda[1], E. Ochiai[2], S. Isozaki[1], K. Minaguchi[1]; [1]Tokai Univ Sch Med., Kanagawa, Japan, [2]Kitasato Univ Sch Med., Kanagawa, Japan

Y-chromosome exhibits 20 major haplogroups of A to T clades, based on SNPs. The majority of Japanese male individuals have C, D, and O clades. The C clade is widely distributed in the Eurasia continent, which overlaps the area of Altaic-speaking populations. In this study, we analyzed the divergence in the C lineage from SNP and short tandem repeat (STR), which were genotyped in the Japanese population, to investigate the anthropological origin as the ancestry. In analysis to DNA samples of unrelated Japanese male individuals (n = 1603), a total of 142 samples (8.9%) of C lineage, 631 (39.4%) of D, 479 (29.9%) of O1b, 283 (17.7%) of O2, and 68 (4.2%) of others were typed by the amplified product length polymorphism method. Then, 121 samples of C lineage were fully subtyped for 65 Y-SNP markers, which were selected from database of the International Society of Genetic Genealogy, by the SNaPshot system. The C samples were subclassified into three major subgroups of C1a1a (50.4%), C2a1 (5.0%) and C2b1 (44.6%), in which the most frequent allele was C1a1a1a* (Z7180) with 23 cases (19.0%). Based on Y-STR haplotypes using the Y-filer plus multiplex system, a median-joining network was constructed using Network 10.2. Two separate clusters of C1a1a and C2b1 were evident. The number of generations to the most recent common ancestor (TMRCA) with 95% CIs was calculated for the two decent clusters using the Ytime package. The subgroups of C1a1a and C2b1 were calculated 128 (58-257) and 165 (79-323) generations, corresponding to 4.0 (1.8-8.0) and 5.1 (2.4-10.0) thousand years, respectively, to TMRCA. Based on the database, C1a1 lineage is a Japanese-specific type, while C2b1 is common in southern China. The phylogenetic tree confirmed two major ancestry flows. One group of C1a1 that migrated to Japan in an ancient age up to around 4.0 thousand years should be indigenous, which is known as the Jomon era. The other that should be later migrated from southern China, which is known as the Yayoi era. This study provides an insight into the ethnic origin of the Japanese population.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3041 † Dynamic clustering of genomics cohorts beyond race, ethnicity-and ancestry

Authors:

H. Mohsen[1], K. Blenman[2], P. Emani[2], Q. Morris[1], J. Carrot-Zhang[1], L. Pusztai[2]; [1]Mem. Sloan Kettering Cancer Ctr., New York, NY, [2]Yale Univ., New Haven, CT

Recent years have witnessed a steady decrease in the use of race categories in genomic studies. While studies that still include race categories vary in type and goal, these categories already build on a history during which racial color lines have been enforced and adjusted in the service of social and political systems of power and disenfranchisement, and when biological knowledge and data collection abilities were highly limited. Fixed, discrete classification systems have also limited the study of human biodiversity and disrupted widely spread genetic and phenotypic continuums across geographic scales. Relatedly, the use of broad and pre-defined stratification schemes—e.g. continental—across traits can risk missing important trait-specific genomic signals. To address these issues, we introduce a dynamic approach to clustering human genomics cohorts on a trait-specific level and without imposing a set of pre-defined categories. We tested our approach on whole exome sequencing datasets in 8 cancer types and partitioned these based on germline variants in cancer-relevant genes that could confer cancer type-specific disease predisposition. Results demonstrate clustering patterns that transcend discrete continent-based ancestry categories across all cancer types. Functional analyses based on cancer type-specific clusterings were also able to capture the fundamental biology underlying cancer and to identify novel potential drivers overlooked by a continent-based clustering model.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3042 † Entwined African and Asian genetic roots ofmedieval peoples of the Swahili coast

Authors:

E. Brielle[1], J. Fleisher[2], S. Wynne-Jones[3,4], K. Sirak[1,5], N. Broomandkhoshbacht[1,5], K. Callan[1,5], E. Curtis[1,5], L. Iliev[1,5], A. M. Lawson[1,5], J. Oppenheimer[1,5], L. Qiu[5], K. The urban peoples of the Swahili coast traded across eastern Africa and the Indian Ocean and were among the first practitioners of Islam among sub-Saharan people. The extent to which these early interactions between Africans and non-Africans were accompanied by genetic exchange remains unknown. Here we report ancient DNA data for 80 individuals from 6 medieval and early modern (AD 1250-1800) coastal towns and an inland town after AD 1650. More than half of the DNA of many of the individuals from coastal towns originates from primarily female ancestors from Africa, with a large proportion—and occasionally more than half—of the DNA coming from Asian ancestors. The Asian ancestry includes components associated with Persia and India, with 80-90% of the Asian DNA originating from Persian men. Peoples of African and Asian origins began to mix by about AD 1000, coinciding with the large-scale adoption of Islam. Before about AD 1500, the Southwest Asian ancestry was mainly Persian-related, consistent with the narrative of the Kilwa Chronicle, the oldest history told by people of the Swahili coast. After this time, the sources of DNA became increasingly Arabian, consistent with evidence of growing interactions with southern Arabia. Subsequent interactions with Asian and African people further changed the ancestry of present-day people of the Swahili coast in relation to the medieval individuals whose DNA we sequenced.

PB3043 Estimating birth prevalence of Fraser syndrome 1 in Quebec.

Authors:

G. Gagnon[1,2], J. Pelletier[1,2], D. Ashton-Beaucage[1,2], M. Sayahian Dekhordi[1,2], V. Chapdelaine[1,2], D. Taliun[1,2], P. Campeau[3,1], C. Bhérer[1,2]; [1]McGill Univ., Montreal, QC, Canada, [2]Victor Phillip Dahdaleh Inst. of Genomic Med. at McGill Univ., Montreal, QC, Canada, [3]CHU Sainte Justine, Montreal, QC, Canada

Fraser syndrome is an autosomal recessive malformation disorder caused by pathogenic variants in three different genes (FRAS1, FREM2, and GRIP1). The main features of this disease include cryptophthalmos, syndactyly, and anomalies of the respiratory and urogenital tract. In our previous work, analysis of pathogenic variants in the French-Canadian population of Quebec revealed that the variant c.370C>T (p.Arg124Ter) in the FRAS1 gene was found at an unusually high frequency in this founder population. This variant has been previously implicated in Fraser syndrome 1 (FS1; MIM 219000). However, no prevalence has been estimated for this syndrome in Quebec, as it has not yet been described in this population. Here we report carrier frequency and prevalence estimates for FS1 in Quebec using whole-genome sequencing (WGS) and genotyping data from the CARTaGENE (CaG) population-based cohort, a multi-ancestry cohort with most participants of French-Canadian ancestry. The p.Arg124Ter variant was the only pathogenic variant previously reported in ClinVar as implicated in FS1 to be identified in CaG. In WGS data (N = 2,157), it is observed in eight European individuals at an allele frequency (AF) of 2.14e-03 (allele count (AC) = 8). By comparing to AF reported in Non-Finnish Europeans from the gnomAD database (v3.1.2), we confirm that this variant is significantly enriched in Quebec (OR = 29.09; p-value = 5.57e-08). Moreover, using CaG genotyping data (N = 24,839), we observe an elevated AF of this variant in some regions of Quebec, suggesting potential regional disease concentrations. Specifically, we find carrier frequencies of 1/96 in Sherbrooke, 1/155 in Quebec City, 1/170 in Trois-Rivières, and 1/173 in Saguenay, while the carrier rate for unrelated individuals of European ancestry is 1/219. Based on AF from CaG WGS and assuming Hardy-Weinberg equilibrium, we estimate a birth prevalence of FS1 in Quebec of 0.34 per 100,000 births. In one mother-child tertiary care center covering 40% of the Quebec population (average 84,000 births per year for Quebec), we identified four cases of FS1 in a decade, which gives a birth prevalence of 0.48 per 100,000 births. Three homozygous cases had the p.Arg124Ter variant, for a birth prevalence of 0.36 per 100,000 births, as predicted from AF in CaG. In summary, our findings provide the first estimation of the birth prevalence of FS1 in Quebec and identify p.Arg124Ter as a candidate founder pathogenic variant in this population. These results have a potential impact on clinical and genetic counselling practices in Quebec.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3044 Estimating the Extra-Pair Paternity Rate in Human Populations: A Case Study of a French-Canadian Population in Quebec

Authors:

G. Martínez; McGill Univ., Montréal, QC, Canada

Large-scale genealogies linked to genetic data offer a unique opportunity to learn about the interplay of demography and genetics. Here, we consider the genotype data of 1464 Y-chromosome-carrying individuals from the CARTaGENE cohort. This cohort includes genome-wide genotype data for 29330 individuals sampled from metropolitan areas in Québec, Canada, of whom 7896 are linked to a deep genealogical database (BALSAC). We used these data to investigate extra-pair paternity (EPP), i.e., the excess mismatch between genetic and genealogical ancestry along the male lineage, mutational processes along the Y chromosome, and relatedness among the first French settlers in Quebec.

In previous studies on European human populations, the per-generation EPP rate has been estimated to be between 1% and 2%. By counting the mismatches between Y chromosome haplogroups and shared genealogical ancestry along the Y chromosome, we obtained a per-generation EPP rate of less than 1%. Accounting for these errors, we estimated the mutation rates along the Y chromosome as a function of paternal age and average relatedness between genealogical founders.

PB3045 Ethiopian genomic diversity is shaped by migration, admixture, and adaptation to local environments but not by linguistic affiliations

Authors:

T. Mersha[1], D. Sertse[2], J. Habtewold[3], A. Tilahun[4]; [1]Cincinnati Children S Hosp. Med. Ctr., Cincinnati, OH, [2]Dept. of Biology, Univ. of Ottawa, Ottawa, ON, Canada, Ottawa, ON, Canada, [3]Hlth.and Applied Microbiol. Lab., Dept. of Pathobiology, Ontario Vet. Coll., Univ. of Guelph, Ontario, ON, [4]5Dept. of Biology, Univ. of Northern Iowa,, Cedar Falls, IA

Ethiopia is a crossroad of human genetic diversity and religious-cultural hub because of its geographic proximity to the middle east which served as a historical trade route between Asia and Europe as well as to the rest of Africa. To get insight into the genetic landscape of the Horn of Africa against the rest of the world, we performed a genetic diversity and admixture analysis in geographically and linguistically diverse populations in Ethiopia, South Sudan, and Somalia and compared them with global populations data from Utah residents with Northern and Western European ancestry (CEU), Maasai in Kinyawa, Kenya (MKK), and Yoruba in Ibadan, Nigeria (YRI). On average, the ancestry proportion of CEU within Ethiopian gene pool ranges 10-15%. Although the Ethiopian Cushitic, Semitic and North Omotic language speakers harbored high genetic diversity on a global scale, they showed the lowest genetic differentiation among each other. The gradients of genetic variations among different populations within the region are likely to be due to continuous gene flow as a result of admixture driven by past and present intra- and inter- ethnic migration and movements. Individuals speaking different languages but live in the same geographic regions are genetically more related than individuals speaking the same language but isolated by boundary which limits gene flow. The genetic diversity, haplotype and allelic distribution among the populations in this study reflects in part historical movement of people and geographic adaptations to specific environmental factors rather than linguistic affiliations. Here, I will discuss genetic evidence about the relationships among Ethiopians and genetic information underlying adaptations to certain environmental conditions.

PB3046 Evidence of potential natural selection in African Americans

Authors:

R. Durodoye[1], J. Jaworski[2], J. Bartlett[1], J. Ulloa[3], H. Diaz-Zabala[4], S. Williams[1], M. Aldrich[4]; [1]Case Western Reserve Univ, Cleveland, OH, [2]VUMC, Nashville, TN, [3]Vanderbilt Univ., Nashville, TN, [4]Vanderbilt Univ. Med. Ctr., Nashville, TN

Introduction. Admixed populations are formed when genetically distinct ancestral populations mix. After admixture, highly differentiated alleles can present in frequencies deviating from the average global ancestry. One explanation for this finding is natural selection. The extent of such selection in African Americans remains unresolved as prior work presented conflicting evidence with regard to putative selection. We looked for evidence of non-random patterns of local ancestry, and tested for evidence of selection in a subset of the Southern Community Cohort Study.

Methods. The sample consisted of 1,375 unrelated African American participants previously genotyped on Illumina arrays (1M to 2.5) from across the Southeastern US. After standard quality control metrics 604,224 markers were available for analysis. We used the software Efficient Local Ancestry Inference (ELAI) to measure African (AFR) and European (EUR) ancestry on an overlapping set of ~583K markers. We performed pairwise comparisons to search for regions exhibiting evidence of genome-wide selection. Tests were done using multiple reference AFR and EUR populations from the 1000 Genome reference dataset. RFMix (v1.5.4) was used to confirm results were not sensitive to the analytical method and potential selection was assessed using the R package 'rehh'.

Results. The average genome-wide AFR ancestry among our samples was 84.4%. A region on chromosome 2 showed an excess of EUR ancestry over 5 standard deviations above the genome-wide mean and was observed in all reference comparisons. In addition, regions on chromosome 11 and chromosome 14 also showed excess EUR ancestry in most of the AFR/EUR comparisons. Findings were replicated in the RFmix analysis. None of these regions have been previously reported as deviating from background ancestry. Additionally, integrated haplotype score analyses indicated evidence of potential selection in these regions and identified patterns consistent with selection in our sample that was not observed in ancestral populations.

Conclusion. Our analyses indicate three potential chromosomal regions under selection post admixture in African Americans. Future analyses include identification of nearby genes and pathway enrichment analysis that explain selection in regions of excess EUR ancestry.

PB3047 Evolution of epigenetic marks: a neutral null model reveals the influence of natural selection and enables dissection of causal underlying pathways.

Authors:

K. Hansen[1], L. Boukas[2], A. Razi[1], H. T. Bjornsson[3]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Children s Natl. Hosp., Washington, DC, [3]Univ. of Iceland, Reykjavik, Iceland

Natural selection acts on phenotypes, and detecting its presence yields profound insights into the evolution of living organisms. Yet, detecting selection on phenotypic traits requires understanding how these traits would evolve in the absence of selection; a neutral null model. This is notoriously challenging. In particular molecular traits other than gene expression have received little to no attention.

Here, we focus on epigenetic marks as an example of a "genome-wide" molecular trait. We formulate a general neutral null model for the evolution of any epigenetic mark associated with genes, and develop a test for selection. Our test respects the foundational aspect of epigenetics: trans-regulation by transcription factors and chromatin modifiers. It leverages estimates of genic intolerance to heterozygous loss-of-function mutations, and the fact that any given mark is observed at multiple genomic sites. Because of the latter, our test is free of many restrictive assumptions and does not require across-species or population-scale data. We illustrate the generality of our approach by applying it to 3 different marks (DNA methylation, H3K4me3, H3K36me3) and a broad range of genomic compartments (promoters, gene bodies, transcriptional end regions). We detect selection on several marks, including an unexpected finding of directional selection on the size of the hypomethylated region around proximal promoters ($p<9.9e-5$), even though this has a negligible correlation with expression.

Our approach also enables accounting for confounders or potential intermediate traits, thereby facilitating investigations into underlying causal processes. First, we find that selection on epigenetic marks is unlikely to be purely a passive consequence of selection on gene expression. This supports a causal role of these marks on gene regulation. Second, we provide evidence (by comparative analyses, trio genomic sequencing data, and simulations) that the selective pressure on DNA methylation and H3K36me3 may partly be explained by their effect on regional mutation rates in the germline, in addition to their involvement in gene regulation. We show that the cumulative effect of mutation rate modification on multiple genomic regions regulated in trans, is strong enough to overcome the drift barrier. Exemplifying the protection of important regions from high mutability, we demonstrate that in humans the more intolerant to loss-of-function mutations a gene is, the lower its coding mutation rate is.

Our framework for selection inference is simple but general, and we anticipate it to be useful for molecular traits beyond epigenetic marks.

PB3048 Evolutionary history of ancient African to Neanderthal admixture through the analysis of Neanderthal Homologous Regions

Authors:

D. Harris[1], A. Platt[1], M. Hansen[1], S. Fan[2], M. McQuillan[1], W. Beggs[1], T. Nyambo[3], S. W. Mpoloka[4], G. Mokone[4], G. Belay[5], C. N. Fokunang[6], A. K. Njamnshi[6], S. Tishkoff[7]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Fudan Univ., Shanghai, China, [3]Kampala Intl. Univ. in Tanzania (KIUT), Dar es Salaam, Tanzania, United Republic of, [4]Univ. of Botswana, Gaborone, Botswana, [5]Addis Ababa Univ., Addis Ababa, Ethiopia, [6]Faculty of Med. and BioMed. Sci., The Univ. of Yaoundé I, Yaoundé, Cameroon, [7]Univ. of Pennsylvania Sch. of Med., Penn Valley, PA

There is strong evidence that anatomically modern humans (AMH) and Neanderthals admixed in Eurasia after the Out-of-Africa expansion. However, recent analyses suggest that there were early AMH migrations from Africa that led to gene flow into Neanderthals, and more recent back migrations of West Eurasians that introduced Neanderthal ancestry to sub-Saharan Africans (SSA). Additional research also revealed extended regions of AMH genomes that are depleted of Neanderthal ancestry (Neanderthal deserts). These deserts are indicative of natural selection acting to remove Neanderthal ancestry due to hybrid incompatibilities. To investigate the admixture and natural selection dynamics between Neanderthals and AMH, we used a method called IBDmix to identify Neanderthal homologous regions (NHRs) in 180 AMH African individuals and developed a statistical model that uses the genetic distance between AMH and Neanderthals to assign the direction of introgression at each NHR as either being from Neanderthal to AMH or AMH to Neanderthal. From the cumulative length of Neanderthal to AMH introgressed NHRs we estimate that SSA individuals' range between 0% and 1% Neanderthal ancestry and that it is significantly positively correlated with their non-SSA ancestry ($R^2 = 0.95$; $p < 2 \times 10^{-16}$). From the cumulative length of AMH to Neanderthal introgressed regions we estimate that 3.79%-4.54% of the Altai Neanderthal genome is of AMH origin. The distribution of the lengths of these regions implies that this AMH introgression occurred ~235,000 years ago. This is long before the out-of-Africa expansion of AMH and may predate the oldest divergences of extant AMH populations (estimated between 150,000 and 285,000 years ago). We found a depletion of AMH introgression in the Neanderthal genome at the locations of Neanderthal deserts in Eurasians. This observation suggests that Neanderthal deserts in AMH genomes are also AMH deserts in Neanderthal genomes, and is consistent with hybrid incompatibilities evolving in similar regions of both AMH and Neanderthal genomes during divergence. We also observed a depletion of AMH introgression in Neanderthal genes, which is consistent with selection against hybrid protein-coding regions. Our analysis of NHRs in a diverse sampling of sub-Saharan Africans adds further support to a model of modern human history that includes: 1) ancient gene flow from AMH to Neanderthals, 2) Neanderthal to AMH gene flow after the out-of-Africa expansion, 3) recent migration and gene flow of non-SSA AMH populations into some SSA populations that introduced small quantities of Neanderthal ancestry. Supported by NIH grants R35GM134957-01 and 5T32DK007314-39.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3049 Evolutionary impact of transposon insertions in ancient humans revealed by machine learning tool*grnTea*

Authors:

Y. Wang[1,2,3], L. Edwards[4], E. Lee[2,1,3]; [1]Harvard Med. Sch., Boston, MA, [2]Boston Children's Hosp., Boston, MA, [3]The Broad Inst. of Harvard and MIT, Cambridge, MA, [4]Massachusetts Inst. of Technology, Cambridge, MA

Detecting transposable element insertions (TEIs) in ancient human DNA (aDNA) can potentially reveal novel genetic mechanisms of human evolution. All existing TEI detection algorithms are designed for modern human genomes, making them unsuitable for TEI detection in highly fragmented and sparsely sequenced aDNA samples. We developed a machine-learning-based tool *grnTea*, that detects TEIs in either selected loci or the entire genome from whole-genome sequencing (WGS) data. We simulated *in silico* TEIs in aDNA WGS data and trained *grnTea* to detect TE families active in humans, *i.e.*, Alu, L1, SVA. Compared to existing methods *MELT* and *xTea*, *grnTea* detects the presence of TEIs with a significantly higher sensitivity and precision, reaching F1-scores of 0.72, 0.82, 0.46 for Alu, L1, SVA, respectively on simulated data. Applications of *grnTea* to published high-coverage Neanderthal and Denisovan WGS data found 862 Alu, 103 L1, and 23 SVA insertions, more than 3 times larger than the published aDNA TEIs while recovering 76.8% of TEIs shared with modern humans. Clustering of archaic humans, along with modern humans and non-human primates based on the TEIs aligns with known genetic relationship. Additionally, our preliminary analyses identified 168 Alu, 26 L1, 1 SVA insertions putatively passed into non-African modern humans through introgression, about 4 times larger than the previous report. These introgressed TEIs (iTEIs) are depleted in exons and intergenic regions, but enriched in 5' UTR, introns, and promoter regions, implying their regulatory roles. Gene ontology analysis shows iTEI enrichment in heterophilic cell-cell adhesion, brain development related processes such as neurogenesis, differentiation, migration, and muscle cell proliferation. Since polymorphic TEIs have been associated with GWAS traits, we mapped iTEIs to GWAS signals and found correlations with obesity-related traits, height, and immune response. Furthermore, we intersected iTEIs with TE-eQTL and TE-sQTL results in modern humans and identified mRNA expression changes in testis and whole blood, and mRNA splicing changes in the brain, skin, heart, whole blood, and adrenal glands. We will expand the QTL analyses with enhanced TEI genotyping in modern humans. We are profiling TEIs in 52 deeply sequenced ancient Eurasians to trace the population allele changes over the last 10,000 years. In summary, we developed *grnTea* as a tool to identify TEIs from ancient WGS data, which will provide valuable TEI resources from 56 ancient humans. Our analyses revealed potential genetic mechanisms of how TEs can impact human evolution.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3050 Evolutionary patterns in historical genomes from Britain

Authors:

K. Anastasiadou, T. Booth, S. Johnston, M. Kelly, J. McCabe, M. Silva, L. Speidel, P. Swali, F. Tait, M. Williams, P. Skoglund; The Francis Crick Inst., London, United Kingdom

Ancient DNA provides a direct way to detect selection and adaptation throughout human history by tracking the trajectories of allelic frequencies over time and identifying changes in genetic variation that can be associated with changes in environmental conditions. A prime example of that is positive selection on lactase persistence in Europe that has been associated with the rise of dairying practices and seems to be driven by a single nucleotide variant, rs4988235. However, the detection of selection on polygenic traits is not as straightforward, as it requires robust genomic data and methods to be able to detect small changes on the whole genome level. In this study, we investigate signals of polygenic evolution with ancient DNA by combining whole genome sequencing, imputation and different approaches with dense sampling and rich phenotypic data, focusing at an initial stage on whole genomes sequenced from more than 200 individuals from Late Medieval (1000-1500 CE) and Post Medieval (1500-1800 CE) Britain, a population with close shared ancestry to the UK Biobank. We estimate polygenic risk scores (PRS) for a number of physiological and anthropometric traits and investigate whether shifts in the distribution of trait values on the population level can be attributed to documented cultural and environmental transitions. We test different methods of PRS calculation and set out a methodological approach of testing for statistically significant shifts in PRS variance over time. Meanwhile, we analyse the PRS in combination with osteological data and explore the use of discordance in genetic and realised value of a trait as an indication for the general health condition of the individual under study. Overall, we expect this study to set the foundations for large-scale studies of polygenic evolution using ancient DNA, providing a new dimension to the interactions between genotype, environment and phenotype over time.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3051 Expanding maps of archaic DNA variants within centromere-spanning haplotypes in complete, telomere-to-telomere (T2T) genomes of modern humans

Authors:

H. Loucks[1], S. Langley[2,3], F. Ryabov[4], J. K. Lucas[5], G. Karpen[2], V. Slon[6], I. A. Alexandrov[6], C. Langley[3], K. H. Miga[5]; [1]Univ. of California Santa Cruz, Santa Cruz, CA, [2]Univ. of California Berkeley, Berkeley, CA, [3]Univ. of California Davis, Davis, CA, [4]Natl. research Univ. Higher Sch. of Economics, Moscor, Russian Federation, [5]UCSC, Santa Cruz, CA, [6]Tel Aviv Univ., Tel Aviv, Israel

Centromeric satellite arrays play an important role in nuclear organization, and kinetochore recruitment and fidelity. Genetic and epigenetic variation within centromeric regions can lead to chromosome instability, which can contribute to cancers and aneuploidies in early development. Despite their importance in cell biology and function, we are only beginning to understand the genetic architecture of these regions and the patterns of evolution across human populations. Previous efforts to study linkage blocks spanning these regions identified centromere-spanning haplotypes, or 'cenhaps'. Meiotic recombination is rare in these regions allowing for intact transmission of entire centromere regions through evolution. Dating based on datasets from the 1000 Genome Consortium (1000G) provided evidence for ancient cenhaps within modern humans. Some of these sequences can be traced back to archaic hominins, and appear to be the result of Neanderthal and Denisovan introgression.
Complete telomere-to-telomere (T2T) reference genomes from humans and non-human primate assemblies offer an unprecedented look into haplotypes and genetic variation within and between cenhaps. Here we present an initial analysis of cenhap structure across the 1000G dataset relative to the first complete human genome (T2T-CHM13). In doing so, we have established a panel of homolog-phased and assembled centromeric regions representing archaic cenhaps on chromosomes 8, 10, 11, and 12. Our initial study revealed new satellite variants of higher order repeats (HOR) that differ in structure and organization from modern cenhaps. Further, we provided refinement of the cenhap structure, uncovered evidence of rare recombination events within peri/centromeric regions, and performed a detailed investigation of genes within archaic cenhaps. The dynamics of repeat expansion, degradation, and mutation are not well understood in these complex regions, and this study provides a new system for studying repeat evolution in the context of shared haplogroup structures. Additionally, this work in its completion aims to provide millions of bases of archaic genetic information to advance our understanding of uncharacterized structural variation in humans.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3052 Exploring recent genetic sharing in the diverse population of Quebec using identity by descent.

Authors:

J. Pelletier[1,2,3], M. Sayahian Dehkordi[1,2,3], A. Diaz-Papkovich[1,3,4], S. Gravel[1,3], D. Taliun[1,2,3], C. Bhérer[1,2,3]; [1]McGill Univ., Montreal, QC, Canada, [2]Canada Excellence Res. Chair in Genomic Med., McGill Univ., Montreal, QC, Canada, [3]Victor Phillip Dahdaleh Inst. of Genomic Med. at McGill Univ., Montreal, QC, Canada, [4]Quantitative Life Sci., McGill Univ., Montreal, QC, Canada

Segments of identity by descent (IBD) reflect genetic sharing between individuals from recent common ancestors. Analyses of IBD patterns in a population allow identification of clusters of individuals with recent genetic sharing, providing insights into relatedness, demographic history and enabling IBD mapping. We leverage IBD segments to study recent genetic sharing in the diverse population of Quebec, Canada. Most of Quebec's genetic studies have focused so far on the well-documented French-Canadian founder population ignoring minor population groups with rich genetic diversity. We used the prospective CARTaGENE population-based cohort, comprising 29,330 participants recruited from urban centers in Quebec and who underwent genome-wide genotyping. We first compared different methods to identify IBD segments shared between all individuals. We utilized iterations of Louvain clustering algorithm in combination with Hudson's FST to identify genetic clusters. We identified 21 clusters, including those of European, African, and Asian ancestry. Combining our IBD clustering results with the self-reported data, we identified eleven non-French Canadian ancestry groups, accounting for more than 10% of the cohort, including Chinese, Filipinos, Haitian, Italian, Latin-American, Lebanese, Moroccan and Vietnamese individuals all of which are known diaspora populations in Quebec, with major migration waves in the 20th century. IBD clustering further identified French-Canadian regional subgroups, replicating known fine-scale patterns of population structure relating to historical migration and subsequent founder effects. We further characterized IBD patterns within genetic clusters. The cluster showing highest average total pairwise IBD sharing length was the French-Canadian cluster representing the Saguenay regional founding group (32.49cM), followed by the cluster of potential Jewish origin (25.66cM) and the cluster of potential acadian origin (22.36cM). To improve our characterization of the ancestry composition of Quebec IBD clusters, we will estimate admixture proportions and compare our results to PCA-based ancestry inference methods and topological approaches such as UMAP and HDBSCAN. Using IBD analysis we identified and characterized population clusters that unveiled recent genetic sharing in the population. We described several population subgroups in CARTaGENE, some of which have been understudied so far. These results will allow us to investigate disease prevalence among genetic clusters and perform IBD mapping, using detailed phenotypic data in CARTaGENE.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3053 Exploring the population history of Khoe-San descendant communities in South Africa

Authors:

S. Edington[1], D. R. Al-Hindi[2], N. Font-Porterias[2,3], A. Surowiec[2], J. Myrick[2], C. Uren[4], P. J. Norman[3], M. Möller[4], B. Henn[2], A. W. Reynolds[1]; [1]Baylor Univ., Waco, TX, [2]UC Davis, Davis, CA, [3]Univ. of Colorado Sch. of Med., Aurora, CO, [4]Stellenbosch Univ., Cape Town, South Africa

The former Cape Colony, centered on the present-day city of Cape Town, South Africa, was one of the first European colonies in Sub-Saharan Africa. Genetic ancestry analyses show that individuals living in Cape Town having substantial amounts of European, East and South Asian, and West African ancestry derived from colonization and the Dutch slave trade. These groups mixed with and absorbed the local Khoekhoe and San peoples during the 17th-18th centuries. However, it is currently unclear how this colonial history impacted the genetic ancestry of communities further into the interior, along the colonial frontier. In this study, we aimed to characterize the impacts of European colonization on the longstanding population history of indigenous populations of southern Africa. We sampled 827 members of Khoe-San and Khoe-San descendant communities across South Africa and genotyped for ~2.2 million genome-wide SNPs on the Illumina H3Africa Array. We analyze global patterns of population structure using ADMIXTURE to infer relative levels of recent admixture from European, Bantu-speaking African, and Asian populations into these communities. Our results demonstrate a cline of Khoe-San ancestry with distance from the Cape Colony. Using local ancestry inference, we estimate the timing of these admixture events for each of the non-Khoe-San ancestries and explored local changes in effective population size. We find differential Indonesian to South Asian ancestries across different communities, reflecting heterogenous migration sources. This project advances our knowledge of population history in Khoe-San and Khoe-San descendent communities for whom few historical records are reliable.

PB3054 Extension of Viviani's theorem for the evaluation of the impact of population stratification on mating type frequencies

Authors:

R. Sebro; Mayo Clinic Florida, Jacksonville Beach, FL

Abstract
Background: Population stratification occurs when a study population is comprised of several subpopulations where there is random mating within subpopulation but not between subpopulations. Wahlund first showed that population stratification results in a predictable deviation of genotypes from that expected assuming Hardy-Weinberg Equilibrium (HWE). More specifically, the Wahlund effect results in decreased heterozygotes (or alternatively stated an excess homozygotes) in a population with population substructure compared to a population in HWE. The aim of this study was to evaluate how the mating type frequencies are altered in population stratification.
Materials and Methods:
Assume a biallelic marker with minor allele B, and major allele A, where allele A has frequency between 0 and 1. We first assume that there is a population with stratification comprised of n subpopulations, where the allele frequency varies between subpopulation, and evaluate the distribution of mating type frequencies in this population at this locus. Next, we extend Viviani's theorem and use de Finetti diagrams to evaluate the distribution of mating type frequencies in a stratified population.
Results:
Population structure results in another predictable phenomenon - an excess in the number of unions between individuals of the same genotype compared to that expected assuming random mating at all loci where the allele frequency differs between subpopulation. This manifests as assortative mating with respect to subpopulation.
Conclusion: This phenomenon can also be reliably confirmed using an extension of Viviani's theorem. Subpopulation-related assortative mating would be expected in a stratified population.

PB3055 Finding chrY haplogroup in samples with ultra-low sequencing depth

Authors:

T. Puurand[1], M. Möls[1], L. Kaplinski[1], T. Kivisild[2], M. Remm[1]; [1]Univ. of Tartu, Tartu, Estonia, [2]KU Leuven, Leuven, Belgium

With our current work we aim to show how three diverse types of tandem repeats that correlate with previously described human chromosome Y haplogroups and how hundreds of thousands of short DNA strings (k-mers) combinatorics allow to find chrY haplogroups from WGS data that is sequenced with coverage less than 0.01x without additional PCR. We also prove considerable decrease of tandem repeats motifs copy numbers which indicate decrease of the repeats total length. Our k-mer selection started with creating 25-mers by step of one along three tandem repeats (DYZ1, DYZ2, DYZ3 and DYZ19) in the Y chromosome (CHM13v2.0 assembly). Each region contains k-mers located multiple times inside the repeated region and k-mers located in other chromosomes. After filtering out multiplications in other chromosomes our final count of chrY specific k-mers was 618393. We queried k-mer frequencies from individual's k-mer lists and normalized them with "NIPT" chrY k-mers to set median values. This normalized value should indicate copy numbers of k-mers in the Y chromosome. Note that there is no need to only have 0 or 1 for values. 23 haplogroups of k-mers separation for the training set of 1000G and Estonian Genome Center WGS individuals were based on Mann-Whitney statistic by normalized average of k-mer counts for every k-mer for one SNP based haplogroup (a) and other haplogroups (b). Copy numbers varied from zero to over 100000. Separation of R1a and R1b fails with full set of haplogroups, and this section was performed separately. Result of separation allowed us to choose k-mers with more and less presence in haplogroups. The union of more and less presented k-mers in 23 haplogroups has 406574 entries for the building model. This model calculates haplogroup specific distances based on a specific training set. Simulated dilutions from the training set of 30x WGS data, chrY haplogroup is detectable in 0.001x sequencing depth, samples that were not used in training were detectable at 0.01x. aDNA and cfDNA samples give promising results, but very few samples contain previously known haplogroups. SNP or exon targeted capture of mess sequencing depth prediction which is important to make an accurate prediction.

PB3056 † Fine-scale population movements and geographic patterns of African Americans over the past 300 years revealed through IBD sharing and pedigree data from 1.7 million people.

Authors:

A. Wolf[1], A. Sedghifar[1], J. Zhang[1], C. Mason[2], P. Milos[2], R. Curtis[2], J. Lang[1], B. Donnelly[1]; [1]Ancestry.com DNA, LLC, San Francisco, CA, [2]Ancestry.com DNA, LLC, Lehi, UT

African Americans constitute the third largest population group in the United States and have a deep interest in exploring their family history. However, African Americans face many barriers to family history research including displacement from, and loss of, formal records—including census, voter lists, and church registries. To facilitate family history research for African Americans, we leveraged our unique collection of DNA and pedigree data to reveal fine-scale movement and geographic patterns of African Americans in the United States over the past 300 years. We used genotype data from approximately 1.7 million research-consented AncestryDNA members to find identity-by-descent (IBD) segments among them. We then recursively ran the *Louvain community detection* method on the resulting IBD networks (individuals as vertices, IBD connections among them as weighted edges) to discover groups of people with significantly more genetic connections to each other than to non-group members. We annotated the network vertices with information from the corresponding individuals' pedigree data. These include surnames, birth dates, and locations of ancestors dating back hundreds of years. The result is a striking set of genetic clusters that map detailed patterns of movement and settlement in the United States over the past 300 years. For example, we are able to visualize population movements from southern states to northern and western states in the mid-1900s that agree with historical records of the Great Migration. As well, we are able to distinguish geographically overlapping groups—such as Louisiana Creole and non-Creole groups—based on differences in genetic ancestry analysis and reported surnames. Overall, our results provide a significant insight into population structure and history of African Americans in the United States. Our results depict both shared historical patterns and varied personal experiences. These resources are an impactful new tool for African Americans to use in their family history research, empowering them to make new personal discoveries, such as pinpointing where their ancestors lived and locating relevant records collections.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3057 Finnish Y chromosome sequencing data suggests dual paths of haplogroup N1a1 into Finland

Authors:

A. Preussner[1], J. Leinonen[1], J. Riikonen[1], M. Pirinen[1,2,3], T. Tukiainen[1]; [1]Inst. for Molecular Med. Finland (FIMM), Helsinki, Finland, [2]Dept. of Publ. Hlth., Faculty of Med., Univ. of Helsinki, Helsinki, Finland, [3]Dept. of Mathematics and Statistics, Univ. of Helsinki, Helsinki, Finland

Y chromosome (chrY) haplogroups differ geographically within Finland, with N1a1-TAT enriched in the northeast and I1-M253 in the southwest, suggested to reflect two separate founding populations. However, to date, the distribution of finer-scale chrY variation beyond these major haplogroups has not been characterized in the population. To better understand the Y-chromosomal landscape in Finland, we studied whole genome sequencing data for the Y chromosome in 1831 Finnish men (born between 1923-1979), with precise geographical origins from the FINRISK project. We assessed the geographical distribution of common chrY haplogroups (freq ≥ 1%) within 19 regions across Finland, determined by paternal birth places (6-392 samples per region), and further examined the relationship between chrY haplogroups and autosomal genetic variation. In addition to detecting the four previously described chrY haplogroups in Finland, N1a1-TAT (69%), I1-M253 (20%), R1a-M420 (5%) and R1b-M343 (4%), we increase the resolution by observing in total 56 common haplogroups in our data, with 27 displaying geographical differences within the country (chisq p<0.05). We show that haplogroup N1a1-TAT, traditionally associated with eastern Finnish ancestry, splits into two unique lineages: N1a1a1a1a2a1-CTS2733 (53%) enriched in the northeast, and N1a1a1a1a1a-VL29 (16%) more frequent in the southwestern coast, specifically in Southwest Finland (64% of N1a1, chisq p=5e-11). Carriers of these two N1a1-TAT lineages displayed differences in their autosomal genome (PC1) in Southwest Finland (wilcoxon p<2e-16) but not elsewhere in Finland, with the VL29 carriers resembling closely southwestern Finns, suggesting its arrival to the southwestern coast may occurred more likely via the Baltic Sea rather than through the mainland. Overall, our results suggest two separate routes of haplogroup N1a1-TAT into Finland, N1a1a1a1a2a1-CTS2733 from the east and N1a1a1a1a1a-VL29 from the southwest. Within other haplogroups, such as I1-M253, we did not observe a similar degree of heterogeneity, although we detected some regional enrichments in its sublineages. In summary, we have characterized detailed chrY variation and its distribution regionally within Finland, providing novel insights into the population history of Finns, particularly within haplogroup N1a1-TAT. Our research further elaborates on the relationship between autosomal genetic structure and chrY haplogroups, providing valuable insights for future studies in population health. Overall, this study highlights the value of reassessing population-level chrY variation with detailed geographical and sequencing data.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3058 † Fundamental limitations on the transferability of polygenic risk scores across human populations.

Authors:

K. Zhang, J. Storey, J. Akey; Princeton Univ., Princeton, NJ

Genome wide association studies (GWAS) have provided insights into the genetic determinants of many traits and diseases and facilitated the construction of polygenic risk scores (PRS) to predict phenotypes in independent samples. However, it is well known that PRS constructed from European cohorts have limited transferability to individuals from other populations. There are many potential factors that contribute to poor transferability of PRS across populations, including differences in patterns of linkage disequilibrium, effect sizes of causal variants, and context specific effects such as gene-gene and gene-environment interactions. Thus, there is considerable interest in delineating the factors that influence transferability so that genomic methods of prediction can be developed that are applicable across populations. It remains unclear, however, whether addressing these potential determinants of transferability will allow predictions to be made across populations, or if there are fundamental limits to transferability. To address this question, we investigated the transferability of PRS in the simplest and most optimal scenario where causal variants and their effect sizes are known and are identical across populations. Using both theory and simulations, we show that transferability is influenced by differences in allele frequencies and non-genetic sources of variation across populations. We further show that even in this simple and ideal setting, transferability can be low across human populations and differences in transferability are a function of the genetic architecture of a trait. Finally, we demonstrate that transferability is improved when the target population has a higher heritability than the discovery population for the trait of interest. Our results provide important insights into how human evolutionary history has imposed fundamental limitations on the transferability of phenotypic predictions across populations.

PB3059 *FXN* protomutation alleles determine population susceptibility to Friedreich ataxia.

Authors:

S. Bidichandani, M. Tackett, C. Lam; Univ. of Oklahoma Hlth.Sci. Ctr., Oklahoma City, OK

Friedreich ataxia (FRDA) is typically caused by homozygosity for an expanded GAA triplet repeat (GAA-TR) in intron 1 of the *FXN* gene that results in length-dependent epigenetic silencing. Disease-causing expanded (E) alleles have 100-1500 triplets while non-disease alleles show a bimodal allelic distribution of <12 triplets (short normal; SN) and >12 triplets (long normal; LN). A shared haplotype between LN and E alleles supports a multistep process in which a unique SN to LN allele transition was followed by subsequent transition to E alleles. Prevalence of FRDA, which is exclusively seen in Europe, the Middle East, North Africa and South Asia, is determined by the population frequency of asymptomatic heterozygous carriers of E alleles. In order to investigate the disparate population distribution, the entire *FXN* locus (~65 kb) was sequenced in multiple individuals. This identified a 23-SNP core haplotype unique to LN and E alleles in susceptible populations. East Asians lack this haplotype, both in existing people and in ancient DNAs dating back tens of thousands of years, consistent with the absence of FRDA in East Asia. A partial haplotype consisting of 22 of 23 core SNPs was seen in ~10% of sub-Saharan Africans, which was associated with LN alleles consisting of <20 triplets, indicating that the original SN to LN transition occurred in Africa. Completion of the 23-SNP core haplotype and transition to LN alleles with >20 triplets, termed protomutation alleles, occurred exclusively in West Eurasians and South Asians. Finally, E alleles have arisen multiple times from protomutation alleles, indicating that population susceptibility to FRDA is determined by the presence of protomutation alleles.

PB3060 Genealogy-based ancestry modelling reveals fine-scale genetic history

Authors:

L. Speidel[1,2], P. Skoglund[2]; [1]UCL, London, United Kingdom, [2]Francis Crick Inst., London, United Kingdom

Ancient DNA has provided a new genetic history of humankind, informing our understanding of present-day genetic variation and disease. However, recent genetic history over short time scales is challenging to reconstruct as it often involves fine-scale ancestry differences, often leaving important historical events below the detection threshold. Methods based on sharing of haplotypes, large chromosomal segments and rare variants can improve on power to observe patterns, but can not be readily used in unbiased ancestry models. Here, we develop a framework for ancestry modelling based on recent genealogical history, and show that it can improve statistical power of ancestry models by an order of magnitude. We apply this framework to ancient genomes and present-day individuals in the UK Biobank to develop a detailed ancestry model of Migration period and Viking Age expansions from and into Scandinavia, where previous studies were largely unable to develop quantitative models. These results demonstrate the ability of genealogy-informed analysis to provide insights into fine-scale genetic history.

PB3061 Genetic affinities of “White and Asian” and “Any other Asian” self-identifying UK Biobank participants.

Authors:

C. Cataldo-Ramirez, T. D. Weaver, B. M. Henn; UC Davis, Davis, CA

It is a well-known limitation in current human genetics research that non-European diversity is under-represented in biobanks which then limits the investigation of genetic architecture for complex traits. This issue is further compounded by the practice of excluding “admixed” participants or individuals who identify with an ethnic label that is ambiguously defined, in an effort to reduce the effects of population stratification on downstream analyses. Here, we characterize the genetic affinities of UK Biobank (UKB) participants who self-identify as “White and Asian” (WA) and “Any Other Asian” (AOA) (n = 2645) by comparing three methods: principal component analysis (PCA), ADMIXTURE, and support vector machines (SVM). All methods were trained or informed by 1000 Genomes Project (1KG) data as a global reference of genetic diversity. Results of the three methods reproduce consistent patterns of clustering. Projecting WA, AOA, and UKB South Asian-identifying participants (Bangladeshi, Indian, Pakistani [n = 6756 post-QC]) onto 1KG PC space identifies at least four clusters within AOA data, while the WA data appear as a cline between European and East Asian groups. The SVM model utilized these PC scores and was trained with 1KG and UKB Pakistani and Bangladeshi groups as reference populations. Classification probabilities of 75% and above resulted in 1878 AOA and WA participants being reassigned into subcontinental genetic groups. This substantially increased the sample size of the UKB South Asian group (by 1432 additional participants). Although human genetic diversity is not biologically discretized by categorical labels, we hope that by clarifying the subcontinental ancestry of these participants and relating their ancestry to other UKB and 1KG groups, research groups can more easily include them in analyses. As demonstrated here with the UKB South Asians, using subcontinental classifications as a starting point has the potential to increase the utility of non-European data, by retaining participants who have been traditionally excluded.

PB3063 Genetic and environmental contributions to ancestry differences in gene expression in the human brain

Authors:

K. Benjamin[1], Q. Chen[2], N. J. Eagles[2], L. Huuki[2], L. Collado-Torres[3], J. Stolz[2], J. Shin[2], A. Paquola[4], T. Hyde[1], J. Kleinman[1], A. Jaffe[1], S. Han[1], D. R. Weinberger[1]; [1]Lieber Inst. for Brain Dev. / Johns Hopkins Med., Baltimore, MD, [2]Lieber Inst. for Brain Dev., Baltimore, MD, [3]Lieber Inst. for Brain Dev. / Johns Hopkins Univ., Baltimore, MD, [4]Lieber Inst. for Brain Dev. / Johns Hopkins Med., Baltimore, MD

Introduction: Health disparities have endured for centuries. In neuroscience and genomics, individuals with recent African ancestry account for less than 5% of large-scale research cohorts for brain disorders but are 20% more likely to experience a major mental health crisis. Insights gained from genome-wide association studies (GWAS) about disease risk are promising for clinical applications. However, the lack of diversity in GWAS limits the accuracy of genetic risk prediction and hinders the development of effective and equitable neurotherapeutics.
Rationale: While diversity in GWAS has increased in recent years, population-based genetic association studies do not directly elucidate the biological mechanisms of risk variants. Recent efforts to investigate the biological impact of genetic variation on molecular traits of diverse populations have focused on improved fine mapping. These prior studies implicitly assume that the genetic mechanisms of risk and resilience are mostly conserved across ancestries; however, differences in the pathogenic role of ApoE in Alzheimer's disease between individuals of African and European genetic ancestries breaks this assumption.
Results: Here, we examined the impact of genetic ancestry on gene expression and DNA methylation (DNAm) in admixed Black American neurotypical individuals to reduce confounding effects of ancestry-related environmental factors. Ancestry-associated differentially expressed genes (DEGs), transcripts, and gene networks, while notably not implicating neurons, are enriched for genes related to immune response and vascular tissue and explain up to 26% of heritability for ischemic stroke, 27% of heritability for Parkinson's disease, and 30% of heritability for Alzhemier's disease. Ancestry-associated DEGs also show general enrichment for heritability of diverse immune-related traits but depletion for psychiatric-related traits. The cell-type enrichments and direction of effects vary by brain region. These DEGs are less evolutionarily constrained and are largely explained by genetic variations; roughly 15% are predicted by DNAm variation implicating environmental exposures. We also compared Black and White Americans, confirming most of these ancestry-associated DEGs and identifying potentially environmentally associated DEGs.
Conclusion: Our results highlight how environment and genetic background affect genetic ancestry differences in gene expression in the human brain; opening new avenues to the development of ancestry-aware therapeutics and paving the way for equitable, personalized medicine.

PB3064 Genetic and environmental drivers of telomere length variation in ethnically diverse Africans.

Authors:

M. McQuillan[1], S. Verhulst[2], M. Hansen[1], W. Beggs[3], D. Wolde Meskel[4], G. Belay[4], T. Nyambo[5], S. Mpoloka[6], G. Mokone[6], C. Fokunang[7], A. Njamnshi[7], A. Aviv[8], S. Tishkoff[9]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Univ. of Groningen, Groningen, Netherlands, [3]Univ Pennsylvania, Philadelphia, PA, [4]Addis Ababa Univ., Addis Ababa, Ethiopia, [5]Kampala Intl. Univ. in Tanzania, Dares Salaam, Tanzania, United Republic of, [6]Univ. of Botswana, Gaborone, Botswana, [7]The Univ. of Yaoundé I, Yaoundé, Cameroon, [8]Rutgers Univ., Newark, NJ, [9]Univ. of Pennsylvania Sch. of Med., Penn Valley, PA

Leukocyte telomere length (LTL) varies significantly across human populations, with individuals of African ancestry having longer LTL than non-Africans. However, the genetic and environmental drivers of LTL variation in Africans remain largely unknown. We report here on the relationship between telomere length, genetics, and environmental factors in ethnically diverse African individuals (n=1818) originating from Botswana, Tanzania, Ethiopia, and Cameroon. We observe significant variation in telomere length among populations [Population Grouping: $F(17,1800) = 29.79$, $p < 2x10^{-16}$], finding that the San hunter-gatherers from Botswana have the longest telomeres (8.2 ± 0.72 kb; mean ± SD), and Fulani pastoralists from Cameroon have the shortest telomeres (6.9 ± 0.71 kb). Genome-wide association analyses using high coverage whole genome sequences reveal suggestive associations at novel variants located within aging-related genes, as well as at predicted loss-of-function alleles in genes that regulate telomerase. We also show that LTL-associated loci from the UK Biobank explain a significant amount of the inter-individual variation in LTL in Africa, suggesting some level of polygenic score transferability between Europe and Africa for this trait. Moreover, we find that *falciparum* malaria endemicity is significantly associated with LTL while adjusting for age, sex, and genetics. Within Africa, populations indigenous to areas with high malaria exposure have shorter LTL than populations indigenous to areas with low malaria exposure. Together, these results shed light on the genetic and environmental drivers of telomere length variation in under-represented African populations. This work is funded by NIH grant R35 GM134957-01, the American Diabetes Association Pathway to Stop Diabetes grant #1-19-VSN-02, and the Center of Excellence in Environmental Toxicology grant T32-ES019851.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3066 Genetic identification of Slavs in Migration Period Europe using an IBD sharing graph

Authors:

P. Flegontov[1,2], L. Viazov[1], O. Flegontova[1], H. Ringbauer[2], D. Reich[3]; [1]Univ. of Ostrava, Ostrava, Czech Republic, [2]Dept. of Human Evolutionary Biology, Harvard Univ., Cambridge, MA, [3]Harvard Univ., Boston, MA

Popular methods of genetic analysis relying on allele frequencies such as PCA, ADMIXTURE and qpAdm are not suitable for distinguishing many populations that were important historical actors in the Migration Period Europe. For instance, differentiating Slavic, Germanic, and Celtic people is very difficult relying on these methods, but very helpful for archaeologists given a large proportion of graves with no inventory and frequent adoption of a different culture. To overcome these problems and to test if archaeological cultural groups in Early Medieval Central/Eastern Europe correspond to populations isolated to some degree, we applied a method based on autosomal haplotypes. Imputation of missing genotypes, phasing and IBD inference were performed for ancient Eurasians using the ancIBD method (Ringbauer et al. 2023, bioRxiv). IBD links for subsets of these individuals are represented as graphs, visualized with a force-directed layout algorithm, and most clusters of distant relatives that were inferred in these graphs with the Leiden algorithm are in remarkable agreement with archaeological evidence. One of these clusters includes nearly all individuals in the dataset annotated archaeologically as "Slavic". Most individuals in this cluster were not buried in the Slavic cultural context, but all of them come from times and places where Slavic presence is likely according to written sources and/or archaeological evidence. These results illustrate the power of the IBD graph approach since we were able to reveal a community of distantly related individuals from very diverse archaeological contexts who could not be identified using the standard archaeogenetic toolkit. Considering also results of other analyses based on allele frequencies (PCA, ADMIXTURE), a hypothesis for the origin of this population can be proposed: it was formed by admixture of a group related to Baltic speakers with East Germanic people and Sarmatians or Scythians, and underwent a major bottleneck. We suppose that the starting point of these demographic processes in Central and Eastern Europe were migrations of Sarmatian populations, pushed out from Volhynia by Goths in the late 2nd century CE.

PB3067 Genetic insights into the recent demographic history of Ireland and Britain

Authors:

A. Shanmugam[1,2,3], A. M. Molloy[4], L. Brody[5], M. Merrigan[6], S. O'Reilly[6], G. L. Cavalleri[1,2,3], R. McLaughlin[7,2,3], R. P. Byrne[7], E. Gilbert[1,3]; [1]Royal Coll. of Surgeons in Ireland, Dublin, Ireland, [2]The SFI Ctr. for Res. Training in Genomics Data Sci., Galway, Ireland, [3]The SFI FutureNeuro Res. Ctr., Dublin, Ireland, [4]Sch. of Med., Trinity Coll. Dublin, Dublin, Ireland, [5]NHGRI (NIH), Bethesda, MD, [6]Genealogical Society of Ireland, Dún Laoghaire, Ireland, [7]Trinity Coll. Dublin, Dublin, Ireland

Background: While subtle, discrete clusters of genetic identity across Ireland and Britain have been identified, their demographic history is unclear.
Methods: Using genotype data from 6,574 individuals with associated regional Irish or British ancestry, we identified Irish and British genetic communities using network community detection. We segregated identity-by-descent (IBD) segments by length and (1) estimated temporal genetic relatedness between communities and (2) inferred recent migration rates over the islands across time-scales. Additionally, we estimated changes in effective population over time. For a subset of the Irish haplotypes, we determined the enrichment/depletion of surnames within the genetic communities.
Results: We find evidence of recent population bottlenecks in the Orcadian, Manx and Welsh communities through patterns of IBD-sharing and ROH while the structure in Ireland is subtler - the communities share relatively more IBD segments and the genetic differences between the Irish communities are more subtle on average when compared to the British communities. The regional effective population size trajectories indicate a similar demographic history throughout the island of Ireland. Further, we observe a stable migration corridor between north-east Ireland and south-west Scotland while there is a recent migration barrier between Leinster and Western Ireland. We observed an enrichment of Anglo-Norman and English surnames in the Wexford community while within West Ulster-Argyll community, we saw an enrichment of Gallowglass and Scottish surnames.
Conclusions: Using these new insights into the regional demographic history of Ireland and Britain across different time periods, we hope to understand the driving forces of rare allele frequencies and disease risk association within these populations.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3068 Genetic landscape of HLA in the Emirati population enabled by long-read Oxford Nanopore whole-genome sequencing.

Authors:

J. Quilez Oliete[1], S. Elavalli[1], G. Katagi[1], T. Cardoso[1], S. Behl[1], P. Merel[1], L. Paulin[2], F. Sedlazeck[2], T. Magalhaes[1], F. Al Marzooqi[1], The Emirati Genome Program; [1]G42 Hlth.care, Abu Dhabi, United Arab Emirates, [2]Baylor Coll. Med., Houston, TX

The Human Leukocyte Antigen (HLA) genomic region is biologically and medically relevant. HLA is highly polymorphic and thus difficult to characterize. Besides, most attempts have been based on short-read and targeted sequencing, restricted to only a subset of HLA genes and targeted mostly European-descent populations, failing to represent worldwide genetic diversity in the entire HLA locus.

Here we first show that we can accurately genotype 13 HLA loci from blood-derived long-read Oxford Nanopore Technologies (ONT) whole-genome sequences (WGS). In 10 individuals whole-genome sequenced in both short-read Illumina and ONT, we observed high quality HLA allele calls (mean HLA*LA Q1>0.99) and >99% genotyping concordance at second-digit resolutions between the two sequencing platforms.

We next characterized HLA genetic diversity in the Emirati population using ~10,000 participants of the Emirati Genome Program (EGP) whole-genome sequenced on ONT at ~41X (38-57X). We observed high-quality HLA allele calls supported by 0.96 per-allele mean Q1 (median = 1.00), per-sample mean Q1 >0.90 for most samples and the coverage supporting allele calls (~30-50X) comparable to that observed genome-wide. We confirmed in the Emirati population that Class Ia HLA genes (A, B and C) are more polymorphic than Class Ib genes (E, F and G). The former show a higher number of unique alleles (N = ~30-50) at low similar allele frequency (AF_{mean} = 0.0148; AF_{SD} = 0.0394), in contrast with the more oligomorphic more frequent Class Ib (N = ~2-4; AF_{mean} = 0.3684; AF_{SD} = 0.401). Class II genes (DPA1, DPB1, DQB1, DRB1, DRB3 and DRB4) showed a broader range of unique alleles typically in <25% of the Emirati cohort. Furthermore, we determined that detecting 1-3 most common alleles captures 90% of the population diversity in E, F and G, while a higher and broader range of ~15-30 and 2-25 alleles are needed for Class Ia and II, respectively.

Finally, we investigated the accuracy of HLA typing from ONT WGS of DNA derived from buccal swab and saliva. Such tissues are less invasive than blood and may facilitate establishing routine HLA typing, e.g. clinical practice. Second-digit resolution HLA genotypes were, on average, >85% concordant between blood and buccal swab and less so (>75%) between blood and saliva.

In summary, (i) we demonstrated that ONT WGS can be used to accurately genotype HLA compared to Illumina, which is still considered as default for HLA typing; (ii) we generated high-quality HLA genotypes in ~10,000 Emirati ONT WGS and pioneered the analysis of HLA genetic diversity in Emiratis; and (iii) we provided a first step in enabling routine HLA typing from non-invasive biological samples.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3069 Genetic network rewiring between distantly related eukaryotic organisms.

Authors:

V. Pereira[1], R. Dandage[1], E. Kuzmin[1,2]; [1]Dept. of Biology, Ctr. for Applied Synthetic Biology, Ctr. for Structural and Functional Genomics, Concordia Univ., Montreal, QC, Canada, [2]Dept. of Human Genetics, Rosalind & Morris Goodman Cancer Inst., McGill Univ., Montreal, QC, Canada

Synthetic lethality represents an extreme example of a genetic interaction that occurs when a combination of mutations in different genes results in lethality, which would not be expected from the combined effects of individual viable single mutants. The extent of genetic interaction network conservation differs from genome sequence conservation between species. Two distantly related eukaryotic organisms such as the two yeast species, the budding yeast, *S. cerevisiae*, and fission yeast, *S. pombe*, diverged ~500 Mya and despite 75% genome conservation, they display 29% genetic interaction network conservation. Other distantly related eukaryotes such as *C. elegans* and *H. sapiens* diverged ~600 Mya. Here, we investigate genetic network rewiring by studying the genetic interactions that underlie conditional essentiality of single mutants between *S. cerevisiae*, *S. pombe*, *C. elegans*, and *H. sapiens*, whereby a gene is essential (ES) in one species but nonessential (NES) in another. We have extensively studied the 2853 *S. cerevisiae* - *S. pombe* orthologs, where ~15% are conditional ES (ES in one species but NES in the other). From 269 conditional NES genes that were ES in *S. pombe* and NES in *S. cerevisiae*, we identified 124 cases, which are rewired by synthetic lethal digenic interactions that modify conditional NES single mutants to synthetic lethal double mutants in *S. cerevisiae*. Single mutant fitness, phenotype rate and genetic interaction degree differentiate conditional NES genes that were rewired by synthetic lethal interactions compared to those which are nonewired. To understand the functional relationship between conditional NES genes and their rewiring synthetic lethal interactions, we overlapped them with common functional standards and found that they are functionally related since they were co-expressed, co-localized, co-annotated, shared protein-protein interactions and showed similar phenotypic profiles suggesting that genetic rewiring of essential genes is local. We have begun to extend these findings to *C. elegans* and *H. sapiens*, where ~21% of *H. sapiens* - *S. cerevisiae* orthologs, ~23% of *C. elegan*s - *S. cerevisiae* orthologs, and ~14% *H. sapiens* - *C. elegans* orthologs are conditional ES. Mapping how these conditional ES genes are rewired by genetic interactions will provides insight into genetic network rewiring between distantly related eukaryotes and should reveal principles of genetic network conservation which can shed light on human diseases, such as cancers, and potential synthetic lethal therapeutic strategies.

PB3070 Genome-wide characterization of de novo tandem repeat mutations in the human genome

Authors:

T. Mokveld[1], E. Dolzhenko[1], H. Dashnow[2], B. van der Sanden[3], B. Pedersen[2], Z. Kronenberg[1], T. Nicholas[2], C. Fanslow[1], C. Lambert[1], N. Koundinya[4], W. Harvey[4], K. Hoekzema[4], J. Knuth[4], G. Garcia[4], K. M. Munson[4], S. Watkins[2], D. W. Neklason[2], A. R. Quinlan[2], C. Gilissen[3], A. Hoischen[3], E. E. Eichler[4], M. A. Eberle[1]; [1]PacBio, Menlo Park, CA, [2]Univ. of Utah, Salt Lake City, UT, [3]Radboudumc, Nijmegen, Netherlands, [4]Univ. of Washington, Seattle, WA

Tandem repeat (TR) expansions at more than 60 loci have been associated with severe diseases, including Fragile X syndrome and Huntington disease. Many of these diseases initially arise in families by a *de novo* TR expansion and worsen in later generations via subsequent expansions and genetic anticipation. Studies aimed at identifying novel pathogenic repeats have been hampered by limitations of short-read sequencing data and shortcomings of existing informatics pipelines. To enable rare disease researchers to comprehensively profile the length and sequence context of TRs in long read sequencing data, we previously developed the Tandem Repeat Genotyping Tool (TRGT). In our trio assessment, TRGT achieves >98% mendelian length consistency for repeats with motifs longer than 2bp when applied to 1 million TR regions. However, the accuracy rate remains insufficient for detecting true *de novo* TR mutations due to the potential >10,000 false positives per trio. Therefore, accurate detection of *de novo* TR mutations remains an open problem.

With this goal in mind, we have formulated a new method, TRGTdn, that works in tandem with TRGT to call *de novo* TR mutations, including expansions and contractions, in parent-offspring trios using long read HiFi data. TRGTdn relies on analyzing familial dissimilarities, which are established by pedigree-aware realignment of sequencing data. Crucially, we significantly enhance accuracy by detecting allele dropout through phasing.

We applied TRGTdn to the four-generational kindred 1463 CEPH pedigree sequenced with PacBio HiFi long reads and Illumina short reads. This multigenerational assessment enabled us to estimate the *de novo* TR mutation rate per generation at >30-60 calls per trio within the profiled TR loci. Mutation lengths ranged from a 2bp expansion to a 260bp contraction. Our analysis of CEPH individual 2189 confirmed 33 of 34 candidate *de novo* mutations through inheritance by at least 1 of their 6 children. Manual inspection of short-read data validated 17 short and structurally simple repeats in this individual.

Additionally, we used TRGTdn to characterize *de novo* mutations in 8 rare disease trios, observing mutation rates comparable to the CEPH pedigree trios. We will present results of our in-depth validation of these events and the characterizations of their sizes, motifs, and mutation types.

In conclusion, TRGTdn is an effective workflow for *de novo* TR mutation detection and characterization, one of the most difficult - and understudied - variant classes in the human genome. The uptake of this approach will enhance our understanding of the structural dynamics of the human genome and the role of TRs in rare genetic diseases.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3071 Genome-wide data from medieval German Jews show that the Ashkenazi founder event pre-dated the 14th century.

Authors:

S. Waldman[1], K. Sczech[2], S. Carmi[3], D. Reich[4,5,6]; [1]Harvard Univ., Newton, MA, [2]City of Erfurt, Erfurt, Germany, [3]The Hebrew Univ. of Jerusalem, Jerusalem, Israel, [4]Harvard Univ., Boston, MA, [5]Harvard Med. Sch., Boston, MA, [6]Broad Inst. of MIT and Harvard, Cambridge, MA

We report genome-wide data from 33 Ashkenazi Jews (AJ), dated to the 14th century, obtained following a salvage excavation at the medieval Jewish cemetery of Erfurt, Germany. The Erfurt individuals are genetically similar to modern AJ, but they show more variability in Eastern European-related ancestry than modern AJ. A third of the Erfurt individuals carried a mitochondrial lineage common in modern AJ and eight carried pathogenic variants known to affect AJ today. These observations, together with high levels of runs of homozygosity, suggest that the Erfurt community had already experienced the major reduction in size that affected modern AJ. The Erfurt bottleneck was more severe, implying substructure in medieval AJ. Overall, our results suggest that the AJ founder event and the acquisition of the main sources of ancestry pre-dated the 14th century and highlight late medieval genetic heterogeneity no longer present in modern AJ.
Our main emphasis here will be on the methodology used to analyze the history of the AJ population in this study. Additionally, I will discuss new data that has been collected since the publication of this study.

PB3072 Genome-Wide Exploration of Positively Selected Loci and Their Association to Disease Phenotypes in 30,000 Individuals from Sri Lanka and Bangladesh

Authors:

M. Kapoor[1], J. Backman[1], M. Riaz[1], Regeneron Genetics Center, M. Mridha, Kanti[2], A. Kasturiratne[3], J. Chambers[4], A. Shuldiner[1]; [1]Regeneron Pharmaceuticals, Tarrytown, NY, [2]BRAC Univ., Dhaka, Bangladesh, [3]Univ. of Kelaniya, Kelaniya, Sri Lanka, [4]Imperial Coll. London, London, United Kingdom

Introduction: The study of diverse global populations is crucial in understanding the role of genetic factors that contribute to their adaptation and survival in distinct geographical regions with unique selective pressures. These genetic factors may illuminate biological mechanisms relevant to human health, including those that incur protection from disease as potential targets for therapeutic development.**Methodology:** The South Asia Biobank (SAB) includes rich baseline demographic, lifestyle, clinical, environmental, and phenotypic data, biological samples and longitudinal follow-up from more than 150,000 South Asian participants. Whole exome sequencing and target sequencing-based genotyping (Twist platform) was performed in first tranche of 30,000 subjects as part of an ongoing collaboration between the Regeneron Genetics Center and SAB. Here, we conducted a genome-wide scan of selection signatures in SAB by estimating locus-specific time to the most recent common ancestor using the ascertained sequentially Markovian coalescent (ASMC) model. **Results:** Principal components and Uniform Manifold Approximation and Projection (UMAP) based analyses mapped each participant to distinct groups or clusters which were highly correlated with self-reported geographical location and local language. A genome-wide scan of selection signatures identified 40 positively selected loci (32 novel) satisfying genome-wide significance. Strong selection signatures were observed at several known loci including *HBB* (thalassemia),*SLC24A5* (skin pigmentation), *HLA* (immune system), and *ENPP7* (metabolism). We also performed similar analyses on Europeans, Africans, East and South Asians from UKBB and identified several positively selected loci unique to each population. Interestingly, we observed enrichment for genes involved in zinc homeostasis that are important in context of South Asians given adaptations to zinc scarcity in soil and diet. Phenome-wide association and enrichment analysis of novel selected loci indicated strong associations with a variety of complex phenotypes including anthropometric traits, immune system and metabolic disorders. **Conclusion:** We conducted a largest genome-wide scan to identify naturally selected loci in South Asians. Our findings underscore the importance of such studies and their potential to yield valuable insights into human adaptation, evolution and population genetics with implications for health and disease.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3073 Genomic history of Armenian population.

Authors:

A. Hovhannisyan[1], A. Manica[2]; [1]Trinity Coll. Dublin, Dublin, Ireland, [2]Univ. of Cambridge, Cambridge, United Kingdom

Armenians have remained underrepresented in modern population genomic studies, despite inhabiting an important region between Western and Eastern Eurasia. Using the first full genomes on Armenians, we studied their origins, population structure, and demographic history. We demonstrated that the Armenian populations from western, central, and eastern parts of the highlands are relatively homogeneous. The Sasun, a population in the south that had been argued to receive the major genetic contribution from Assyrians, was instead shown to have derived its slightly divergent genetic profile from a bottleneck occurred in the recent past. We investigated the debated question on the genetic origin of Armenians and failed to find any significant support for historical suggestions by Herodotus of their Balkan-related ancestry. We also checked the degree of continuity of the population and found that Armenians have remained unadmixed through the Neolithic and at least until the first part of the Bronze Age. However, by incorporating temporally spaced ancient genomes from Armenia, we detected a genetic input from a source linked to Levantine Early Farmers during, or just after the Late Bronze Age, indicating that this period has been marked by large-scale migrations in the whole region.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3074 Geography and study design in the biobank era: a population genetics-informed approach to the discovery of rare deleterious variants in human populations

Authors:

M. Steiner[1], D. Rice[2], C. Porras[1], J. Novembre[2]; [1]Univ. of Chicago, Chicago, IL, [2]Univ Chicago, Chicago, IL

The discovery of rare, large effect alleles and their phenotypic associations in human populations is critical to our understanding of biological mechanisms and an increasingly important component of the drug discovery pipeline. The availability of human whole genome sequencing (WGS) data at biobank scale provides an unprecedented opportunity to characterize rare variants. Given the growing number of biobanks being established globally and investments available for human genetic sequencing, one may consider whether it is advantageous to sequence as many individuals as possible in one geographic location (which we refer to as "narrow sampling") or to sequence individuals from as many geographic locations as possible ("broad sampling"). This question is particularly interesting in the context of rare deleterious alleles, which are known to be clustered in geographic space near their area of origin due to underlying evolutionary processes. With this motivation in mind, we present a novel theoretical framework to study the impact of spatial sampling design on the discovery of rare variants. In particular, we develop a population genetic model for the distribution of carriers of deleterious alleles in a structured population - accounting for dispersal, drift, selection, mutation, and uneven spatial sampling simultaneously. Analysis of our model suggests that, for a fixed sample size, broader sampling will result in the capturing of a greater number of deleterious variants, but each variant will be at reduced frequency within the sample; in contrast, narrow sampling yields fewer variants but each is found at higher frequency within the sample. To investigate how these different discovery profiles impact the power to discover associations between phenotypes and rare deleterious variants, we then integrate our work with statistical genetic models to identify trade-offs for genome-wide association studies (GWAS) and burden test studies. We find that under our model, the effect of spatial sampling design on GWAS and burden test power depends on several interconnected factors related to the genetic architecture, including effect sizes of the variants and spatial autocorrelation in the environmental component of the trait. Lastly, we validate key results using WGS data from the UK Biobank. We anticipate that our quantitative analyses will help to inform a broader discussion regarding best practices for study design in the biobank era.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3075 Identification of medically actionable variation in admixed individuals from Mexico

Authors:

C. Gonzaga-Jauregui, T. Sepulveda-Morales, I. A. Perez-Alvarado, M. A. Arciniega-Sanchez, C. Van Hout; Intl. Lab. for Human Genome Res., Univ. Natl. Autónoma de México (LIIGH-UNAM), Queretaro, Mexico

The field of human genomics suffers from unequal representation and diversity. Studies of European ancestry individuals comprise about 90% of all genomic data available, whilst less than 0.5% of genomic studies have been performed in Latin American individuals. In 2022 Ziyatdinov et al. reported the sequencing of 141,046 exomes and 9,950 genomes from Mexican individuals from the Mexico City Prospective Study (MCPS), the largest genomic sequencing study in a non-European ancestry population. Along with the preprint, aggregated frequency data on this dataset was publicly released.

To assess the potential health impact on individuals from this population and evaluate the benefit of performing genomic sequencing studies in underrepresented populations, we used the publicly available data for the MCPS to identify medically actionable variation in this poorly genomically characterized population. Using the list of genes curated and published by the ACMG for reporting of secondary findings that are medically actionable, we have identified 382 directly sequenced variants in MCPS impacting 52 of the 73 genes in the ACMG SF v3.0 list. The five genes with the greatest number of actionable variants were *BRCA2*, *BRCA1*, *GAA*, *MLH1*, *LDLR*, and *RYR1*. However, the greatest number of individuals were impacted by variants in *BRCA1*, *LDLR*, *BRCA2*, *TMEM43* and *DSG2*, suggesting a substantial risk for breast and ovarian cancer, familial hypercholesterolemia, and arrhythmogenic right ventricular cardiomyopathy in this population. Additionally, we identified novel loss-of-function likely pathogenic variants in these medically actionable genes that are unique to the Mexican population and not reported elsewhere to date. Overall, we estimate that about 5% of the individuals in this cohort are carriers for a medically actionable variant where early screening and therapeutic interventions may result in improved health outcomes and reduced mortality.

Our analyses present the best estimate of medically actionable variation that may be expected to be found in admixed Mexican individuals. Consistent with other studies and similar analyses, we estimate that approximately 2% to 5% of individuals from outbred populations will carry variants of medical relevance that warrant early interventions and may be useful to guide public health policies.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3076 Identifying and interpreting lineage-specific fixed differences between modern humans, archaic humans, and non-human primates.

Authors:

D. Tagore, R. Bierman, J. M. Akey; Lewis-Sigler Inst. for Integrative Genomics, Princeton Univ., Princeton, NJ

The explosion of whole-genome sequence data from contemporary individuals and ancient DNA is enabling high-resolution catalogs of lineage-specific fixed differences between modern humans, archaic humans (Neanderthals and Denisovans), and non-human primates to be constructed. These catalogs contain the genetic substrates that define uniquely hominin and human phenotypes and the chronology of evolutionary changes that distinguish hominins from non-human primates and modern humans from archaic humans. Although the interpretation of lineage-specific fixed differences remains daunting, the development of powerful functional genomics resources is enabling novel approaches to prioritize, identify, and test hypotheses about putatively causal genetic changes between lineages. Here, we describe an updated and densely annotated catalog of fixed differences between modern humans, archaic humans, and non-human primates from over 500,000 whole-genome sequences derived from multiple large-scale sequencing projects and sequence data we have generated from understudied human populations. As expected, the predicted number of functionally important lineage-specific fixed differences is larger for regulatory versus protein-coding DNA. Through integrating myriad functional genomics data from ENCODE, NIH Roadmap Epigenomics, GTEx, and CRISPR screens, we identify lineage-specific fixed differences between hominins and non-human primates and between modern humans and archaic humans that we predict perturb specific regulatory networks and changes in gene expression. We also leverage our high-resolution catalog of lineage-specific fixed differences to test hypotheses about the evolution of compensatory changes, estimate rates of back mutations and predict their functional and phenotypic consequences, and interpret deserts of archaic ancestry in modern humans. In summary, we will describe a carefully curated and powerful resource of lineage-specific fixed differences that provides novel insights into the genetic changes over the past ~15 million years of human evolutionary history.

PB3077 Identifying health disparities and differential healthcare usage within the biobank at the Colorado Center for Personalized Medicine using identity-by-descent clustering

Authors:

M. Fisher[1], J. Shortt[1], N. Rafaels[2], S. Chavan[3], N. Pozdeyev[3], H. Smith[1], C. Caggiano[4], R. Shemirani[5], N. Zaitlen[4], V. Arboleda[4], E. Kenny[6], K. Crooks[7], C. Gignoux[8]; [1]Univ. of Colorado Anschutz Med. Campus, Aurora, CO, [2]Univ. of Colorado Sch. of Med., Aurora, CO, [3]Univ. of Colorado, Aurora, CO, [4]UCLA, Los Angeles, CA, [5]Icahn Sch. of Med. at Mount Sinai, Palo Alto, CA, [6]Icahn Sch. of Med. at Mount Sinai, New York, NY, [7]Univ Colorado, Aurora, CO, [8]U Colorado, Anschutz Med. Campus, Aurora, CO

Population-scale biobanks increasingly power insights into both the genetic and environmental factors that influence health. Here, we use a non-parametric, data-driven approach to identify high-resolution population substructures among 73,346 participants in the Colorado Center for Personalized Medicine (CCPM) biobank, use these structures to better characterize the risk of disease, and discuss how this information can be used to understand the factors that influence health. We identified 148,142,648 identity by descent (IBD) segments indicative of recent shared ancestry using identity by descent LocAlity Sensitive Hashing (iLASH) between pairs of unrelated individuals enrolled in CCPM. We clustered individuals using cumulative IBD sharing with iterative Louvain clustering to identify 71 distinct genetic communities. Genetic communities have both overlapping and distinct genetic similarity profiles compared to global reference panels. Using linked electronic health record (EHR) information to derive 1563 phecodes, we investigate associations between genetic communities and different phecodes, generating hypotheses on health disparities experienced by specific genetic communities. At 5% FDR, we identified 395 associations between 270 unique phecodes and 60 unique genetic communities. Interestingly, we identified dozens of associations between phecodes and communities where communities with similar genetic similarity profiles had opposite directions of effect for the same phecode, including skin cancer, type 2 diabetes, and nonhypertensive congestive heart failure. Importantly, we believe that while genetic relatedness can identify this population structure, different environmental factors are the primary drivers of differential risk between communities. These findings offer new insights into health disparities and healthcare usage within the CCPM population.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3078 † Identifying mutator alleles in humans based on a proxy genome-wide association study

Authors:

V. Getseva[1], I. Agarwal[1,2], M. Przeworski[1]; [1]Columbia Univ., New York, NY, [2]Univ. of Oxford, Oxford, United Kingdom

Germline mutation rates are known to vary across individuals, families, and populations, and to evolve over time, but the causes of these differences remain poorly understood. In humans, the variance in the number of de novo single nucleotide variants is largely explained by parental ages but appears to have additional sources as well. Moreover, rare “mutator alleles” that increase mutation rates have recently been mapped in mice, rhesus macaques, and human trios that were ascertained for offspring with severe disease phenotypes. These findings raise the possibility that mutator alleles contribute non-negligibly to inter-individual variation in mutation rates in humans. To evaluate this possibility, we conducted a form of proxy genome-wide association study (GWAS) in whole exome sequences of “white British” individuals from the UK Biobank, a sample that includes a large number of close relatives as well as more distantly related individuals. Specifically, we considered putatively-neutral mutations seen only in one individual in the sample (i.e., “private” or singleton mutations) as a proxy for individual mutation rates. As we show, these private mutations, while not all de novo, nonetheless accrued quite recently (typically, over the last several generations). To map modifiers, we then test for association between the number and type of private mutations and the loss of function of ~11K genes using a mixed linear model. In parallel, we consider whether missense and loss of function mutations in known DNA replication and repair genes sit in a genomic region of increased diversity, as expected if they are mutators. Thus, we provide the first genome-wide survey of mutator alleles in humans.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3079 Identifying Sex-by-Ancestry Interactions of Asthma in African Descent Admixed Individuals

Authors:

K. Ellis[1], T. Miller Fleming[1], P. Straub[1], J. Jaworski[1], V. E. Kerchberger[1], K. Actkins[2], E. G. Atkinson[3], L. K. Davis[1]; [1]Vanderbilt Univ. Med. Ctr., Nashville, TN, [2]NIH, Cary, NC, [3]Baylor Coll. of Med., Houston, TX

Asthma is heterogeneous, complex, and demonstrates both sex and ancestry disparities in the United States. The prevalence ratio for women to men is 1.7:1, and African Americans experience asthma at higher rates compared to their white counterparts. Notably, Black women have the highest rate of asthma diagnoses and mortality. This disparity is thought to be due to a combination of ancestry specific genetic risk factors, racial health disparities, and gender disparities in social determinants of health. Prior studies indicate that African descent admixed individuals bear greater and disparate global genetic risk for asthma than non-African descent admixed individuals. Effects of asthma risk variants among African descent admixed individuals may also vary, by local ancestry and by sex, as local ancestry estimates vary widely according to geographic origin of African descent and demographic histories. Despite the awareness of how sex and ancestry separately influence asthma susceptibility, existing literature fails to examine the interaction between these two risk factors. Moreover, existing literature often fails to thoroughly examine asthma susceptibility in African descent admixed individuals, leaving a detrimental gap in the literature that stalls equitable precision medicine advancements and widens health disparities. **We hypothesize that sex moderates the effect of ancestry-specific X-chromosome risk factors for asthma susceptibility.** By leveraging genetic and phenotypic data from the *All of Us* Research Program, our cohort consists of 49,005 (4,845 cases, 44,160 controls) African descent admixed individuals, with 28,199 individuals having two X chromosomes and 20,806 individuals having one X chromosome and one Y chromosome. We aim to quantify the independent, joint, and interaction effects of sex and genetic ancestry on asthma diagnosis in African descent admixed individuals. We will characterize local ancestry across the X-chromosome to jointly test local ancestry and risk allele counts associated with asthma. We will then fit the resulting sex-stratified covariate-adjusted effect estimates for SNP risk alleles and local ancestry to logistic regression models. Results will be shared along with lessons learned regarding the unique challenges of local ancestry assignment on the X chromosome in a large biobank sample.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3080 Incorporating functional information into ancient DNA based selection scans.

Authors:

L. Poyraz[1], L. Colbran[2], I. Mathieson[2]; [1]Columbia Univ., New York, NY, [2]Univ. of Pennsylvania, Philadelphia, PA

Ancient DNA can directly reveal the contribution of natural selection to human genomic variation. However, while ancient DNA based methods have been successful in identifying genomic signals of selection, inferring the phenotypic effects of that selection has been difficult. Evidence from genome-wide association studies suggests that most trait-associated variants are non-coding, indicating that a large proportion of the phenotypic effects of selection will also act through non-coding variation and the transcriptome.

Since we cannot measure gene expression directly in ancient individuals, we used an approach (PrediXcan) developed to predict gene expression from genotype data. We developed this approach into a gene-level test for regulatory shifts due to selection across a time transect of 4500 years. We predicted the expression of 17,834 protein coding genes for each individual in a population of 91 modern and 684 ancient individuals from Britain using PrediXcan models trained on the genotypes and transcriptomes of 49 tissues from the GTEx project. Based on linear regression models of expression against time, 36 genes (FDR < 0.05) had evidence for significant shifts in expression levels. We compared the results from our transcriptome-wide scan to a genome-wide scan based on estimating per-SNP selection coefficients from time series data, and to an approach based on combining classical selection statistics (iHS and SDS) with PrediXcan models.

We highlight several genes with directional regulatory change, including the previously known targets of selection LCT and FADS1, and other genes in those regions. The transcriptome-wide scan identified 14 genes out of 150 in the genomic selection peak in the HLA region. Moreover, we identified a signal for reduced expression of *OAS3*, corroborating experimental evidence for an association between the adaptively introgressed Neandertal haplotype in the *OAS* region and the reduced expression of *OAS3* in response to viral immune triggers. Finally, we found 10 novel signals of selection on gene expression not captured by scans based on genomic signatures of selection that do not incorporate functional information. These results demonstrate the potential of combining this information and ancient DNA to elucidate the consequences of selection and highlight the fact that most of the gene expression changes resulting from selection are of genes that are not themselves the direct targets of selection.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3081 Integration of Gene-Level Annotation and Visualization in the Updated Functional Annotation of Variants Online Resource (FAVOR)

Authors:

H. Zhou[1], V. Verma[1], X. Li[1], L. Zilin[1], S. McCabe[2], E. Van Buren[1], X. Lin[3]; [1]Harvard, Boston, MA, [2]Indiana Univ. Sch. of Med., Indianapolis, IN, [3]Harvard T.H. Chan Sch Pub Hlth, Boston, MA

Rapid advancements in large-scale whole genome sequencing (WGS) studies conducted on biobanks have led to the identification of numerous coding and non-coding variants. These studies offer an unparalleled resource for gaining insights into the genetic underpinnings of human diseases. In this context, variant functional annotations play a crucial role in the analysis of WGS data, interpretation of results, and prioritization of causal variants associated with diseases or traits. Furthermore, understanding gene functions becomes essential due to the strong relationship between variant functions and the genes they impact. We develop a new version of the Functional Annotation of Variants Online Resources (FAVOR). This new version of FAVOR offers an extensive and multifaceted online portal for variant and gene functional annotation. The latest version of FAVOR offers a comprehensive summary and visualization of findings for all nine billion possible single nucleotide variants (SNVs) across the entire genome, as well as for all well-studied human genes. In addition to supporting rapid variant-, gene-, and region-level queries of variant functional annotations, the new version of FAVOR also provides highly detailed gene-level functional annotation. This means that users can delve into comprehensive information about the functional impact of variants on specific genes, enabling a thorough analysis and understanding of gene-level effects. FAVOR now offers an enhanced platform that facilitates both broad-scale queries and in-depth exploration of variant and gene functional annotations. The updated version of FAVOR are available at https://favor.genohub.org.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3082 Introgression of structural variation in human *OCA2* informs archaic hominins pigmentation.

Authors:

K. Kim, P. Hallast, F. Yilmaz, C. Lee; The Jackson Lab. for Genomic Med., Farmington, CT

Over the last decade, there is growing evidence that part of the modern human gene pool originated from now-extinct, archaic hominins (AH) such as Neanderthal and Denisovan. However, most of the evidence has been in the form of single-nucleotide variations (SNVs) due to the inherent limitations of short-read sequencing as well as the degraded nature of AH genomes. Here, we explore AH-originated structural variations (SVs) by genotyping SVs in two high-coverage AH genomes (Altai Neanderthal and Denisovan) and comparing them to the comprehensive SV call sets from the 1000 Genomes Project and the Human Genome Diversity Project. We identified 153 AH-originated SVs that are absent in both African and great ape genomes, but present in both AH and non-African genomes. 49 of these SVs were not detectable using SNV information alone due to their weak linkage disequilibrium with surrounding SNVs. Among the 153 potentially introgressed SVs, we found a Denisovan-originated intronic insertion in *OCA2*, a gene that has been shown to play a role in human pigmentation including iris, skin, and hair color. The insertion has an ~64% allele frequency in Bougainville, one of the Solomon Islands populations, and less than 18% frequency in other human populations. The insertion in *OCA2* is linked (genotype correlation r^2>0.6) to hair color and skin-associated SNVs in the Genotype-Tissue Expression (GTEx) project and the UK biobank data. Given that indigenous people with blonde hair and dark skin are commonly observed in the Solomon Islands, these results suggest a new allele that may explain pigmentation variation in the area and give us insights into the hair color of Denisovans.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3083 Investigating Mitochondrial Lineages in a Historic Afro-descendant Peruvian Population with Ancient DNA

Authors:

L. Pott[1], J. Zolik[1], J. L. Santa Cruz Alcalá[2,3,4], C. Maass[5], M. A. Nieves-Colón[1]; [1]Univ. of Minnesota, Minneapolis, MN, [2]Univ. Natl. Mayor de San Marcos, Lima, Peru, [3]APACHETA Consultores, Lima, Peru, [4]Museo Virtual de la Cultura Afro Peruana, San Luis de Cañete, Peru, [5]Defense POW/MIA Accounting Agency, Washington, DC

Human populations in Latin America have a long history of voluntary and forced migration from Europe, Asia, and Africa, which created highly complex patterns of admixture. However, Afro-descendant populations remain understudied. Between the 15th and 19th centuries, European colonizers forcibly transported over 12 million Africans to the Americas through the Transatlantic Slave Trade. Around 500 Africans were brought to the *Hacienda La Quebrada* sugar plantation in San Luis District, Peru. Recent excavations uncovered 245 individuals in an 18th-19th century burial ground for the enslaved people who worked on the plantation and their descendants. We are collaborating with archaeologists and community members in a community-engaged research project to learn more about patterns of genetic diversity among the people buried in this cemetery. In one of the first ancient DNA (aDNA) studies of an Afro-diasporic community in Peru, we assess the maternal lineages of these individuals. To investigate the preservation of skeletal remains in the cemetery and their suitability for aDNA analysis, we identified a subset of individuals (n=30) with good macroscopic tooth preservation and sampled dentin from them. aDNA extractions were successful, and we detected quantifiable DNA in 28 out of 30 samples. Following shotgun sequencing of 28 single-stranded libraries, sequenced reads exhibit characteristic patterns of aDNA damage that authenticate them as ancient. We recovered nuclear genomes at an average depth of 0.00071X and mitochondrial genomes at an average depth of 2.3X. The proportion of endogenous DNA varied greatly among the samples. Two samples with excellent preservation had an endogenous DNA content over 1% and will be candidates for target enrichment and deeper sequencing. We also identified the mitochondrial haplogroups of three individuals with >5X mitochondrial coverage, revealing diversity in their maternal ancestries. Two individuals belong to haplogroup subclades B2 and C1b, which are commonly found among Indigenous Americans. One individual belongs to subclade L2c2a1, which is associated with southern populations in Africa and the Bantu expansion. Future work will include nuclear and mitochondrial target enrichment to characterize additional haplogroups, as well as to identify the biogeographical origins and admixture patterns of these individuals. This work will contribute to a better understanding of the genomic impacts of slavery and the demographic history of this understudied Afro-descendant population.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3084 Investigating the contrast in ROH between Newfoundland founder population and ancestral British-Irish population based on 1000 Genomes data

Authors:

S. Demiriz, M. E. MacMillan, T. Furneaux, B. Ballew; Sequence Bio, St. John's, NL, Canada

The Newfoundland population exhibits characteristics of a founder effect due to a genetic bottleneck caused by the initial settlement of the island by British and Irish settlers circa 1600. Due to factors including a lack of easy means of travel around the island and cultural expectations, settlers mostly lived and married within the same town and religion, resulting in the preservation of genetically isolated subpopulations.
Runs of homozygosity (ROH) are two contiguous homozygous segments of a common ancestor in an individual, which enables us to evaluate the relative distance of a population from its ancestral origin. However, ROH data of any given population carries meaning only when juxtaposed with that of other populations. The 1000 Genomes project, with its collection of genomic data primarily from Europe and other continents, allowed us to compare our findings in Newfoundland against it.
As in other populations with founder characteristics, the Newfoundland population shows differences in ROH lengths compared to other European populations. Our aims in this study were to (i) highlight the close connection between Newfoundland and its genetic heritage from its British-Irish ancestry; (ii) contrast the lengths of Newfoundland ROH with those of populations included in the 1000 Genomes project; and (iii) investigate the extent of the Newfoundland founder effect by comparing it with other known founder populations such as the Finnish. Finally, we attempted to define the three main subpopulations of Newfoundland - Irish, English and admixed - based on available data such as PCA, reported religion, and ancestry, and investigate any correlations with each subpopulation’s respective ROH patterns.
We assessed the effects of various computational methods such as measuring ROH with and without LD pruning, whether to filter on MAF and what threshold to use, and compared orthogonal methods of ROH calculation via functionality from different software packages. The entire process is configured to run reproducibly and at scale, and can be easily adapted to display different sets of comparisons with minimal changes in configuration.

Malaspinas[1]; [1]Univ. of Lausanne, Lausanne, Switzerland, [2]Univ. of Copenhagen, Copenhagen, Denmark, [3]Univ. of Vienna, Vienna, Austria, [4]Ka Haka Hoki Mai Te Mana Tupuna, Hanga Roa, Rapa Nui, Chile, [5]Rapa Nui Museum (previous affiliation), Hanga Roa, Rapa Nui, Chile, [6]Musée Natl. d'Histoire Naturelle, Paris, France, [7]Curtin Univ., Bentley, Australia

Rapa Nui (Easter Island) is a speck of land in the Pacific Ocean, at the easternmost vertex of the Polynesian triangle. Polynesians peopled the island between 1,500 and 800 years ago, which is famous for its massive stone statues, the moai. However, the history of its people has been told time and time again as an example of ecological suicide ("ecocide"), with resources overexploitation that led to deforestation, famine, wars and population collapse in the 1600s. Compared to other Polynesian islands, natural resources are scarce, biodiversity is low, and most of the land is barren without trees. Although it has been shown that the island was once covered by a dense forest, evidence against the ecocide is growing. Firstly, the Polynesian rats (*Rattus exulans*) are the most likely culprit of deforestation. Secondly, it is disputed that such environmental change led to a population collapse in the light of archaeological and demographic studies. However, up until now, genetics has been absent from this debate. Here, we use ancient DNA to investigate a potential collapse of the Rapanui population in the 1600s. We sequenced the genomes of 15 ancient Rapanui, radiocarbon dated to the beginning of the 19th century, thus pre-dating the 1860's slave trade raids that resulted in a *de facto* genocide. We showed that they had a Polynesian origin, with 10% of Native American gene flow dated to the 15th century. We found no close relatives (up to 3rd degree) among these ancient Rapanui and estimated very low amounts of inbreeding, despite a large proportion of their genomes being in runs of homozygosity. Our estimates of recent effective population size (Ne) suggest that the Rapanui were a small population (less than 3000 individuals), which steadily grew after peopling the island, with no evidence of a second strong bottleneck associated with the ecocide. To further characterize the population history, we simulated genomes that replicated the Rapanui population history. We employed one- or two-bottleneck demographic models, with the former representing the island founding and the latter corresponding to a potential population collapse. By performing a permutation test, we rejected that weak and strong second bottlenecks generated data that were similarly distant to the observed Ne (1,000,000 permutations, p-value=0). Together with the analysis of distance metric values, these findings suggest that a second strong bottleneck is inconsistent with the observed data. Altogether, these results add to the mounting evidence that the Rapanui history is an example of human resilience and ingenuity in the face of environmental changes, and not the most well-known case of self-inflicted collapse.

PB3086 Leveraging Large Genealogies for Realistic Population Genetics Simulations.

Authors:

L. Anderson-Trocme[1], S. Zabad[2], A. Wohns[3], K. Tayeb[1], S. Gravel[2], J. Novembre[1]; [1]Univ. of Chicago, Chicago, IL, [2]McGill Univ., Montreal, QC, Canada, [3]Broad Inst., Cambridge, MA

Population scale genealogies encode the process by which individuals in a population move through space and time. Although well-studied models such as the Wright-Fisher model create genealogies that capture the mean and variance in offspring number, they do not capture the idiosyncratic dynamics of real populations. To move beyond this, we took advantage of the French Canadian pedigree -- with over 5M digitized records, it is one of the largest and most complete spatially linked population scale genealogies available for research.

Anderson-Trocmé et al. (2023) illustrated how genealogy-aware simulations can accurately capture real population structure. However, there remains a wide gap between theoretical models used to understand evolution and empirical genealogies, which encode a wide range of demographic effects.

To address this gap, we computed demographic parameters (e.g. population sizes, migration rates, etc.) from the French Canadian genealogy and encoded them into the Demes format so as to be readily compatible with popular tools like SLiM and msprime. Furthermore, we developed a forwards-in-time genealogy simulation framework that accommodates additional features of complex assortative mating preferences, such as age disparity and relatedness rates.

The combination of empirical demographic parameters and our simulation framework enables an unprecedented ability to tease apart the relative influence demographic factors have on broader population structure. Moreover, because we use the Demes format, we can directly compare simulation tools. Finally, because the French Canadian genealogy is spatially resolved, we explore deme models at various scales of geographic resolutions to gain insights into concepts of effective populations.

In conclusion, this project allows us to assess the accuracy of standard population genetic assumptions in large cohorts. Our work bridges an important gap between empirical populations and theoretical models through a more nuanced understanding of how subtle demographic forces shape population structure at both fine and broad scales.

Sch., Boston, MA, [7]Molecular Epidemiology, Dept. of Med. Sci., and Sci. for Life Lab., Uppsala Univ., Uppsala, Sweden, [8]Analytic and Translational Genetics Unit, Massachusetts Gen. Hosp.,, Boston, MA

Sibling similarities have long been used to quantify the genetic contribution to phenotypic variability, the so-called heritability. When suggested to be heritable, for a common polygenic disease GWAS is employed to identify its associated common variants, and for a Mendelian or monogenic disease, a rare-variant association analysis, with one disease being studied per analysis. Sibling similarities in lifetime reproductive success (LRS), however, offer a unique opportunity to systematically reveal the genetic architecture of many diseases in a hypothesis-free manner. Leveraging 14 million well-phenotyped sibling pairs available in the Finnish and Swedish nationwide multi-generation registry, we propose a novel framework aiming to answer how complex the disease architecture is, genetically (G) and environmentally (E). For a total of 1,646 diseases (14 categories), we quantified the LRS of disease-affected individuals ($LRS_{affected}$) and their unaffected siblings ($LRS_{unaffected}$) separately for each sex and then grouped diseases based on the estimated LRS. We hypothesized that: (a) If a disease largely reduces $LRS_{affected}$ but has no impact on $LRS_{unaffected}$, it's likely to be driven by G (eg, de novo mutation, monogenic variants) or E that are specific to the affected individuals; (b) If a disease slightly reduces both $LRS_{affected}$ and $LRS_{unaffected}$, it's likely to be driven by G (polygenic variants) or E that are shared between siblings; (c) If a disease reduces $LRS_{affected}$ but increases $LRS_{unaffected}$, it's under balancing selection possibly because of G by E; and (d) if a disease exhibits different patterns in males and females, we then consider this disease is selected in a sex-dependent manner. We saw 40 diseases in males and 65 in females largely reduced $LRS_{affected}$. However, unlike model (a) assuming no change in $LRS_{unaffected}$, for many such diseases, $LRS_{unaffected}$ was significantly reduced as well (model (b)), suggesting that many Mendelian diseases might also be impacted by polygenic variations. Balancing selection is seen for several diseases (model (c)) and is usually coupled with a sex-specific manner (model (d)). For example, alcohol dependence significantly reduced LRS in affected men and women and unaffected brothers, but with favorable LRS in unaffected sisters. Diseases with lower LRS are generally rarer in prevalence (a consequence of contemporary selection) and more heritable, especially in men. By studying fitness in 14 million sibling pairs from two nations, we inferred a comprehensive picture of the complex architecture of human diseases. The findings of this work can be used to inform the design of future genetic studies.

PB3088 Local ancestry inference in the MHC locus.

Authors:

H. Andrade[1], C. Passos[1], K. Nunes[1], C. Dinardo[2], A. Ferraz[3], C. Teixeira[4], S. Garcia[5], B. Custer[6,7], E. Sabino[8], S. Kelly[6,9], D. Meyer[1]; [1]Univ.e de São Paulo, São Paulo, Brazil, [2]Fundação Pró-sangue, Hemocentro de São Paulo, São Paulo, Brazil, [3]HEMOPE, Recife, Brazil, [4]Hemominas, Belo Horizonte, Brazil, [5]HEMORIO, Rio de Janeiro, Brazil, [6]Epidemiology, Vitalant Res. Inst., San Francisco, CA, [7]Dept. of Lab. Med., Univ. of California San Francisco, San Francisco, CA, [8]Inst. de Med. Tropical, Departamento de Moléstias Infecciosas e Parasitárias da Faculdade de Med. da Univ.e de São Paulo, São Pulo, Brazil, [9]Univ. of California San Francisco Benioff Children's Hosp. Oakland, Oakland, CA

Using methods that assign continental-level ancestries to genomic segments (i.e., Local Ancestry Inference LAI), studies identified an excess of African ancestry in the MHC locus in human populations (e.g., Mexicans, Colombians). A hypothesis to explain this finding is that African ancestry in the MHC is favored in these admixed populations. However, the MHC has features that raise concerns about the reliability of LAI: difficulty in phasing and extremely high (and extensively shared) SNP-level polymorphism. This has led to concerns that LAI calls for the MHC may be biased to overestimate the most diverse parental population. Here, we analyze the reliability and reproducibility of LAI using different subsets of SNPs, to measure the impact of features of the data upon downstream findings. We used the whole genome sequencing data of 2629 individuals from the Recipient Epidemiology and Donor Evaluation Study-III Brazil Sickle Cell Disease Cohort and applied the Gnomix tool to infer LAI. We compared LAI that: (a) included all the 400,000 SNPs in chromosome 6 (WGS data); (b) included only a subset of 30,000 6 SNPs in chromosome 6, corresponding to those in the Axiom Transfusion Medicine Array (Array data); (c) removed SNPs within HLA genes, or in their flanking regions (which have potential calling errors). For regions outside the MHC, ancestry estimates are unaltered when using any filter (46.8% African, 45,1% European, and 8.1% Native American in all scenarios). However, the results for the MHC are extremely sensitive to the inclusion criteria: for the lower SNP density Array analysis (regardless of the inclusion of HLA SNPs), we find an excess of African ancestry in the MHC (mean of 51.4% AFR, 40.4% EUR, and 8.2% NAM), whereas with high SNP density WGS data (with or without the HLA SNPs) we no longer find an excess of African ancestry in the MHC (46.5% AFR, 45% EUR, and 8.5% NAM, similar to values for the whole chromosome). We compared the WGS and the array set of SNPs for other chromosomes, and only the MHC presented marked differences in ancestry pattern, reaching a difference of 8% in African ancestry depending on the inclusion criteria. Because of the extremely high density of SNPs in MHC, analyses that define windows by a fixed number of variants will have unusually small windows in the MHC (50% smaller in the WGS set and 10% in the array set), with higher non-independence between the SNPs, potentially contributing to unreliable estimation of LAI in the MHC region. While our approach showed that LAI in the MHC is highly sensitive to SNP density, our lack of a gold standard means we cannot associate the different densities to accuracies. Simulation approaches will be key to answer this question.

PB3089 Local Ancestry-Aware Genotype Principal Component Analysis on Chronic Kidney Disease GWAS signals.

Authors:

W. Gonzalez-Rivera, P. Woo-Yeong, K. Frazer, M. Gymrek, M. D'Antonio; Univ. of California, San Diego, San Diego, CA

Genomic research has traditionally underrepresented the genetic diversity of the United States, particularly the Latinx population, which has resulted in significant biases and limitations in understanding the genetic basis of diseases and traits. Challenges arise in including Latinx individuals in genetic studies because of their complex admixed genomic structure. While previous studies have leveraged local ancestry inference to better model admixed individuals in association studies, this approach relies on using a number of predefined ancestry labels from a reference panel. Here, we developed Local Ancestry-Aware Genotype Principal Component Analysis (LA-GPCA), which instead uses a quantitative notion that improves the detection of genetic variants associated with diseases and traits in admixed populations.

As a test case, we conducted a genome wide association study (GWAS) using global ancestry principal components (PCs) as covariates on the UK Biobank for Chronic Kidney Disease (CKD) and Glomerular Filtration Rate (eGFR), which measures kidney function. From this analysis, we identified significant signals on chromosomes 15 and 4 in multiple populations. To further explore these signals, we applied LA-GPCA, which involved extracting a 1 Mb region surrounding each of the lead variants, rs2453533 and rs4859682, respectively in the chromosome 15 and 4 loci. Subsequently, we applied a pruning technique by analyzing linkage disequilibrium (LD) patterns within windows of 50kb, shifting the window by 10 variants after each analysis, and pruning variants with an $R^2 \geq 0.1$, performing a PC analysis on the remaining variants to obtain LA-GPCs. We next repeated our GWAS on these two regions using both global genotype PCs and LA-GPCs and compared the summary statistics with the original GWAS. Our analysis showed that chromosome 15 locus harbors GWAS signals specific to the EUR, SAS and AFR populations, whereas the signal in chromosome 4 locus was shared across all populations.

We are further exploring refining LA-GPCA as an approach to analyze local haplotype structures in genetic association studies. The goal is to develop a method for conducting genetic studies in diverse and admixed populations that is independent of assigning local ancestry labels but rather deconvolutes the local pattern of common genetic variations into shared and divergent haplotypes which can be directly utilized in GWAS. Removing ancestry labels and developing an ancestry-agnostic GWAS could overcome limitations in studying admixed populations, leading to the identification of universally associated genetic variants for disease and traits across diverse populations.

PB3090 LoGicAl: Local ancestry and genotype calling uncertainty adjusted ancestry-specific allele frequency estimation from admixed populations.

Authors:

J. Wang, S. Zollner; Univ. of Michigan, Ann Arbor, MI

Knowing allele frequency distributions across different populations provides important insights into population-enriched genetic drivers of disease etiologies, design of replication genome-wide association studies, transferability of polygenic risk scores, and interpopulation demographic histories. The allele frequency itself is insufficient to describe the heterogeneous patterns of genetic variation across different admixed populations since allele frequency does not account for their complex population histories and inherent heterogeneous ancestry background. Existing computational programs developed to deconstruct allele frequencies of the underlying ancestral populations from admixed populations are typically based on "best-guess" local ancestry and genotype, thereby ignoring uncertainty in upstream local ancestry and genotype calling steps, which will eventually bias the estimates.

Here, we introduce LoGicAl, a novel ancestry-specific allele frequency estimation tool, which adjusts for both ancestry calling uncertainty and genotype calling uncertainty. LoGicAl models probabilistic local ancestry and genotypes while accounting for phasing uncertainties with a EM algorithm. It informs ancestry-specific allele frequency estimates by averaging alternate allele dosages across each individual, which are defined by probabilistic local ancestry calls, genotype likelihoods and allele frequency distributions. LoGicAl is capable of interpreting large-scale (N > 10,000) phased or unphased multi-way admixture data generated from array-based or sequence-based genotyping techniques.

In simulation studies, we evaluated the impact of sample size, allele frequency, population structure, and uncertainty in genotyping and ancestry calls on estimates obtained from LoGicAl and from methods not adjusting for the uncertainties. The results demonstrate high estimation accuracy of LoGicAl in both array-based and low-coverage or high-coverage sequence-based genotyping data with different degrees of ancestry calling uncertainty (Pearson's R with true values > 0.999). The simulation studies also demonstrate that ignoring the uncertainties inflates bias in estimating the allele frequencies 12-fold on average, even with large sample size (~10K). In the absence of uncertainties, LoGicAl reduces running time by 66% over other methods while maintaining estimation accuracy and reduces bias for rare varaints. We provide a new, computationally efficient program that provides precise estimates of ancestral allele frequencies, thus improving the genomic analysis of admixed populations.

PB3091 Measuring constraint against missense variation in the context of AlphaFold2 protein structures

Authors:

M. Silk[1,2], L. Thibaut[1,2], Genome Aggregation Database (gnomAD) Consortium, K. M. de Lange[1,2], D. G. MacArthur[1,2,3]; [1]Garvan Inst. of Med. Res., Sydney, Australia, [2]Murdoch Children's Res. Inst., Melbourne, Australia, [3]Univ. of New South Wales, Sydney, Australia

Catalogues of genetic variation such as gnomAD and UK Biobank have proven invaluable in the diagnosis of rare disease. Beyond simply identifying patient-ascertained variants that are rare or absent in the population, these databases can also be used to identify genes and sub-regions of genes depleted of variation (constrained), and therefore likely functionally important. Missense constraint is of particular interest in healthcare due to the diverse effects missense variants can have on protein structure and function, and the difficulty in interpreting their consequences.

Currently, the majority of region-specific missense constraint measurements are applied to linear DNA sequence. However, genetic variation mapped to the protein tertiary structure can uncover additional functionally important regions, as distant parts of a gene sequence often exist close together in the protein tertiary structure. Advances in protein structure prediction, including AlphaFold2 and ESMFold, have massively expanded on the proportion of the proteome with a valid, high-confidence structure prediction, allowing constraint to be assessed across the full proteome.

We present Protein Observed/Expected missense constraint in 3D structures (PrOEmis3D), a measure of constraint to missense variation across 18,609 AlphaFold2 protein tertiary structures using the gnomAD v2 database of over 125,000 human exomes. Constrained regions are dynamically defined based on genomic context using well-established mutational models that correct for genomic context, sequence coverage and CpG methylation. We show that regions with low PrOEmis3D scores (constrained) are highly enriched for ClinVar variants compared with regions with high PrOEmis3D scores (tolerant) (Mann Whitney U test; $p < 10^{-50}$). These measurements are accurate across proteins of varying sizes and configurations. Additionally, measurements are calculated for each codon within the protein's genetic sequence, providing direct and easily accessible clinical utility.

Session Title: Evolutionary and Population Genetics Poster Session II

PB3092 Microevolutionary processes analysis in the human genome

Authors:

A. Urnikyte, L. Pranckeniene, V. Kucinskas; Vilnius Univ., Vilnius, Lithuania

Introduction: Differences in the relative fitness of genomic variants are foundational, without these, neither natural selection nor adaption can exist. This research aimed to analyze two major microevolutionary forces, mutations and positive selection, using the whole genome sequencing data of Lithuanians collected from two generations. Here, we aim to answer the main question - how commonly are mutations under selection in modern humans, and how do allele frequencies change from generation to generation. Material and methods: The detection of mutations and the signatures of positive selection and relative fitness across different age groups, including newborns (generation I), their parents (generation II), and the root ancestor (considered as a generation of the 1000 genome project (generation III)), was performed using whole genome sequencing data. Signs of positive natural selection were infered using Tajima's D, FST and cross-population extended haplotype homozygosity (XP-EHH) statistical methods. Selected SNPs were annotated using ANNOVAR in GRCh37 (hg19), RefSeqGene, dbSNP151 and CADD v.1.3. Visual Studio 2017 and C# language were used to write the calculation software for relative fitness, and a graphical presentation and analysis of the results was performed using the Rcmdr and ggplot packages.Results: This study demonstrated that when exploring the landscapes of relative fitness on each chromosome, the overall pattern of relative fitness background remains consistent across both generations. However, a general tendency of relative fitness decrease was observed. We hypothesize that the newly formed genome variants or those with a very low frequency from the previous generation had insufficient time to be significantly influenced by natural selection. Consequently, in the subsequent generation, the force of natural selection acting upon them is stronger, resulting in a decrease in their cumulative relative fitness. Furthermore, the strong natural selection pressure on the genetic regions that encode the NEGR1 and PTPN1/PTNP21 genes were also identified, highlighting the evolution of the Lithuanian population’s genome over generations, and possible genomic “deficiencies” for better adaptation. Conclusions: This research contributes to the advancement of scientific knowledge and holds particular significance in elucidating the relationship between natural selection and adaptation.

Session Title: Evolutionary and Population Genetics Poster Session III

PB3093 Mixed Turkic and Mongolic ancestry reveals complex history and origin of the Tu and other Chinese populations.

Authors:

D. Tabin[1], N. Patterson[2], T. Zeng[1], D. Reich[3]; [1]Harvard, Dept. of Human Evolutionary biology, Cambrdige, MA, [2]Broad Inst MIT & Harvard, Cambridge, MA, [3]Harvard Univ, Boston, MA

Turkic and Mongolic speakers have had a long and complex history of interaction with each other and with other neighboring populations. Due in part to this complex history, there is debate about whether or not the two groups share a common linguistic origin. We provide new genetic evidence regarding these patterns by leveraging the fact that Turkic and Mongolic peoples have differential sources of both West and East Eurasian ancestry, which we show can be used to disentangle Turkic and Mongolic ancestry in admixed populations. We find variable proportions of Turkic- and Mongolic-associate ancestry in modern Chinese Turko-Mongolic ethnic minorities including the Salar, Bonan, Dongxiang, Daur, Mongola, and Tu. Most have ancestry from both groups with notable exceptions such as the Salar who are consistent with having no Mongolic ancestry. While Chinese connections to and interactions with the Eurasian Steppe can be seen as early as the Shang Dynasty, genetic dating of the most recent wave of admixture suggests that the modern mixture of ancestries present in these populations were formed during the heyday of the Mongol empire. A plausible scenario is that these groups were formed by Turkic and Mongolic speakers, possibly soldiers, settling and admixing with Chinese and Tibetan peoples. Many of these admixed populations would have then undergone a language shift towards the Mongolic prestige language, a scenario that would be consistent with the joint genetic, linguistic, and historical evidence.

Session Title: Evolutionary and Population Genetics Poster Session I

PB3094 Molecular insights from telomere-to-telomere assemblies of diverse human Y chromosomes across 185,000 years of evolution

Authors:
